1 Introduction

1.1 Features summary

On-chip modules available within the family include the following features:

- Three dual issue, 32-bit CPU core complexes (e200z7), two of which run in lockstep
 - Power Architecture embedded specification compliance
 - Instruction set enhancement allowing variable length encoding (VLE), optional encoding of mixed 16-bit and 32-bit instructions, for code size footprint reduction
 - On the two computational cores: Signal processing extension (SPE1.1) instruction support for digital signal processing (DSP)
 - Single-precision floating point operations
 - On the two computational cores: 16 KB I-Cache and 16 KB D-Cache
 - Hardware cache coherency between cores
- 16 hardware semaphores
- 3-channel CRC module
- 8 MB on-chip flash memory
 - Supports read during program and erase operations, and multiple blocks allowing EEPROM emulation
- 512 KB on-chip general-purpose SRAM including 64 KB standby RAM
- Two multichannel direct memory access controllers (eDMA)
 - 64 channels per eDMA
- Dual core Interrupt Controller (INTC)
- Dual phase-locked loops (PLLs) with stable clock domain for peripherals and frequency modulation (FM) domain for computational shell
- Crossbar Switch architecture for concurrent access to peripherals, flash memory, or RAM from multiple bus masters with End-To-End ECC
- External Bus Interface (EBI) for calibration and application use
- System Integration Unit (SIU)
- Error Injection Module (EIM) and Error Reporting Module (ERM)
- Four protected port output (PPO) pins
- Boot Assist Module (BAM) supports serial bootload via CAN or SCI
- Three second-generation Enhanced Time Processor Units (eTPUs)
 - 32 channels per eTPU
 - Total of 36 KB code RAM
 - Total of 9 KB parameter RAM

- Enhanced Modular Input/Output System (eMIOS) supporting 32 unified channels with each channel capable of single action, double action, pulse width modulation (PWM) and modulus counter operation
- Two Enhanced Queued Analog-to-Digital Converter (eQADC) modules with:
 - Two separate analog converters per eQADC module
 - Support for a total of 70 analog input pins, expandable to 182 inputs with off-chip multiplexers
 - Interface to twelve hardware Decimation Filters
 - Enhanced "Tap" command to route any conversion to two separate Decimation Filters
- Four independent 16-bit Sigma-Delta ADCs (SDADCs)
- 10-channel Reaction Module
- Ethernet (FEC)
- Two PSI5 modules
- Two SENT Receiver (SRX) modules supporting 12 channels
- Zipwire: SIPI and LFAST modules
- Five Deserial Serial Peripheral Interface (DSPI) modules
- Five Enhanced Serial Communication Interface (eSCI) modules
- Four Controller Area Network (FlexCAN) modules
- Two M_CAN modules that support FD
- Fault Collection and Control Unit (FCCU)
- Clock Monitor Units (CMUs)
- Tamper Detection Module (TDM)
- Cryptographic Services Engine (CSE)
 - Complies with *Secure Hardware Extension (SHE) Functional Specification Version 1.1* security functions
 - Includes software selectable enhancement to key usage flag for MAC verification and increase in number of memory slots for security keys
- PASS module to support security features
- Nexus development interface (NDI) per IEEE-ISTO 5001-2003 standard, with some support for 2010 standard
- Device and board test support per Joint Test Action Group (JTAG) IEEE 1149.1 and 1149.7
- On-chip voltage regulator controller (VRC) that derives the core logic supply voltage from the high-voltage supply
- On-chip voltage regulator for flash memory
- Self Test capability

1.2 Block diagram

The following figure shows a top-level block diagram of the MPC5777C. The purpose of the block diagram is to show the general interconnection of functional modules through the crossbar switch.

| Symbol | Parameter | Conditions ¹ | Value | | Unit |
|--------|--|-------------------------|-------|-----|------|
| | | | Min | Max | |
| MSL | Moisture sensitivity level ¹¹ | — | — | 3 | — |

1. Voltages are referred to V_{SS} if not specified otherwise
2. Allowed 1.45 V – 1.5 V for 60 seconds cumulative time at maximum $T_J = 150\text{ °C}$; remaining time as defined in note -1 and note -1
3. Allowed 1.375 V – 1.45 V for 10 hours cumulative time at maximum $T_J = 150\text{ °C}$; remaining time as defined in note -1
4. 1.32 V – 1.375 V range allowed periodically for supply with sinusoidal shape and average supply value below 1.275 V at maximum $T_J = 150\text{ °C}$
5. Allowed 5.5 V – 6.0 V for 60 seconds cumulative time with no restrictions, for 10 hours cumulative time device in reset, $T_J = 150\text{ °C}$; remaining time at or below 5.5 V
6. Allowed 3.6 V – 4.5 V for 60 seconds cumulative time with no restrictions, for 10 hours cumulative time device in reset, $T_J = 150\text{ °C}$; remaining time at or below 3.6 V
7. The maximum input voltage on an I/O pin tracks with the associated I/P supply maximum. For the injection current condition on a pin, the voltage will be equal to the supply plus the voltage drop across the internal ESD diode from I/O pin to supply. The diode voltage varies greatly across process and temperature, but a value of 0.3V can be used for nominal calculations.
8. The sum of all controller pins (including both digital and analog) must not exceed 200 mA. A V_{DDEX}/V_{DDEHx} power segment is defined as one or more GPIO pins located between two V_{DDEX}/V_{DDEHx} supply pins.
9. The average current values given in [I/O pad current specifications](#) should be used to calculate total I/O segment current.
10. Solder profile per IPC/JEDEC J-STD-020D
11. Moisture sensitivity per JEDEC test method A112

3.2 Electromagnetic interference (EMI) characteristics

Test reports with EMC measurements to IC-level IEC standards are available on request.

To find application notes that provide guidance on designing your system to minimize interference from radiated emissions, go to nxp.com and perform a keyword search for "radiated emissions."

3.3 Electrostatic discharge (ESD) characteristics

Table 2. ESD Ratings^{1, 2}

| Symbol | Parameter | Conditions | Value | Unit |
|-----------|------------------------------------|-----------------|-------|------|
| V_{HBM} | ESD for Human Body Model (HBM) | All pins | 2000 | V |
| V_{CDM} | ESD for Charged Device Model (CDM) | Corner pins | 750 | V |
| | | Non-corner pins | 500 | |

1. All ESD testing is in conformity with CDF-AEC-Q100 Stress Test Qualification for Automotive Grade Integrated Circuits.
2. A device will be defined as a failure if after exposure to ESD pulses the device no longer meets the device specification requirements.

3.4 Operating conditions

The following table describes the operating conditions for the device, and for which all specifications in the data sheet are valid, except where explicitly noted.

If the device operating conditions are exceeded, the functionality of the device is not guaranteed.

| I_{IC} | DC injection current (per pin) ^{16, 17, 18} | Digital pins and analog pins | -3.0 | — | 3.0 | mA |
| I_{MAXSEG} | Maximum current per power segment ^{19, 20} | — | -80 | — | 80 | mA |

- Maximum operating frequency is applicable to the computational cores and platform for the device. See the Clocking chapter in the MPC5777C Microcontroller Reference Manual for more information on the clock limitations for the various IP blocks on the device.
- If frequency modulation (FM) is enabled for the maximum operating frequency of 264 MHz or 306 MHz, the maximum frequency still cannot exceed this value when frequency modulation is enabled (frequency modulation must spread down from the maximum).
- 132 MHz applies to the MPC5777C part number with 264 MHz operating frequency. 153 MHz applies to the version with 306 MHz operating frequency.
- 200 MHz applies to the MPC5777C part number with 264 MHz max operating frequency. 240 MHz applies to the version with 306 MHz operating frequency.
- The maximum specification for operating junction temperature T_J must be respected. [Thermal characteristics](#) provides details.
- Core voltage as measured on device pin to guarantee published silicon performance
- During power ramp, voltage measured on silicon might be lower. Maximum performance is not guaranteed, but correct silicon operation is guaranteed. See power management and reset management for description.
- Maximum core voltage is not permitted for entire product life. See absolute maximum rating.
- When internal LVD/HVDs are disabled, external monitoring is required to guarantee device operation. Failure to monitor externally supply voltage may result in erroneous operation of the device.
- This LVD/HVD disabled supply voltage condition only applies after LVD/HVD are disabled by the application during the reset sequence, and the LVD/HVD are active until that point.
- This spec does not apply to V_{DDEH1} .
- When internal flash memory regulator is used:
 - Flash memory read operation is supported for a minimum V_{DDPMC} value of 3.15 V.
 - Flash memory read, program, and erase operations are supported for a minimum V_{DDPMC} value of 3.5 V.

Electrical characteristics

When flash memory power is supplied externally (V_{DDPMC} shorted to V_{DDFLA}): The V_{DDPMC} range must be within the limits specified for LVD_FLASH and HVD_FLASH monitoring. Table 1 provides the monitored LVD_FLASH and HVD_FLASH limits.

13. If the standby RAM regulator is not used, the V_{STBY} supply input pin must be tied to ground.
14. V_{STBY_BO} is the maximum voltage that sets the standby RAM brownout flag in the device logic. The minimum voltage for RAM data retention is guaranteed always to be less than the V_{STBY_BO} maximum value.
15. For supply voltages between 3.0 V and 4.0 V there will be no guaranteed precision of ADC (accuracy/linearity). ADC will recover to a fully functional state when the voltage rises above 4.0 V.
16. Full device lifetime without performance degradation
17. I/O and analog input specifications are only valid if the injection current on adjacent pins is within these limits. See the absolute maximum ratings table for maximum input current for reliability requirements.
18. The I/O pins on the device are clamped to the I/O supply rails for ESD protection. When the voltage of the input pin is above the supply rail, current will be injected through the clamp diode to the supply rail. For external RC network calculation, assume a typical 0.3 V drop across the active diode. The diode voltage drop varies with temperature.
19. The sum of all controller pins (including both digital and analog) must not exceed 200 mA. A V_{DDEX}/V_{DDEHx} power segment is defined as one or more GPIO pins located between two V_{DDEX}/V_{DDEHx} supply pins.
20. The average current values given in I/O pad current specifications should be used to calculate total I/O segment current.

3.5 DC electrical specifications

NOTE

I_{DDA_MISC} is the sum of current consumption of IRC, I_{TRNG} , and I_{STBY} in the 5 V domain. IRC current is provided in the IRC specifications.

NOTE

I/O, XOSC, EQADC, SDADC, and Temperature Sensor current specifications are in those components' dedicated sections.

- This value is considering the use of the internal core regulator with the simulation of an external transistor with the minimum value of h_{FE} of 60.
- This bandgap reference is for EQADC calibration and Temperature Sensors.

3.6 I/O pad specifications

The following table describes the different pad types on the chip.

Table 5. I/O pad specification descriptions

| Pad type | Description |
|--------------------------|--|
| General-purpose I/O pads | General-purpose I/O and EBI data bus pads with four selectable output slew rate settings; also called SR pads |
| EBI pads | Provide necessary speed for fast external memory interfaces on the EBI CLKOUT, address, and control signals; also called FC pads |
| LVDS pads | Low Voltage Differential Signal interface pads |
| Input-only pads | Low-input-leakage pads that are associated with the ADC channels |

NOTE

Each I/O pin on the device supports specific drive configurations. See the signal description table in the device reference manual for the available drive configurations for each I/O pin.

NOTE

Throughout the I/O pad specifications, the symbol V_{DDEx} represents all V_{DDEx} and V_{DDEHx} segments.

3.6.3 I/O pad current specifications

The I/O pads are distributed across the I/O supply segments. Each I/O supply segment is associated with a V_{DDEX} supply segment.

Table 11 provides I/O consumption figures.

To ensure device reliability, the average current of the I/O on a single segment should remain below the I_{MAXSEG} value given in Table 1.

To ensure device functionality, the average current of the I/O on a single segment should remain below the I_{MAXSEG} value given in Table 3.

NOTE

The MPC5777C I/O Signal Description and Input Multiplexing Tables are contained in a Microsoft Excel® file attached to the Reference Manual. In the spreadsheet, select the I/O Signal Table tab.

The EBI power segments have been designed to operate within the maximum per-segment current specification when the pins on the segment are used for EBI function. If the pins are used instead for GPIO function, the user must ensure the sum of the current used on each pin in the segment does not exceed the spec.

1. Ensure that the f_{PLL0IN} frequency divided by PLLDIG_PLL0DV[PREDIV] is in the range 8 MHz to 20 MHz.
2. PLL0IN clock retrieved directly from either internal IRC or external XOSC clock. Input characteristics are granted when using internal IRC or external oscillator is used in functional mode.
3. 200 MHz applies to the MPC5777C part number with 264 MHz operating frequency. 240 MHz applies to the version with 306 MHz operating frequency.
4. Noise on the V_{DD} supply with frequency content below 40 kHz and above 50 MHz is filtered by the PLL. Noise on the V_{DD} supply with frequency content in the range of 40 kHz – 50 MHz must be filtered externally to the device.

| V _{EXTAL} | Oscillation amplitude on the EXTAL pin after startup ⁶ | — | 0.5 | 1.6 | V |
| V _{HYS} | Comparator hysteresis | — | 0.1 | 1.0 | V |
| I _{XTAL} | XTAL current ^{6, 7} | — | — | 14 | mA |

1. This value is determined by the crystal manufacturer and board design.
2. Proper PC board layout procedures must be followed to achieve specifications.
3. Crystal recovery time is the time for the oscillator to settle to the correct frequency after adjustment of the integrated load capacitor value.
4. See crystal manufacturer's specification for recommended load capacitor (C_L) values. The external oscillator requires external load capacitors when operating in a "low" transconductance range. Account for on-chip stray capacitance (C_{S_EXTAL}/C_{S_XTAL}) and PCB capacitance when selecting a load capacitor value. When operating in a "medium" or "high" transconductance range, the integrated load capacitor value is selected via software to match the crystal manufacturer's specification, while accounting for on-chip and PCB capacitance.
5. Select a "low," "medium," or "high" setting using the UTEST Miscellaneous DCF client's XOSC_LF_EN and XOSC_EN_HIGH fields. "Low" is the setting commonly used for crystals at 8 MHz, "medium" is commonly used for crystals greater than 8 MHz to 20 MHz, and "high" is commonly used for crystals greater than 20 MHz to 40 MHz. However, the user must characterize carefully to determine the best g_m setting for the intended application because crystal load capacitance, board layout, and other factors affect the g_m value that is needed. The user may need an additional Rshunt to optimize g_m depending on the system environment. Use of overtone crystals is not recommended.
6. Amplitude on the EXTAL pin after startup is determined by the ALC block (that is, the Automatic Level Control Circuit). The function of the ALC is to provide high drive current during oscillator startup, while reducing current after oscillation to reduce power, distortion, and RFI, and to avoid over-driving the crystal. The operating point of the ALC is dependent on the crystal value and loading conditions.
7. I_{XTAL} is the oscillator bias current out of the XTAL pin with both EXTAL and XTAL pins grounded. This is the maximum current during startup of the oscillator. The current after oscillation is typically in the 2–3 mA range and is dependent on the load and series resistance of the crystal. Test circuit is shown in [Figure 1](#).

- 128 sampling cycles (LST=128), differential conversion, pregain of x4
- Stop mode recovery time is the time from the setting of either of the enable bits in the ADC Control Register to the time that the ADC is ready to perform conversions. Delay from power up to full accuracy = 8 ms.
- At $V_{RH_EQ} - V_{RL_EQ} = 5.12$ V, one count = 1.25 mV without using pregain. Based on 12-bit conversion result; does not account for AC and DC errors
- INL and DNL are tested from $V_{RL} + 50$ LSB to $V_{RH} - 50$ LSB.

5. At $V_{RH_EQ} - V_{RL_EQ} = 5.12$ V, one LSB = 1.25 mV.
6. Below disruptive current conditions, the channel being stressed has conversion values of \$3FF for analog inputs greater than V_{RH} and \$000 for values less than V_{RL} . Other channels are not affected by non-disruptive conditions.
7. Exceeding limit may cause conversion error on stressed channels and on unstressed channels. Transitions within the limit do not affect device reliability or cause permanent damage.
8. Input must be current limited to the value specified. To determine the value of the required current-limiting resistor, calculate resistance values using $V_{POSCLAMP} = V_{DDA} + 0.5$ V and $V_{NEGCLAMP} = -0.3$ V, then use the larger of the calculated values.
9. Condition applies to two adjacent pins at injection limits.
10. Performance expected with production silicon.
11. All channels have same $10\text{ k}\Omega < R_s < 100\text{ k}\Omega$ Channel under test has $R_s = 10\text{ k}\Omega$, $I_{INJ} = I_{INJMAX}, I_{INJMIN}$.
12. The TUE specification is always less than the sum of the INL, DNL, offset, and gain errors due to cancelling errors.
13. TUE, Gain, and Offset specifications do not apply to differential conversions.
14. Variable gain is controlled by setting the PRE_GAIN bits in the ADC_ACR1-8 registers to select a gain factor of $\times 1$, $\times 2$, or $\times 4$. Settings are for differential input only. Tested at $\times 1$ gain. Values for other settings are guaranteed as indicated.
15. Guaranteed 10-bit monotonicity.
16. At $V_{RH_EQ} - V_{RL_EQ} = 5.12$ V, one LSB = 1.25 mV.

3.8.2 Sigma-Delta ADC (SDADC)

The SDADC is a 16-bit Sigma-Delta analog-to-digital converter with a 333 Ksps maximum output conversion rate.

NOTE

The voltage range is 4.5 V to 5.5 V for SDADC specifications, except where noted otherwise.

- For input voltage above the maximum and below the clamp voltage of the input pad, there is no latch-up concern, and the signal will only be “clipped.”
- V_{INP} is the input voltage applied to the positive terminal of the SDADC
- V_{INM} is the input voltage applied to the negative terminal of the SDADC
- Sampling is generated internally $f_{\text{SAMPLING}} = f_{\text{ADCD_M}}/2$
- For Gain = 16, SDADC resolution is 15 bit.
- Calibration of gain is possible when gain = 1. Offset Calibration should be done with respect to $0.5 \cdot V_{\text{RH_SD}}$ for differential mode and single ended mode with negative input = $0.5 \cdot V_{\text{RH_SD}}$. Offset Calibration should be done with respect to 0 for single ended mode with negative input = 0. Both Offset and Gain Calibration is guaranteed for +/-5% variation of $V_{\text{RH_SD}}$, +/-10% variation of $V_{\text{DDA_SD}}$, +/-50 C temperature variation.
- Offset and gain error due to temperature drift can occur in either direction (+/-) for each of the SDADCs on the device.
- SDADC is functional in the range $3.6 \text{ V} < V_{\text{DDA_SD}} < 4.0 \text{ V}$: SNR parameter degrades by 3 dB. SDADC is functional in the range $3.0 \text{ V} < V_{\text{RH_SD}} < 4.0 \text{ V}$: SNR parameter degrades by 9 dB.
- SNR values guaranteed only if external noise on the ADC input pin is attenuated by the required SNR value in the frequency range of $f_{\text{ADCD_M}} - f_{\text{ADCD_S}}$ to $f_{\text{ADCD_M}} + f_{\text{ADCD_S}}$, where $f_{\text{ADCD_M}}$ is the input sampling frequency and $f_{\text{ADCD_S}}$ is the output sample frequency. A proper external input filter should be used to remove any interfering signals in this frequency range.
- Input impedance in differential mode $Z_{\text{IN}} = Z_{\text{DIFF}}$
- Input impedance given at $f_{\text{ADCD_M}} = 16 \text{ MHz}$. Impedance is inversely proportional to SDADC clock frequency. $Z_{\text{DIFF}}(f_{\text{ADCD_M}}) = (16 \text{ MHz} / f_{\text{ADCD_M}}) \cdot Z_{\text{DIFF}}$, $Z_{\text{CM}}(f_{\text{ADCD_M}}) = (16 \text{ MHz} / f_{\text{ADCD_M}}) \cdot Z_{\text{CM}}$.
- Input impedance in single-ended mode $Z_{\text{IN}} = (2 \cdot Z_{\text{DIFF}} \cdot Z_{\text{CM}}) / (Z_{\text{DIFF}} + Z_{\text{CM}})$
- V_{INTCM} is the Common Mode input reference voltage for the SDADC. It has a nominal value of $(V_{\text{RH_SD}} - V_{\text{RL_SD}}) / 2$.
- The ±1% passband ripple specification is equivalent to $20 \cdot \log_{10}(0.99) = 0.087 \text{ dB}$.
- Propagation of the information from the pin to the register CDR[CDATA] and the flags SFR[DFFEF] and SFR[DFFF] is given by the different modules that must be crossed: delta/sigma filters, high pass filter, FIFO module, and clock domain synchronizers. The time elapsed between data availability at the pin and internal SDADC module registers is given by the following formula, where $f_{\text{ADCD_S}}$ is the after decimation ADC output data rate, $f_{\text{ADCD_M}}/2$ is the modulator sampling rate and $f_{\text{FM_PER_CLK}}$ is the frequency of the peripheral bridge clock feeds to the ADC S/D module.

$$\text{REGISTER LATENCY} = t_{\text{LATENCY}} + 0.5/f_{\text{ADCD_S}} + 2(\sim+1)/f_{\text{ADCD_M}} + 2(\sim+1)/f_{\text{FM_PER_CLK}}$$

The (~+1) symbol refers to the number of clock cycles uncertainty (from 0 to 1 clock cycle) to be added due to resynchronization of the signal during clock domain crossing.

Some further latency may be added by the target module (core, DMA, interrupt) controller to process the data received from the SDADC module.
- This capacitance does not include pin capacitance, that can be considered together with external capacitance, before sampling switch.

3.9 Temperature Sensor

The following table describes the Temperature Sensor electrical characteristics.

| C _{IN} | Differential input capacitance ¹¹ | — | — | 3.5 | 6.0 | pF |
| I _{LVDS_RX} | Receiver DC current consumption | Enabled | — | — | 0.5 | mA |

1. The LVDS pad startup and receiver electrical characteristics in this table apply to both the LFAST and the MSC/DSPi LVDS pad except where noted in the conditions.
2. All startup times are defined after a 2 peripheral bridge clock delay from writing to the corresponding enable bit in the LVDS control registers (LCR) of the LFAST and High-Speed Debug modules.
3. Startup times are valid for the maximum external loads CL defined in both the LFAST/HSD and MSC/DSPi transmitter electrical characteristic tables.
4. Bias startup time is defined as the time taken by the current reference block to reach the settling bias current after being enabled.
5. Total transmitter startup time from power down to normal mode is t_{STRT_BIAS} + t_{PD2NM_TX} + 2 peripheral bridge clock periods.
6. Total transmitter startup time from sleep mode to normal mode is t_{SM2NM_TX} + 2 peripheral bridge clock periods. Bias block remains enabled in sleep mode.
7. Total receiver startup time from power down to normal mode is t_{STRT_BIAS} + t_{PD2NM_RX} + 2 peripheral bridge clock periods.
8. Total receiver startup time from power down to sleep mode is t_{PD2SM_RX} + 2 peripheral bridge clock periods. Bias block remains enabled in sleep mode.
9. Absolute min = 0.15 V – (285 mV/2) = 0 V
10. Absolute max = 1.6 V + (285 mV/2) = 1.743 V
11. Total internal capacitance including receiver and termination, co-bonded GPIO pads, and package contributions. For bare die devices, subtract the package value given in [Figure 1](#).

1. The specifications in this table apply to both the interprocessor bus and debug LFAST interfaces.
2. The 480 MHz frequency is achieved with a 10 MHz or 20 MHz reference clock. With a 13 MHz or 26 MHz reference, the VCO frequency is 468 MHz.
3. The time from the PLL enable bit register write to the start of phase locks is maximum 2 clock cycles of the peripheral bridge clock that is connected to the PLL on the device.
4. Measured at the transmitter output across a 100 Ohm termination resistor on a device evaluation board. See [Figure 1](#).

3.11 Power management: PMC, POR/LVD, power sequencing

3.11.1 Power management electrical characteristics

The power management module monitors the different power supplies. It also generates the internal supplies that are required for correct device functionality. The power management is supplied by the V_{DDPMC} supply.

3.11.1.1 LDO mode recommended power transistors

Only specific orderable part numbers of MPC5777C support LDO regulation mode. See [Ordering information](#) for MPC5777C parts that support this regulation mode.

The following NPN transistors are recommended for use with the on-chip LDO voltage regulator controller: ON Semiconductor™ NJD2873. The collector of the external transistor is preferably connected to the same voltage supply source as the output stage of the regulator.

The following table describes the characteristics of the power transistors.

Table 24. Recommended operating characteristics

| Symbol | Parameter | Value | Unit |
|----------------|---|--------|------|
| h_{FE} | DC current gain (Beta) | 60-550 | — |
| P_D | Absolute minimum power dissipation | 1.60 | W |
| I_{CMaxDC} | Maximum DC collector current | 2.0 | A |
| $V_{CE_{SAT}}$ | Collector to emitter saturation voltage | 300 | mV |
| V_{BE} | Base to emitter voltage | 0.95 | V |
| V_c | Minimum voltage at transistor collector | 2.5 | V |

Electrical characteristics

The following table shows the recommended components to be used in LDO regulation mode.

Table 25. Recommended operating characteristics

3.11.1.2 SMPS mode recommended external components and characteristics

The following table shows the recommended components to be used in SMPS regulation mode.

Table 26. Recommended operating characteristics

| Part name | Part type | Nominal | Description |
|-----------|-----------|---------------------|---|
| Q1 | p-MOS | 3 A - 20 V | SQ2301ES / FDC642P or equivalent: low threshold p-MOS, $V_{th} < 2.0$ V, R_{dson} @ 4.5 V < 100 m Ω , $C_g < 5$ nF |
| D1 | Schottky | 2 A - 20 V | SS8P3L or equivalent: Vishay™ low V_f Schottky diode |
| L | Inductor | 3-4 μ H - 1.5 A | Buck shielded coil low ESR |
| CI | Capacitor | 22 μ F - 20 V | Ceramic capacitor, total ESR < 70 m Ω |
| CE | Capacitor | 0.1 μ F - 7 V | Ceramic—one capacitor for each V_{DD} pin |
| CV | Capacitor | 22 μ F - 20 V | Ceramic V_{DDPMC} (optional 0.1 μ F capacitor in parallel) |
| CD | Capacitor | 22 μ F - 20 V | Ceramic supply decoupling capacitor, ESR < 50 m Ω (as close as possible to the p-MOS source) |
| R | Resistor | 2.0-4.7 k Ω | Pullup for power p-MOS gate |
| CB | Capacitor | 22 μ F - 20 V | Ceramic, connect 100 nF capacitor in parallel (as close as possible to package to reduce current loop from V_{DDPWR} to V_{SSPWR}) |

The following diagram shows the SMPS configuration connection.

**Figure 13. SMPS configuration****NOTE**

The REGSEL pin is tied to V_{DDPMC} to select SMPS. If REGSEL is 0, the chip boots with the linear regulator.

See [Power sequencing requirements](#) for details about V_{DDPMC} and V_{DDPWR} .

The SMPS regulator characteristics appear in the following table.

3.11.2 Power management integration

To ensure correct functionality of the device, use the following recommended integration scheme for LDO mode.

Figure 14. Recommended supply pin circuits

The following table describes the supply stability capacitances required on the device for proper operation.

Table 28. Device power supply integration

| Symbol | Parameter | Conditions | Value ¹ | | | Unit |

1. See [Figure 1](#) for capacitor integration.
2. Recommended X7R or X5R ceramic low ESR capacitors, ±15% variation over process, voltage, temperature, and aging.
3. Each V_{DD} pin requires both a 47 nF and a 0.01 μF capacitor for high-frequency bypass and EMC requirements.
4. Recommended X7R or X5R ceramic low ESR capacitors, ±15% variation over process, voltage, temperature, and aging.
5. Each V_{DDPMC} pin requires both a 47 nF and a 0.01 μF capacitor for high-frequency bypass and EMC requirements.
6. The actual capacitance should be selected based on the I/O usage in order to keep the supply voltage within its operating range.
7. The recommended flash regulator composition capacitor is 2.0 μF typical X7R or X5R, with -50% and +35% as min and max. This puts the min cap at 0.75 μF.
8. For noise filtering it is recommended to add a high frequency bypass capacitance of 0.1 μF between V_DDA_EQA/B and V_{SSA_EQ}.
9. For noise filtering it is recommended to add a high frequency bypass capacitance of 0.1 μF between REF_{BYP}CA/B and V_{SS}.
10. For noise filtering it is recommended to add a high frequency bypass capacitance of 0.1 μF between V_DDA_SD and V_{SSA_SD}.

3.11.3 Device voltage monitoring

The LVD/HVDs for the device and their levels are given in the following table. Voltage monitoring threshold definition is provided in the following figure.

- LVD is released after $t_{VDRELEASE}$ temporization when upper threshold is crossed; LVD is asserted $t_{VDASSERT}$ after detection when lower threshold is crossed.
- HVD is released after $t_{VDRELEASE}$ temporization when lower threshold is crossed; HVD is asserted $t_{VDASSERT}$ after detection when upper threshold is crossed.
- POR098_c threshold is an untrimmed value, before the completion of the power-up sequence. All other LVD/HVD thresholds are provided after trimming.
- LV internal supply levels are measured on device internal supply grid after internal voltage drop.
- LV external supply levels are measured on the die side of the package bond wire after package voltage drop.
- V_{DDFLA} range is guaranteed when internal flash memory regulator is used.

3.11.4 Power sequencing requirements

Requirements for power sequencing include the following.

NOTE

In these descriptions, *star route layout* means a track split as close as possible to the power supply source. Each of the split tracks is routed individually to the intended end connection.

1. For both LDO mode and SMPS mode, V_{DDPMC} and V_{DDPWR} must be connected together (shorted) to ensure aligned voltage ramping up/down. In addition:
 - For SMPS mode, a star route layout of the power track is required to minimize mutual noise. If SMPS mode is not used, the star route layout is not required. V_{DDPWR} is the supply pin for the SMPS circuitry.
 - For 3.3 V operation, V_{DDFLA} must also be star routed and shorted to V_{DDPWR} and V_{DDPMC} . This triple connection is required because 3.3 V does not guarantee correct functionality of the internal V_{DDFLA} regulator. Consequently, V_{DDFLA} is supplied externally.
2. V_{DDA_MISC} : IRC operation is required to provide the clock for chip startup.
 - The V_{DDPMC} , V_{DD} , and V_{DDEH1} (reset pin pad segment) supplies are monitored. They hold IRC until all of them reach operational voltage. In other words, V_{DDA_MISC} must reach its specified minimum operating voltage before or at the same time that all of these monitored voltages reach their respective specified minimum voltages.
 - An alternative is to connect the same supply voltage to both V_{DDEH1} and V_{DDA_MISC} . This alternative approach requires a star route layout to minimize mutual noise.
3. Multiple V_{DDEX} supplies can be powered up in any order.

During any time when V_{DD} is powered up but V_{DDEX} is not yet powered up: pad outputs are unpowered.

During any time when V_{DDEX} is powered up before all other supplies: all pad output buffers are tristated.
4. Ramp up V_{DDA_EQ} before V_{DD} . Otherwise, a reset might occur.
5. When the device is powering down while using the internal SMPS regulator, V_{DDPMC} and V_{DDPWR} supplies must ramp down through the voltage range from 2.5 V to 1.5 V in less than 1 second. Slower ramp-down times might result in reduced lifetime reliability of the device.

3.12 Flash memory specifications

3.12.1 Flash memory program and erase specifications

NOTE

All timing, voltage, and current numbers specified in this section are defined for a single embedded flash memory within an SoC, and represent average currents for given supplies and operations.

Table 30 shows the estimated Program/Erase times.

Table 30. Flash memory program and erase specifications

| Symbol | Characteristic ¹ | Typ ² | Factory Programming ^{3, 4} | | Field Update | | | Unit |

| t _{64kers} | 64 KB Block erase time | 315 | 490 | 590 | 420 | 1,600 | | ms |
| t _{64kpgm} | 64 KB Block program time | 138 | 180 | 210 | 170 | 1,600 | | ms |
| t _{256kers} | 256 KB Block erase time | 884 | 1,520 | 2,030 | 1,080 | 4,000 | — | ms |
| t _{256kpgm} | 256 KB Block program time | 552 | 720 | 880 | 650 | 4,000 | — | ms |

1. Program times are actual hardware programming times and do not include software overhead. Block program times assume quad-page programming.
2. Typical program and erase times represent the median performance and assume nominal supply values and operation at 25 °C. Typical program and erase times may be used for throughput calculations.
3. Conditions: ≤ 150 cycles, nominal voltage.
4. Plant Programming times provide guidance for timeout limits used in the factory.
5. Typical End of Life program and erase times represent the median performance and assume nominal supply values. Typical End of Life program and erase values may be used for throughput calculations.
6. Conditions: -40°C ≤ T_J ≤ 150°C, full spec voltage.

3.12.2 Flash memory Array Integrity and Margin Read specifications

Table 31. Flash memory Array Integrity and Margin Read specifications

| Symbol | Characteristic | Min | Typical | Max ¹ | Units ² |
|-----------------|---|--------|---------|------------------------------|--------------------|
| $t_{ai16kseq}$ | Array Integrity time for sequential sequence on 16 KB block. | — | — | 512 x Tperiod x Nread | — |
| $t_{ai32kseq}$ | Array Integrity time for sequential sequence on 32 KB block. | — | — | 1024 x Tperiod x Nread | — |
| $t_{ai64kseq}$ | Array Integrity time for sequential sequence on 64 KB block. | — | — | 2048 x Tperiod x Nread | — |
| $t_{ai256kseq}$ | Array Integrity time for sequential sequence on 256 KB block. | — | — | 8192 x Tperiod x Nread | — |
| $t_{mr16kseq}$ | Margin Read time for sequential sequence on 16 KB block. | 73.81 | — | 110.7 | μs |
| $t_{mr32kseq}$ | Margin Read time for sequential sequence on 32 KB block. | 128.43 | — | 192.6 | μs |
| $t_{mr64kseq}$ | Margin Read time for sequential sequence on 64 KB block. | 237.65 | — | 356.5 | μs |
| $t_{mr256kseq}$ | Margin Read time for sequential sequence on 256 KB block. | 893.01 | — | 1,339.5 | μs |

1. Array Integrity times need to be calculated and is dependent on system frequency and number of clocks per read. The equation presented require Tperiod (which is the unit accurate period, thus for 200 MHz, Tperiod would equal 5e-9) and Nread (which is the number of clocks required for read, including pipeline contribution. Thus for a read setup that requires 6 clocks to read with no pipeline, Nread would equal 6. For a read setup that requires 6 clocks to read, and has the address pipeline set to 2, Nread would equal 4 (or 6 - 2).)
2. The units for Array Integrity are determined by the period of the system clock. If unit accurate period is used in the equation, the results of the equation are also unit accurate.

1. All Nexus timing relative to MCKO is measured from 50% of MCKO and 50% of the respective signal. Nexus timing specified at $V_{DD} = 1.08\text{ V to }1.32\text{ V}$, $V_{DDE} = 3.0\text{ V to }3.6\text{ V}$, V_{DD33} and $V_{DDSYN} = 3.0\text{ V to }3.6\text{ V}$, $T_A = T_L$ to T_H , and $C_L = 30\text{ pF}$ with $DSC = 0b10$.
2. MDO, MSEO, and EVTO data is held valid until next MCKO low cycle.
3. This is a functionally allowable feature. However, it may be limited by the maximum frequency specified by the absolute minimum TCK period specification.
4. This value is TDO propagation time plus 2 ns setup time to sampling edge.
5. This may require a maximum clock speed that is less than the maximum functional capability of the design depending on the actual system frequency being used.
6. Applies to TMS pin timing for the bit frame when using the 1149.7 advanced protocol.
7. The \overline{RDY} pin timing is asynchronous to MCKO. The timing is guaranteed by design to function correctly.

1. EBI timing specified at $V_{DD} = 1.08\text{ V}$ to 1.32 V , $V_{DDE} = 3.0\text{ V}$ to 3.6 V , $T_A = T_L$ to T_H , and $C_L = 30\text{ pF}$ with $SIU_PCR[DSC] = 11b$ for ADDR/CTRL and $SIU_PCR[SRC] = 11b$ for DATA/ALE.
2. Speed is the nominal maximum frequency. Max speed is the maximum speed allowed including frequency modulation (FM).
3. Depending on the internal bus speed, set the $SIU_ECCR[EBDF]$ bits correctly not to exceed maximum external bus frequency. The maximum external bus frequency is 66 MHz.
4. Refer to D_CLKOUT pad timing in [Table 2](#).
5. ALE hold time spec is temperature dependant. 1.0 ns spec applies for temperature range -40 to 0°C . 2.0ns spec applies to temperatures $> 0^\circ\text{C}$. This spec has no dependency on the $SIU_ECCR[EBTS]$ bit.

3.13.9 DSPI timing with CMOS and LVDS pads

NOTE

The DSPI in TSB mode with LVDS pads can be used to implement the Micro Second Channel (MSC) bus protocol.

DSPI channel frequency support is shown in [Table 42](#). Timing specifications are shown in [Table 43](#), [Table 44](#), [Table 45](#), [Table 46](#), and [Table 47](#).

Table 42. DSPI channel frequency support

| DSPI use mode | | Max usable frequency (MHz) ^{1, 2} |
|--------------------|---|--|
| CMOS (Master mode) | Full duplex – Classic timing (Table 43) | 17 |
| | Full duplex – Modified timing (Table 44) | 30 |

- All output timing is worst case and includes the mismatching of rise and fall times of the output pads.
- When a characteristic involves two signals, the pad drive and load conditions apply to each signal's pad, unless specified otherwise.
- All timing values for output signals in this table are measured to 50% of the output voltage.
- Pad drive is defined as the PCR[SRC] field setting in the SIU. Timing is guaranteed to same drive capabilities for all signals; mixing of pad drives may reduce operating speeds and may cause incorrect operation.
- N is the number of clock cycles added to time between PCS assertion and SCK assertion and is software programmable using DSPI_CTARx[PSSCK] and DSPI_CTARx[CSSCK]. The minimum value is 2 cycles unless TSB mode or Continuous SCK clock mode is selected, in which case, N is automatically set to 0 clock cycles (PCS and SCK are driven by the same edge of DSPI_CLKn).
- t_{SYS} is the period of DSPI_CLKn clock, the input clock to the DSPI module. Maximum frequency is 100 MHz (min t_{SYS} = 10 ns).
- M is the number of clock cycles added to time between SCK negation and PCS negation and is software programmable using DSPI_CTARx[PASC] and DSPI_CTARx[ASC]. The minimum value is 2 cycles unless TSB mode or Continuous SCK

Electrical characteristics

clock mode is selected, in which case, M is automatically set to 0 clock cycles (PCS and SCK are driven by the same edge of DSPI_CLKn).

8. t_{SDC} is only valid for even divide ratios. For odd divide ratios the fundamental duty cycle is not 50:50. For these odd divide ratios cases, the absolute spec number is applied as jitter/uncertainty to the nominal high time and low time.
9. PCSx and \overline{PCSS} using same pad configuration.
10. Input timing assumes an input slew rate of 1 ns (10% – 90%) and uses TTL / Automotive voltage thresholds.
11. SOUT Data Valid and Data hold are independent of load capacitance if SCK and SOUT load capacitances are the same value.

| | | SOUT data hold time after SCK CPHA = 1 ¹⁰ | LVDS | 15 pF to 25 pF differential | -7.5 | — | ns |

- When a characteristic involves two signals, the pad drive and load conditions apply to each signal's pad, unless specified otherwise.
- All timing values for output signals in this table are measured to 50% of the output voltage.
- Pad drive is defined as the PCR[*SRC*] field setting in the SIU. Timing is guaranteed to same drive capabilities for all signals; mixing of pad drives may reduce operating speeds and may cause incorrect operation.
- N is the number of clock cycles added to time between PCS assertion and SCK assertion and is software programmable using DSPI_CTARx[PSSCK] and DSPI_CTARx[CSSCK]. The minimum value is 2 cycles unless TSB mode or Continuous SCK clock mode is selected, in which case, N is automatically set to 0 clock cycles (PCS and SCK are driven by the same edge of DSPI_CLKn).
- t_{SYS} is the period of DSPI_CLKn clock, the input clock to the DSPI module. Maximum frequency is 100 MHz (min t_{SYS} = 10 ns).
- M is the number of clock cycles added to time between SCK negation and PCS negation and is software programmable using DSPI_CTARx[PASC] and DSPI_CTARx[ASC]. The minimum value is 2 cycles unless TSB mode or Continuous SCK clock mode is selected, in which case, M is automatically set to 0 clock cycles (PCS and SCK are driven by the same edge of DSPI_CLKn).
- t_{SDC} is only valid for even divide ratios. For odd divide ratios the fundamental duty cycle is not 50:50. For these odd divide ratios cases, the absolute spec number is applied as jitter/uncertainty to the nominal high time and low time.
- Input timing assumes an input slew rate of 1 ns (10% – 90%) and LVDS differential voltage = ±100 mV.
- P is the number of clock cycles added to delay the DSPI input sample point and is software programmable using DSPI_MCR[SMPL_PT]. The value must be 0, 1 or 2. If the baud rate divide ratio is /2 or /3, this value is automatically set to 1.
- SOUT Data Valid and Data hold are independent of load capacitance if SCK and SOUT load capacitances are the same value.

3.13.10.2 MII transmit signal timing (TXD[3:0], TX_EN, and TX_CLK)

The transmitter functions correctly up to a TX_CLK maximum frequency of 25 MHz +1%. There is no minimum frequency requirement. The system clock frequency must be at least equal to or greater than the TX_CLK frequency.

The transmit outputs (TXD[3:0], TX_EN) can be programmed to transition from either the rising or falling edge of TX_CLK, and the timing is the same in either case. This options allows the use of noncompliant MII PHYs.

Refer to the *MPC5777C Microcontroller Reference Manual's* Fast Ethernet Controller (FEC) chapter for details of this option and how to enable it.

4.1.1 General notes for thermal characteristics

An estimation of the chip junction temperature, T_J, can be obtained from the equation:

$$T_J = T_A + (R_{\theta JA} * P_D)$$

Equation 1

where:

T_A = ambient temperature for the package (°C)

R_{θJA} = junction-to-ambient thermal resistance (°C/W)

P_D = power dissipation in the package (W)

The thermal resistance values used are based on the JEDEC JESD51 series of standards to provide consistent values for estimations and comparisons. The difference between the values determined for the single-layer (1s) board compared to a four-layer board that has two signal layers, a power and a ground plane (2s2p), demonstrate that the effective thermal resistance is not a constant. The thermal resistance depends on the:

- Construction of the application board (number of planes)

- Effective size of the board which cools the component
- Quality of the thermal and electrical connections to the planes
- Power dissipated by adjacent components

Connect all the ground and power balls to the respective planes with one via per ball. Using fewer vias to connect the package to the planes reduces the thermal performance. Thinner planes also reduce the thermal performance. When the clearance between the vias leave the planes virtually disconnected, the thermal performance is also greatly reduced.

As a general rule, the value obtained on a single-layer board is within the normal range for the tightly packed printed circuit board. The value obtained on a board with the internal planes is usually within the normal range if the application board has:

- One oz. (35 micron nominal thickness) internal planes
- Components are well separated
- Overall power dissipation on the board is less than 0.02 W/cm²

The thermal performance of any component depends on the power dissipation of the surrounding components. In addition, the ambient temperature varies widely within the application. For many natural convection and especially closed box applications, the board temperature at the perimeter (edge) of the package is approximately the same as the local air temperature near the device. Specifying the local ambient conditions explicitly as the board temperature provides a more precise description of the local ambient conditions that determine the temperature of the device.

At a known board temperature, the junction temperature is estimated using the following equation:

$$T_J = T_B + (R_{\theta JB} * P_D)$$

Equation 2

where:

T_B = board temperature for the package perimeter (°C)

$R_{\theta JB}$ = junction-to-board thermal resistance (°C/W) per JESD51-8

P_D = power dissipation in the package (W)

When the heat loss from the package case to the air does not factor into the calculation, the junction temperature is predictable if the application board is similar to the thermal test condition, with the component soldered to a board with internal planes.

The thermal resistance is expressed as the sum of a junction-to-case thermal resistance plus a case-to-ambient thermal resistance:

$$R_{\theta JA} = R_{\theta JC} + R_{\theta CA}$$

Equation 3

where:

$R_{\theta JA}$ = junction-to-ambient thermal resistance ($^{\circ}\text{C}/\text{W}$)

$R_{\theta JC}$ = junction-to-case thermal resistance ($^{\circ}\text{C}/\text{W}$)

$R_{\theta CA}$ = case to ambient thermal resistance ($^{\circ}\text{C}/\text{W}$)

$R_{\theta JC}$ is device related and is not affected by other factors. The thermal environment can be controlled to change the case-to-ambient thermal resistance, $R_{\theta CA}$. For example, change the air flow around the device, add a heat sink, change the mounting arrangement on the printed circuit board, or change the thermal dissipation on the printed circuit board surrounding the device. This description is most useful for packages with heat sinks where 90% of the heat flow is through the case to heat sink to ambient. For most packages, a better model is required.

A more accurate two-resistor thermal model can be constructed from the junction-to-board thermal resistance and the junction-to-case thermal resistance. The junction-to-case thermal resistance describes when using a heat sink or where a substantial amount of heat is dissipated from the top of the package. The junction-to-board thermal resistance describes the thermal performance when most of the heat is conducted to the printed circuit board. This model can be used to generate simple estimations and for computational fluid dynamics (CFD) thermal models. More accurate compact Flotherm models can be generated upon request.

To determine the junction temperature of the device in the application on a prototype board, use the thermal characterization parameter (Ψ_{JT}) to determine the junction temperature by measuring the temperature at the top center of the package case using the following equation:

$$T_J = T_T + (\Psi_{JT} \times P_D)$$

Equation 4

where:

T_T = thermocouple temperature on top of the package ($^{\circ}\text{C}$)

Ψ_{JT} = thermal characterization parameter ($^{\circ}\text{C}/\text{W}$)

P_D = power dissipation in the package (W)

The thermal characterization parameter is measured in compliance with the JESD51-2 specification using a 40-gauge type T thermocouple epoxied to the top center of the package case. Position the thermocouple so that the thermocouple junction rests on the package. Place a small amount of epoxy on the thermocouple junction and approximately 1 mm of wire extending from the junction. Place the thermocouple wire flat against the package case to avoid measurement errors caused by the cooling effects of the thermocouple wire.

When board temperature is perfectly defined below the device, it is possible to use the thermal characterization parameter (Ψ_{JPB}) to determine the junction temperature by measuring the temperature at the bottom center of the package case (exposed pad) using the following equation:

$$T_J = T_B + (\Psi_{JPB} \times P_D)$$

Equation 5

where:

T_T = thermocouple temperature on bottom of the package (°C)

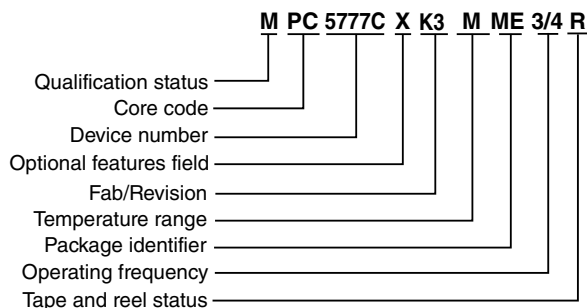

Ψ_{JT} = thermal characterization parameter (°C/W)

P_D = power dissipation in the package (W)

5 Ordering information

[Figure 49](#) and [Table 57](#) describe orderable part numbers for the MPC5777C.

Temperature range
M = -40 °C to 125 °C

Package identifier
ME = 416 MAPBGA Pb-Free
MO = 516 MAPBGA Pb-Free

Tape and reel status
R = Tape and reel
(blank) = Trays

Qualification status
P = Pre-qualification
M = Fully spec. qualified, general market flow
S = Fully spec. qualified, automotive flow

Operating frequency
3 = 2 x 264 MHz
4 = 2 x 306 MHz

Optional features field

(blank) = ISO-compliant CAN FD not available, trimmed for SMPS or external regulator, and includes SHE-compliant security firmware version 2.07
A = ISO-compliant CAN FD not available, trimmed for SMPS or external regulator, and includes SHE-compliant security firmware version 2.08
R = ISO-compliant CAN FD not available, trimmed for LDO regulator, and includes SHE-compliant security firmware version 2.08
C = ISO-compliant CAN FD available, trimmed for SMPS or external regulator, and includes SHE-compliant security firmware version 2.07
D = ISO-compliant CAN FD available, trimmed for SMPS or external regulator, and includes SHE-compliant security firmware version 2.08
L = ISO-compliant CAN FD available, trimmed for LDO regulator, and includes SHE-compliant security firmware version 2.08
S = ISO-compliant CAN FD available, trimmed for SMPS or external regulator, and includes RSA-enhanced security firmware
T = ISO-compliant CAN FD available, trimmed for LDO regulator, and includes RSA-enhanced security firmware

Note: Not all options are available on all devices.

| Part number ¹ | Package description | Speed (MHz) ² | Operating temperature ³ | |
|--------------------------|---|--------------------------|------------------------------------|-----------------------|
| | | | Min (T _L) | Max (T _H) |
| SPC5777CCK3MME3 | MPC5777C 416 package Lead-free (Pb-free) | 264 | -40 °C | 125 °C |
| SPC5777CK3MME3 | MPC5777C 416 package Lead-free (Pb-free) | 264 | -40 °C | 125 °C |
| SPC5777CCK3MMO3 | MPC5777C 516 package Lead-free (Pb-free) | 264 | -40 °C | 125 °C |
| SPC5777CK3MMO3 | MPC5777C 516 package Lead-free (Pb-free) | 264 | -40 °C | 125 °C |

- All packaged devices are PPC5777C, rather than MPC5777C or SPC5777C, until product qualifications are complete. The unpackaged device prefix is PCC, rather than SCC, until product qualification is complete.

Not all configurations are available in the PPC parts.

- For the operating mode frequency of various blocks on the device, see [Table 1](#).
- The lowest ambient operating temperature is referenced by T_L; the highest ambient operating temperature is referenced by T_H.
