## 4.2.1 General Notes for Specifications at Maximum Junction Temperature

An estimation of the chip junction temperature,  $T_J$ , can be obtained from the equation:

$$T_J = T_A + (R_{\theta JA} * P_D) \quad \text{Eqn. 1}$$

where:

$T_A$  = ambient temperature for the package ( $^{\circ}\text{C}$ )

$R_{\theta JA}$  = junction to ambient thermal resistance ( $^{\circ}\text{C}/\text{W}$ )

$P_D$  = power dissipation in the package (W)

The junction to ambient thermal resistance is an industry standard value that provides a quick and easy estimation of thermal performance. Unfortunately, there are two values in common usage: the value determined on a single layer board and the value obtained on a board with two planes. For packages such as the TEPBGA, these values can be different by a factor of two. Which value is closer to the application depends on the power dissipated by other components on the board. The value obtained on a single layer board is appropriate for the tightly packed printed circuit board. The value obtained on the board with the internal planes is usually appropriate if the board has low power dissipation and the components are well separated.

When a heat sink is used, the thermal resistance is expressed as the sum of a junction to case thermal resistance and a case to ambient thermal resistance:

$$R_{\theta JA} = R_{\theta JC} + R_{\theta CA} \quad \text{Eqn. 2}$$

where:

$R_{\theta JA}$  = junction to ambient thermal resistance ( $^{\circ}\text{C}/\text{W}$ )

$R_{\theta JC}$  = junction to case thermal resistance ( $^{\circ}\text{C}/\text{W}$ )

$R_{\theta CA}$  = case to ambient thermal resistance ( $^{\circ}\text{C}/\text{W}$ )

$R_{\theta JC}$  is device related and cannot be influenced by the user. The user controls the thermal environment to change the case to ambient thermal resistance,  $R_{\theta CA}$ . For instance, the user can change the size of the heat sink, the air flow around the device, the interface material, the mounting arrangement on printed circuit board, or change the thermal dissipation on the printed circuit board surrounding the device.

To determine the junction temperature of the device in the application when heat sinks are not used, the Thermal Characterization Parameter ( $\Psi_{JT}$ ) can be used to determine the junction temperature with a measurement of the temperature at the top center of the package case using the following equation:

$$T_J = T_T + (\Psi_{JT} * P_D) \quad \text{Eqn. 3}$$

where:

$T_T$  = thermocouple temperature on top of the package ( $^{\circ}\text{C}$ )

$\Psi_{JT}$  = thermal characterization parameter ( $^{\circ}\text{C}/\text{W}$ )

$P_D$  = power dissipation in the package (W)

The thermal characterization parameter is measured per JESD51-2 specification using a 40 gauge type T thermocouple epoxied to the top center of the package case. The thermocouple should be positioned so that the thermocouple junction rests on the

## Electrical Characteristics

package. A small amount of epoxy is placed over the thermocouple junction and over about 1 mm. of wire extending from the junction. The thermocouple wire is placed flat against the package case to avoid measurement errors caused by cooling effects of the thermocouple wire.

<sup>2</sup> Parameter cannot be tested; this value is based on simulation and characterization.

## 4.6 Power Up/Down Sequencing

There is no power sequencing required among power sources during power up and power down in order to operate within specification as long as the following two rules are met:

- When VDDREG is tied to a nominal 3.3V supply, VDD33 and VDDSYN must be both shorted to VDDREG.
- When VDDREG is tied to a 5V supply, VDD33 and VDDSYN must be tied together and shall be powered by the internal 3.3V regulator.

The recommended power supply behavior is as follows: Use 25 V/millisecond or slower rise time for all supplies. Power up each  $V_{DDE}/V_{DDEH}$  first and then power up  $V_{DD}$ . For power down, drop  $V_{DD}$  to 0 V first, and then drop all  $V_{DDE}/V_{DDEH}$  supplies. There is no limit on the fall time for the power supplies.

Although there are no power up/down sequencing requirements to prevent issues like latch-up, excessive current spikes, etc., the state of the I/O pins during power up/down varies according to [Table 12](#) and [Table 13](#).

**Table 12. Power Sequence Pin States for MH and AE pads**

VDD	VDD33	VDDE	MH Pad	MH+LVDS Pads <sup>1</sup>	AE/up-down Pads

<sup>1</sup> MH+LVDS pads are output-only.

<sup>1</sup> The pad pre-drive circuitry will function normally but since VDDE is unpowered the outputs will not drive high even though the output pmos can be enabled.

### 4.6.1 Power-Up

If  $V_{DDE}/V_{DDEH}$  is powered up first, then a threshold detector tristates all drivers connected to  $V_{DDE}/V_{DDEH}$ . There is no limit to how long after  $V_{DDE}/V_{DDEH}$  powers up before  $V_{DD}$  must power up. If there are multiple  $V_{DDE}/V_{DDEH}$  supplies, they can be powered up in any order. For each  $V_{DDE}/V_{DDEH}$  supply not powered up, the drivers in that  $V_{DDE}/V_{DDEH}$  segment exhibit the characteristics described in the next paragraph.

## Electrical Characteristics

If  $V_{DD}$  is powered up first, then all pads are loaded through the drain diodes to  $V_{DDE}/V_{DDEH}$ . This presents a heavy load that pulls the pad down to a diode above  $V_{SS}$ . Current injected by external devices connected to the pads must meet the current injection specification. There is no limit to how long after  $V_{DD}$  powers up before  $V_{DDE}/V_{DDEH}$  must power up.

The rise times on the power supplies are to be no faster than 25 V/millisecond.

### 4.6.2 Power-Down

If  $V_{DD}$  is powered down first, then all drivers are tristated. There is no limit to how long after  $V_{DD}$  powers down before  $V_{DDE}/V_{DDEH}$  must power down.

If  $V_{DDE}/V_{DDEH}$  is powered down first, then all pads are loaded through the drain diodes to  $V_{DDE}/V_{DDEH}$ . This presents a heavy load that pulls the pad down to a diode above  $V_{SS}$ . Current injected by external devices connected to the pads must meet the current injection specification. There is no limit to how long after  $V_{DDE}/V_{DDEH}$  powers down before  $V_{DD}$  must power down.

There are no limits on the fall times for the power supplies.

### 4.6.3 Power Sequencing and POR Dependent on $V_{DDA}$

During power up or down,  $V_{DDA}$  can lag other supplies (of magnitude greater than  $V_{DDEH}/2$ ) within 1 V to prevent any forward-biasing of device diodes that causes leakage current and/or POR. If the voltage difference between  $V_{DDA}$  and  $V_{DDEH}$  is more than 1 V, the following will result:

- Triggers POR (ADC monitors on  $V_{DDEH1}$  segment which powers the RESET pin) if the leakage current path created, when  $V_{DDA}$  is sufficiently low, causes sufficient voltage drop on  $V_{DDEH1}$  node monitored crosses low-voltage detect level.
- If  $V_{DDA}$  is between 0–2 V, powering all the other segments (especially  $V_{DDEH1}$ ) will not be sufficient to get the part out of reset.
- Each  $V_{DDEH}$  will have a leakage current to  $V_{DDA}$  of a magnitude of  $((V_{DDEH} - V_{DDA} - 1 \text{ V (diode drop)})/200 \text{ KOhms})$  up to  $(V_{DDEH}/2 = V_{DDA} + 1 \text{ V})$ .
- Each  $V_{DD}$  has the same behavior; however, the leakage will be small even though there is no current limiting resistor since  $V_{DD} = 1.32 \text{ V max.}$

## 4.7.1 I/O Pad Current Specifications

The power consumption of an I/O segment is dependent on the usage of the pins on a particular segment. The power consumption is the sum of all output pin currents for a particular segment. The output pin current can be calculated from [Table 15](#) based on the voltage, frequency, and load on the pin. Use linear scaling to calculate pin currents for voltage, frequency, and load parameters that fall outside the values given in [Table 15](#).

The AC timing of these pads are described in the [Section 4.11.2, “Pad AC Specifications.”](#)

#### 4.7.2 I/O Pad $V_{DD33}$ Current Specifications

The power consumption of the  $V_{DD33}$  supply is dependent on the usage of the pins on all I/O segments. The power consumption is the sum of all input and output pin  $V_{DD33}$  currents for all I/O segments. The  $V_{DD33}$  current draw on fast speed pads can be calculated from Table 16 dependent on the voltage, frequency, and load on all F type pins. The  $V_{DD33}$  current draw on medium pads can be calculated from Table 16 dependent on voltage and independent on the frequency and load on all MH type pins. Use linear scaling to calculate pin currents for voltage, frequency, and load parameters that fall outside the values given in Table 16.

The AC timing of these pads are described in the Section 4.11.2, “Pad AC Specifications.”

12	Modulation Rate Limits <sup>13</sup>	$f_{mod}$	0.400	1	MHz
13	Predivider output frequency range <sup>14</sup>	$f_{prediv}$	4	10	MHz

<sup>1</sup> All values given are initial design targets and subject to change.

<sup>2</sup> Crystal and External reference frequency limits depend on device relying on PLL to lock prior to release of reset, default PREDIV/EPREDIV, MFD/EMFD default settings, and VCO frequency range. Absolute minimum loop frequency is 4 MHz.

<sup>3</sup> Upper tolerance of less than 1% is allowed on 40MHz crystal.

<sup>4</sup> "Loss of Reference Frequency" is the reference frequency detected internally, which transitions the PLL into self clocked mode.

<sup>5</sup> Self clocked mode frequency is the frequency that the PLL operates at when the reference frequency falls below  $f_{LOR}$ . This frequency is measured at D\_CLKOUT. A default RFD value of (0x05) is used in SCM mode, and the programmed MFD and RFD values have no effect

<sup>6</sup> This specification applies to the period required for the PLL to re-lock after changing the MFD frequency control bits in the synthesizer control register (SYNCR). From power up with crystal oscillator reference, lock time will be additive with crystal startup time.

<sup>7</sup> For Flexray operation, duty cycle requirements are higher.

<sup>8</sup> Jitter is the average deviation from the programmed frequency measured over the specified interval at maximum  $f_{sys}$ . Measurements are made with the device powered by filtered supplies and clocked by a stable external clock signal. Noise injected into the PLL circuitry via  $V_{DDSYN}$  and  $V_{SSSYN}$  and variation in crystal oscillator frequency increase the  $C_{jitter}$  percentage for a given interval. D\_CLKOUT divider set to divide-by-2.

<sup>9</sup> Values are with frequency modulation disabled. If frequency modulation is enabled, jitter is the sum of  $C_{jitter} + C_{mod}$ .

<sup>10</sup> Modulation depth selected must not result in  $f_{pll}$  value greater than the  $f_{pll}$  maximum specified value.

<sup>11</sup> Maximum and minimum variation from programmed modulation depth is pending characterization. Depth settings available in control register are: 2%, 3%, and 4% peak-to-peak.

<sup>12</sup> Depth tolerance is the programmed modulation depth  $\pm 0.25\%$  of  $F_{sys}$ . Violating the VCO min/max range may prevent the system from exiting reset.

<sup>13</sup> Modulation rates less than 400 kHz will result in exceedingly long FM calibration durations. Modulation rates greater than 1 MHz will result in reduced calibration accuracy.

<sup>14</sup> Violating this range will cause the VCO max/min range to be violated with the default MFD settings out of reset.

<sup>1</sup> All values given are initial design targets and subject to change.

<sup>2</sup> This parameter is meant for those who do not use quartz crystals or resonators, but instead use CAN oscillators in crystal mode. In that case,  $V_{\text{extal}} - V_{\text{xtal}} \geq 400\text{ mV}$  criterion has to be met for oscillator's comparator to produce output clock.

<sup>3</sup>  $I_{\text{xtal}}$  is the oscillator bias current out of the XTAL pin with both EXTAL and XTAL pins grounded.

<sup>4</sup>  $C_{\text{PCB\_EXTAL}}$  and  $C_{\text{PCB\_XTAL}}$  are the measured PCB stray capacitances on EXTAL and XTAL, respectively.

<sup>1</sup> Stop mode recovery time is the time from the setting of either of the enable bits in the ADC Control Register to the time that the ADC is ready to perform conversions. Delay from power up to full accuracy = 8 ms.

<sup>2</sup> At V<sub>RH</sub> - V<sub>RL</sub> = 5.12 V, one count = 1.25 mV without using pregain.

<sup>3</sup> INL and DNL are tested from V<sub>RL</sub> + 50 LSB to V<sub>RH</sub> - 50 LSB. The eQADC is guaranteed to be monotonic at 10 bit accuracy (12 bit resolution selected).

<sup>4</sup> New design target. Actual specification will change following characterization. Margin for manufacturing has not been fully included.

<sup>5</sup> At V<sub>RH</sub> - V<sub>RL</sub> = 5.12 V, one LSB = 1.25 mV.

<sup>6</sup> The value is valid at 8 MHz, it is ±8 counts at 16 Mhz.

<sup>7</sup> Below disruptive current conditions, the channel being stressed has conversion values of \$3FF for analog inputs greater than V<sub>RH</sub> and \$000 for values less than V<sub>RL</sub>. Other channels are not affected by non-disruptive conditions.

<sup>8</sup> Exceeding limit may cause conversion error on stressed channels and on unstressed channels. Transitions within the limit do not affect device reliability or cause permanent damage.

<sup>9</sup> Input must be current limited to the value specified. To determine the value of the required current-limiting resistor, calculate resistance values using V<sub>POSCLAMP</sub> = V<sub>DDA</sub> + 0.5 V and V<sub>NEGCLAMP</sub> = -0.3 V, then use the larger of the calculated values.

<sup>10</sup> Condition applies to two adjacent pins at injection limits.

<sup>11</sup> Performance expected with production silicon.

<sup>12</sup> All channels have same 10 kΩ < R<sub>s</sub> < 100 kΩ Channel under test has R<sub>s</sub> = 10 kΩ, I<sub>INJ</sub> = I<sub>INJMAX</sub>, I<sub>INJMIN</sub>.

<sup>13</sup> The TUE specification is always less than the sum of the INL, DNL, offset, and gain errors due to cancelling errors.

<sup>14</sup> TUE does not apply to differential conversions.

<sup>15</sup> Voltages between V<sub>RL</sub> and V<sub>RH</sub> will not cause damage to the pins. However, they may not be converted accurately if the differential voltage is above the maximum differential voltage. In addition, conversion errors may occur if the common mode voltage of the differential signal violates the Differential Input common mode voltage specification.

<sup>2</sup> Speed is the nominal maximum frequency of platform clock ( $f_{platt}$ ). Max speed is the maximum speed allowed including frequency modulation (FM). 270 MHz parts allow for 264 Mhz for system core clock ( $f_{sys}$ ) + 2% FM.

<sup>3</sup> The minimum DSPI Cycle Time restricts the baud rate selection for given system clock rate. These numbers are calculated based on two devices communicating over a DSPI link.

<sup>4</sup> The actual minimum SCK cycle time is limited by pad performance.

<sup>5</sup> The maximum value is programmable in DSPI\_CTAR $n$ [PSSCK] and DSPI\_CTAR $n$ [CSSCK].

<sup>6</sup> The maximum value is programmable in DSPI\_CTAR $n$ [PASC] and DSPI\_CTAR $n$ [ASC].

<sup>7</sup> For example, external master should start SCK clock not earlier than 3 system clock periods after assertion SS

<sup>8</sup> This number is calculated assuming the SMPL\_PT bitfield in DSPI\_MCR is set to 0b10.

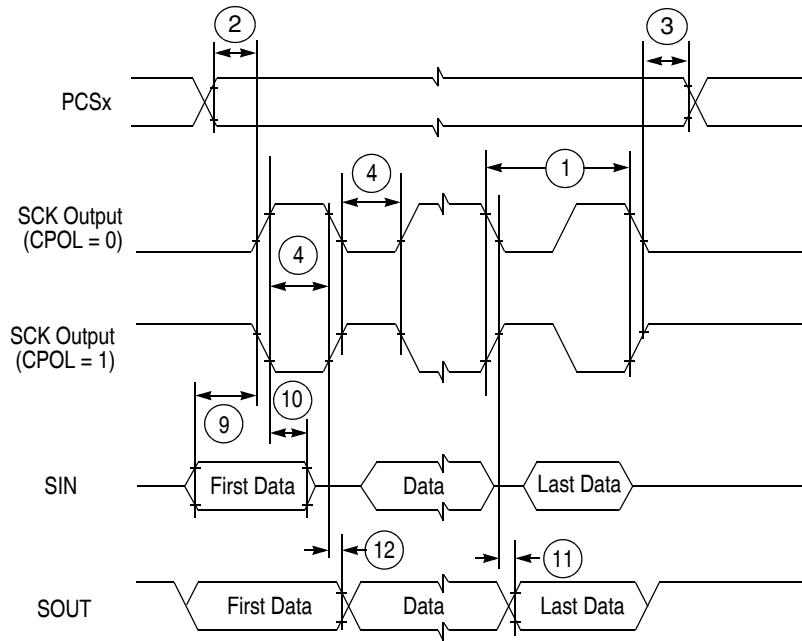

The DSPI in this device can be configured to serialize data to an external device that implements the Microsecond Bus protocol. DSPI pins support 5 V logic levels or Low Voltage Differential Signalling (LVDS) for data and clock signals to improve high speed operation.

## 6 Product Documentation

This data sheet is labeled as a particular type: Product Preview, Advance Information, or Technical Data. Definitions of these types are available at: <http://www.nxp.com>.

The following documents are required for a complete description of the device and are necessary to design properly with the parts:

- *MPC5674F Microprocessor Reference Manual* (document number MPC5674FRM).

## Appendix A Signal Properties and Muxing

The following table shows the signals properties for each pin on the MPC5674F. For each port pin that has an associated SIU\_PCR $n$  register to control its pin properties, the supported functions column lists the functions associated with the programming of the SIU\_PCR $n$ [PA] bit in the order: Primary function (P), Function 2 (F2), Function 3 (F3), and GPIO (G). See [Figure 49](#).

<sup>1</sup> The GPIO number is the same as the corresponding pad configuration register (SIU\_PCRn) number in pins that have GPIO functionality; functionality, this number is the PCR number.

<sup>2</sup> The primary signal name is used as the pin label on the BGA map for identification purposes. However, the primary signal function is not indicated by a dash in the following table columns: Signal Functions, P/F/G, and I/O Type.

<sup>3</sup> P/A/G stands for Primary/Alternate/GPIO. This column indicates which function on a pin is Primary, Alternate 1, Alternate 2, (Alternate 3), or Alternate 4.

<sup>4</sup> Each line in the Function column corresponds to a separate signal function on the pin. For all device I/O pins, the primary, alternate, or designated in the PA field of the SIU\_PCRn registers except where explicitly noted.

<sup>5</sup> MH = High voltage, medium speed

F = Fast speed

FS = Fast speed with slew

AE = Analog with ESD protection circuitry (up/down = pull up and pull down circuits included in the pad)

VHV = Very high voltage

<sup>6</sup> VDDE (fast I/O) and VDDEH (slow I/O) power supply inputs are grouped into segments. Each segment of VDDEH pins can connect to a power supply input. Each segment of VDDE pins can connect to a separate 1.8–3.3 V (±10%) power supply.

<sup>7</sup> The Status During Reset pin is sampled after the internal POR is negated. Prior to exiting POR, the signal has a high impedance. The signal is: O – output, I – input, Up – weak pull up enabled, Down – weak pulldown enabled, Low – output driven low, High – output driven high, Reset or until JCOMP assertion). A dash on the left side of the slash denotes that both the input and output buffers for the pin are off. A slash denotes that there is no weak pull up/down enabled on the pin. The signal name to the left or right of the slash indicates the pin name.

<sup>8</sup> The Function After Reset of a GPI function is general purpose input. A dash on the left side of the slash denotes that both the input and output buffers for the pin are off. A dash on the right side of the slash denotes that there is no weak pull up/down enabled on the pin.

<sup>9</sup> This signal name includes eTPU\_C functionality that this device does not have. This is for forward compatibility with devices that have clock propagation through the device.

<sup>10</sup> During and just after POR negates, internal pull resistors can be enabled, resulting in as much as 4 mA of current draw. The pull resistors are disabled through the device.

<sup>11</sup> NMI does not have a PCR PA configuration; it is enabled when NMI is enabled through the SIU\_IREEER and SIU\_IFEER registers.

- <sup>12</sup> Nexus reset is different than system reset; MDO 1-11 are enabled when trace (RPM or FPM) is enabled, and MDO 12-15 when FPM trace are also dependent on trace (RPM or FPM) being enabled.
- <sup>13</sup> The Nexus pins don't have a "primary" function as they are not configured by the SIU. The pins are selected by asserting JCOMP and have no effect on the function of these pins once enabled.
- <sup>14</sup> MCKO is disabled from reset; it can be enabled from the tool (controlled by Nexus NPC\_PCR register).
- <sup>15</sup> Do not connect pin directly to a power supply or ground.
