MAX98372ETJ+**

## MAX98372

## Digital Input Class D Amplifier with DHT and Brownout Protection

### General Description

The MAX98372 is a high-efficiency, mono Class D audio amplifier featuring dynamic headroom tracking (DHT) and brownout protection. DHT automatically optimizes the headroom available to the Class D amplifier as the power supply voltage varies, due to sudden transients and declining battery life to maintain a consistent listening experience. A wide 5.5V to 18V supply range allows the device to reach 19W into an 8Ω load.

The MAX98372's flexible digital audio interface (DAI) supports I<sup>2</sup>S, left-justified, and TDM formats. The digital audio interface accepts 32kHz, 44.1kHz, 48kHz, 88.2kHz, and 96kHz sample rates with 16-/24-/32-bit data supported for all data formats. In TDM mode, the device can support up to 16 channels of audio data. A unique clocking structure eliminates the need for an external MCLK signal that is typically needed for PCM communication. This reduces pin count and simplifies board layout.

Active emissions limiting with edge rate control minimizes EMI and eliminates the need for output filtering found in traditional Class D devices.

An 8-bit PVDD supply voltage ADC enables the dynamic headroom tracking circuit. DHT optimizes audio program peak behavior as the supply voltage varies and provides flexible user-defined parameters.

Thermal foldback protection ensures robust behavior when the thermal limits of the device are exercised. The circuit can be enabled to automatically reduce the output power above a user specified temperature. This allows for uninterrupted music playback even at high ambient temperatures. Traditional thermal protection is also available in addition to robust overcurrent protection.

All MAX98372 control is performed using a standard 2-wire, I<sup>2</sup>C interface. One of sixteen slave addresses can be selected through two, four-level address pins. The IC is available in a 0.4mm pitch, 30-bump WLP and 32-pin TQFN packages. It is specified over the extended, -40°C to +85°C temperature range.

### Applications

- Tablets
- Notebook Computers
- Soundbars

### Benefits and Features

- Wide Supply Range (5.5V to 18V)
- Dynamic Headroom Tracking Maintains a Consistent Listening Experience
- Integrated Thermal Foldback Allows Robust Operation in a WLP Package
- Remote Output Sensing Allows Up to 20dB THD+N Improvement When Ferrites Are Used
- Class D Edge Rate Control Enables Filterless Operation
- 110dB A-Weighted Dynamic Range
- Output Power at 1% THD+N:
  - 15.7W into 8Ω, V<sub>PVDD</sub> = 17V
  - 13.2W into 4Ω, V<sub>PVDD</sub> = 12V
- Output Power at 10% THD+N:
  - 19W into 8Ω, V<sub>PVDD</sub> = 17V
  - 15.8W into 4Ω, V<sub>PVDD</sub> = 12V
- Speaker Amplifier Efficiency
  - 91% at 10W into 8Ω, V<sub>PVDD</sub> = 12V
  - 81% at 15W into 4Ω, V<sub>PVDD</sub> = 12V
- ALC Provides Battery Brownout Protection
- Extensive Click-and-Pop Suppression
- 30-Bump, 0.4mm WLP and 32-Pin TQFN Packages

### Simplified Block Diagram

Detailed Functional Diagram

**Absolute Maximum Ratings**

PVDD to PGND .....-0.3V to +20V  
 OUT\_ to PGND .....-0.3V to (V<sub>PVDD</sub> + 0.3V)  
 V<sub>REFC</sub> to AGND .....-0.3V to +2.2V  
 DVDD to DGND.....-0.3V to +2.2V  
 SDA, SCL, ADDR\_, IRQ to DGND.....-0.3V to +2.2V  
 BCLK, LRCLK, DIN,  
 RESET to DGND .....-0.3V to (V<sub>DVDD</sub> + 0.3V)  
 AGND, DGND to PGND .....-0.1V to +0.1V

Short-Circuit Duration  
 Between OUTP, OUTN and PGND or PVDD ..... Continuous  
 Between OUTP and OUTN ..... Continuous  
 Continuous Power Dissipation (T<sub>A</sub> = +70°C) for Multilayer Board  
 (derate 27mW/°C above +70°C for WLP) .....2.16W  
 (derate 34.5mW/°C above +70°C for TQFN).....2.76W  
 Junction Temperature..... +150°C  
 Operating Temperature Range..... -40°C to +85°C  
 Storage Temperature Range ..... -65°C to +150°C  
 Soldering Temperature (reflow)..... +260°C

Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

**Package Thermal Characteristics (Note 1)**

<p>WLP                  Junction-to-Ambient Thermal Resistance (θ<sub>JA</sub>) .....+37°C/W                  Junction-to-Board Thermal Resistance (θ<sub>JB</sub>).....+33.4°C/W</p>	<p>TQFN                  Junction-to-Ambient Thermal Resistance (θ<sub>JA</sub>).....+29°C/W                  Junction-to-Board Thermal Resistance (θ<sub>JB</sub>).....+19.3°C/W</p>
---	---

**Note 1:** Package thermal resistances were obtained using the method described in JEDEC specification JESD51-7, using a four-layer board. For detailed information on package thermal considerations, refer to [www.maximintegrated.com/thermal-tutorial](http://www.maximintegrated.com/thermal-tutorial).

**Electrical Characteristics**

(V<sub>PVDD</sub> = 12V, V<sub>DVDD</sub> = V<sub>RESET</sub> = 1.8V, V<sub>GND</sub> = 0V, C<sub>PVDD</sub> = 1x 220µF, 2x 10µF, 2x 0.1µF, C<sub>REFC</sub> = 1µF, C<sub>DVDD</sub> = 1µF, Z<sub>SPK</sub> = open, AC measurement bandwidth 20Hz to 22kHz, f<sub>S</sub> = 48kHz, 24-bit data, T<sub>A</sub> = T<sub>MIN</sub> to T<sub>MAX</sub>, unless, otherwise noted. Typical values are at T<sub>A</sub> = +25°C.) (Note 2)

PARAMETER	SYMBOL	CONDITION		MIN	TYP	MAX	UNITS

Bump/Pin Configurations

Bump/Pin Configurations (continued)

## Bump/Pin Description

PIN		NAME	SUPPLY RAIL	FUNCTION
WLP	TQFN			
A1	9	OUTNSNS	PVDD	Negative Speaker Amplifier Output Sense. If not used, connect to OUTN.
A2, A3 E2, E3	10-12, 28-30	PVDD	—	Speaker Amplifier Power Supply. Bypass each bump pair to PGND with a 10 $\mu$ F and a 0.1 $\mu$ F, and a single 220 $\mu$ F per device.
A4	15	DVDD	—	Digital Core, Digital Audio Interface, and I <sup>2</sup> C Control Power Supply. Bypass to DGND with a 1 $\mu$ F.
A5	16	ADDR1	DVDD	Four-Level I <sup>2</sup> C Slave Address Select Input. See the <i>Slave Address Selection</i> section for additional information (Table 40).
A6	17	SCL	DVDD	I <sup>2</sup> C Control Clock Input
B1, B2	6-8	OUTN	PVDD	Negative Speaker Amplifier Output
B3, C1–C3, D3	3-5	PGND	—	Speaker Amplifier Ground
B4	14	DGND	—	Digital Ground
B5	18	ADDR0	DVDD	Four-Level I <sup>2</sup> C Slave Address Select Input. See the <i>Slave Address Selection</i> section for additional information (Table 40).
B6	19	SDA	DVDD	I <sup>2</sup> C Control Data Input/Output
C4, D4	27, 13	AGND	—	Analog Ground
C5	20	DOUT	DVDD	Bidirectional ICC Link Data
C6	21	LRCLK	DVDD	DAI Left/Right Clock Input. LRCLK is the audio sample rate clock and determines whether audio data is routed to the left or right channel. In TDM mode, LRCLK is a frame sync pulse with programmable width.
D1, D2	1-2, 32	OUTP	PVDD	Positive Speaker Amplifier Output
D5	22	$\overline{\text{IRQ}}$	DVDD	Hardware Interrupt Output. $\overline{\text{IRQ}}$ can be programmed to pull low when individual bits in the flag registers change value. Connect a 10k $\Omega$ pullup resistor for full output swing.
D6	23	DIN	DVDD	DAI Audio Data Input
E1	31	OUTPSNS	PVDD	Positive Speaker Amplifier Output Sense. If not used, connect to OUTP.
E4	26	V <sub>REFC</sub>	PVDD	Internal Regulator Decoupling Point. Bypass to AGND with a 1 $\mu$ F.
E5	25	$\overline{\text{RESET}}$	DVDD	Active-Low Hardware Reset. Drive low to place the device into low power reset mode and reset the device registers to their power-on-reset (POR) states.
E6	24	BCLK	DVDD	DAI Bit Clock Input
—	—	EP	—	Exposed Pad. Connect exposed thermal pad to AGND.

**Detailed Description**

The MAX98372 is a high-efficiency mono Class D audio amplifier that features thermal foldback protection and ADCs for sensing battery supply voltage and onboard temperature.

The MAX98372 can operate over a wide range of supply voltage (PVDD), and has extensive on-board digital signal processing to enable dynamic headroom tracking (DHT). This feature automatically adjusts the output signal to fit into the available supply voltage range. The DHT can be completely bypassed for operation with fixed, regulated supply voltages.

The MAX98372 provides automatic level control (ALC) for battery brownout protection. This is achieved by reducing amplifier gain when the battery voltage drops below the selected threshold. ALC threshold, maximum attenuation, and attack/release rates are programmable.

Active emissions limiting edge rate and overshoot control circuitry, together with Class D modulation, minimize the electromagnetic interference (EMI) traditionally associated with Class D amplifiers. In systems that use less than 18in of speaker cable, an output filter is unnecessary to meet standard EMI limits.

Two ADCs monitor PVDD supply voltage and die temperature. The PVDD supply voltage value can be read using the I<sup>2</sup>C interface. The temperature ADC can

be read back through I<sup>2</sup>C, however, accurate readings only occur after the die temperature exceeds +100°C.

The DAI supports I<sup>2</sup>S, left-justified, and TDM formatted data at the following sample rates: 32kHz, 44.1kHz, 48kHz, 88.2kHz, and 96kHz. Audio bit depths of 16, 24, and 32 bits are supported for input data. The DAI operates from BCLK to allow the device to function without MCLK.

Thermal foldback allows the device to smoothly attenuate the audio output in an effort to prevent destructive thermal behavior. Above a set threshold, the gain of the replay path reduces at a (user programmable) dB/°C rate to a 12dB maximum attenuation. Thermal monitoring capabilities alert the host when die temperature has triggered the thermal foldback circuit, or is approaching the maximum operating temperature. If maximum die temperature is exceeded, the device shuts down to protect itself. Short-circuit protection ensures that accidental shorts or high-current events do not cause damage to the IC.

Device status is communicated to the host through a hardware interrupt ( $\overline{IRQ}$ ) and status registers accessible through the I<sup>2</sup>C interface.

The MAX98372 is fully programmable through the I<sup>2</sup>C interface. ADDR0, ADDR1 connections select one of sixteen I<sup>2</sup>C slave addresses. Shutdown mode is directly controlled through the I<sup>2</sup>C interface, or a hardware shutdown can be asserted through the  $\overline{RESET}$  pin.

**Interrupts**

The MAX98372 supports programmable interrupts for sending feedback to the host about events that have occurred on-chip. [Table 2](#) lists the available interrupt sources. Interrupts are output on  $\overline{\text{IRQ}}$ , an active-low open-drain output.

**Status**

Each interrupt source has 1 bit to indicate the real-time STATUS of the source. This bit is read only.

**State**

Each interrupt source has a STATE bit that is set whenever a rising edge occurs on the associated STATUS bit regardless of the state of the associated ENABLE bit. This bit is read only.

**Flag**

Each interrupt source has a FLAG bit to indicate that a rising edge has occurred on the associated STATUS bit and the associated ENABLE bit is set. This bit is read only.

**Enable**

Each interrupt source has an ENABLE bit to indicate that the associated FLAG bit is set whenever the STATE bit is set. This bit is read/write.

**Clear**

Each interrupt has a CLEAR bit that clears the associated STATE and FLAG bits when a 1 is written. Writing a 0 has no effect. This bit is write only.

**Table 2. Interrupt Sources**

NAME	DESCRIPTION
Overtemperature Begin Event	Indicates when the die overtemperature threshold has been exceeded.
Overtemperature End Event	Indicates when the die overtemperature threshold is no longer exceeded including 20°C of hysteresis.
Thermal Warning Begin Event	Indicates when the thermal warning threshold has been exceeded.
Thermal Warning End Event	Indicates that the die temperature was previously above the thermal warning threshold and has now dropped below the threshold.
Speaker Current Event	Indicates when the speaker amplifier current limit has been exceeded.
Invalid Slot Event	Indicates that a slot has been selected that is not available due to one or more of the following reasons: The (number of bits per channel) x (channels per frame) does not allow for the selected slot (I <sup>2</sup> S mode only). The number of BCLK cycles per frame does not allow for the selected slot (TDM mode only).
Thermal Foldback Event	Indicates that the thermal foldback limiter is operating in the attack or release phase.
Thermal Foldback End Event	Indicates that the die temperature was previously above the thermal threshold and has now dropped below the threshold.
V <sub>PVDD</sub> Overflow Event	Indicates that the V <sub>PVDD</sub> supply voltage has reached the V <sub>PVDD</sub> ADC's maximum input level.
PVDD UVLO Event	Indicates that PVDD has dropped below the minimum allowed voltage.
DHT Active Event	Indicates that the DHT circuit is applying compression to the signal.
Limiter Active Event	Indicates that the limiter circuit is applying a hard limit (infinite compression) to the signal.
ICC Overcurrent Event	Indicates that an overcurrent event is in progress on DOUT.
ALC Active Event	Indicates that ALC is operating in attack, hold, or release phase.
ALC Mute Event	Indicates that ALC has entered Mute.
ALC Infinite Hold Event	Indicates that the ALC has entered infinite hold mode.

**Table 3. Interrupt Registers**

<b>Interrupt Status 0</b>			
Interrupt Status bits reflect real-time fault conditions. If the fault condition is less than 3-4 LRCLK cycles, the Live Status bit holds high for 3–4 LRCLK cycles.			
ADDRESS	BIT	NAME	DESCRIPTION
<u>0x01</u>	7	0	Unused: Read back is 0.
	6	0	Unused: Read back is 0.
	5	THERMFB_STATUS	<b>Die Thermal Foldback Status</b> 0: The die temperature is below the thermal warning threshold. 1: The die temperature is above the thermal warning threshold and the signal is being dynamically attenuated.
	4	0	Unused: Read back is 0.
	3	THERMWARN_STATUS	<b>Die Overtemperature Warning Status</b> 0: The die temperature is below the thermal warning threshold. 1: The die temperature is above the thermal warning threshold.
	2	0	Unused: Read back is 0.
	1	THERMSHDN_STATUS	<b>Die Overtemperature Status</b> 0: The die temperature is below the maximum die temperature. 1: The die temperature exceeds the maximum die temperature.
	0	0	Unused: Read back is 0.

**Table 3. Interrupt Registers (continued)**

<b>Interrupt Status 1</b>			
Interrupt Status bits reflect real-time fault conditions. If the fault condition is less than 3–4 LRCLK cycles, the Live Status bit holds high for 3–4 LRCLK cycles.			
ADDRESS	BIT	NAME	DESCRIPTION
<u>0x02</u>	7	0	Unused: Read back is 0.
	6	ICCOVC_STATUS	<b>ICC Overcurrent Status</b> 0: No overcurrent event on the DOUT is in progress. 1: Overcurrent event on the DOUT is in progress.
	5	LMTRACT_STATUS	<b>Limiter Active Status</b> 0: Limiter is not active. 1: Limiter is active.
	4	INVALSLOT_STATUS	<b>Invalid Slot Status</b> 0: Slot is valid. 1: Slot is invalid, one or more possible error conditions apply: a. The (number of bits per channel) * (channels per frame) does not allow for the selected slot. (I2S mode only) b. The number of BCLK cycles per frame does not allow for the selected slot. (TDM mode only).
	3	DHTACT_STATUS	<b>DHT Active Status</b> 0: Dynamic Headroom Tracking is not attacking or releasing. 1: Dynamic Headroom Tracking is active and is attacking or releasing.
	2	SPKCURNT_STATUS	<b>Speaker Overcurrent Status</b> 0: Speaker current is below the current limit. 1: Speaker current is above the current limit.
	1	PVDDOVFL_STATUS	<b>PVDD Supply Voltage Monitor Overflow Status</b> 0: The PVDD supply voltage is below the PVDD ADC's maximum input level. 1: The PVDD supply voltage has exceeded the PVDD ADC's maximum input level
	0	PVDDUVLO_STATUS	<b>PVDD Supply Voltage Undervoltage Status</b> 0: The PVDD supply voltage is above the PVDD UVLO level. 1: The PVDD supply voltage is below the PVDD UVLO threshold, and the part is shutdown.

**Digital Audio Interface**

The digital audio interface (DAI) is highly flexible, supporting common sample rates (Table 4) with 16/24/32-bit depth for I<sup>2</sup>S/left-justified data as well as up to 16 slots in a time division multiplexed (TDM) format.

Operating in slave mode only, the MAX98372 eliminates the need for the external MCLK signal that is typically used in I<sup>2</sup>S applications by generating MCLK internally. This reduces EMI and improves the RF immunity of the IC. Table 5 lists the supported BCLK frequencies when operating in this mode.

**Table 4. Supported Sample Rates**

ADDRESS	BIT	NAME	DESCRIPTION
0x11	3	SPK_SR[3:0]	<b>Speaker Path Sample Rate Select</b> 0000–0101: Reserved 0110: 32kHz 0111: 44.1kHz 1000: 48kHz (default) 1001: Reserved 1010: 88.2kHz 1011: 96kHz 1100–1111: Reserved

	0		

**Interface Format**

The MAX98372 supports standard I<sup>2</sup>S, left-justified, and TDM data formats. I<sup>2</sup>S and left-justified formats support two audio channels of 16-, 24- or 32-bit depth. TDM supports up to 16 audio channels of 16-, 24-, or 32-bit depth. The IC supports slave operation only, and the LRCLK and BCLK pins operate as inputs.

I<sup>2</sup>S (Figure 5) and left-justified (Figure 6) modes configure the LRCLK signal to transition before each channel. With the default I<sup>2</sup>S settings LRCLK low indicates left channel while LRCLK high indicates the right channel. The MSB of the audio word is latched on the second active BCLK edge after an LRCLK transition. In left-justified mode, the MSB of the audio word is latched on the first active BCLK edge after an LRCLK transition.

TDM mode (Figure 7) uses a frame sync pulse instead of a 50% duty cycle frame clock. The frame sync pulse (applied to the LRCLK pin) is equal to one BCLK period as a minimum, although the interface operates with longer periods; the rising edge of LRCLK is used to indicate the start of a new frame. The falling edge can occur at any time as long as it does not violate the setup time requirements of the LRCLK rising edge. In TDM, latch the MSB of the first audio word on the first or second active BCLK edge after an LRCLK rising edge.

**Configuring the DAI Format**

Specify the format by configuring the LRCLK invert, BCLK active edge, data delay, and TDM mode configuration bits (Table 6).

**Table 6. Configuration for Digital Audio Interface Format**

ADDRESS	BIT	NAME	DESCRIPTION
0x14	7	CHANSZ[1:0]	<b>Configures Channel Word Length</b> 00: 8 bits            10: 24 bits (default) 01: 16 bits            11: 32 bits

	1	CHANSEL	<b>Non-TDM LRCLK Starting Edge</b> 0: Falling LRCLK indicates the start of a stereo pair. Channel 0 when LRCLK is low, channel 1 when LRCLK is high. (default) 1: Rising LRCLK indicates the start of a stereo pair. Channel 0 when LRCLK is high, channel 1 when LRCLK is low.
	0	0	Unused: Read back is 0.

**Configuring the Digital Audio Input**

The DAI may be configured to accept a mono PCM input, placed from anywhere from slots 1 to 16 of digital audio in TDM mode. In I<sup>2</sup>S and left-justified modes, two channels are available.

Route mono data directly to the speaker amplifier. If the input is stereo, input the right channel to the device and mix with the left channel if desired. Sum left and right channels with the amplitude divided by 2 to reduce the DAC input and avoid saturation. Stereo summing and L or R choices are limited to 2 adjacent slots on the TDM bus.

**Digital Passband Filtering**

The MAX98372 features an optional highpass filter with selectable corner frequency (50Hz, 100Hz, 200Hz, 400Hz, and 800Hz), or a DC-blocking filter with a cutoff frequency of 2Hz (80dB attenuation). The MAX98372 supports 5 sample rates: 32kHz, 44.1kHz, 48kHz, 88.2kHz, or 96kHz. For 32kHz, 44.1kHz, and 48kHz, a linear phase, half-band filter effectively defines the response. For 96kHz operation, a different filter characteristic is employed with a smooth roll off above 20kHz. Set the digital highpass filter corner frequency through the DACHPF bits in control register 0x1C (Table 9). Create user-programmed filtering

through the biquad filter coefficients by setting the DACHPF[2:0] bits to 111. See the *Biquad Filter* section.

The MAX98372 also features a configurable PVDD ADC filter. This cutoff frequency of this filter can be adjusted by setting the PVDD\_ADC\_BW bits in register 0x1C. These filtered PVDD ADC measurements can be fed to the DHT or limiter. Filtered or unfiltered PVDD ADC readings can be sent to the DHT and limiter. To send filtered data to the limiter or DHT, set the PVDD\_FILTER\_TO\_LMTR or PVDD\_FILTER\_TO\_DHT bits, respectively. See Table 9.

	1		
	0		

**Biquad Filter**

The digital biquad filter has five user-programmable coefficients (B0, B1, B2, A1, and A2), and each individual coefficient is 3 bytes (24 bits) long (A0 is fixed at 1). They occupy 15 consecutive registers (Table 10) and each set of three registers (per coefficient) must be programmed consecutively for the settings to take effect. The coefficients are stored using a two's complement format where the first 4 bits are the integer portion and the last 20 bits are the decimal portion that results in an approximate +8 to -8 range for each coefficient.

The digital biquad coefficients are uninitialized at power-up, and if the filter is going to be used, the coefficients must be programmed before the device and biquad filter are enabled. The transfer function is:

$$H(z) = \frac{B_0 + B_1 * Z^{-1} + B_2 * Z^{-2}}{1 + A_1 * Z^{-1} + A_2 * Z^{-2}}$$

**Signal Path Delay**

Delay through the signal path is minimized by use of efficient signal processing and hardware DSP. Delay is affected by the configuration of various blocks and filters in the signal path. Typical delay, listed in number of audio samples, is shown in Table 11.

**Table 10. Biquad Filter Coefficient Registers**

**PVDD ADC**

The PVDD ADC has an effective 8kHz sample rate, 8-bit resolution and full scale input of 18V. The bandwidth of the output is user programmable to reject both high frequency and audio band noise from the supply, and to tradeoff reaction time to follow the supply accurately. The PVDD\_ADC values are used to by the DHT and Limiter circuits. These values can be read back over I<sup>2</sup>C through the PVDD\_ADC Register located at 0x34. See [Table 12](#).

The PVDD ADC readback is real time and is dependant on the PVDD\_ADC\_BW register setting in register 0x1C.

**Digital Volume Control**

A user-controlled digital volume control with an attenuation range of 0dB to -63dB in 0.5dB steps, as well as a mute setting is available. Volume ramping is available and configurable with through the DVOL\_RAMP\_BYP bit in the digital volume control register. See [Table 13](#).

**Output Voltage Scaling**

The MAX98372 operates over a large supply voltage range. As a result, the part must be configured to scale the output signals across possible PVDD supply range. SPK\_GAIN\_MAX applies gain after the DAC to achieve this voltage scaling.

Digital gain can be applied before the DAC by using the DPGA\_CLIP register. In conjunction with the SPK\_GAIN\_MAX setting, the overall full-scale behavior of the device is set.

The DPGA and SPK\_GAIN\_MAX register settings are shown in [Table 14](#).

Gain through the signal path is referenced to the full-scale output of the DAC, which is 2.1dBV. The MAX98372 output level can be calculated based on the digital input signal level and selected amplifier gain.

$$\text{Output signal level (dBV)} = \text{input signal level (dBFS)} + 2.1\text{dBV} + \text{SPK\_GAIN\_MAX (dB)}$$

where 0dBFS is referenced to 0dBV.

**Dynamic Headroom Tracking**

The MAX98372 features dynamic headroom tracking (DHT) to preserve constant dynamic range in the presence of a varying supply. DHT maintains consistent volume and listening levels up to a predefined point, below full scale. DHT maintains the headroom of the amplifier at signal peaks that occur above this level (referred to as the rotation point or RP) up to full scale to ensure consistent, smooth compression of these signals in the presence of supply variations.

A key element in tracking available headroom is the PVDD ADC. The output of the ADC feeds the DHT circuitry with the necessary inputs to calculate the amount of compression (if any) applied to signal peaks. Filtering can be applied to the PVDD ADC readings used by the DHT by using the PVDD\_FILT\_TO\_DHT bit (Table 9).

The dynamic headroom tracking function relies heavily on two parameters to be effective. The first is the SPK\_GAIN\_MAX setting explained in the *Output Voltage Scaling* section. This sets the maximum no-load peak output voltage ( $V_{MPO}$ ) that the class D amplifier reproduces when fed with a full-scale (0dBFS) signal. The second parameter is the rotation point (RP). The rotation point sets the level in dBFS above which compression is applied to the output signal, if the PVDD voltage level drops below  $V_{MPO}$ .

DHT uses a parameter called SPK\_GAIN\_MIN to control the maximum compression ratio. This parameter can enable the addition of a second inflection point on the Transfer function.

Figure 8. Example of Dynamic Headroom Tracking in Mode 1 Operation

The behavior of DHT has 3 modes, depending on the measured value of  $V_{PVDD}$  by the PVDD ADC:

**MODE 1:** PVDD voltage is greater than maximum peak output voltage. If  $V_{PVDD}$  is greater than  $V_{MPO}$  then there is no action taken by the DHT block. There is sufficient headroom for the amplifier to linearly represent any signal up to and including 0dBFS; the signal transfer function is unaffected.

**MODE 2:**  $V_{PVDD}$  is less than  $V_{MPO}$ , and greater than the output voltage as set by the Rotation Point register setting ( $V_{EXP\_RP}$ ). For example, if the RP is set for -6dBFS, then the peak voltage on the output ( $V_{EXP\_RP}$ ) would be  $V_{MPO}/2$ . If this is the case, the transfer function for signals below the RP is reproduced exactly as in Mode 1. Any signals between RP and 0dBFS are now subject to an audio compression function, acting in the DSP block of the MAX98372. This acts with appropriate attenuation for peaks over the RP in magnitude with programmable attack and release times (see the *DHT Ballistics* section). [Figure 9](#) and [Figure 10](#) show the effect on the transfer function.

The compression ratios in Mode 2 are effectively defined by the combination of: PVDD, RP, SPK\_GAIN\_MAX, and SPK\_GAIN\_MIN settings. The ballistics of the compressor

(in both Mode 2 and Mode 3) are set by the parameters in [Table 16](#) and [Figure 21](#).

**MODE 3a:** PVDD voltage is less than the rotation points maximum output voltage,  $V_{EXP\_RP}$ . When the rotation point is set to a high value (for example -6dBFS) this mode applies. If  $V_{PVDD}$  is less than  $V_{EXP\_RP}$ , then hard limiting is applied to peaks and the effective RP is now set by the need to fit peak signals into the available PVDD range. The MAX98372 automatically determines a new RP based on the PVDD ADC. Normally, RP is set so that this mode is never used, and the  $V_{EXP\_RP}$  as set by the RP and SPK\_GAIN\_MAX combination should reflect the lowest PVDD value expected. In this mode, the SPK\_GAIN\_MIN parameter is set to be well below the  $V_{EXP\_RP}$ .

Figure 9. Example of Dynamic Headroom Tracking in Mode 2 Operation with a High RP

Figure 10. Example of Dynamic Headroom Tracking in Mode 2 Operation with a Low RP

Table 15. Speaker Gain Minimum Voltage

ADDRESS	BIT	NAME	DESCRIPTION
0x31	7	SPK_GAIN_MIN[3:0]	<b>Speaker Gain Min (V<sub>p</sub>):</b> 0000: 5.37 (9.5dB)      0111: 12.03 (16.5dB) 0001: 6.03 (10.5dB)      1000: 13.5 (17.5dB) 0010: 6.77 (11.5dB)      1001: 15.15 (18.5dB) 0011: 7.59 (12.5dB)      1010: 16.99 (19.5dB) 0100: 8.52 (13.5dB)      1011: 18.0 (20.0dB) 0101: 9.56 (14.5dB)      1100–1111: Reserved 0110: 10.72 (15.5dB)
	6		
	5		
	4		
	3		
	2		
	1		
	0		

**MODE 3b:** PVDD voltage is less than the speaker gain minimum output voltage. When the rotation point is set to a low value (for example -30dBFS) this mode applies. If  $V_{PVDD}$  is less than  $SPK\_GAIN\_MIN$ , the DHT cannot

compress the signal any further. So the compression ratio stays fixed, and as PVDD decreases below  $SPK\_GAIN\_MIN$ , the output signal starts to clip. This clipping can be eliminated if the limiter is enabled in addition to the DHT.

Figure 11. Example of Dynamic Headroom Tracking in Mode 3a Operation

Figure 10 and Figure 12 show an additional parameter, SPK\_GAIN\_MIN, on the transfer function plots. This parameter is useful when a lower RP is selected. SPK\_GAIN\_MIN provides a means to create a maximum compression ratio. When the input signal reaches the

maximum output voltage that PVDD can provide, the output signal starts to clip (Figure 12). This behavior may not be desirable, but the clipping can be eliminated by enabling the limiter. See Figure 13.

Figure 12. Example of Dynamic Headroom Tracking in Mode 3b Operation

The transfer function shown in Figure 13 is typically preferable to the transfer function shown in Figure 12. When DHT and the limiter are used together, it allows for creation of a second inflection point on the transfer

function. This second inflection point reduces the transition from compression to limiting and minimizes the audible impact of signal manipulation by the DHT.

Figure 13. Example of Dynamic Headroom Tracking in Mode 3b with Limiter

**DHT Ballistics**

When an input signal exceeds the rotation point, DHT applies attenuation to the signal over some amount of time (this is configurable through the DHT\_ATK\_RATE register 0x32). The instant that the large signal is input to the MAX98372, the output tries to reproduce that signal without any attenuation from the DHT. Over time, the DHT applies compression to ensure that the signal can fit within the available PVDD voltage. If a large enough input signal is applied there can be hard clipping on the output for a short time (Figure 14). However, after the full attack time has completed, there should be no clipping. Hard clipping can also be prevented by using the limiter. See the Limiter section.

Observing the output waveform, notice that the amount of attenuation applied increases up to when  $V_{IN}(dBFS) = PVDD$  (dBFS). Once  $V_{IN}(dBFS)$  is greater than  $PVDD$ (dBFS) the amount of attenuation observed in the output waveform appears to decrease. This is a result of the output clipping against the PVDD voltage level. The DHT still takes the same amount of time to apply the compression as though it had the headroom to reproduce the signal.

The amount of compression applied by DHT depends on a few parameters: SPK\_GAIN\_MAX, PVDD, input signal amplitude, and the rotation point.

To establish where PVDD is relative to speaker gain max, use the following equation:

Figure 14. Dynamic Headroom Tracking Attack Functionality

Equation 1

$$PVDD(\text{dBFS}) = 20\log\left(\frac{PVDD(\text{V})}{V_{MPO}}\right)$$

where PVDD(V) is the voltage readback from the PVDD ADC, and V<sub>MPO</sub> is the maximum peak output voltage (V<sub>MPO</sub>), see [Figure 14](#). For example, if V<sub>PVDD</sub> = 12V and V<sub>MPO</sub> = 12V, then PVDD(dBFS) = 0dBFS. It should be noted that 0dBFS is the maximum value for PVDD(dBFS). If solving Equation 1 returns a value greater than 0 then 0dBFS should be used for further calculations. This is important as DHT only ever applies attenuation and never positive gain.

If V<sub>PVDD</sub> = 8.4V and V<sub>SPK\_GAIN\_MAX</sub> = 12V, then solving Eq 1 gives -3.098dBFS. This is PVDD's level relative to SPK\_GAIN\_MAX in dB. To find the expected compressed output voltage, use the following equation:

Equation 2

$$\text{ATTENUATION}(\text{dB}) = PVDD(\text{dBFS}) + \text{Input}(\text{dBFS}) \times \left(\frac{-PVDD(\text{dBFS})}{V_{RP}(\text{dBFS})}\right)$$

When PVDD(dBFS) = 0, the PVDD and the fraction term drop out, which gives attenuation equal to zero. This makes sense because when PVDD(dBFS) = 0, there is sufficient headroom to playback any signal input into the MAX98372 and no compression is applied.

A nontrivial case might be if V<sub>PVDD</sub> = 8.4V, V<sub>MPO</sub> = 12V, rotation point = -10dBFS, and the input signal level is -5dBFS. Next, we solve equation 3 with these values:

Equation 3

$$\begin{aligned} &= PVDD(\text{dBFS}) + \text{Input}(\text{dBFS}) \times \left(\frac{-PVDD(\text{dBFS})}{V_{RP}(\text{dBFS})}\right) \\ &= -3.098\text{dBFS} + -5\text{dBFS} \times \left(\frac{3.098\text{dBFS}}{-10\text{dBFS}}\right) \\ &= -1.54\text{dBFS} \end{aligned}$$

For this example, the total amount of compression applied by DHT 1.54dB. DHT attack rate and DHT attack step can be configured to apply the 1.54dB of attenuation of over a programmable amount of time.

As a rule of thumb, attack times (product of attack rate, attack step, and number of steps) faster than 600µs are not achievable. This is independent of sample rate. Input data is rectified, filtered and converted to the log domain. The DSP compares the input data with filtered data from the PVDD ADC then compression is applied within the DSP. The compressed data must be converted back to linear scale and then output. The large number of complex computations required in the DSP requires a fixed 600µs to complete the compression algorithm. As a result, attack times faster than 600µs are not possible. See [Table 16](#).

Continuing the same example when the input signal size decreases below the rotation point DHT releases the 1.54dB of attenuation it applied to the signal. The release time for DHT is configurable through Register 0x33. See [Table 17](#).

### Limiter

The MAX98372 features a programmable limiter that is used to compress large near full-scale signals. The input signal level where the attenuation is applied varies based on how the Limiter Threshold Select register is set.

When LMTR\_TH\_SEL is set to 00, the limiter threshold is user configurable through register LMTR\_THC. See [Table 20](#).

When LMTR\_TH\_SEL is set to 01, the threshold is determined by SPK\_GAIN\_MAX. [Table 21](#) provides the threshold values.

When LMTR\_TH\_SEL is set to 10 or 11, the part looks at the PVDD ADC and the SPK\_GAIN\_MAX setting and determines the maximum output swing that the part can deliver without clipping. Input signals that require more voltage than is available on PVDD are limited to prevent clipping. Filtering can be applied to the PVDD ADC readings used by the limiter with the PVDD\_FILT\_TO\_LMTR bit ([Table 9](#)).

The limiter attack and release rates are measured in absolute time and are independent of sample rate. The limiter has its own set of configurable ballistics ([Figure 30](#)).

### Thermal ADC

The MAX98372 features a die temperature monitoring ADC. This 6-bit ADC with a 100kHz sample rate reports the die temperature from +100°C to +163°C. THRM\_MIN\_TEMP sets the temperature at which the thermal foldback circuit initially activates. The measurements from the thermal ADC can be filtered before they are used by the thermal foldback circuit, or the values can pass directly without being filtered. THRM\_FILT\_SEL controls the filter selection.

**Table 21. Limiter Threshold**

0x0A	-1
0x09	-2
0x08	-3
...	...
0x01	-10
0x00	-11

### Thermal Protection

The MAX98372 continuously monitors die temperature to ensure that the temperature does not exceed the maximum of +150°C (typ). The device can warn the host if die temperature is approaching the limit and turns off the speaker amplifier if the limit is exceeded. The interrupt registers are maintained to ensure that host is alerted of the overtemperature event. Thermal recovery behavior of the device is determined by the state of TDHSN\_AUTO\_RESTART bit in the Restart Behavior (0x4D) register. If TSHDN\_AUTO\_RESTART is reset, a drop in the die temperature below the thermal foldback threshold triggers an interrupt to the host, indicating that it is safe to turn on the speaker amplifier and resume audio playback. If TSHDN\_AUTO\_RESTART is set, the device will turn on the speaker amplifier when the die temperature drops below the thermal foldback threshold setting.

### Thermal Foldback

To allow a smoother audio response to high temperature events, the MAX98372 features a thermal foldback loop. As the die temperature rises above a threshold of set by THRM\_MIN\_TEMP register (+120°C by default), the audio path is subjected to increasing attenuation, up to a maximum of -12dB. See [Table 23](#).

The thermal foldback feature can be turned on through the THRM\_FB\_EN bit, default is off (Table 25). The release rate of the attenuation and the slope of the effect can be set by the user (Table 24), the attack time is fixed at 10µs/dB.

THRM\_HOLD controls how long the temperature must stay on one side of the hysteresis threshold. THRM\_REL controls the release rate of the attenuation applied by the thermal foldback circuit. THRM\_SLOPE controls the amount of attenuation per °C. See Table 24.

Regardless of whether the thermal foldback feature is enabled, the thermal warning bit in the interrupt registers assert and generate an interrupt through the Interrupt Mask register when thermal foldback threshold temperature is crossed.

**Automatic Level Control (ALC)**

The MAX98372 automatic level control feature (ALC) reduces the amplifier gain at the PGA if the battery voltage drops below a programmable brownout threshold preventing battery collapse. ALC compares PVDD to the programmable brownout threshold set by ALC\_TH and ALC\_RANGE. When PVDD drops below the brownout threshold the ALC reduces amplifier gain at a programmable attack rate and step size set by ALC\_ATK\_RATE and ALC\_ATK\_STEP. The gain change occurs immediately even when zero-cross detection is enabled. PGA gain reduction is programmable from 1dB to 9dB in 1dB steps below the nominal setting of the GAIN register (register 0x64, ALC\_MAX\_ATTEN). If gain reductions cause the battery voltage to rise above the brownout threshold, the gain reduction stops to a level where PVDD again drops below the brownout threshold after a programmable debounce time set by ALC\_RLS\_DBT. The rate at which the gain is restored is set by ALC\_RLS\_RATE and ALC\_RLS\_CFG. If the battery supply voltage remains below the brownout threshold after the amplifier gain has been reduced by programmed setting, the speaker amplifier is, by default, muted after a programmable delay time set by

ALC\_MUTE\_DLY. The battery debounce time ALC\_RLS\_DBT is the time the battery must be above the threshold before moving to the RELEASE state either from the MUTE state or the HOLD state. The transition to MUTE can be disabled by resetting the ALC\_MUTE\_EN bit. If ALC\_RLS\_DBT is set to infinite hold, the gain remains either muted or at the programmed reduction level below the nominal PGA gain setting until the ALS\_RLS\_TGR bit is set. When ALC\_MUTE\_EN bit is set the gain remains at programmed reduction value below the PGA gain setting until PVDD rises above the brownout threshold. ALC gain reductions are independent of the minimum attenuation setting of the PGA. If enabled, gain ramping has no effect on ALC attack, release or mute actions. [Figure 16–Figure 19](#) provide examples of how the ALC behaves in four scenarios. If PVDD is held close to the ALC threshold, ALC will be stuck in a state of intermediate attenuation. Intermediate Attenuation means that ALC started to reduce gain but never reaches the programmed maximum attenuation. Gain is constant in this state, in-between original gain and maximum attenuation as ALC is neither attacking or releasing. [Figure 20](#) shows an example of ALC Intermediate attenuation.

**DOUT Operation and Data format**

The MAX98372 features a bidirectional DOUT pin to provide feedback data to the applications processor and other MAX98372s. The data output from DOUT shares the status of amplifier DHT, thermal foldback adjustments, and ALC status. The data format used to frame the data carried on DOUT is the same as the data format of the input data on the DIN pin. The DOUT pin only drives out during the slot assigned to the amplifier by TX\_CH#\_EN

bit. At all other times, the pin is an input (to allow other devices to drive the DOUT signal).

The data output on the DOUT pin is structured as shown in [Figure 21](#).

Where DHT\_INFO[7:0] contains the DHT attenuation (in dB), THERM\_INFO [5:0] contains the thermal foldback attenuation, and ALC[0] contains transmitter devices' ALC comparator status broadcast out to other amplifiers on the same bus. It is decoded as shown in [Figure 21](#).

**Table 31. DHT INFO**

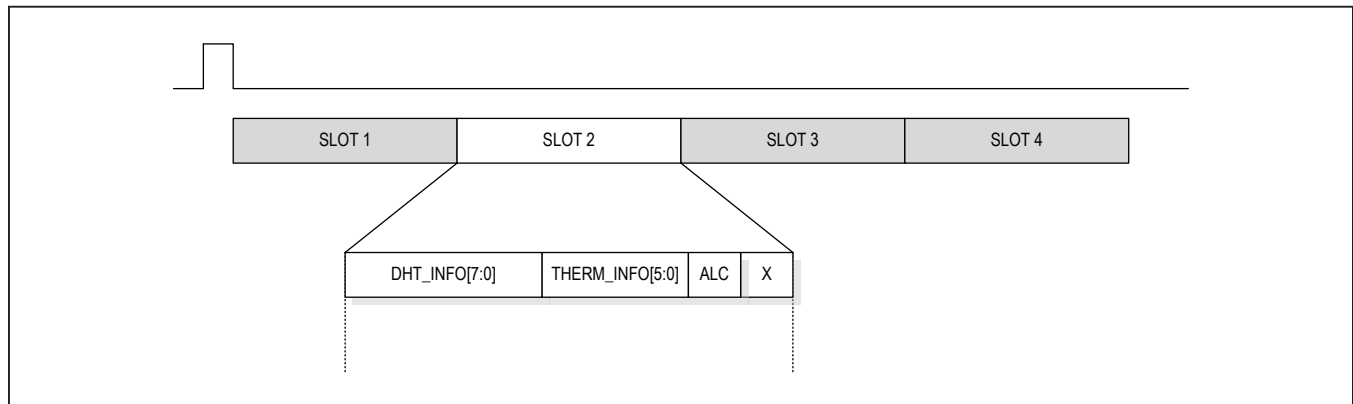

Figure 21. DOUT Data Structure

**Table 33. Thermal and DHT Link Enables**

ADDRESS	BIT	NAME	DESCRIPTION
0x4E	2	ALC_LINK_EN	0: Disable ALC link. 1: Enable ALC link.
	1	THRM_LINK_EN	0: Disable THRM link. 1: Enable THRM link.
	0	DHT_LINK_EN	0: Disable DHT link. 1: Enable DHT link.

The THRM\_LINK\_EN, DHT\_LINK\_EN, and ALC\_LINK\_EN are intended to be used as the global enables of receive data function of the ICC. It should also be noted that for the ICC to function properly ICC\_OC\_ENA bit in register 0x5C must be set to 1 so that the overcurrent protection on DOUT is enabled.

**Interchip Communication**

The MAX98372 features an interchip communication (ICC) bus that facilitates synchronized gain adjustments between groups of MAX98372 amplifiers.

**Multiamplifier Grouping**

By setting registers 0x3A through register 0x3F, registers 0x60 and 0x61, it is possible to group MAX98372 amplifiers so that any gain adjustments due to DHT and/or thermal foldback and/or ALC status are synchronized.

Each amplifier is configured by a register setting to monitor DOUT during certain slots. The slots selected define to which group each amplifier belongs. Therefore, each amplifier in a group must have the same settings for RX enables. Each individual amplifier must also have only one TX\_CH# enable set as well as the corresponding RX\_CH# enable.

For example, if there are four amplifiers and two groups are needed, then one configuration may be that amplifiers 1 and 3 would belong to one group and amplifiers 2 and

4 belong to another. Assign amplifier 1 to broadcast on slot 0 through the TX\_CH0\_EN bit enable and amplifier 3 to broadcast on slot 2 through the TX\_CH2\_EN bit. Then configure both amplifiers to enable RX enable to listen to both slots 0 and 2, so both amplifiers would have RX\_DHT\_CH0\_EN and RX\_DHT\_CH2\_EN enabled. While this configuration groups the amplifier in the same DHT group, there is another set of grouping registers for thermal foldback. These registers can be configured identically or differently to accommodate the desired behavior. To configure the second group, set amplifier 2 to broadcast on slot 1 through TX\_CH1\_EN and set amplifier 4 to broadcast on slot 3 through TX\_CH3\_EN. Then configure both amplifiers to enable RX enable to listen to both slots 1 and 3, so both amps would have RX\_DHT\_CH1\_EN and RX\_DHT\_CH3\_EN enabled.

By definition, the minimum size of a group is two amplifiers, so the maximum number of groups that is supported is eight. A group can contain as many as 16 amplifiers, but then only one group is supported.

It is a requirement of the host processor to ensure that the RX register bits are set to the same values across all amplifiers intended to be used in a group. Devices in the same DHT group must also be configured with the same DHT parameters (SPK\_GAIN\_MAX, RP, and ballistics) to achieve a balanced response across the group. The same is true of the THERM group and ALC group.

**Double Data Drive**

If the shared DOUT trace has a high capacitance that needs to be driven at high speed then the double-data drive feature can be used. This gives a longer drive time for each device.

When the BCLK is less than or equal to 25MHz, DOUT can be clocked with standard clocking: data changes on the falling edge and is valid on the rising edge of each BCLK (Table 35).

When the BCLK is greater than 25MHz, DOUT should be clocked using a double-data drive method: data changes on the falling edge and is valid on the second rising edge.

In this way, the DOUT data transfer rate is effectively half of the BCLK speed. This is accomplished by setting DRIVE\_MODE = 1.

This has implications for the supported slot lengths. When double-data drive is enabled, only 32-bit slot lengths are permitted.

Additional MAX98372 devices correctly interpret the double-data drive format (if enabled). Any other attached hardware, such as an applications processor, which is expecting standard timing, needs to ensure that it omits away the information captured on the nonvalid rising edge each time and reconstruct the samples accordingly.

**Class D Output Stage**

The MAX98372 Class D output stage with active emissions limiting and spread spectrum provides optimum suppression and control of output switching harmonics that most directly contribute to EMI and radiated emissions. Programmable speaker edge rate control is available to help tweak EMI performance. As the edge rate increases the efficiency goes up slightly, and as the edge

rate slows the efficiency goes down. Set the speaker edge rate with bits SPK\_EDGE bits in register 0x4A.

The default Class D output switching frequency is 472kHz for the best THD performance. To trade off THD performance for higher efficiency the output switching frequency can be set to 330kHz by setting SPK\_SWCLK to 1.

Changes to the SPK\_EN bit should only be made when Global Enable (EN) is set low. See [Table 42](#) for speaker configuration.

**Table 42. Speaker Configuration**

**Ultra-Low EMI Filterless Output Stage**

Traditional Class D amplifiers require the use of external LC filters, or shielding, to meet electromagnetic-interference (EMI) regulation standards. The active emissions limiting edge-rate control circuitry reduce EMI emissions so that with 12in of speaker cable the MAX98372 passes the EN55022B standard without the need for external filtering components.

Maxim’s spread-spectrum modulation mode flattens wideband spectral components while proprietary techniques ensure that the cycle-to-cycle variation of the switching period does not degrade audio reproduction or efficiency. The ICs’ spread-spectrum modulator randomly varies the switching frequency by as much as  $\pm 18.6\text{kHz}$  around 330kHz center frequency, or by  $\pm 39.4\text{kHz}$  around 478.75kHz center frequency. Above 10MHz, the wideband spectrum looks like noise for EMI purposes.

**V<sub>DVDD</sub> and V<sub>PVDD</sub> UVLO**

The MAX98372 monitors both DVDD and PVDD for low voltage conditions that would prevent the speaker amplifier from operating normally. If the voltage on DVDD drops below the DVDD-UVLO threshold (V<sub>DVDD-UVLO</sub>), the device is placed in hardware shutdown. All the I<sup>2</sup>C internal registers reset to their default values. The device can be commanded to leave this state through the I<sup>2</sup>C command if the voltage on DVDD later exceeds the V<sub>DVDD-UVLO</sub> threshold.

If the voltage PVDD drops below the PVDD-UVLO threshold, the audio output is muted to prevent the PVDD supply from being used by the amplifier. If the voltage on PVDD later exceeds the V<sub>PVDD-UVLO</sub> threshold, the device can be commanded to unmute through the I<sup>2</sup>C command.

**Click-and-Pop Suppression**

The MAX98372 speaker amplifier features Maxim's comprehensive click-and-pop suppression. During power-up and power-down, the click-and-pop suppression circuitry reduces any audible transient sources internal to the device.

At startup, the PGA gain is automatically ramped from mute to the desired setting at a rate of 200µs/dB. Similarly, the gain is ramped down to mute at shutdown at the same rate. For faster startup and shutdown, disable gain ramping.

During normal operation, any requested gain changes are ramped from the old value to the new value at a value determined by the ballistics within the volume control block.

**Amplifier Current Limit**

The MAX98372 features current limit protection that protects the device against shorts. If the output current of the speaker amplifier exceeds the current limit (6A typ) the IC disables the outputs for approximately 100µs. After 100ms, the outputs are reenabled. If the fault condition still exists, the IC continues to disable and reenable the outputs until the fault condition is removed. Set OVC\_SEL low to disable this behavior (Table 44). The current limit protects against both high-current and short-circuit events.

**Thermal Shutdown Recovery**

When the temperature of the die exceeds +150°C, the part enters thermal shutdown. However, the MAX98372 features a configurable thermal shutdown autorecovery mode. When the die temperature has decreased by 30°C from the thermal shutdown event, the MAX98372 attempts to resume the previous operating state. Set TSHDN\_AUTO\_RESTART high to enable autorecovery mode (Table 44).

**Output Sensing When Using Ferrites**

The MAX98372 features two remote sensing pins OUTN\_SNS and OUTP\_SNS. Remotely sensing the voltage at the load provides a THD+N advantage over sensing at the DUT output when ferrite beads are used (Figure 29). The remote sense lines connect the output signal at the load to the inverting terminal of the internal error amplifier of the Class D (Figure 28). Ferrites are highly nonlinear so sensing at the load versus at the output pins ensures that any signal degradation caused by the filtering components is appropriately compensated.

However, in many applications, there may not be a need to filter the output with a ferrite bead.

**Clocking Architecture**

The MAX98372 includes a flexible clocking architecture and operation with no MCLK input.

A configurable internal clock monitor circuit monitors the internal clock source (BCLK) and automatically places the device in software shutdown if the clock source is removed. Set CMON\_ENA high to enable the clock monitor. This prevents unwanted signals from being applied to the speaker during a fault condition. When CMON\_AUTO\_RESTART is high, the device automatically returns to normal operation when the clock source is subsequently reapplied (Table 44).

**Reset**

The MAX98372 features an active-low hardware reset. When the voltage-on reset is pulled low, the part enters global shutdown. To reenab the part, the reset pin must be pulled high and a global enable I<sup>2</sup>C command must be issued.

**Hardware Reset**

When the reset pin is pulled low, the device is in its lowest power-down state and communication over I<sup>2</sup>C is not possible. After exiting reset mode, all registers are set to their default POR values.

Also, if DVDD is removed while PVDD is still applied, the device goes into a hardware shutdown mode and communication through I<sup>2</sup>C is not possible.

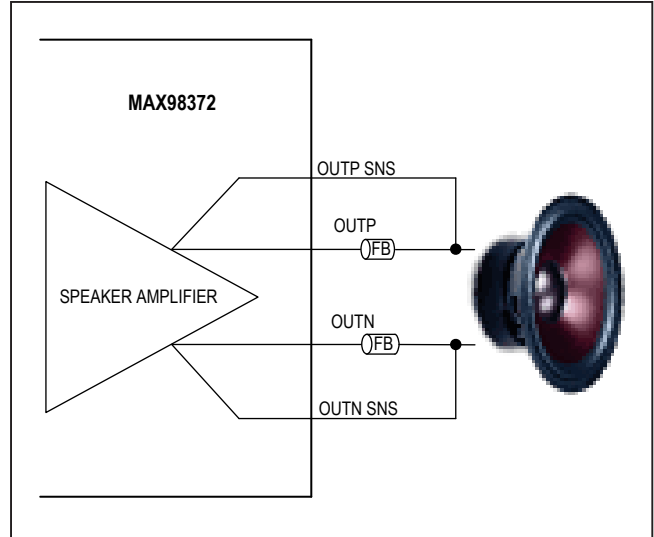

Figure 28. Typical Application Circuit with Ferrites Beads Used

ADDRESS	BIT	NAME	DESCRIPTION
<a href="#">0x51</a>	0	RST	<b>Reset</b> 0: No action is taken. 1: Reset. All registers return to their POR (default) values.

**Table 46. Global Enable Register**

ADDRESS	BIT	NAME	DESCRIPTION
<a href="#">0x50</a>	0	EN	<b>Global Enable:</b> 0: Disabled 1: Enabled

### Software Reset

Write 1 to bit 0 of register 0x51 to trigger a software reset. Software reset is used to return most registers to their default (POR) states. Biquad equalizer coefficients are not reset.

The software reset register is a write only register. As a result, a read of this register always returns 0x00. Writing logic-high to RST triggers a software register reset, while writing a logic-low to RST has no effect.

Also if PVDD is removed while DVDD is still applied the device goes into software shutdown mode where all blocks are disabled except I<sup>2</sup>C control block.

### I<sup>2</sup>C Serial Interface

The MAX98372 features an I<sup>2</sup>C 2-wire serial interface consisting of a serial data line (SDA) and a serial clock line (SCL). SDA and SCL facilitate communication between the IC and the master at clock rates up to 400kHz. [Figure 30](#) shows the 2-wire interface timing diagram. The master generates SCL and initiates data transfer on the bus. The master device writes data to the IC by transmitting the proper slave address followed by the register address and then the data word. Each transmit sequence is framed by a START (S) or REPEATED START (Sr) condition and a STOP (P) condition. Each word transmitted to the IC is 8 bits long and is followed by an acknowledge clock pulse. A master reading data from the IC transmits the proper slave address followed by a series of nine SCL pulses. The IC transmits data on SDA in sync with the master-

generated SCL pulses. The master acknowledges receipt of each byte of data. Each read sequence is framed by a START (S) or REPEATED START (Sr) condition, a not acknowledge, and a STOP (P) condition. SDA operates as both an input and an open-drain output. A pullup resistor, typically greater than 500Ω, is required on SDA. SCL operates only as an input. A pullup resistor, typically greater than 500Ω, is required on SCL if there are multiple masters on the bus, or if the single master has an open-drain SCL output. Series resistors in line with SDA and SCL are optional. Series resistors protect the digital inputs of the IC from high voltage spikes on the bus lines, and minimize crosstalk and undershoot of the bus signals.

### Bit Transfer

One data bit is transferred during each SCL cycle. The data on SDA must remain stable during the high period of the SCL pulse. Changes in SDA while SCL is high are control signals. See the *START and STOP Conditions* section.

### START and STOP Conditions

SDA and SCL idle high when the bus is not in use. A master initiates communication by issuing a START condition. A START condition is a high-to-low transition on SDA with CL high. A STOP condition is a low-to-high transition on SDA while SCL is high ([Figure 30](#)). A START condition from the master signals the beginning of a transmission to the IC. The master terminates transmission, and frees the bus, by issuing a STOP condition. The bus remains active if a REPEATED START condition is generated instead of a STOP condition.

Figure 30. START, STOP, and REPEATED START Conditions

**Early Stop Conditions**

The IC recognizes a STOP condition at any point during data transmission except if the STOP condition occurs in the same high pulse as a START condition. For proper operation, do not send a STOP condition during the same SCL high pulse as the START condition.

**Slave Address**

The slave address is defined as the seven most significant bits (MSBs) followed by the read/write bit. For the IC, the seven most significant bits are programmable through the ADDR1 and ADDR0 bumps. Setting the read/write bit to 1 configures the IC for read mode. Setting the read/write bit to 0 configures the IC for write mode. The slave

address is the first byte of information sent to the IC after the START condition.

**Acknowledge**

The acknowledge bit (ACK) is a clocked 9th bit that the IC uses to handshake receipt each byte of data when in write mode [Figure 31](#). The IC pulls down SDA during the entire master-generated 9th clock pulse if the previous byte is successfully received. Monitoring ACK allows for detection of unsuccessful data transfers. An unsuccessful data transfer occurs if a receiving device is busy or if a system fault has occurred. In the event of an unsuccessful data transfer, the bus master reattempts communication. The master pulls down SDA during the 9th clock cycle to acknowledge receipt of data when the IC is in read mode. An acknowledge is sent by the master after each read byte to allow data transfer to continue. A not-acknowledge is sent when the master reads the final byte of data from the IC, followed by a STOP condition.

**Write Data Format**

A write to the IC includes transmission of a START condition, the slave address with the R/W bit set to 0, one byte of data to configure the internal register address pointer, one or more bytes of data, and a STOP condition. [Figure 32](#) illustrates the proper frame format for writing one byte of data to the IC. [Figure 33](#) illustrates the frame format for writing n-bytes of data to the IC.

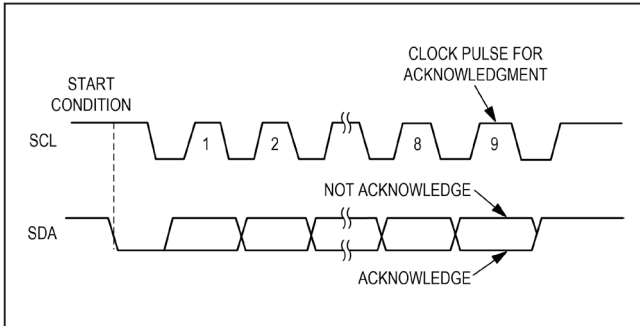

Figure 31. Acknowledge

Figure 32. Writing One Byte of Data to the MAX98372

Figure 33. n-Bytes of Data to the MAX98372

The slave address with the R/W bit set to 0 indicates that the master intends to write data to the IC. The IC acknowledges receipt of the address byte during the master-generated 9th SCL pulse.

The second byte transmitted from the master configures the IC's internal register address pointer. The pointer tells the IC where to write the next byte of data. An acknowledge pulse is sent by the IC upon receipt of the address pointer data.

The third byte sent to the IC contains the data that is written to the chosen register. An acknowledge pulse from the IC signals receipt of the data byte. The address pointer autoincrements to the next register address after each received data byte. This autoincrement feature allows a master to write to sequential registers within one continuous frame. The master signals the end of transmission by issuing a STOP condition.

**Read Data Format**

Send the slave address with the R/W bit set to 1 to initiate a read operation. The IC acknowledges receipt of its slave address by pulling SDA low during the 9th SCL clock pulse. A START command followed by a read command resets the address pointer to register 0x00.

The first byte transmitted from the IC is the content of register 0x00. Transmitted data is valid on the rising edge of SCL. The address pointer autoincrements after each read data byte. This autoincrement feature allows all registers to be read sequentially within one continuous frame. A STOP condition can be issued after any number of read data bytes. If a STOP condition is issued followed by another read operation, the first data byte to be read is from register 0x00.

The address pointer can be preset to a specific register before a read command is issued. The master presets the address pointer by first sending the IC's slave address with the R/W bit set to 0 followed by the register address. A REPEATED START condition is then sent followed by the slave address with the R/W bit set to 1. The IC then transmits the contents of the specified register. The address pointer autoincrements after transmitting the first byte.

The master acknowledges receipt of each read byte during the acknowledge clock pulse. The master must acknowledge all correctly received bytes except the last byte. The final byte must be followed by a not acknowledge from the master and then a STOP condition. [Figure 34](#) illustrates the frame format for reading one byte from the IC. [Figure 35](#) illustrates the frame format for reading multiple bytes from the IC.

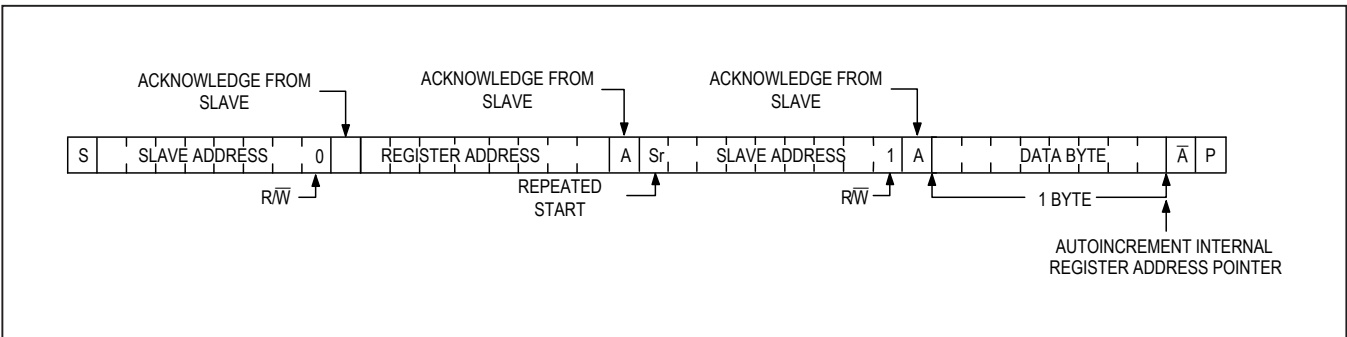

Figure 34. Reading One Byte of Data from the MAX98372

Figure 35. Reading n-Bytes of Data from the MAX98372

### I<sup>2</sup>C Slave Addresses

The MAX98372 is configured using the I<sup>2</sup>C control bus. The addresses effectively allow unique audio endpoint destinations in systems that use multiples of the device. The IC uses hardware select slave addresses determined by the configuration of ADDR0, ADDR1 as shown in [Table 47](#). See the [I<sup>2</sup>C Serial Interface](#) section for a complete interface description.

## Applications Information

### Layout and Grounding

Proper layout and grounding are essential for optimum performance. Use at least 4 PCB layers, and add thermal vias to the ground/power plane close to the MAX98372 to ensure good thermal performance and high-end output power. Good grounding improves audio performance and prevents switching noise from coupling into the audio signal. Ground the power signals and the analog signals of the IC separately at the system ground plane, to prevent switching interference from corrupting sensitive analog signals.

Place the recommended supply decoupling capacitors as close as possible to the IC. The PVDD-to-PGND connection must be kept short and should have minimum trace length and loop area to ensure optimal performance.

Use wide, low-resistance output, supply and ground traces. As load impedance decreases, the current drawn from the device outputs increase. At higher current, the resistance of the output traces decreases the power delivered to the load. For example, if 2W is delivered from the speaker output to a 4Ω load through a 100mΩ trace, 49mW is consumed in the trace. If power is delivered through a 10mΩ trace, only 5mW is consumed in the trace. Wide output, supply, and ground traces also improve the power dissipation of the device.

The MAX98372 is inherently designed for excellent RF immunity. For best performance, add ground fills around all signal traces on the top and bottom PCB planes.

The MAX98372 TQFN package features an exposed thermal pad on its underside. Connect the exposed thermal pad to AGND.

It is generally advisable to follow the layout of the MAX98372 evaluation kit as closely as is practical in the application.

Thermal and performance measurements shown in this data sheet were measured with a 6-layer board with 2 signal layers and 4 ground layers. As a result, the EV kit performance is likely better than what can be achieved with a JEDEC standard board.

### WLP Applications Information

For the latest application details on WLP construction, dimensions, tape carrier information, PCB techniques, bump-pad layout, and recommended reflow temperature profile, as well as the latest information on reliability testing results, refer to the Application Note 1891: *Wafer-Level Packaging (WLP) and Its Applications*. The recommended PCB pad size is 0.23mm.

### Startup Sequence

- 1) Apply the nominal voltage to the DVDD and PVDD pins.
- 2) Apply logic-high to the  $\overline{\text{RESET}}$  pin and wait at least 500μs for I<sup>2</sup>C communication to become available.
- 3) Program the device to the desired mode of operation.
  - Program the digital audio interface inputs and outputs.
  - Program the speaker output amplifier gain and set SPK\_EN (this bit must only be toggled when EN is low).
  - Program the PVDD and thermal ADC.
  - Program the DHT and thermal foldback.
  - Set global enable (EN) high.
- 4) Digital audio data (PCM) can be applied to the IC before or after the global enable is set high.
  - When applying an audio signal to an active IC, the signal should be ramped.

### Shutdown Sequence

- 1) Set global enable (EN) low.
- 2) Remove digital audio (PCM) clocks.
- 3) Apply logic-low signal to  $\overline{\text{RESET}}$  pin.
- 4) Remove power from PVDD and DVDD pins.

TITLE:  
PACKAGE OUTLINE, 16,20,28,32,40L  
THIN QFN, 5x5x0.75mm

APPROVAL \_\_\_\_\_ DOCUMENT CONTROL NO. 21-0140 REV. AE 2/3

-DRAWING NOT TO SCALE-

Package Information (continued)

For the latest package outline information and land patterns (footprints), go to [www.maximintegrated.com/packages](http://www.maximintegrated.com/packages). Note that a "+", "#", or "-" in the package code indicates RoHS status only. Package drawings may show a different suffix character, but the drawing pertains to the package regardless of RoHS status.

NOTES:

1. DIMENSIONING & TOLERANCING CONFORM TO ASME Y14.5M-1994.
2. ALL DIMENSIONS ARE IN MILLIMETERS. ANGLES ARE IN DEGREES.
3. N IS THE TOTAL NUMBER OF TERMINALS.
4. THE TERMINAL #1 IDENTIFIER AND TERMINAL NUMBERING CONVENTION SHALL CONFORM TO JE3D 95-1 SPP-012. DETAILS OF TERMINAL #1 IDENTIFIER ARE OPTIONAL, BUT MUST BE LOCATED WITHIN THE ZONE INDICATED. THE TERMINAL #1 IDENTIFIER MAY BE EITHER A MOLD OR MARKED FEATURE.
5. DIMENSION b APPLIES TO METALLIZED TERMINAL AND IS MEASURED BETWEEN 0.25 mm AND 0.30 mm FROM TERMINAL TIP.
6. ND AND NE REFER TO THE NUMBER OF TERMINALS ON EACH D AND E SIDE RESPECTIVELY.
7. DEPOPULATION IS POSSIBLE IN A SYMMETRICAL FASHION.
8. DRAWING CONFORMS TO JEDEC MO220, EXCEPT EXPOSED PAD DIMENSION FOR T2855-3, T2855-6, T4055-1 AND T4055-2.
9. WARPAGE SHALL NOT EXCEED 0.10 mm.
10. MARKING IS FOR PACKAGE ORIENTATION REFERENCE ONLY.
11. REFER TO DIMENSION VARIATION TABLE FOR LEAD LENGTH VARIATION
12. APPLICABLE ONLY FOR PACKAGES WITH TIGHT CORNER LEADS METAL TO METAL CLEARANCE.
13. NUMBER OF LEADS SHOWN ARE FOR REFERENCE ONLY.
14. LEAD CENTERLINES TO BE AT TRUE POSITION AS DEFINED BY BASIC DIMENSION "e", ±0.05.
15. MATERIAL MUST BE COMPLIANT WITH MAXIM SPECIFICATION 10-0131 FOR SUBSTANCE CONTENT, MUST BE Eu ROHS COMPLIANT WITHOUT EXEMPTION AND PB-FREE.
16. ALL DIMENSIONS APPLY TO BOTH LEADED (-) AND PbFREE (+) PKG. CODES.

1. REFERENCE PKG. OUTLINE: 21-0140
2. LAND PATTERN COMPLIES TO: IPC7351A.
3. TOLERANCE: +/- 0.02 mm.
4. ALL DIMENSIONS APPLY TO BOTH LEADED (-) AND PbFREE (+) PKG. CODES.
5. ALL DIMENSIONS IN MM.

-DRAWING NOT TO SCALE-

This document (including dimensions, notes & specs) is a recommendation based on typical circuit board manufacturing parameters. Since land pattern design depend on many factors unknown to Maxim (eg. user's board manufacturing specs), user must determine suitability for use. This document is subject to change without notice. Contact technical support at <http://www.maxim-ic.com/support> for further questions.

TITLE: PACKAGE LAND PATTERN, 32L TQFN, 5x5 MM			
APPROVAL	DOCUMENT CONTROL NO. 90-0012	REV. E	1/1

## Revision History

REVISION NUMBER	REVISION DATE	DESCRIPTION	PAGES CHANGED
0	9/15	Initial release	—
1	1/16	Updated <i>Electrical Characteristics</i> table DIN Frame Delay after LRCLK Edge parameter, replaced Figure 7	12, 48
2	2/17	Added TQFN package information to <i>Absolute Maximum Ratings</i> and <i>Package Information</i> sections (including package outline drawings), updated Tables 1, 3–6, 9, 24, 26–30, 33, 42–44, added four new figures (Figure 24–Figure 27), added <i>Startup Sequence</i> and <i>Shutdown Sequence</i> sections, added MAX98372ETJ+ and MAX98372ETJ+T in <i>Ordering Information</i> table	8, 29, 43–45, 51, 66, 72–75, 83–86, 88, 93–99
3	8/17	Updated <i>Electrical Characteristics</i> table with current limit specs for different packages	11
4	3/20	Updated <i>Bump/Pin Configurations</i> diagram, <i>Bump/Pin Description</i> table, <i>Layout and Grounding</i> section	24, 25, 92

For pricing, delivery, and ordering information, please visit Maxim Integrated's online storefront at <https://www.maximintegrated.com/en/storefront.html>.

Maxim Integrated cannot assume responsibility for use of any circuitry other than circuitry entirely embodied in a Maxim Integrated product. No circuit patent licenses are implied. Maxim Integrated reserves the right to change the circuitry and specifications without notice at any time. The parametric values (min and max limits) shown in the *Electrical Characteristics* table are guaranteed. Other parametric values quoted in this data sheet are provided for guidance.
