NCV7750

Quad Low-Side Relay Driver

The NCV7750 is an automotive four channel low-side driver providing drive capability up to 600 mA per channel. Output control is via a SPI port and offers convenient reporting of faults for open load (or short to ground), overload, and overtemperature conditions. Additionally, parallel control of the outputs is addressable (in pairs) via the INx pins.

A dedicated limp-home mode pin (LHI) enables OUT1-OUT4.

Each output driver is protected for overload current and includes an output clamp for inductive loads.

The NCV7750 is available in a SSOP-24 fused lead package.

Features

- 4 Low-Side Channels
- 600 mA Low-Side Drivers
 - ◆ $R_{DS(on)}$ 1.1 Ω (Typ), 2.2 Ω (Max)
- 16-bit SPI Control
 - ◆ Frame Error Detection (8-bit)
 - ◆ Daisy Chain Capable
- Parallel Input Pins for PWM operation
- Power Up Without Open Circuit Detection Active (for LED applications)
- Low Quiescent Current in Sleep and Standby Modes
- Limp Home Functionality
- 3.3 V and 5 V compatible Digital Input Supply Range
- Fault Reporting
 - ◆ Open Load Detection (selectable)
 - ◆ Overload
 - ◆ Overtemperature
- Power-on Reset (VDD, VDDA)
- SSOP-24 Package (internally fused leads)
- NCV Prefix for Automotive and Other Applications Requiring Unique Site and Control Change Requirements; AEC-Q100 Qualified and PPAP Capable
- These are Pb-Free Devices

Applications

- Automotive Body Control Unit
- Automotive Engine Control Unit
- Relay Drive
- LED Drive
- Stepper Motor Driver

PACKAGE PIN DESCRIPTION

SSOP-24	Symbol	Description
1	GND	Ground.
2	GND	Ground.
3	OUT1	Channel 1 low-side drive output. Requires an external pull-up device for operation.
4	OUT2	Channel 2 low-side drive output. Requires an external pull-up device for operation.
5	OUT3	Channel 3 low-side drive output. Requires an external pull-up device for operation.
6	OUT4	Channel 4 low-side drive output. Requires an external pull-up device for operation.
7	NC	No Connection
8	NC	No Connection
9	NC	No Connection
10	NC	No Connection
11	GND	Ground.
12	GND	Ground.
13	VDD	Digital Power Supply for SO output (3.3 V or 5 V).
14	IN4	Parallel control of OUT4. Ground if not used for best EMI performance. Alternatively keep open and internal pull-down will hold the input low. (120 k Ω pull down resistor).
15	IN3	Parallel control of OUT3. Ground if not used for best EMI performance. Alternatively keep open and internal pull-down will hold the input low. (120 k Ω pull down resistor).
16	IN2	Parallel control of OUT2. Ground if not used for best EMI performance. Alternatively keep open and internal pull-down will hold the input low. (120 k Ω pull down resistor).
17	IN1	Parallel control of OUT1. Ground if not used for best EMI performance. Alternatively keep open and internal pull-down will hold the input low. (120 k Ω pull down resistor).
18	LHI	Limp Home Input. Active High. A high on this pin powers up the device and activates the respective output drive INx designator. Input SPI commands are ignored, but the output register reports faults. (Read capability only. No write capability.) All registers are reset coming out of LHI mode. Ground if not used for best EMI performance. Alternatively keep open and internal pull-down resistor (120 k Ω) will hold the input low.
19	SO	SPI serial data output. Output high voltage level referenced to pin VDD.
20	SCLK	SPI clock (120 k Ω pull down resistor).
21	EN	Global Enable (active high). (120 k Ω pull down resistor).
22	SI	SPI serial data input (120 k Ω pull down resistor).
23	CSB	SPI Chip Select "Bar" (120 k Ω pull up resistor to VDD).
24	VDDA	Analog Power Supply Input voltage (5 V).

DETAILED OPERATING DESCRIPTION

Power Outputs

The NCV7750 provides four independent 600mA power transistors with their source connection referenced to the ground pin and with their drain connection brought out to individual pins resulting in 4 independent low-side drivers. Output driver location on one side of the IC layout provides for optimum pcb layout to the loads.

Internal clamping structures are provided to limit transient voltages when switching inductive loads. Each output has an overload detection current of 0.6 A (min) where the drivers turn-off and stay latched off. An Overload Current Shut-Down Delay Time of 3 μ s (min) is designed into the IC as a filter allowing for spikes in current which may occur during normal operation and allowing for protection from overload conditions.

Faults can be cleared with the SPI input register (**command 00**), via a power-on-reset, or coming out of LHI mode. Fault detection is provided in real time. Detection is provided both during output turn-on and with output already on. (See Page 17, Clearing the Fault Registers)

The NCV7750 is available in a SSOP-24 package.

Output Control (SPI)

Each output driver is controlled via a digital SPI port after the device has powered up (out of POR) and enabled via the

EN pin. The NCV7750 device will go through a power up reset each time the EN pin is toggled low to high resulting in a device setup of default values as described in the Register Specifics section. Standby Mode, Input Mode, ON Mode, and OFF Mode are all selectable via the SPI for each channel independently.

Power up, Power-On Reset (UVLO mode)

Both VDD and VDDA supply an independent power-on-reset function to the IC. Coming out of power-on-reset all input bits are set to a 1 (OFF Mode) and all output bits are set to a 0 except for the TER bit which is set to a 1. The device cannot operate without both supplies above their respective power-on reset thresholds with the exception of LHI mode. During LHI mode, VDD POR is ignored and the device is only affected by VDDA POR.

The NCV7750 powers up into the Global OFF Mode without the open circuit diagnostic current enabled. This allows the device to be turned on via EN = 0 to EN = 1 with LED loads avoiding illumination of the LED loads (reference Figure 21 State Diagram). All other paths to Global OFF Mode enable open circuit diagnostic current.

Table 1. MODES OF OPERATION

Modes of Operation	Conditions	Description
UVLO Mode	VDD or VDDA below their respective POR thresholds	All outputs off in this mode. Coming out of this mode with EN = 1 sets all channels in the OFF mode without open circuit diagnostic current enabled. With LHI = 1 and EN = x, the part enters limp home mode.
OFF Mode	SPI Control (Command 11)	Output off. Open circuit diagnostic current is disabled (powerup mode). Open circuit diagnostic current is enabled (normal mode).
Global OFF Mode	SPI Control All Channels (Command 11)	Output off. Open circuit diagnostic current is disabled (powerup mode). Open circuit diagnostic current is enabled (normal mode).
ON Mode	SPI Control (Command 10)	Output on.
Limp Home Mode (LHI)	LHI = high, EN = x	Dedicated output turn on control of OUT1-OUT4 using IN1-IN4.
Low Iq Mode	EN = LHI = low	Provides a state with the lowest quiescent current for V _{DD} and VDDA.
Standby Mode	SPI Control (Command 00)	Provides an OFF state with Open circuit diagnostic current disabled.
Global Standby Mode	SPI Control All Channels (Command 00)	Provides a reduced quiescent current mode. Provides an OFF state with Open circuit diagnostic current disabled.
Input Mode	SPI Control (Command 01)	Directs output channel to be driven from INx input pins.

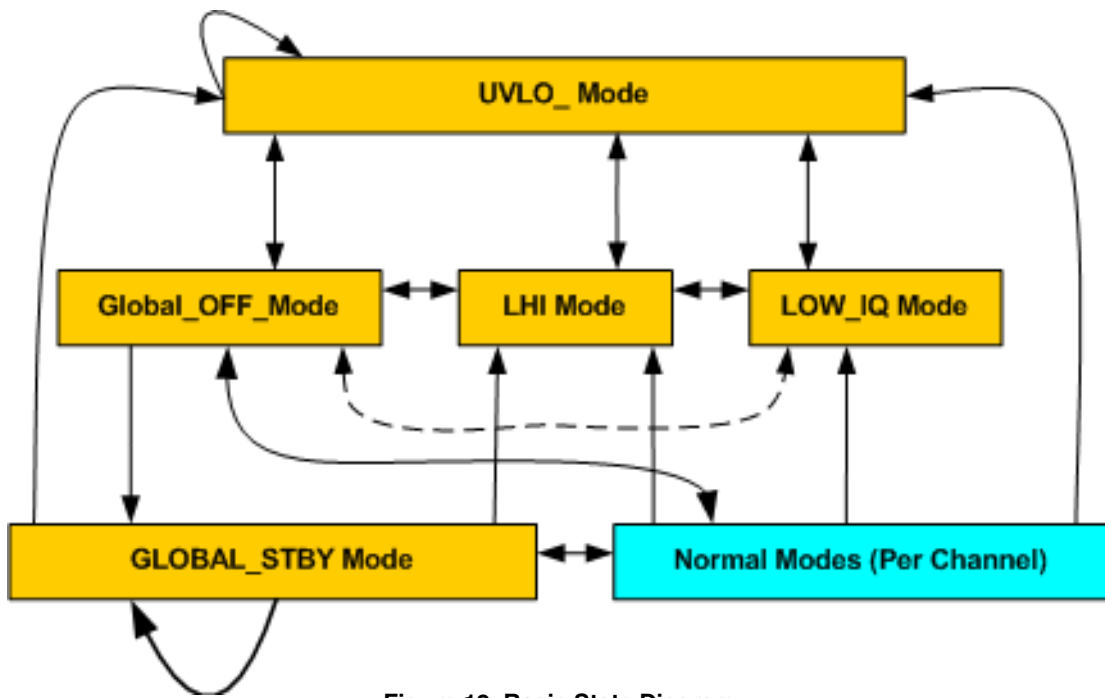

Figure 19. Basic State Diagram

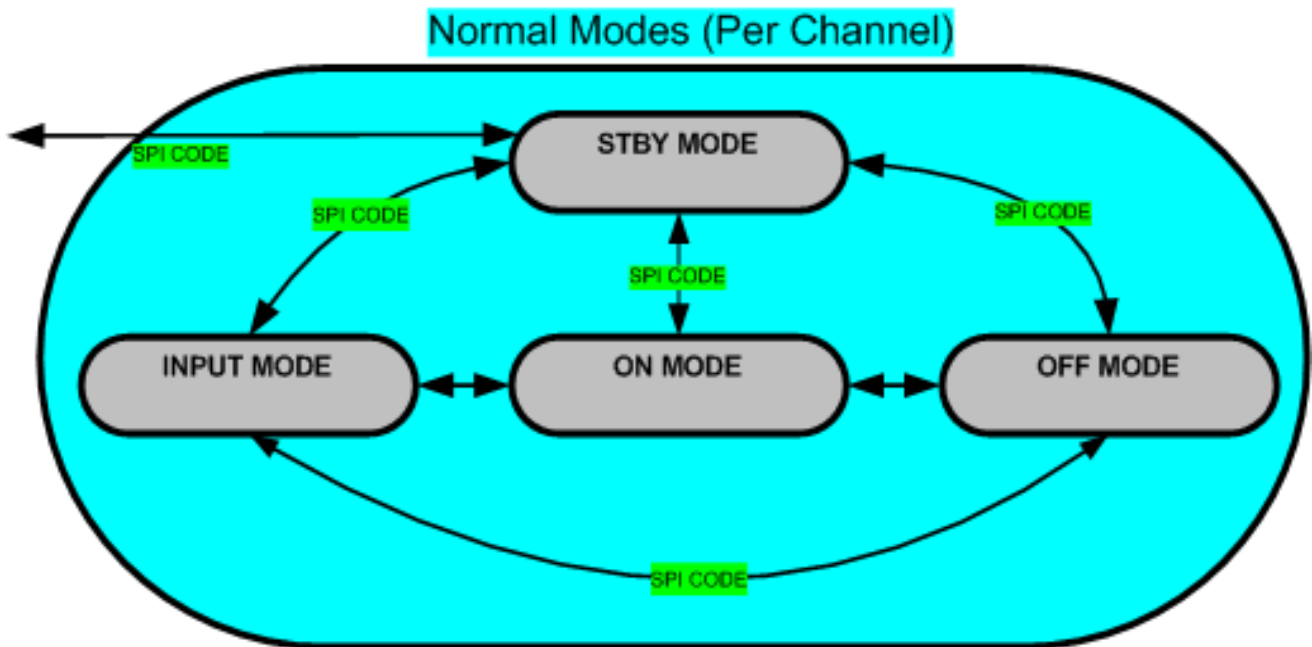

Figure 20. Normal Operation State Diagram

Figure 21. Detailed State Diagram

* --- dotted line indicates bidirectional path.

** Operational down to $VDD=0V$. SO reports above $VDD > POR$

Limp Home and PWM operation (INx control)

Pulse Width Modulation techniques are allowed utilizing the parallel inputs (INx).

Output pins (OUTx) are programmed for use in conjunction with the INx pins using the SPI command (**command 01**).

The LHI pin controls the operation of the INx pins.

LHI = Low and EN = High

With LHI=low, outputs are controlled by the INx pins (via SPI programming).

IN1 controls channels OUT1.

IN2 controls channels OUT2.

IN3 controls channels OUT3.

IN4 controls channels OUT4.

Alternatively, any of the four channels can be commanded off.

Output pins (OUTx) are programmed for use in conjunction with the INx pins using the SPI command (**command 01**).

It's important to note faults occurring during PWM operation (LHI=low) must be cleared via the SPI or POR.

LHI = High

To go into limp home mode, bring LHI=high, the corresponding outputs of IN1–IN4 will turn on or off.

During Limp Home Mode, overload and overtemperature sensing are functional, and are reported via the SPI port. But, since input SPI commands are ignored with LHI = high, driver turn-off (overload or overtemperature) occurring when LHI=high can only be re-initiated by toggling LHI or through a POR of VDDA.

All registers are reset coming out of LHI mode. The device enters OFF mode (EN = 1) or Low Iq Mode (EN = 0) depending on the state of the EN pin. Open Load diagnostics are disabled in both cases.

UVLO (Under Voltage Lockout with LHI = High)

A breach of VDDA Power-On Reset thresholds will cause the outputs to turn off and enter the UVLO mode. In LHI mode (LHI = 1), VDD POR is ignored. If VDD is below the operation of SO drive capability, fault information is preserved and can be retrieved when SO drive capability is restored.

TER

A transmission error bit (TER) is set ("1") when exiting the Limp Home Mode into Global Off Mode.

See Frame Detection Transmission Error Section for operation details.

Enable Input (EN)

The EN input pin is a logic controlled input with a voltage threshold between 0.8 V and 2.0 V. The device powers up when EN goes from low to high, and exits Low Iq Mode (with LHI = 0 V) into global Off Mode. Device power up is also controlled via the Limp Home Input (LHI) as an OR'd condition. The EN input is a don't care when the LHI pin is driven from low to high. In this situation, the device enters Limp Home Mode.

Output Drive Clamping

Internal zener diodes (Z1 & Z2, Figure 22) help to protect the output drive transistors from the expected fly back energy generated from an inductive load turning off. Z1 provides the voltage setting of the clamp (along with V_{gs} of the output transistor and Z2) while Z2 isolates Z1 from normal turn-on activity.

The output clamp voltage is specified between 36 V and 44 V. This includes clamping operation during unpowered input supplies (VDD and VDDA). Device protection will be provided when the load is driven from an alternative driver source. This is an important feature when considering protecting for load dump with an un-powered IC.

NCV7750

Figure 22. Output Clamp

Overtemperature / Thermal Shutdown

The NCV7750 incorporates four individual thermal sensors located in proximity to each output driver. A channel is latched off upon the detection of an overtemperature event. This allows operation of unaffected channels before, during, and after a channel detection of overtemperature. The thermal shutdown detection threshold is typically 175°C with 25°C of hysteresis.

Open Load Detection

Open Load Detection is achieved for each output with the Open Load Detection Threshold Voltage reference voltage (Vol) and its' corresponding Open Load Diagnostic Sink Current (when the output driver (OUTx) is off). The output driver maintains its' functionality with and without the open fault bit set (Iol) (i.e. it can turn on and off).

During normal operation, the open circuit impedance (Roc) is 0 Ω. This sets the voltage on OUTx to V_{BAT} volts. As long as V_{BAT} is above Vol no open circuit fault will be recognized. The voltage appearing on OUTx is a result of V_{BAT} and the voltage drop across Roc realized by the current flow created by Iol.

The NCV7750 voltage level trip points are referenced to ground. The threshold range is between 1.0 V and 2.5 V.

With a nominal battery voltage (V_{BAT}) of 14 V, the resultant worst case thresholds of detection are as follows.

$$\frac{(V_{\text{BAT}} - \text{OpenLoadDetectionThresholdVoltage})}{\text{OpenLoadDiagnosticSinkCurrent}} = \text{OpenLoad Impedance}$$

$$\frac{(14 \text{ V} - 2.5 \text{ V})}{100 \mu\text{A}} = 115 \text{ k}\Omega \qquad \frac{(14 \text{ V} - 1.0 \text{ V})}{20 \mu\text{A}} = 650 \text{ k}\Omega$$

NCV7750

Figure 23. Open Load Detection

NOTE: Detection of an open load condition is limited by the Parallel Control Output turn-off time and the Open Load Detection Time specifications. The maximum allowable frequency of operation for PWM (pulse width modulation) using the INx inputs is calculated from the maximum limits of these specifications. INx must be low for longer than the sum of these maximum specifications (50 μ sec and 200 μ sec). Assuming a 50% duty cycle yields a maximum frequency of operation of $[1/(2*(50\mu + 200\mu))]=2$ kHz.

LED Loads

The NCV7750 features a power up feature for the Global OFF Mode enabling the part to power up in a mode without the open load diagnostic current enabled. This averts any unintended illumination of LED loads during power up.

Programming Features

The NCV7750 provides two registers.

1. Input Register. Input for IC mode state and output driver state control.
2. Output Register. Provides diagnostic information on the output driver condition.

Clearing the Fault Registers

Registers are reset with the following conditions.

1. Channel in Standby Mode. (corresponding addressed channel)
2. Power-on reset of VDD. (all channels)
3. Power-on reset of VDDA. (all channels)
4. EN low. (all channels)
5. Coming out of Limp Home Mode(LHI). (all channels)

SPI-Interface

The device provides a 16 bit SPI-interface for output drive control and fault reporting. Data is imported into the NCV7750 through the SI (serial input) pin. Data is exported out of the NCV7750 through the SO (serial output) pin.

The input-frame (SI) (2 bits / channel) is used to command the output stages.

The response frame (SO) provides channel-specific (2 bits / channel) status information fault reporting.

Words should be composed of 16 bits MSB (most significant bit) transmitted first.

SO Output Driver

The digital power supply connection (VDD) to the SO output driver enables the system designer to interface the NCV7750 to both 3.3V and 5V logic systems. Figure 24 shows the internal connection of the SO pin.

Figure 24. SO Output Driver

Overload

Each output has an overload detection current of 0.6 A (min) where the drivers turn-off and stay latched off when an overload condition is detected. A latched off condition must be cleared via the SPI port before it can be turned on. An Overload Current Shut-Down Delay Time of 3 μ s (min) is designed into the IC as a filter allowing for spikes in current which may occur during normal operation and allowing for protection from overload conditions.

Overload is functional during Limp Home (LHI=high). Commands are ignored during Limp Home, but faults can still be retrieved via the SPI.

Frame Detection Transmission Error (TER)

The NCV7750 detects the number of bits transmitted after CSB goes low. Bit counts not a multiple of 8 (16 bit minimum) are reported as a fault on the TER bit. The transmission error information (TER) is available on SO after CSB goes low until the first rising SCLK edge. Reference the Serial Peripheral Interface diagram (Figure 29).

In addition to unqualified bit counts setting TER = 1, the bit will also be set by

1. Coming out of UVLO.
2. Transitioning from Limp Home Mode to Global Off Mode.
3. Transitioning from Low Iq Mode to Global Off Mode.

The TER bit is cleared by sending a valid SPI command.

The TER bit is multiplexed with the SPI SO data and OR'd with the SI input (Figure 25) to allow for reporting in a serial daisy chain configuration. A TER error bit as a "1" automatically propagates through the serial daisy chain circuitry from the SO output of one device to the SI input of the next during the TER retrieval time when CSB goes low to the 1st rising edge of the clock pulse. The SPI register controls the muxing of the output of the OR gate and the SO' output of the SPI register using the S mux select pin. This is shown in Figures 26 and 27 first as the daisy chained devices connected with no Transmission Error (Figure 26) and subsequently with a Transmission Error in device 1 propagating through to device 2 (Figure 27).

TER False Reporting

SI should be in a low state during TER status retrieval (from CSB going low to the 1st rising edge of the clock pulse). Figure 28 demonstrates what could happen if SI is a one during TER status retrieval. In this situation a "1" on SI propagates to SO regardless of the state of TER. Hence a transmission error (TER) could be reported when it is not true.

NCV7750

Figure 25. TER SPI Link

Figure 26. TER (no error)

Figure 27. TER Error Propagation

Figure 28. TER False Reporting

NOTE: TER is valid from CSB going low until the 1st low-to-high transition of SCLK to allow for propagation of the SI signal. Reference Figure 29.
For proper TER status retrieval, SI should be in a low state.

TER Information Retrieval

TER information retrieval is as simple as bringing CSB high-to-low. No clock signals are required.

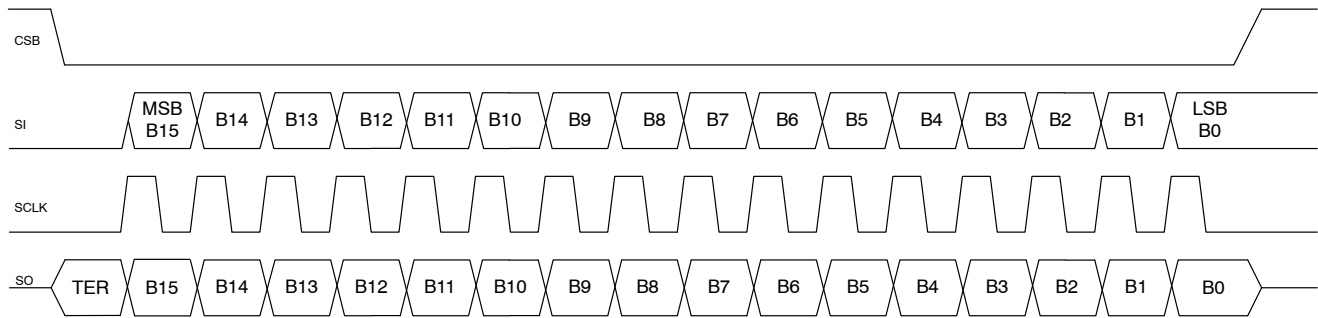

Figure 29. Serial Peripheral Interface

The timing diagram highlighted in Figure 29 shows the SPI interface communication.

Note:

1. The MSB (most significant bit) is the first transmitted bit.
2. Data is sampled from SI on the falling edge of SCLK
3. Data is shifted out from SO on the rising edge of SCLK
4. SCLK should be in a low state when CSB makes a transition.

Frame Detection

Input word integrity (SI) is evaluated by the use of a frame consistency check. The word frame length is compared to an $n * 8$ bit (where n is an integer) acceptable word length (16-bit minimum) before the data is latched into the input register. This guarantees the proper word length has been imported and allows for daisy chain operation applications with 8-bit SPI devices.

The frame length detector is enabled with the CSB falling edge and the SCLK rising edge.

Reference the valid SPI frame shown below. (Figure 30)

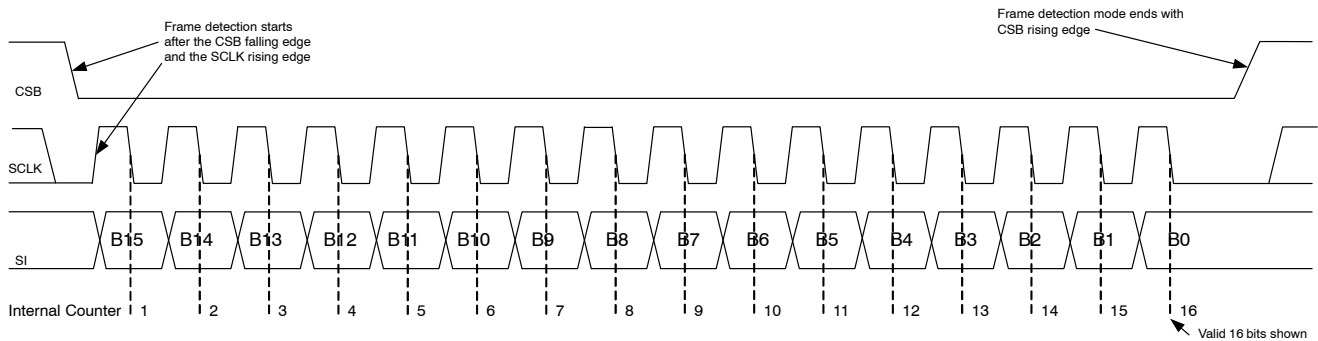

Figure 30. Frame Detection

NCV7750

DAISY CHAIN SETUP

Serial Connection

Daisy chain setups are possible with the NCV7750. The serial setup shown in Figure 31 highlights the NCV7750 along with any 16 bit device using a similar SPI protocol. Particular attention should be focused on the fact that the first 16 bits which are clocked out of the SO pin when the CSB pin transitions from a high to a low will be the Diagnostic Output Data from the Fault Output Register. These are the bits representing the status of the IC. Additional programming bits should be clocked in which follow the Diagnostic Output bits. The timing diagram shows a typical transfer of data from the microprocessor to the SPI connected IC's.

Figure 31. Serial Daisy Chain

Figure 32. Serial Daisy Chain Timing Diagram

Table 2. SERIAL DAISY CHAIN DATA PATTERN

	CLK = 16 bits	CLK = 32 bits	CLK = 48 bits	CLK = 64 bits
IC4	1st CMD	2nd CMD	3rd CMD	4th CMD
IC3	IC4 DIAG	1st CMD	2nd CMD	3rd CMD
IC2	IC3 DIAG	IC4 DIAG	1st CMD	2nd CMD
IC1	IC2 DIAG	IC3 DIAG	IC4 DIAG	1st CMD
micro	IC1 DIAG	IC2 DIAG	IC3 DIAG	IC4 DIAG

Table 2 refers to the transition of data over time of the Serial Daisy Chain setup of Figure 31 as word bits are shifted through the system. 64 bits are needed for complete transport of data in the example system. Each column of the table displays the status after transmittal of each word (in 16 bit increments) and the location of each word packet along the way.

8-bit Devices

The NCV7750 is also compatible with 8 bit devices due to the features of the frame detection circuitry. The internal bit counter of the NCV7750 starts counting clock pulses when CSB goes low. The 1st valid word consists of 16 bits and each subsequent word must be comprised of just 8-bits (reference the Frame Detection Section).

Figure 33. Serial Daisy Chain with 8-bit Devices

Parallel Connection

A more efficient way (time focused) to control multiple SPI compatible devices is to connect them in a parallel fashion and allow each device to be controlled in a multiplex mode. Figure 34 shows a typical connection between the microprocessor or microcontroller and multiple SPI compatible devices. In a serial daisy chain configuration, the programming information for the last device in the serial string must first pass through all the previous devices. The parallel control setup eliminates that requirement, but at the cost of additional control pins from the microprocessor for each individual CSB (chip select bar) pin for each controllable device. Serial data is only recognized by the device that is activated through its' respective CSB pin.

Figure 35 shows the waveforms for typical operation when addressing IC1.

Figure 34. Parallel Connection

Figure 35. Parallel Connection Timing Diagram

Stepper Motor Operation

The NCV7750 device is capable of driving stepper motors. Stepper motors require 4 low-side drive outputs. Figure 36 below illustrates a Unipolar stepper motor setup. For proper operation, the code listed in Table 3 should be used (and repeated) for one way operation (clockwise). For reverse direction, simply reverse the code and repeat (counterclockwise). Outputs 1–4 are utilized for one stepper usage. During operation waveforms similar to Figure 37 can be expected on the OUTx pins.

Figure 36. Stepper Motor Operation Setup

Figure 38. SPI Register Overview

Figure 38 displays the functions controlled and reported via the SPI port. The input register (Table 4) controls the input source (parallel or SPI) and the SPI input data. The output register (Table 5) transmits the output fault bits and the frame detection integrity.

NCV7750

SI SPI Input Data (16-bit serial structure of input word)

The 16-bit data received (SI) is decoded into instructions for each channel per the table below.

After a power-on reset, all register bits are set to a 1.

Table 4. SPI INPUT DATA

Unused		Unused		Unused		Unused		Channel 4		Channel 3		Channel 2		Channel 1	
MSB												LSB			
B15	B14	B13	B12	B11	B10	B9	B8	B7	B6	B5	B4	B3	B2	B1	B0

INPUT DATA REGISTER

Field	Bits	Description		
channel x (x = 1–4)	7, 6 5, 4 3, 2 1, 0	Command		
		00	Channel Stand-by Mode Fast channel turn off Corresponding Channel Fault Register reset	
			Diagnostic Current	Disabled
		01	Input Mode Channel Input directed to INx. (reference PWM operation section).	
			Diagnostic Current	Enabled in OFF State.
		10	ON Mode Channel turned on.	
			Diagnostic Current	Disabled
		11	OFF Mode Channel turned off.	
			Diagnostic Current	Enabled (Disabled after POR)*

*For proper LED load operation.

SO (fault diagnostic retrieval)

Output fault diagnostics from the output fault diagnostic register are shifted out on any 16 bit word clocked into Serial Input (SI).

Only output fault diagnostics and frame detection errors are available through the serial output (SO).

Table 5. SPI OUTPUT DATA

TER	X	X	X	X	X	X	X	X	X	OL4	D4	OL3	D3	OL2	D2	OL1	D1
