## 10.5 Register Map

Table 10-6 on page 478 lists the GPTM registers. The offset listed is a hexadecimal increment to the register's address, relative to that timer's base address:

- Timer 0: 0x4003.0000
- Timer 1: 0x4003.1000
- Timer 2: 0x4003.2000
- Timer 3: 0x4003.3000

Note that the GP Timer module clock must be enabled before the registers can be programmed (see page 257). There must be a delay of 3 system clocks after the Timer module clock is enabled before any Timer module registers are accessed.

**Table 10-6. Timers Register Map**

| Offset | Name         | Type | Reset       | Description                  | See page |
|--------|--------------|------|-------------|------------------------------|----------|
| 0x000  | GPTMCFG      | R/W  | 0x0000.0000 | GPTM Configuration           | 480      |
| 0x004  | GPTMTAMR     | R/W  | 0x0000.0000 | GPTM Timer A Mode            | 481      |
| 0x008  | GPTMTBMR     | R/W  | 0x0000.0000 | GPTM Timer B Mode            | 483      |
| 0x00C  | GPTMCTL      | R/W  | 0x0000.0000 | GPTM Control                 | 485      |
| 0x018  | GPTMIMR      | R/W  | 0x0000.0000 | GPTM Interrupt Mask          | 488      |
| 0x01C  | GPTMRIS      | RO   | 0x0000.0000 | GPTM Raw Interrupt Status    | 490      |
| 0x020  | GPTMMIS      | RO   | 0x0000.0000 | GPTM Masked Interrupt Status | 493      |
| 0x024  | GPTMICR      | W1C  | 0x0000.0000 | GPTM Interrupt Clear         | 496      |
| 0x028  | GPTMTAILR    | R/W  | 0xFFFF.FFFF | GPTM Timer A Interval Load   | 498      |
| 0x02C  | GPTMTBILR    | R/W  | 0x0000.FFFF | GPTM Timer B Interval Load   | 499      |
| 0x030  | GPTMTAMATCHR | R/W  | 0xFFFF.FFFF | GPTM Timer A Match           | 500      |
| 0x034  | GPTMTBMATCHR | R/W  | 0x0000.FFFF | GPTM Timer B Match           | 501      |
| 0x038  | GPTMTAPR     | R/W  | 0x0000.0000 | GPTM Timer A Prescale        | 502      |
| 0x03C  | GPTMTBPR     | R/W  | 0x0000.0000 | GPTM Timer B Prescale        | 503      |
| 0x040  | GPTMTAPMR    | R/W  | 0x0000.0000 | GPTM TimerA Prescale Match   | 504      |
| 0x044  | GPTMTBPMR    | R/W  | 0x0000.0000 | GPTM TimerB Prescale Match   | 505      |
| 0x048  | GPTMTAR      | RO   | 0xFFFF.FFFF | GPTM Timer A                 | 506      |
| 0x04C  | GPTMTBR      | RO   | 0x0000.FFFF | GPTM Timer B                 | 507      |
| 0x050  | GPTMTAV      | RW   | 0xFFFF.FFFF | GPTM Timer A Value           | 508      |

Table 10-6. Timers Register Map (*continued*)

| Offset | Name    | Type | Reset       | Description        | See page |
|--------|---------|------|-------------|--------------------|----------|
| 0x054  | GPTMTBV | RW   | 0x0000.FFFF | GPTM Timer B Value | 509      |

## 10.6 Register Descriptions

The remainder of this section lists and describes the GPTM registers, in numerical order by address offset.

**Register 1: GPTM Configuration (GPTMCFG), offset 0x000**

This register configures the global operation of the GPTM module. The value written to this register determines whether the GPTM is in 32- or 16-bit mode.

**Important:** Bits in this register should only be changed when the TAEN and TBEN bits in the **GPTMCTL** register are cleared.

**GPTM Configuration (GPTMCFG)**

Timer 0 base: 0x4003.0000  
 Timer 1 base: 0x4003.1000  
 Timer 2 base: 0x4003.2000  
 Timer 3 base: 0x4003.3000  
 Offset 0x000  
 Type R/W, reset 0x0000.0000

|       | 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18      | 17  | 16  |

## Register 2: GPTM Timer A Mode (GPTMTAMR), offset 0x004

This register configures the GPTM based on the configuration selected in the **GPTMCFG** register. When in PWM mode, set the TAAMS bit, clear the TACMR bit, and configure the TAMR field to 0x1 or 0x2.

This register controls the modes for Timer A when it is used individually. When Timer A and Timer B are concatenated, this register controls the modes for both Timer A and Timer B, and the contents of **GPTMTBMR** are ignored.

**Important:** Bits in this register should only be changed when the TAEN bit in the **GPTMCTL** register is cleared.

### GPTM Timer A Mode (GPTMTAMR)

Timer 0 base: 0x4003.0000  
 Timer 1 base: 0x4003.1000  
 Timer 2 base: 0x4003.2000  
 Timer 3 base: 0x4003.3000  
 Offset 0x004  
 Type R/W, reset 0x0000.0000

### Register 3: GPTM Timer B Mode (GPTMTBMR), offset 0x008

This register configures the GPTM based on the configuration selected in the **GPTMCFG** register. When in PWM mode, set the TBAMS bit, clear the TBCMR bit, and configure the TBMR field to 0x1 or 0x2.

This register controls the modes for Timer B when it is used individually. When Timer A and Timer B are concatenated, this register is ignored and **GPTMTBMR** controls the modes for both Timer A and Timer B.

**Important:** Bits in this register should only be changed when the TBEN bit in the **GPTMCTL** register is cleared.

#### GPTM Timer B Mode (GPTMTBMR)

Timer 0 base: 0x4003.0000  
 Timer 1 base: 0x4003.1000  
 Timer 2 base: 0x4003.2000  
 Timer 3 base: 0x4003.3000  
 Offset 0x008  
 Type R/W, reset 0x0000.0000

## Register 4: GPTM Control (GPTMCTL), offset 0x00C

This register is used alongside the **GPTMCFG** and **GMTMTnMR** registers to fine-tune the timer configuration, and to enable other features such as timer stall and the output trigger. The output trigger can be used to initiate transfers on the ADC module.

**Important:** Bits in this register should only be changed when the TnEN bit for the respective timer is cleared.

### GPTM Control (GPTMCTL)

Timer 0 base: 0x4003.0000  
 Timer 1 base: 0x4003.1000  
 Timer 2 base: 0x4003.2000  
 Timer 3 base: 0x4003.3000  
 Offset 0x00C  
 Type R/W, reset 0x0000.0000

**Register 5: GPTM Interrupt Mask (GPTMIMR), offset 0x018**

This register allows software to enable/disable GPTM controller-level interrupts. Setting a bit enables the corresponding interrupt, while clearing a bit disables it.

**GPTM Interrupt Mask (GPTMIMR)**

## Register 6: GPTM Raw Interrupt Status (GPTMRIS), offset 0x01C

This register shows the state of the GPTM's internal interrupt signal. These bits are set whether or not the interrupt is masked in the **GPTMIMR** register. Each bit can be cleared by writing a 1 to its corresponding bit in **GPTMICR**.

### GPTM Raw Interrupt Status (GPTMRIS)

Timer 0 base: 0x4003.0000  
 Timer 1 base: 0x4003.1000  
 Timer 2 base: 0x4003.2000  
 Timer 3 base: 0x4003.3000  
 Offset 0x01C  
 Type RO, reset 0x0000.0000

## Register 7: GPTM Masked Interrupt Status (GPTMMIS), offset 0x020

This register show the state of the GPTM's controller-level interrupt. If an interrupt is unmasked in **GPTMIMR**, and there is an event that causes the interrupt to be asserted, the corresponding bit is set in this register. All bits are cleared by writing a 1 to the corresponding bit in **GPTMICR**.

### GPTM Masked Interrupt Status (GPTMMIS)

Timer 0 base: 0x4003.0000  
 Timer 1 base: 0x4003.1000  
 Timer 2 base: 0x4003.2000  
 Timer 3 base: 0x4003.3000  
 Offset 0x020  
 Type RO, reset 0x0000.0000

## Register 8: GPTM Interrupt Clear (GPTMICR), offset 0x024

This register is used to clear the status bits in the **GPTMRIS** and **GPTMMIS** registers. Writing a 1 to a bit clears the corresponding bit in the **GPTMRIS** and **GPTMMIS** registers.

### GPTM Interrupt Clear (GPTMICR)

Timer 0 base: 0x4003.0000  
 Timer 1 base: 0x4003.1000  
 Timer 2 base: 0x4003.2000  
 Timer 3 base: 0x4003.3000  
 Offset 0x024  
 Type W1C, reset 0x0000.0000

Register 9: GPTM Timer A Interval Load (GPTMTAILR), offset 0x028

When the timer is counting down, this register is used to load the starting count value into the timer. When the timer is counting up, this register sets the upper bound for the timeout event.

When a GPTM is configured to one of the 32-bit modes, **GPTMTAILR** appears as a 32-bit register (the upper 16-bits correspond to the contents of the **GPTM Timer B Interval Load (GPTMTBILR)** register). In a 16-bit mode, the upper 16 bits of this register read as 0s and have no effect on the state of **GPTMTBILR**.

GPTM Timer A Interval Load (GPTMTAILR)

Timer 0 base: 0x4003.0000  
Timer 1 base: 0x4003.1000  
Timer 2 base: 0x4003.2000  
Timer 3 base: 0x4003.3000  
Offset 0x028  
Type R/W, reset 0xFFFF.FFFF

| Bit/Field | Name  | Type | Reset       | Description                                                                                                                                     |

Register 10: GPTM Timer B Interval Load (GPTMTBILR), offset 0x02C

When the timer is counting down, this register is used to load the starting count value into the timer. When the timer is counting up, this register sets the upper bound for the timeout event.

When a GPTM is configured to one of the 32-bit modes, the contents of bits 15:0 in this register are loaded into the upper 16 bits of the **GPTMTAILR** register. Reads from this register return the current value of Timer B and writes are ignored. In a 16-bit mode, bits 15:0 are used for the load value. Bits 31:16 are reserved in both cases.

**Register 11: GPTM Timer A Match (GPTMTAMATCHR), offset 0x030**

This register is loaded with a match value. Interrupts can be generated when the timer value is equal to the value in this register in one-shot or periodic mode.

In Edge-Count mode, this register along with **GPTMTAILR**, determines how many edge events are counted. The total number of edge events counted is equal to the value in **GPTMTAILR** minus this value.

In PWM mode, this value along with **GPTMTAILR**, determines the duty cycle of the output PWM signal.

When a GPTM is configured to one of the 32-bit modes, **GPTMTAMATCHR** appears as a 32-bit register (the upper 16-bits correspond to the contents of the **GPTM Timer B Match (GPTMTBMATCHR)** register). In a 16-bit mode, the upper 16 bits of this register read as 0s and have no effect on the state of **GPTMTBMATCHR**.

**GPTM Timer A Match (GPTMTAMATCHR)**

Timer 0 base: 0x4003.0000

**Register 17: GPTM Timer A (GPTMTAR), offset 0x048**

This register shows the current value of the Timer A counter in all cases except for Input Edge Count and Time modes. In the Input Edge Count mode, this register contains the number of edges that have occurred. In the Input Edge Time mode, this register contains the time at which the last edge event took place. Also in Input Edge-Count mode, bits 23:16 contain the upper 8 bits of the count.

When a GPTM is configured to one of the 32-bit modes, **GPTMTAR** appears as a 32-bit register (the upper 16-bits correspond to the contents of the **GPTM Timer B (GPTMTBR)** register). In the 16-bit Input Edge Count, Input Edge Time, and PWM modes, bits 15:0 contain the value of the counter and bits 23:16 contain the value of the prescaler, which is the upper 8 bits of the count. Bits 31:24 always read as 0. To read the value of the prescaler in 16-bit One-Shot and Periodic modes, read bits [23:16] in the **GPTMTAV** register.

**GPTM Timer A (GPTMTAR)**

## 11 Watchdog Timers

A watchdog timer can generate an interrupt or a reset when a time-out value is reached. The watchdog timer is used to regain control when a system has failed due to a software error or due to the failure of an external device to respond in the expected way. The LM3S8C62 microcontroller has two Watchdog Timer Modules, one module is clocked by the system clock (Watchdog Timer 0) and the other is clocked by the PIOSC (Watchdog Timer 1). The two modules are identical except that WDT1 is in a different clock domain, and therefore requires synchronizers. As a result, WDT1 has a bit defined in the **Watchdog Timer Control (WDTCTL)** register to indicate when a write to a WDT1 register is complete. Software can use this bit to ensure that the previous access has completed before starting the next access.

The Stellaris<sup>®</sup> LM3S8C62 controller has two Watchdog Timer modules with the following features:

- 32-bit down counter with a programmable load register
- Separate watchdog clock with an enable
- Programmable interrupt generation logic with interrupt masking
- Lock register protection from runaway software
- Reset generation logic with an enable/disable
- User-enabled stalling when the microcontroller asserts the CPU Halt flag during debug

The Watchdog Timer can be configured to generate an interrupt to the controller on its first time-out, and to generate a reset signal on its second time-out. Once the Watchdog Timer has been configured, the lock register can be written to prevent the timer configuration from being inadvertently altered.

## 11.1 Block Diagram

Figure 11-1. WDT Module Block Diagram

## 11.2 Functional Description

The Watchdog Timer module generates the first time-out signal when the 32-bit counter reaches the zero state after being enabled; enabling the counter also enables the watchdog timer interrupt. After the first time-out event, the 32-bit counter is re-loaded with the value of the **Watchdog Timer Load (WDTLOAD)** register, and the timer resumes counting down from that value. Once the Watchdog Timer has been configured, the **Watchdog Timer Lock (WDTLOCK)** register is written, which prevents the timer configuration from being inadvertently altered by software.

If the timer counts down to its zero state again before the first time-out interrupt is cleared, and the reset signal has been enabled by setting the RESEN bit in the **WDTCTL** register, the Watchdog timer asserts its reset signal to the system. If the interrupt is cleared before the 32-bit counter reaches its second time-out, the 32-bit counter is loaded with the value in the **WDTLOAD** register, and counting resumes from that value.

If **WDTLOAD** is written with a new value while the Watchdog Timer counter is counting, then the counter is loaded with the new value and continues counting.

Writing to **WDTLOAD** does not clear an active interrupt. An interrupt must be specifically cleared by writing to the **Watchdog Interrupt Clear (WDTICR)** register.

The Watchdog module interrupt and reset generation can be enabled or disabled as required. When the interrupt is re-enabled, the 32-bit counter is preloaded with the load register value and not its last state.

### 11.2.1 Register Access Timing

Because the Watchdog Timer 1 module has an independent clocking domain, its registers must be written with a timing gap between accesses. Software must guarantee that this delay is inserted between back-to-back writes to WDT1 registers or between a write followed by a read to the registers. The timing for back-to-back reads from the WDT1 module has no restrictions. The WRC bit in the **Watchdog Control (WDTCTL)** register for WDT1 indicates that the required timing gap has elapsed. This bit is cleared on a write operation and set once the write completes, indicating to software that another write or read may be started safely. Software should poll **WDTCTL** for WRC=1 prior to accessing another register. Note that WDT0 does not have this restriction as it runs off the system clock.

## 11.3 Initialization and Configuration

To use the WDT, its peripheral clock must be enabled by setting the WDT bit in the **RCGC0** register, see page 249.

The Watchdog Timer is configured using the following sequence:

1. Load the **WDTLOAD** register with the desired timer load value.
2. If WDT1, wait for the WRC bit in the **WDTCTL** register to be set.
3. If the Watchdog is configured to trigger system resets, set the RESEN bit in the **WDTCTL** register.
4. If WDT1, wait for the WRC bit in the **WDTCTL** register to be set.
5. Set the INTEN bit in the **WDTCTL** register to enable the Watchdog and lock the control register.

If software requires that all of the watchdog registers are locked, the Watchdog Timer module can be fully locked by writing any value to the **WDTLOCK** register. To unlock the Watchdog Timer, write a value of 0x1ACC.E551.

## 11.4 Register Map

Table 11-1 on page 513 lists the Watchdog registers. The offset listed is a hexadecimal increment to the register's address, relative to the Watchdog Timer base address:

- WDT0: 0x4000.0000
- WDT1: 0x4000.1000

Note that the Watchdog Timer module clock must be enabled before the registers can be programmed (see page 249).

**Table 11-1. Watchdog Timers Register Map**

## 11.5 Register Descriptions

The remainder of this section lists and describes the WDT registers, in numerical order by address offset.

Register 1: Watchdog Load (WDTLOAD), offset 0x000

This register is the 32-bit interval value used by the 32-bit counter. When this register is written, the value is immediately loaded and the counter restarts counting down from the new value. If the **WDTLOAD** register is loaded with 0x0000.0000, an interrupt is immediately generated.

Watchdog Load (WDTLOAD)

WDT0 base: 0x4000.0000  
WDT1 base: 0x4000.1000  
Offset 0x000  
Type R/W, reset 0xFFFF.FFFF

| Bit/Field | Name    | Type | Reset       | Description         |
|-----------|---------|------|-------------|---------------------|
| 31:0      | WDTLOAD | R/W  | 0xFFFF.FFFF | Watchdog Load Value |

Register 2: Watchdog Value (WDTVALUE), offset 0x004

This register contains the current count value of the timer.

Watchdog Value (WDTVALUE)

WDT0 base: 0x4000.0000  
WDT1 base: 0x4000.1000  
Offset 0x004  
Type RO, reset 0xFFFF.FFFF

| Bit/Field | Name     | Type | Reset       | Description                                                 |
|-----------|----------|------|-------------|-------------------------------------------------------------|
| 31:0      | WDTVALUE | RO   | 0xFFFF.FFFF | Watchdog Value<br>Current value of the 32-bit down counter. |

### Register 3: Watchdog Control (WDTCTL), offset 0x008

This register is the watchdog control register. The watchdog timer can be configured to generate a reset signal (on second time-out) or an interrupt on time-out.

When the watchdog interrupt has been enabled by setting the INTEN bit, all subsequent writes to the INTEN bit are ignored. The only mechanism that can re-enable writes to this bit is a hardware reset.

**Important:** Because the Watchdog Timer 1 module has an independent clocking domain, its registers must be written with a timing gap between accesses. Software must guarantee that this delay is inserted between back-to-back writes to WDT1 registers or between a write followed by a read to the registers. The timing for back-to-back reads from the WDT1 module has no restrictions. The WRC bit in the **Watchdog Control (WDTCTL)** register for WDT1 indicates that the required timing gap has elapsed. This bit is cleared on a write operation and set once the write completes, indicating to software that another write or read may be started safely. Software should poll **WDTCTL** for WRC=1 prior to accessing another register. Note that WDT0 does not have this restriction as it runs off the system clock and therefore does not have a WRC bit.

#### Watchdog Control (WDTCTL)

WDT0 base: 0x4000.0000

WDT1 base: 0x4000.1000

Offset 0x008

Type R/W, reset 0x0000.0000 (WDT0) and 0x8000.0000 (WDT1)

|       |          |    |          |    |    |    |    |    |    |    |    |    |    |    |       |     |

Once enabled, all writes are ignored. |

Register 4: Watchdog Interrupt Clear (WDTICR), offset 0x00C

This register is the interrupt clear register. A write of any value to this register clears the Watchdog interrupt and reloads the 32-bit counter from the **WDTLOAD** register. Value for a read or reset is indeterminate.

Watchdog Interrupt Clear (WDTICR)

WDT0 base: 0x4000.0000  
WDT1 base: 0x4000.1000  
Offset 0x00C  
Type WO, reset -

| Bit/Field | Name      | Type | Reset | Description              |

Register 8: Watchdog Lock (WDTLOCK), offset 0xC00

Writing 0x1ACC.E551 to the **WDTLOCK** register enables write access to all other registers. Writing any other value to the **WDTLOCK** register re-enables the locked state for register writes to all the other registers. Reading the **WDTLOCK** register returns the lock status rather than the 32-bit value written. Therefore, when write accesses are disabled, reading the **WDTLOCK** register returns 0x0000.0001 (when locked; otherwise, the returned value is 0x0000.0000 (unlocked)).

Watchdog Lock (WDTLOCK)

WDT0 base: 0x4000.0000  
WDT1 base: 0x4000.1000  
Offset 0xC00  
Type R/W, reset 0x0000.0000

## 12 Analog-to-Digital Converter (ADC)

An analog-to-digital converter (ADC) is a peripheral that converts a continuous analog voltage to a discrete digital number. Two identical converter modules are included, which share 16 input channels.

The Stellaris® ADC module features 12-bit conversion resolution and supports 16 input channels, plus an internal temperature sensor. Each ADC module contains four programmable sequencers allowing the sampling of multiple analog input sources without controller intervention. Each sample sequencer provides flexible programming with fully configurable input source, trigger events, interrupt generation, and sequencer priority. A digital comparator function is included which allows the conversion value to be diverted to a digital comparator module. Each ADC module provides eight digital comparators. Each digital comparator evaluates the ADC conversion value against its two user-defined values to determine the operational range of the signal. The trigger source for ADC0 and ADC1 may be independent or the two ADC modules may operate from the same trigger source and operate on the same or different inputs. A phase shifter can delay the start of sampling by a specified phase angle. When using both ADC modules, it is possible to configure the converters to start the conversions coincidentally or within a relative phase from each other, see “Sample Phase Control” on page 541.

The Stellaris LM3S8C62 microcontroller provides two ADC modules with each having the following features:

- 16 shared analog input channels
- 12-bit precision ADC with an accurate 10-bit data compatibility mode
- Single-ended and differential-input configurations
- On-chip internal temperature sensor
- Maximum sample rate of one million samples/second
- Optional phase shift in sample time programmable from 22.5° to 337.5°
- Four programmable sample conversion sequencers from one to eight entries long, with corresponding conversion result FIFOs
- Flexible trigger control
  - Controller (software)
  - Timers
  - Analog Comparators
  - PWM
  - GPIO
- Hardware averaging of up to 64 samples
- Digital comparison unit providing eight digital comparators
- Converter uses an internal 3-V reference or an external reference

- Power and ground for the analog circuitry is separate from the digital power and ground
- Efficient transfers using Micro Direct Memory Access Controller ( $\mu$ DMA)
  - Dedicated channel for each sample sequencer
  - ADC module uses burst requests for DMA

## 12.1 Block Diagram

The Stellaris microcontroller contains two identical Analog-to-Digital Converter modules. These two modules, ADC0 and ADC1, share the same 16 analog input channels. Each ADC module operates independently and can therefore execute different sample sequences, sample any of the analog input channels at any time, and generate different interrupts and triggers. Figure 12-1 on page 536 shows how the two modules are connected to analog inputs and the system bus.

**Figure 12-1. Implementation of Two ADC Blocks**

Figure 12-2 on page 537 provides details on the internal configuration of the ADC controls and data registers.

Figure 12-2. ADC Module Block Diagram

## 12.2 Signal Description

The following table lists the external signals of the ADC module and describes the function of each. The ADC signals are analog functions for some GPIO signals. The column in the table below titled "Pin Mux/Pin Assignment" lists the GPIO pin placement for the ADC signals. The AINx and VREFA analog signals are not 5-V tolerant and go through an isolation circuit before reaching their circuitry. These signals are configured by clearing the corresponding DEN bit in the **GPIO Digital Enable (GPIODEN)** register and setting the corresponding AMSEL bit in the **GPIO Analog Mode Select (GPIOAMSEL)** register. For more information on configuring GPIOs, see "General-Purpose Input/Outputs (GPIOs)" on page 410.

Table 12-1. Signals for ADC (100LQFP)

| Pin Name | Pin Number | Pin Mux / Pin Assignment | Pin Type | Buffer Type <sup>a</sup> | Description                          |
|----------|------------|--------------------------|----------|--------------------------|--------------------------------------|

| AIN15    | G1         | PD0                      | I        | Analog                   | Analog-to-digital converter input 15.                                                                                                                                                                                                                                                                                      |
| VREFA    | A7         | PB6                      | I        | Analog                   | This input provides a reference voltage used to specify the input voltage at which the ADC converts to a maximum value. In other words, the voltage that is applied to VREFA is the voltage with which an AINn signal is converted to 4095. The VREFA input is limited to the range specified in Table 24-22 on page 1038. |

a. The TTL designation indicates the pin has TTL-compatible voltage levels.

## 12.3 Functional Description

The Stellaris ADC collects sample data by using a programmable sequence-based approach instead of the traditional single or double-sampling approaches found on many ADC modules. Each *sample sequence* is a fully programmed series of consecutive (back-to-back) samples, allowing the ADC to collect data from multiple input sources without having to be re-configured or serviced by the processor. The programming of each sample in the sample sequence includes parameters such as the input source and mode (differential versus single-ended input), interrupt generation on sample completion, and the indicator for the last sample in the sequence. In addition, the  $\mu$ DMA can be used to more efficiently move data from the sample sequencers without CPU intervention.

### 12.3.1 Sample Sequencers

The sampling control and data capture is handled by the sample sequencers. All of the sequencers are identical in implementation except for the number of samples that can be captured and the depth of the FIFO. Table 12-3 on page 539 shows the maximum number of samples that each sequencer can capture and its corresponding FIFO depth. Each sample that is captured is stored in the FIFO. In this implementation, each FIFO entry is a 32-bit word, with the lower 12 bits containing the conversion result.

**Table 12-3. Samples and FIFO Depth of Sequencers**

| Sequencer | Number of Samples | Depth of FIFO |
|-----------|-------------------|---------------|
| SS3       | 1                 | 1             |
| SS2       | 4                 | 4             |
| SS1       | 4                 | 4             |
| SS0       | 8                 | 8             |

For a given sample sequence, each sample is defined by bit fields in the **ADC Sample Sequence Input Multiplexer Select (ADCSSMUXn)** and **ADC Sample Sequence Control (ADCSSCTLn)** registers, where "n" corresponds to the sequence number. The **ADCSSMUXn** fields select the input pin, while the **ADCSSCTLn** fields contain the sample control bits corresponding to parameters such as temperature sensor selection, interrupt enable, end of sequence, and differential input mode. Sample sequencers are enabled by setting the respective **ASENn** bit in the **ADC Active Sample Sequencer (ADCACTSS)** register and should be configured before being enabled. Sampling is then initiated by setting the **SSn** bit in the **ADC Processor Sample Sequence Initiate (ADCPSSI)** register. In addition, sample sequences may be initiated on multiple ADC modules simultaneously using the **GSYNC** and **SYNCWAIT** bits in the **ADCPSSI** register during the configuration of each ADC module. For more information on using these bits, refer to page 578.

When configuring a sample sequence, multiple uses of the same input pin within the same sequence are allowed. In the **ADCSSCTLn** register, the **IEN** bits can be set for any combination of samples, allowing interrupts to be generated after every sample in the sequence if necessary. Also, the **END** bit can be set at any point within a sample sequence. For example, if Sequencer 0 is used, the **END** bit can be set in the nibble associated with the fifth sample, allowing Sequencer 0 to complete execution of the sample sequence after the fifth sample.

After a sample sequence completes execution, the result data can be retrieved from the **ADC Sample Sequence Result FIFO (ADCSSFIFOn)** registers. The FIFOs are simple circular buffers that read a single address to "pop" result data. For software debug purposes, the positions of the FIFO head and tail pointers are visible in the **ADC Sample Sequence FIFO Status (ADCSSFSTATn)** registers along with **FULL** and **EMPTY** status flags. If a write is attempted when the FIFO is full, the write does not occur and an overflow condition is indicated. Overflow and underflow conditions are monitored using the **ADCOSTAT** and **ADCUSTAT** registers.

### 12.3.2 Module Control

Outside of the sample sequencers, the remainder of the control logic is responsible for tasks such as:

- Interrupt generation
- DMA operation
- Sequence prioritization
- Trigger configuration
- Comparator configuration
- External voltage reference
- Sample phase control

Most of the ADC control logic runs at the ADC clock rate of 14-18 MHz. The internal ADC divider is configured for 16-MHz operation automatically by hardware when the system XTAL is selected.

#### 12.3.2.1 Interrupts

The register configurations of the sample sequencers and digital comparators dictate which events generate raw interrupts, but do not have control over whether the interrupt is actually sent to the interrupt controller. The ADC module's interrupt signals are controlled by the state of the MASK bits in the **ADC Interrupt Mask (ADCIM)** register. Interrupt status can be viewed at two locations: the **ADC Raw Interrupt Status (ADCRIIS)** register, which shows the raw status of the various interrupt signals; and the **ADC Interrupt Status and Clear (ADCISC)** register, which shows active interrupts that are enabled by the **ADCIM** register. Sequencer interrupts are cleared by writing a 1 to the corresponding IN bit in **ADCISC**. Digital comparator interrupts are cleared by writing a 1 to the **ADC Digital Comparator Interrupt Status and Clear (ADCDCISC)** register.

#### 12.3.2.2 DMA Operation

DMA may be used to increase efficiency by allowing each sample sequencer to operate independently and transfer data without processor intervention or reconfiguration. The ADC module provides a request signal from each sample sequencer to the associated dedicated channel of the  $\mu$ DMA controller. The ADC does not support single transfer requests. A burst transfer request is asserted when the interrupt bit for the sample sequence is set (IE bit in the **ADCSSCTLn** register is set).

The arbitration size of the  $\mu$ DMA transfer must be a power of 2, and the associated IE bits in the **ADCSSCTLn** register must be set. For example, if the  $\mu$ DMA channel of SS0 has an arbitration size of four, the IE3 bit (4th sample) and the IE7 bit (8th sample) must be set. Thus the  $\mu$ DMA request occurs every time 4 samples have been acquired. No other special steps are needed to enable the ADC module for  $\mu$ DMA operation.

Refer to the "Micro Direct Memory Access ( $\mu$ DMA)" on page 350 for more details about programming the  $\mu$ DMA controller.

#### 12.3.2.3 Prioritization

When sampling events (triggers) happen concurrently, they are prioritized for processing by the values in the **ADC Sample Sequencer Priority (ADCSSPRI)** register. Valid priority values are in the range of 0-3, with 0 being the highest priority and 3 being the lowest. Multiple active sample

sequencer units with the same priority do not provide consistent results, so software must ensure that all active sample sequencer units have a unique priority value.

#### 12.3.2.4 Sampling Events

Sample triggering for each sample sequencer is defined in the **ADC Event Multiplexer Select (ADCEMUX)** register. Trigger sources include processor (default), analog comparators, an external signal on GPIO PB4, a GP Timer, a PWM generator, and continuous sampling. The processor triggers sampling by setting the SSx bits in the **ADC Processor Sample Sequence Initiate (ADCPSSI)** register.

Care must be taken when using the continuous sampling trigger. If a sequencer's priority is too high, it is possible to starve other lower priority sequencers. Generally, a sample sequencer using continuous sampling should be set to the lowest priority. Continuous sampling can be used with a digital comparator to cause an interrupt when a particular voltage is seen on an input.

#### 12.3.2.5 Sample Phase Control

The trigger source for ADC0 and ADC1 may be independent or the two ADC modules may operate from the same trigger source and operate on the same or different inputs. If the converters are running at the same sample rate, they may be configured to start the conversions coincidentally or with one of 15 different discrete phases relative to each other. The sample time can be delayed from the standard sampling time in 22.5° increments up to 337.5° using the **ADC Sample Phase Control (ADCSPC)** register. Figure 12-3 on page 541 shows an example of various phase relationships at a 1 Msps rate.

**Figure 12-3. ADC Sample Phases**

This feature can be used to double the sampling rate of an input. Both ADC module 0 and ADC module 1 can be programmed to sample the same input. ADC module 0 could sample at the standard position (the PHASE field in the **ADCSPC** register is 0x0). ADC module 1 can be configured to sample at 180 (PHASE = 0x8). The two modules can be synchronized using the GSYNC and SYNCWAIT bits in the **ADC Processor Sample Sequence Initiate (ADCPSSI)** register. Software could then combine the results from the two modules to create a sample rate of two million samples/second at 16 MHz as shown in Figure 12-4 on page 542.

**Figure 12-4. Doubling the ADC Sample Rate**

Using the **ADCSPC** register, ADC0 and ADC1 may provide a number of interesting applications:

- Coincident sampling of different signals. The sample sequence steps run coincidentally in both converters.
  - ADC Module 0, **ADCSPC** = 0x0, sampling AIN0
  - ADC Module 1, **ADCSPC** = 0x0, sampling AIN1
- Skewed sampling of the same signal. The sample sequence steps are 1/2 of an ADC clock (500  $\mu$ s for a 1Ms/s ADC) out of phase with each other. This configuration doubles the conversion bandwidth of a single input when software combines the results as shown in Figure 12-5 on page 542.
  - ADC Module 0, **ADCSPC** = 0x0, sampling AIN0
  - ADC Module 1, **ADCSPC** = 0x8, sampling AIN0

**Figure 12-5. Skewed Sampling**

### 12.3.3 Hardware Sample Averaging Circuit

Higher precision results can be generated using the hardware averaging circuit, however, the improved results are at the cost of throughput. Up to 64 samples can be accumulated and averaged to form a single data entry in the sequencer FIFO. Throughput is decreased proportionally to the

number of samples in the averaging calculation. For example, if the averaging circuit is configured to average 16 samples, the throughput is decreased by a factor of 16.

By default the averaging circuit is off, and all data from the converter passes through to the sequencer FIFO. The averaging hardware is controlled by the **ADC Sample Averaging Control (ADCSAC)** register (see page 580). A single averaging circuit has been implemented, thus all input channels receive the same amount of averaging whether they are single-ended or differential.

Figure 12-6 on page 543 shows an example in which the **ADCSAC** register is set to 0x2 for 4x hardware oversampling and the IE1 bit is set for the sample sequence, resulting in an interrupt after the second averaged value is stored in the FIFO.

**Figure 12-6. Sample Averaging Example**

### 12.3.4 Analog-to-Digital Converter

The Analog-to-Digital Converter (ADC) module uses a Successive Approximation Register (SAR) architecture to deliver a 12-bit, low-power, high-precision conversion value. The ADC defaults to a 10-bit conversion result, providing backwards compatibility with previous generations of Stellaris microcontrollers. To enable 12-bit resolution, set the RES bit in the **ADC Control (ADCCTL)** register. The successive-approximation algorithm uses a current mode D/A converter to achieve lower settling time, resulting in higher conversion speeds for the A/D converter. In addition, built-in sample-and-hold circuitry with offset-calibration circuitry improves conversion accuracy. The ADC must be run from the PLL or a 14- to 18-MHz clock source.

The ADC operates from both the 3.3-V analog and 1.2-V digital power supplies. The ADC clock can be configured to reduce power consumption when ADC conversions are not required (see “System Control” on page 192). The analog inputs are connected to the ADC through custom pads and specially balanced input paths to minimize the distortion on the inputs. Detailed information on the ADC power supplies and analog inputs can be found in “Analog-to-Digital Converter (ADC)” on page 1037.

### 12.3.4.1 Internal Voltage Reference

The band-gap circuitry generates an internal 3.0 V reference that can be used by the ADC to produce a conversion value from the selected analog input. The range of this conversion value is from 0x000 to 0xFFF in 12-bit mode, or 0x3FF in 10-bit mode. In single-ended-input mode, the 0x000 value corresponds to an analog input voltage of 0.0 V; the 0xFFF in 12-bit mode, or 0x3FF in 10-bit mode value corresponds to an analog input voltage of 3.0 V. This configuration results in a resolution of approximately 0.7 mV in 12-bit mode and 2.9 mV per ADC code in 10-bit mode. While the analog input pads can handle voltages beyond this range, the ADC conversions saturate in under-voltage and over-voltage cases. Figure 12-7 on page 544 shows the ADC conversion function of the analog inputs.

Figure 12-7. Internal Voltage Conversion Result

### 12.3.4.2 External Voltage Reference

The ADC can use an external voltage reference to produce the conversion value from the selected analog input by configuring the VREF field in the **ADC Control (ADCCTL)** register. The VREF field specifies whether to use the internal, an external reference in the 3.0 V range, or an external reference in the 1.0 V range. While the range of the conversion value remains the same (0x000 to 0xFFF or 0x3FF), the analog voltage associated with the 0xFFF or 0x3FF value corresponds to the value of the voltage when using the 3.0-V setting and three times the voltage when using the 1.0-V setting, resulting in a smaller voltage resolution per ADC code. Ground is always used as the reference level for the minimum conversion value. Analog input voltages above the external voltage reference saturate to 0xFFF or 0x3FF while those below 0.0 V continue to saturate at 0x000. The  $V_{REFA}$  specification defines the useful range for the external voltage reference, see Table 24-22 on page 1038. Care must be taken to supply a reference voltage of acceptable quality.

Figure 12-8 on page 545 shows the ADC conversion function of the analog inputs when using the 3.0-V setting on the external voltage reference. Figure 12-9 on page 546 shows the ADC conversion function when using the 1.0-V setting on the external voltage reference.

The external voltage reference can be more accurate than the internal reference by using a high-precision source or trimming the source.

**Figure 12-8. External Voltage Conversion Result with 3.0-V Setting**

Figure 12-9. External Voltage Conversion Result with 1.0-V Setting

### 12.3.5 Differential Sampling

In addition to traditional single-ended sampling, the ADC module supports differential sampling of two analog input channels. To enable differential sampling, software must set the Dn bit in the **ADCSSCTL0n** register in a step's configuration nibble.

When a sequence step is configured for differential sampling, the input pair to sample must be configured in the **ADCSSMUXn** register. Differential pair 0 samples analog inputs 0 and 1; differential pair 1 samples analog inputs 2 and 3; and so on (see Table 12-4 on page 546). The ADC does not support other differential pairings such as analog input 0 with analog input 3.

Table 12-4. Differential Sampling Pairs

| Differential Pair | Analog Inputs |
|-------------------|---------------|
| 0                 | 0 and 1       |
| 1                 | 2 and 3       |
| 2                 | 4 and 5       |
| 3                 | 6 and 7       |
| 4                 | 8 and 9       |
| 5                 | 10 and 11     |
| 6                 | 12 and 13     |
| 7                 | 14 and 15     |

The voltage sampled in differential mode is the difference between the odd and even channels:

$\Delta V$  (differential voltage) =  $V_{IN\_EVEN}$  (even channel) –  $V_{IN\_ODD}$  (odd channel), therefore:

- If  $\Delta V = 0$ , then the conversion result = 0x1FF for 10-bit and 0x7FF for 12-bit

- If  $\Delta V > 0$ , then the conversion result  $> 0x1FF$  (range is  $0x1FF-0x3FF$ ) for 10-bit and  $> 0x7FF$  (range is  $0x7FF - 0xFFF$ ) for 12-bit
- If  $\Delta V < 0$ , then the conversion result  $< 0x1FF$  (range is  $0-0x1FF$ ) for 10-bit and  $< 0x7FF$  (range is  $0 - 0x7FF$ ) for 12-bit

The differential pairs assign polarities to the analog inputs: the even-numbered input is always positive, and the odd-numbered input is always negative. In order for a valid conversion result to appear, the negative input must be in the range of  $\pm 1.5$  V of the positive input. If an analog input is greater than 3 V or less than 0 V (the valid range for analog inputs), the input voltage is clipped, meaning it appears as either 3 V or 0 V, respectively, to the ADC.

Figure 12-10 on page 547 shows an example of the negative input centered at 1.5 V. In this configuration, the differential range spans from -1.5 V to 1.5 V. Figure 12-11 on page 548 shows an example where the negative input is centered at 0.75 V, meaning inputs on the positive input saturate past a differential voltage of -0.75 V because the input voltage is less than 0 V. Figure 12-12 on page 548 shows an example of the negative input centered at 2.25 V, where inputs on the positive channel saturate past a differential voltage of 0.75 V since the input voltage would be greater than 3 V.

**Figure 12-10. Differential Sampling Range,  $V_{IN\_ODD} = 1.5$  V**

Figure 12-11. Differential Sampling Range,  $V_{IN\_ODD} = 0.75\text{ V}$ Figure 12-12. Differential Sampling Range,  $V_{IN\_ODD} = 2.25\text{ V}$ 

### 12.3.6 Internal Temperature Sensor

The temperature sensor serves two primary purposes: 1) to notify the system that internal temperature is too high or low for reliable operation and 2) to provide temperature measurements for calibration of the Hibernate module RTC trim value.

The temperature sensor does not have a separate enable, because it also contains the bandgap reference and must always be enabled. The reference is supplied to other analog modules; not just the ADC. In addition, the temperature sensor has a second power-down input in the 3.3 V domain which provides control by the Hibernate module.

The internal temperature sensor provides an analog temperature reading as well as a reference voltage. This reference voltage, *SENS0*, is given by the following equation:

$$SENS0 = 2.7 - ((T + 55) / 75)$$

This relation is shown in Figure 12-13 on page 549.

**Figure 12-13. Internal Temperature Sensor Characteristic**

The temperature sensor reading can be sampled in a sample sequence by setting the TS<sub>n</sub> bit in the **ADCSSCTL<sub>n</sub>** register. The temperature reading from the temperature sensor can also be given as a function of the ADC value. The following formula calculates temperature (in °C) based on the ADC reading:

$$\text{Temperature} = 147.5 - ((225 \times \text{ADC}) / 4095)$$

### 12.3.7 Digital Comparator Unit

An ADC is commonly used to sample an external signal and to monitor its value to ensure that it remains in a given range. To automate this monitoring procedure and reduce the amount of processor

overhead that is required, each module provides eight digital comparators. Conversions from the ADC that are sent to the digital comparators are compared against the user programmable limits in the **ADC Digital Comparator Range (ADCDCMPn)** registers. If the observed signal moves out of the acceptable range, a processor interrupt can be generated and/or a trigger can be sent to the PWM module. The digital comparators four operational modes (Once, Always, Hysteresis Once, Hysteresis Always) can be applied to three separate regions (low band, mid band, high band) as defined by the user.

#### 12.3.7.1 Output Functions

ADC conversions can either be stored in the ADC Sample Sequence FIFOs or compared using the digital comparator resources as defined by the SnDCOP bits in the **ADC Sample Sequence n Operation (ADCSSOPn)** register. These selected ADC conversions are used by their respective digital comparator to monitor the external signal. Each comparator has two possible output functions: processor interrupts and triggers.

Each function has its own state machine to track the monitored signal. Even though the interrupt and trigger functions can be enabled individually or both at the same time, the same conversion data is used by each function to determine if the right conditions have been met to assert the associated output.

##### *Interrupts*

The digital comparator interrupt function is enabled by setting the CIE bit in the **ADC Digital Comparator Control (ADCDCCTLn)** register. This bit enables the interrupt function state machine to start monitoring the incoming ADC conversions. When the appropriate set of conditions is met, and the DCONSSx bit is set in the **ADCIM** register, an interrupt is sent to the interrupt controller.

##### *Triggers*

The digital comparator trigger function is enabled by setting the CTE bit in the **ADCDCCTLn** register. This bit enables the trigger function state machine to start monitoring the incoming ADC conversions. When the appropriate set of conditions is met, the corresponding digital comparator trigger to the PWM module is asserted.

#### 12.3.7.2 Operational Modes

Four operational modes are provided to support a broad range of applications and multiple possible signaling requirements: Always, Once, Hysteresis Always, and Hysteresis Once. The operational mode is selected using the CIM or CTM field in the **ADCDCCTLn** register.

##### *Always Mode*

In the Always operational mode, the associated interrupt or trigger is asserted whenever the ADC conversion value meets its comparison criteria. The result is a string of assertions on the interrupt or trigger while the conversions are within the appropriate range.

##### *Once Mode*

In the Once operational mode, the associated interrupt or trigger is asserted whenever the ADC conversion value meets its comparison criteria, and the previous ADC conversion value did not. The result is a single assertion of the interrupt or trigger when the conversions are within the appropriate range.

**Hysteresis-Always Mode**

The Hysteresis-Always operational mode can only be used in conjunction with the low-band or high-band regions because the mid-band region must be crossed and the opposite region entered to clear the hysteresis condition. In the Hysteresis-Always mode, the associated interrupt or trigger is asserted in the following cases: 1) the ADC conversion value meets its comparison criteria or 2) a previous ADC conversion value has met the comparison criteria, and the hysteresis condition has not been cleared by entering the opposite region. The result is a string of assertions on the interrupt or trigger that continue until the opposite region is entered.

**Hysteresis-Once Mode**

The Hysteresis-Once operational mode can only be used in conjunction with the low-band or high-band regions because the mid-band region must be crossed and the opposite region entered to clear the hysteresis condition. In the Hysteresis-Once mode, the associated interrupt or trigger is asserted only when the ADC conversion value meets its comparison criteria, the hysteresis condition is clear, and the previous ADC conversion did not meet the comparison criteria. The result is a single assertion on the interrupt or trigger.

**12.3.7.3 Function Ranges**

The two comparison values, COMP0 and COMP1, in the **ADC Digital Comparator Range (ADCDCMPn)** register effectively break the conversion area into three distinct regions. These regions are referred to as the low-band (less than or equal to COMP0), mid-band (greater than COMP0 but less than or equal to COMP1), and high-band (greater than COMP1) regions. COMP0 and COMP1 may be programmed to the same value, effectively creating two regions, but COMP1 must always be greater than or equal to the value of COMP0. A COMP1 value that is less than COMP0 generates unpredictable results.

**Low-Band Operation**

To operate in the low-band region, either the CIC field or the CTC field in the **ADCDCCTLn** register must be programmed to 0x0. This setting causes interrupts or triggers to be generated in the low-band region as defined by the programmed operational mode. An example of the state of the interrupt/trigger signal in the low-band region for each of the operational modes is shown in Figure 12-14 on page 552. Note that a "0" in a column following the operational mode name (Always, Once, Hysteresis Always, and Hysteresis Once) indicates that the interrupt or trigger signal is de-asserted and a "1" indicates that the signal is asserted.

Figure 12-14. Low-Band Operation (CIC=0x0 and/or CTC=0x0)

### Mid-Band Operation

To operate in the mid-band region, either the CIC field or the CTC field in the **ADDCCTLn** register must be programmed to 0x1. This setting causes interrupts or triggers to be generated in the mid-band region according the operation mode. Only the Always and Once operational modes are available in the mid-band region. An example of the state of the interrupt/trigger signal in the mid-band region for each of the allowed operational modes is shown in Figure 12-15 on page 553. Note that a "0" in a column following the operational mode name (Always or Once) indicates that the interrupt or trigger signal is de-asserted and a "1" indicates that the signal is asserted.

Figure 12-15. Mid-Band Operation (CIC=0x1 and/or CTC=0x1)

**High-Band Operation**

To operate in the high-band region, either the CIC field or the CTC field in the **ADCDCCTLn** register must be programmed to 0x3. This setting causes interrupts or triggers to be generated in the high-band region according the operation mode. An example of the state of the interrupt/trigger signal in the high-band region for each of the allowed operational modes is shown in Figure 12-16 on page 554. Note that a "0" in a column following the operational mode name (Always, Once, Hysteresis Always, and Hysteresis Once) indicates that the interrupt or trigger signal is de-asserted and a "1" indicates that the signal is asserted.

Figure 12-16. High-Band Operation (CIC=0x3 and/or CTC=0x3)

## 12.4 Initialization and Configuration

In order for the ADC module to be used, the PLL must be enabled and programmed to a supported crystal frequency in the **RCC** register (see page 208). Using unsupported frequencies can cause faulty operation in the ADC module.

### 12.4.1 Module Initialization

Initialization of the ADC module is a simple process with very few steps: enabling the clock to the ADC, disabling the analog isolation circuit associated with all inputs that are to be used, and reconfiguring the sample sequencer priorities (if needed).

The initialization sequence for the ADC is as follows:

1. Enable the ADC clock by using the **RCGC0** register (see page 249).
2. Enable the clock to the appropriate GPIO modules via the **RCGC2** register (see page 266). To find out which GPIO ports to enable, refer to “Signal Description” on page 537.
3. Set the GPIO AFSEL bits for the ADC input pins (see page 433). To determine which GPIOs to configure, see Table 22-4 on page 987.
4. Configure the AINx and VREFA signals to be analog inputs by clearing the corresponding DEN bit in the **GPIO Digital Enable (GPIODEN)** register (see page 444).
5. Disable the analog isolation circuit for all ADC input pins that are to be used by writing a 1 to the appropriate bits of the **GPIOAMSEL** register (see page 449) in the associated GPIO block.

6. If required by the application, reconfigure the sample sequencer priorities in the **ADCSSPRI** register. The default configuration has Sample Sequencer 0 with the highest priority and Sample Sequencer 3 as the lowest priority.

## 12.4.2 Sample Sequencer Configuration

Configuration of the sample sequencers is slightly more complex than the module initialization because each sample sequencer is completely programmable.

The configuration for each sample sequencer should be as follows:

1. Ensure that the sample sequencer is disabled by clearing the corresponding **ASENn** bit in the **ADCACTSS** register. Programming of the sample sequencers is allowed without having them enabled. Disabling the sequencer during programming prevents erroneous execution if a trigger event were to occur during the configuration process.
2. Configure the trigger event for the sample sequencer in the **ADCEMUX** register.
3. For each sample in the sample sequence, configure the corresponding input source in the **ADCSSMUXn** register.
4. For each sample in the sample sequence, configure the sample control bits in the corresponding nibble in the **ADCSSCTLn** register. When programming the last nibble, ensure that the **END** bit is set. Failure to set the **END** bit causes unpredictable behavior.
5. If interrupts are to be used, set the corresponding **MASK** bit in the **ADCIM** register.
6. Enable the sample sequencer logic by setting the corresponding **ASENn** bit in the **ADCACTSS** register.

## 12.5 Register Map

Table 12-5 on page 555 lists the ADC registers. The offset listed is a hexadecimal increment to the register's address, relative to that ADC module's base address of:

- ADC0: 0x4003.8000
- ADC1: 0x4003.9000

Note that the ADC module clock must be enabled before the registers can be programmed (see page 249). There must be a delay of 3 system clocks after the ADC module clock is enabled before any ADC module registers are accessed.

**Table 12-5. ADC Register Map**

| Offset | Name     | Type  | Reset       | Description                    | See page |
|--------|----------|-------|-------------|--------------------------------|----------|

## 12.6 Register Descriptions

The remainder of this section lists and describes the ADC registers, in numerical order by address offset.

**Register 1: ADC Active Sample Sequencer (ADCACTSS), offset 0x000**

This register controls the activation of the sample sequencers. Each sample sequencer can be enabled or disabled independently.

**ADC Active Sample Sequencer (ADCACTSS)**

ADC0 base: 0x4003.8000

ADC1 base: 0x4003.9000

Offset 0x000

Type R/W, reset 0x0000.0000

|       |          |    |    |    |    |    |    |    |    |    |    |    |       |       |       |       |

## Register 2: ADC Raw Interrupt Status (ADCRIS), offset 0x004

This register shows the status of the raw interrupt signal of each sample sequencer. These bits may be polled by software to look for interrupt conditions without sending the interrupts to the interrupt controller.

### ADC Raw Interrupt Status (ADCRIS)

ADC0 base: 0x4003.8000  
 ADC1 base: 0x4003.9000

### Register 3: ADC Interrupt Mask (ADCIM), offset 0x008

This register controls whether the sample sequencer and digital comparator raw interrupt signals are sent to the interrupt controller. Each raw interrupt signal can be masked independently. Only a single DCONSSn bit should be set at any given time. Setting more than one of these bits results in the INRDC bit from the **ADCRIS** register being masked, and no interrupt is generated on any of the sample sequencer interrupt lines.

#### ADC Interrupt Mask (ADCIM)

## Register 4: ADC Interrupt Status and Clear (ADCISC), offset 0x00C

This register provides the mechanism for clearing sample sequencer interrupt conditions and shows the status of interrupts generated by the sample sequencers and the digital comparators which have been sent to the interrupt controller. When read, each bit field is the logical AND of the respective INR and MASK bits. Sample sequencer interrupts are cleared by writing a 1 to the corresponding bit position. Digital comparator interrupts are cleared by writing a 1 to the appropriate bits in the **ADCDCISC** register. If software is polling the **ADCRIS** instead of generating interrupts, the sample sequence INRn bits are still cleared via the **ADCISC** register, even if the INn bit is not set.

### ADC Interrupt Status and Clear (ADCISC)

**Register 5: ADC Overflow Status (ADCOSTAT), offset 0x010**

This register indicates overflow conditions in the sample sequencer FIFOs. Once the overflow condition has been handled by software, the condition can be cleared by writing a 1 to the corresponding bit position.

**ADC Overflow Status (ADCOSTAT)**

**Register 7: ADC Underflow Status (ADCUSTAT), offset 0x018**

This register indicates underflow conditions in the sample sequencer FIFOs. The corresponding underflow condition is cleared by writing a 1 to the relevant bit position.

**ADC Underflow Status (ADCUSTAT)**

ADC0 base: 0x4003.8000

ADC1 base: 0x4003.9000

Offset 0x018

Type R/W1C, reset 0x0000.0000

**Register 8: ADC Sample Sequencer Priority (ADCSSPRI), offset 0x020**

This register sets the priority for each of the sample sequencers. Out of reset, Sequencer 0 has the highest priority, and Sequencer 3 has the lowest priority. When reconfiguring sequence priorities, each sequence must have a unique priority for the ADC to operate properly.

**ADC Sample Sequencer Priority (ADCSSPRI)**

**Register 9: ADC Sample Phase Control (ADCSPC), offset 0x024**

This register allows the ADC module to sample at one of 16 different discrete phases from 0.0° through 337.5°. For example, the sample rate could be effectively doubled by sampling a signal using one ADC module configured with the standard sample time and the second ADC module configured with a 180.0° phase lag.

**Note:** Care should be taken when the PHASE field is non-zero, as the resulting delay in sampling the AINx input may result in undesirable system consequences. The time from ADC trigger to sample is increased and could make the response time longer than anticipated. The added latency could have ramifications in the system design. Designers should carefully consider the impact of this delay.

**Register 10: ADC Processor Sample Sequence Initiate (ADCPSSI), offset 0x028**

This register provides a mechanism for application software to initiate sampling in the sample sequencers. Sample sequences can be initiated individually or in any combination. When multiple sequences are triggered simultaneously, the priority encodings in **ADCSSPRI** dictate execution order.

This register also provides a means to configure and then initiate concurrent sampling on all ADC modules. To do this, the first ADC module should be configured. The **ADCPSSI** register for that module should then be written. The appropriate SS bits should be set along with the SYNCWAIT bit. Additional ADC modules should then be configured following the same procedure. Once the final ADC module is configured, its **ADCPSSI** register should be written with the appropriate SS bits set along with the GSYNC bit. All of the ADC modules then begin concurrent sampling according to their configuration.

**ADC Processor Sample Sequence Initiate (ADCPSSI)**

ADC0 base: 0x4003.8000

ADC1 base: 0x4003.9000

Offset 0x028

Type R/W, reset -

**Register 11: ADC Sample Averaging Control (ADCSAC), offset 0x030**

This register controls the amount of hardware averaging applied to conversion results. The final conversion result stored in the FIFO is averaged from  $2^{AVG}$  consecutive ADC samples at the specified ADC speed. If AVG is 0, the sample is passed directly through without any averaging. If AVG=6, then 64 consecutive ADC samples are averaged to generate one result in the sequencer FIFO. An AVG=7 provides unpredictable results.

**ADC Sample Averaging Control (ADCSAC)**

ADC0 base: 0x4003.8000  
 ADC1 base: 0x4003.9000  
 Offset 0x030  
 Type R/W, reset 0x0000.0000

## Register 12: ADC Digital Comparator Interrupt Status and Clear (ADCDCISC), offset 0x034

This register provides status and acknowledgement of digital comparator interrupts. One bit is provided for each comparator.

### ADC Digital Comparator Interrupt Status and Clear (ADCDCISC)

ADC0 base: 0x4003.8000

ADC1 base: 0x4003.9000

Offset 0x034

Type R/W1C, reset 0x0000.0000

## Register 13: ADC Control (ADCCTL), offset 0x038

This register configures various ADC module attributes, including the ADC resolution and the voltage reference. The resolution of the ADC defaults to 10-bit for backwards compatibility with other members of the Stellaris family, but can be configured to 12-bit resolution. The voltage reference for the conversion can be the internal 3.0-V reference, an external voltage reference in the range of 2.4 V to 3.06 V, or an external voltage reference in the range of 0.8 V to 1.02 V.

### ADC Control (ADCCTL)

ADC0 base: 0x4003.8000

ADC1 base: 0x4003.9000

Offset 0x038

Type R/W, reset 0x0000.0000

## Register 14: ADC Sample Sequence Input Multiplexer Select 0 (ADCSSMUX0), offset 0x040

This register defines the analog input configuration for each sample in a sequence executed with Sample Sequencer 0. This register is 32 bits wide and contains information for eight possible samples.

### ADC Sample Sequence Input Multiplexer Select 0 (ADCSSMUX0)

| 3:0       | MUX0 | R/W  | 0x0   | 1st Sample Input Select<br>The MUX0 field is used during the first sample of a sequence executed with the sample sequencer. It specifies which of the analog inputs is sampled for the analog-to-digital conversion.  |

**Register 15: ADC Sample Sequence Control 0 (ADCSSCTL0), offset 0x044**

This register contains the configuration information for each sample for a sequence executed with a sample sequencer. When configuring a sample sequence, the END bit must be set for the final sample, whether it be after the first sample, eighth sample, or any sample in between. This register is 32 bits wide and contains information for eight possible samples.

|           |      |      |       | Value Description                                                                                                                                                                                                                                           |
|           |      |      |       | 1 The eighth sample is the last sample of the sequence.                                                                                                                                                                                                     |
|           |      |      |       | 0 Another sample in the sequence is the final sample.                                                                                                                                                                                                       |
|           |      |      |       | It is possible to end the sequence on any sample position. Software must set an ENDn bit somewhere within the sequence. Samples defined after the sample containing a set ENDn bit are not requested for conversion even though the fields may be non-zero. |

**Register 16: ADC Sample Sequence Result FIFO 0 (ADCSSFIFO0), offset 0x048**

**Register 17: ADC Sample Sequence Result FIFO 1 (ADCSSFIFO1), offset 0x068**

**Register 18: ADC Sample Sequence Result FIFO 2 (ADCSSFIFO2), offset 0x088**

**Register 19: ADC Sample Sequence Result FIFO 3 (ADCSSFIFO3), offset 0x0A8**

**Important:** This register is read-sensitive. See the register description for details.

This register contains the conversion results for samples collected with the sample sequencer (the **ADCSSFIFO0** register is used for Sample Sequencer 0, **ADCSSFIFO1** for Sequencer 1, **ADCSSFIFO2** for Sequencer 2, and **ADCSSFIFO3** for Sequencer 3). Reads of this register return conversion result data in the order sample 0, sample 1, and so on, until the FIFO is empty. If the FIFO is not properly handled by software, overflow and underflow conditions are registered in the **ADCSTAT** and **ADCUSTAT** registers.

#### ADC Sample Sequence Result FIFO n (ADCSSFIFO<sub>n</sub>)

ADC0 base: 0x4003.8000

ADC1 base: 0x4003.9000

Offset 0x048

Type RO, reset -

**Register 20: ADC Sample Sequence FIFO 0 Status (ADCSSFSTAT0), offset 0x04C**

**Register 21: ADC Sample Sequence FIFO 1 Status (ADCSSFSTAT1), offset 0x06C**

**Register 22: ADC Sample Sequence FIFO 2 Status (ADCSSFSTAT2), offset 0x08C**

**Register 23: ADC Sample Sequence FIFO 3 Status (ADCSSFSTAT3), offset 0x0AC**

This register provides a window into the sample sequencer, providing full/empty status information as well as the positions of the head and tail pointers. The reset value of 0x100 indicates an empty FIFO with the head and tail pointers both pointing to index 0. The **ADCSSFSTAT0** register provides status on FIFO0, which has 8 entries; **ADCSSFSTAT1** on FIFO1, which has 4 entries; **ADCSSFSTAT2** on FIFO2, which has 4 entries; and **ADCSSFSTAT3** on FIFO3 which has a single entry.

#### ADC Sample Sequence FIFO 0 Status (ADCSSFSTAT0)

ADC0 base: 0x4003.8000  
 ADC1 base: 0x4003.9000  
 Offset 0x04C  
 Type RO, reset 0x0000.0100

**Register 24: ADC Sample Sequence 0 Operation (ADCSSOP0), offset 0x050**

This register determines whether the sample from the given conversion on Sample Sequence 0 is saved in the Sample Sequence FIFO0 or sent to the digital comparator unit.

**ADC Sample Sequence 0 Operation (ADCSSOP0)**

## Register 25: ADC Sample Sequence 0 Digital Comparator Select (ADCSSDC0), offset 0x054

This register determines which digital comparator receives the sample from the given conversion on Sample Sequence 0, if the corresponding SnDCOP bit in the **ADCSSOP0** register is set.

### ADC Sample Sequence 0 Digital Comparator Select (ADCSSDC0)

ADC0 base: 0x4003.8000

ADC1 base: 0x4003.9000

Offset 0x054

Type R/W, reset 0x0000.0000

**Register 26: ADC Sample Sequence Input Multiplexer Select 1 (ADCSSMUX1), offset 0x060****Register 27: ADC Sample Sequence Input Multiplexer Select 2 (ADCSSMUX2), offset 0x080**

This register defines the analog input configuration for each sample in a sequence executed with Sample Sequencer 1 or 2. These registers are 16 bits wide and contain information for four possible samples. See the **ADCSSMUX0** register on page 584 for detailed bit descriptions. The **ADCSSMUX1** register affects Sample Sequencer 1 and the **ADCSSMUX2** register affects Sample Sequencer 2.

**Register 28: ADC Sample Sequence Control 1 (ADCSSCTL1), offset 0x064****Register 29: ADC Sample Sequence Control 2 (ADCSSCTL2), offset 0x084**

These registers contain the configuration information for each sample for a sequence executed with Sample Sequencer 1 or 2. When configuring a sample sequence, the END bit must be set for the final sample, whether it be after the first sample, fourth sample, or any sample in between. These registers are 16-bits wide and contain information for four possible samples. See the **ADCSSCTL0** register on page 586 for detailed bit descriptions. The **ADCSSCTL1** register configures Sample Sequencer 1 and the **ADCSSCTL2** register configures Sample Sequencer 2.

**ADC Sample Sequence Control 1 (ADCSSCTL1)**

**Register 30: ADC Sample Sequence 1 Operation (ADCSSOP1), offset 0x070****Register 31: ADC Sample Sequence 2 Operation (ADCSSOP2), offset 0x090**

This register determines whether the sample from the given conversion on Sample Sequence n is saved in the Sample Sequence n FIFO or sent to the digital comparator unit. The **ADCSSOP1** register controls Sample Sequencer 1 and the **ADCSSOP2** register controls Sample Sequencer 2.

**ADC Sample Sequence 1 Operation (ADCSSOP1)**

**Register 32: ADC Sample Sequence 1 Digital Comparator Select (ADCSSDC1), offset 0x074****Register 33: ADC Sample Sequence 2 Digital Comparator Select (ADCSSDC2), offset 0x094**

These registers determine which digital comparator receives the sample from the given conversion on Sample Sequence n if the corresponding SnDCOP bit in the **ADCSSOPn** register is set. The **ADCSSDC1** register controls the selection for Sample Sequencer 1 and the **ADCSSDC2** register controls the selection for Sample Sequencer 2.

**ADC Sample Sequence 1 Digital Comparator Select (ADCSSDC1)**

Register 34: ADC Sample Sequence Input Multiplexer Select 3 (ADCSSMUX3), offset 0x0A0

This register defines the analog input configuration for the sample executed with Sample Sequencer 3. This register is 4 bits wide and contains information for one possible sample. See the **ADCSSMUX0** register on page 584 for detailed bit descriptions.

ADC Sample Sequence Input Multiplexer Select 3 (ADCSSMUX3)

ADC0 base: 0x4003.8000  
ADC1 base: 0x4003.9000  
Offset 0x0A0  
Type R/W, reset 0x0000.0000

**Register 35: ADC Sample Sequence Control 3 (ADCSSCTL3), offset 0x0A4**

This register contains the configuration information for a sample executed with Sample Sequencer 3. The END0 bit is always set as this sequencer can execute only one sample. This register is 4 bits wide and contains information for one possible sample. See the **ADCSSCTL0** register on page 586 for detailed bit descriptions.

| 1 | The sample is sent to the digital comparator unit specified by the S0DCSEL bit in the <b>ADCSSDC03</b> register, and the value is not written to the FIFO. |
| 0 | The sample is saved in Sample Sequence FIFO3.                                                                                                              |

## Register 37: ADC Sample Sequence 3 Digital Comparator Select (ADCSSDC3), offset 0x0B4

This register determines which digital comparator receives the sample from the given conversion on Sample Sequence 3 if the corresponding SnDCOP bit in the **ADCSSOP3** register is set.

### ADC Sample Sequence 3 Digital Comparator Select (ADCSSDC3)

ADC0 base: 0x4003.8000  
 ADC1 base: 0x4003.9000  
 Offset 0x0B4  
 Type R/W, reset 0x0000.0000

## Register 38: ADC Digital Comparator Reset Initial Conditions (ADCDCRIC), offset 0xD00

This register provides the ability to reset any of the digital comparator interrupt or trigger functions back to their initial conditions. Resetting these functions ensures that the data that is being used by the interrupt and trigger functions in the digital comparator unit is not stale.

### ADC Digital Comparator Reset Initial Conditions (ADCDCRIC)

ADC0 base: 0x4003.8000

ADC1 base: 0x4003.9000

Offset 0xD00

Type R/W, reset 0x0000.0000

**Register 39: ADC Digital Comparator Control 0 (ADCDCTL0), offset 0xE00**

**Register 40: ADC Digital Comparator Control 1 (ADCDCTL1), offset 0xE04**

**Register 41: ADC Digital Comparator Control 2 (ADCDCTL2), offset 0xE08**

**Register 42: ADC Digital Comparator Control 3 (ADCDCTL3), offset 0xE0C**

**Register 43: ADC Digital Comparator Control 4 (ADCDCTL4), offset 0xE10**

**Register 44: ADC Digital Comparator Control 5 (ADCDCTL5), offset 0xE14**

**Register 45: ADC Digital Comparator Control 6 (ADCDCTL6), offset 0xE18**

**Register 46: ADC Digital Comparator Control 7 (ADCDCTL7), offset 0xE1C**

This register provides the comparison encodings that generate an interrupt and/or PWM trigger. See "Interrupt/ADC-Trigger Selector" on page 882 for more information on using the ADC digital comparators to trigger a PWM generator.

#### ADC Digital Comparator Control 0 (ADCDCTL0)

ADC0 base: 0x4003.8000

ADC1 base: 0x4003.9000

Offset 0xE00

Type R/W, reset 0x0000.0000

|---|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1 | Enables the trigger function state machine. The ADC conversion data is used to determine if a trigger should be generated according to the programming of the CTC and CTM fields. |
| 0 | Disables the trigger function state machine. ADC conversion data is ignored by the trigger function.                                                                              |

| 1:0       | CIM  | R/W  | 0x0   | <p>Comparison Interrupt Mode</p> <p>This field specifies the mode by which the interrupt comparison is made.</p> <p>Value Description</p> <p>0x0 Always<br/>This mode generates an interrupt every time the ADC conversion data falls within the selected operational region.</p> <p>0x1 Once<br/>This mode generates an interrupt the first time that the ADC conversion data enters the selected operational region.</p> <p>0x2 Hysteresis Always<br/>This mode generates an interrupt when the ADC conversion data falls within the selected operational region and continues to generate the interrupt until the hysteresis condition is cleared by entering the opposite operational region.<br/>Note that the hysteresis modes are only defined for CTC encodings of 0x0 and 0x3.</p> <p>0x3 Hysteresis Once<br/>This mode generates an interrupt the first time that the ADC conversion data falls within the selected operational region. No additional interrupts are generated until the hysteresis condition is cleared by entering the opposite operational region.<br/>Note that the hysteresis modes are only defined for CTC encodings of 0x0 and 0x3.</p> |

**Register 47: ADC Digital Comparator Range 0 (ADCDDCMP0), offset 0xE40**

**Register 48: ADC Digital Comparator Range 1 (ADCDDCMP1), offset 0xE44**

**Register 49: ADC Digital Comparator Range 2 (ADCDDCMP2), offset 0xE48**

**Register 50: ADC Digital Comparator Range 3 (ADCDDCMP3), offset 0xE4C**

**Register 51: ADC Digital Comparator Range 4 (ADCDDCMP4), offset 0xE50**

**Register 52: ADC Digital Comparator Range 5 (ADCDDCMP5), offset 0xE54**

**Register 53: ADC Digital Comparator Range 6 (ADCDDCMP6), offset 0xE58**

**Register 54: ADC Digital Comparator Range 7 (ADCDDCMP7), offset 0xE5C**

This register defines the comparison values that are used to determine if the ADC conversion data falls in the appropriate operating region.

**Note:** The value in the COMP1 field must be greater than or equal to the value in the COMP0 field or unexpected results can occur.

If the RES bit in the **ADCCTL** register is clear, selecting 10-bit resolution, use only bits [25:16] in the COMP1 field and bits [9:0] in the COMP0 field; otherwise unexpected results can occur.

#### ADC Digital Comparator Range 0 (ADCDDCMP0)

ADC0 base: 0x4003.8000

ADC1 base: 0x4003.9000

Offset 0xE40

Type R/W, reset 0x0000.0000

## 13 Universal Asynchronous Receivers/Transmitters (UARTs)

The Stellaris<sup>®</sup> LM3S8C62 controller includes two Universal Asynchronous Receiver/Transmitter (UART) with the following features:

- Programmable baud-rate generator allowing speeds up to 5 Mbps for regular speed (divide by 16) and 10 Mbps for high speed (divide by 8)
- Separate 16x8 transmit (TX) and receive (RX) FIFOs to reduce CPU interrupt service loading
- Programmable FIFO length, including 1-byte deep operation providing conventional double-buffered interface
- FIFO trigger levels of 1/8, 1/4, 1/2, 3/4, and 7/8
- Standard asynchronous communication bits for start, stop, and parity
- Line-break generation and detection
- Fully programmable serial interface characteristics
  - 5, 6, 7, or 8 data bits
  - Even, odd, stick, or no-parity bit generation/detection
  - 1 or 2 stop bit generation
- IrDA serial-IR (SIR) encoder/decoder providing
  - Programmable use of IrDA Serial Infrared (SIR) or UART input/output
  - Support of IrDA SIR encoder/decoder functions for data rates up to 115.2 Kbps half-duplex
  - Support of normal 3/16 and low-power (1.41-2.23  $\mu$ s) bit durations
  - Programmable internal clock generator enabling division of reference clock by 1 to 256 for low-power mode bit duration
- Support for communication with ISO 7816 smart cards
- Full modem handshake support (on UART1)
- LIN protocol support
- Standard FIFO-level and End-of-Transmission interrupts
- Efficient transfers using Micro Direct Memory Access Controller ( $\mu$ DMA)
  - Separate channels for transmit and receive
  - Receive single request asserted when data is in the FIFO; burst request asserted at programmed FIFO level

- Transmit single request asserted when there is space in the FIFO; burst request asserted at programmed FIFO level

## 13.1 Block Diagram

Figure 13-1. UART Module Block Diagram

## 13.2 Signal Description

The following table lists the external signals of the UART module and describes the function of each. The UART signals are alternate functions for some GPIO signals and default to be GPIO signals at reset, with the exception of the U0Rx and U0Tx pins which default to the UART function. The column in the table below titled "Pin Mux/Pin Assignment" lists the possible GPIO pin placements for these UART signals. The AFSEL bit in the **GPIO Alternate Function Select (GPIOAFSEL)** register (page 433) should be set to choose the UART function. The number in parentheses is the encoding that must be programmed into the PMCN field in the **GPIO Port Control (GPIOPCTL)** register (page 450) to assign the UART signal to the specified GPIO port pin. For more information on configuring GPIOs, see "General-Purpose Input/Outputs (GPIOs)" on page 410.

Table 13-1. Signals for UART (100LQFP)

| Pin Name | Pin Number                       | Pin Mux / Pin Assignment                                       | Pin Type | Buffer Type <sup>a</sup> | Description                                                                 |
|----------|----------------------------------|----------------------------------------------------------------|----------|--------------------------|-----------------------------------------------------------------------------|
| U0RX     | 26                               | PA0 (1)                                                        | I        | TTL                      | UART module 0 receive. When in IrDA mode, this signal has IrDA modulation.  |
| U0Tx     | 27                               | PA1 (1)                                                        | O        | TTL                      | UART module 0 transmit. When in IrDA mode, this signal has IrDA modulation. |
| U1DSR    | 47                               | PF0 (9)                                                        | I        | TTL                      | UART module 1 Data Set Ready modem output control line.                     |
| U1Rx     | 10<br>12<br>23<br>26<br>66<br>92 | PD0 (5)<br>PD2 (1)<br>PC6 (5)<br>PA0 (9)<br>PB0 (5)<br>PB4 (7) | I        | TTL                      | UART module 1 receive. When in IrDA mode, this signal has IrDA modulation.  |
| U1Tx     | 11<br>13<br>22<br>27<br>67<br>91 | PD1 (5)<br>PD3 (1)<br>PC7 (5)<br>PA1 (9)<br>PB1 (5)<br>PB5 (7) | O        | TTL                      | UART module 1 transmit. When in IrDA mode, this signal has IrDA modulation. |

a. The TTL designation indicates the pin has TTL-compatible voltage levels.

Table 13-2. Signals for UART (108BGA)

| Pin Name | Pin Number                        | Pin Mux / Pin Assignment                                       | Pin Type | Buffer Type <sup>a</sup> | Description                                                                 |
|----------|-----------------------------------|----------------------------------------------------------------|----------|--------------------------|-----------------------------------------------------------------------------|
| U0RX     | L3                                | PA0 (1)                                                        | I        | TTL                      | UART module 0 receive. When in IrDA mode, this signal has IrDA modulation.  |
| U0Tx     | M3                                | PA1 (1)                                                        | O        | TTL                      | UART module 0 transmit. When in IrDA mode, this signal has IrDA modulation. |
| U1DSR    | M9                                | PF0 (9)                                                        | I        | TTL                      | UART module 1 Data Set Ready modem output control line.                     |
| U1Rx     | G1<br>H2<br>M2<br>L3<br>E12<br>A6 | PD0 (5)<br>PD2 (1)<br>PC6 (5)<br>PA0 (9)<br>PB0 (5)<br>PB4 (7) | I        | TTL                      | UART module 1 receive. When in IrDA mode, this signal has IrDA modulation.  |
| U1Tx     | G2<br>H1<br>L2<br>M3<br>D12<br>B7 | PD1 (5)<br>PD3 (1)<br>PC7 (5)<br>PA1 (9)<br>PB1 (5)<br>PB5 (7) | O        | TTL                      | UART module 1 transmit. When in IrDA mode, this signal has IrDA modulation. |

a. The TTL designation indicates the pin has TTL-compatible voltage levels.

### 13.3 Functional Description

Each Stellaris UART performs the functions of parallel-to-serial and serial-to-parallel conversions. It is similar in functionality to a 16C550 UART, but is not register compatible.

The UART is configured for transmit and/or receive via the TXE and RXE bits of the **UART Control (UARTCTL)** register (see page 642). Transmit and receive are both enabled out of reset. Before any control registers are programmed, the UART must be disabled by clearing the UARTEN bit in

**UARTCTL.** If the UART is disabled during a TX or RX operation, the current transaction is completed prior to the UART stopping.

The UART module also includes a serial IR (SIR) encoder/decoder block that can be connected to an infrared transceiver to implement an IrDA SIR physical layer. The SIR function is programmed using the **UARTCTL** register.

### 13.3.1 Transmit/Receive Logic

The transmit logic performs parallel-to-serial conversion on the data read from the transmit FIFO. The control logic outputs the serial bit stream beginning with a start bit and followed by the data bits (LSB first), parity bit, and the stop bits according to the programmed configuration in the control registers. See Figure 13-2 on page 619 for details.

The receive logic performs serial-to-parallel conversion on the received bit stream after a valid start pulse has been detected. Overrun, parity, frame error checking, and line-break detection are also performed, and their status accompanies the data that is written to the receive FIFO.

**Figure 13-2. UART Character Frame**

### 13.3.2 Baud-Rate Generation

The baud-rate divisor is a 22-bit number consisting of a 16-bit integer and a 6-bit fractional part. The number formed by these two values is used by the baud-rate generator to determine the bit period. Having a fractional baud-rate divider allows the UART to generate all the standard baud rates.

The 16-bit integer is loaded through the **UART Integer Baud-Rate Divisor (UARTIBRD)** register (see page 638) and the 6-bit fractional part is loaded with the **UART Fractional Baud-Rate Divisor (UARTFBRD)** register (see page 639). The baud-rate divisor (BRD) has the following relationship to the system clock (where *BRDI* is the integer part of the BRD and *BRDF* is the fractional part, separated by a decimal place.)

$$BRD = BRDI + BRDF = \text{UARTSysClk} / (\text{ClkDiv} * \text{Baud Rate})$$

where *UARTSysClk* is the system clock connected to the UART, and *ClkDiv* is either 16 (if HSE in **UARTCTL** is clear) or 8 (if HSE is set).

The 6-bit fractional number (that is to be loaded into the DIVFRAC bit field in the **UARTFBRD** register) can be calculated by taking the fractional part of the baud-rate divisor, multiplying it by 64, and adding 0.5 to account for rounding errors:

$$\text{UARTFBRD}[\text{DIVFRAC}] = \text{integer}(\text{BRDF} * 64 + 0.5)$$

The UART generates an internal baud-rate reference clock at 8x or 16x the baud-rate (referred to as Baud8 and Baud16, depending on the setting of the HSE bit (bit 5) in **UARTCTL**). This reference clock is divided by 8 or 16 to generate the transmit clock, and is used for error detection during receive operations. Note that the state of the HSE bit has no effect on clock generation in ISO 7816 smart card mode (when the SMART bit in the **UARTCTL** register is set).

Along with the **UART Line Control, High Byte (UARTLCRH)** register (see page 640), the **UARTIBRD** and **UARTFBRD** registers form an internal 30-bit register. This internal register is only updated

when a write operation to **UARTLCRH** is performed, so any changes to the baud-rate divisor must be followed by a write to the **UARTLCRH** register for the changes to take effect.

To update the baud-rate registers, there are four possible sequences:

- **UARTIBRD** write, **UARTFBRD** write, and **UARTLCRH** write
- **UARTFBRD** write, **UARTIBRD** write, and **UARTLCRH** write
- **UARTIBRD** write and **UARTLCRH** write
- **UARTFBRD** write and **UARTLCRH** write

### 13.3.3 Data Transmission

Data received or transmitted is stored in two 16-byte FIFOs, though the receive FIFO has an extra four bits per character for status information. For transmission, data is written into the transmit FIFO. If the UART is enabled, it causes a data frame to start transmitting with the parameters indicated in the **UARTLCRH** register. Data continues to be transmitted until there is no data left in the transmit FIFO. The **BUSY** bit in the **UART Flag (UARTFR)** register (see page 634) is asserted as soon as data is written to the transmit FIFO (that is, if the FIFO is non-empty) and remains asserted while data is being transmitted. The **BUSY** bit is negated only when the transmit FIFO is empty, and the last character has been transmitted from the shift register, including the stop bits. The UART can indicate that it is busy even though the UART may no longer be enabled.

When the receiver is idle (the **UnRx** signal is continuously 1), and the data input goes Low (a start bit has been received), the receive counter begins running and data is sampled on the eighth cycle of **Baud16** or fourth cycle of **Baud8** depending on the setting of the **HSE** bit (bit 5) in **UARTCTL** (described in “Transmit/Receive Logic” on page 619).

The start bit is valid and recognized if the **UnRx** signal is still low on the eighth cycle of **Baud16** (**HSE** clear) or the fourth cycle of **Baud 8** (**HSE** set), otherwise it is ignored. After a valid start bit is detected, successive data bits are sampled on every 16th cycle of **Baud16** or 8th cycle of **Baud8** (that is, one bit period later) according to the programmed length of the data characters and value of the **HSE** bit in **UARTCTL**. The parity bit is then checked if parity mode is enabled. Data length and parity are defined in the **UARTLCRH** register.

Lastly, a valid stop bit is confirmed if the **UnRx** signal is High, otherwise a framing error has occurred. When a full word is received, the data is stored in the receive FIFO along with any error bits associated with that word.

### 13.3.4 Serial IR (SIR)

The UART peripheral includes an IrDA serial-IR (SIR) encoder/decoder block. The IrDA SIR block provides functionality that converts between an asynchronous UART data stream and a half-duplex serial SIR interface. No analog processing is performed on-chip. The role of the SIR block is to provide a digital encoded output and decoded input to the UART. When enabled, the SIR block uses the **UnTx** and **UnRx** pins for the SIR protocol. These signals should be connected to an infrared transceiver to implement an IrDA SIR physical layer link. The SIR block can receive and transmit, but it is only half-duplex so it cannot do both at the same time. Transmission must be stopped before data can be received. The IrDA SIR physical layer specifies a minimum 10-ms delay between transmission and reception. The SIR block has two modes of operation:

- In normal IrDA mode, a zero logic level is transmitted as a high pulse of 3/16th duration of the selected baud rate bit period on the output pin, while logic one levels are transmitted as a static LOW signal. These levels control the driver of an infrared transmitter, sending a pulse of light

for each zero. On the reception side, the incoming light pulses energize the photo transistor base of the receiver, pulling its output LOW and driving the UART input pin LOW.

- In low-power IrDA mode, the width of the transmitted infrared pulse is set to three times the period of the internally generated IrLPBaud16 signal (1.63  $\mu$ s, assuming a nominal 1.8432 MHz frequency) by changing the appropriate bit in the **UARTCR** register. See page 637 for more information on IrDA low-power pulse-duration configuration.

Figure 13-3 on page 621 shows the UART transmit and receive signals, with and without IrDA modulation.

**Figure 13-3. IrDA Data Modulation**

In both normal and low-power IrDA modes:

- During transmission, the UART data bit is used as the base for encoding
- During reception, the decoded bits are transferred to the UART receive logic

The IrDA SIR physical layer specifies a half-duplex communication link, with a minimum 10-ms delay between transmission and reception. This delay must be generated by software because it is not automatically supported by the UART. The delay is required because the infrared receiver electronics might become biased or even saturated from the optical power coupled from the adjacent transmitter LED. This delay is known as latency or receiver setup time.

### 13.3.5 ISO 7816 Support

The UART offers basic support to allow communication with an ISO 7816 smartcard. When bit 3 (SMART) of the **UARTCTL** register is set, the UnTx signal is used as a bit clock, and the UnRx signal is used as the half-duplex communication line connected to the smartcard. A GPIO signal can be used to generate the reset signal to the smartcard. The remaining smartcard signals should be provided by the system design. The maximum clock rate in this mode is system clock / 16.

When using ISO 7816 mode, the **UARTLCRH** register must be set to transmit 8-bit words (WLEN bits 6:5 configured to 0x3) with EVEN parity (PEN set and EPS set). In this mode, the UART automatically uses 2 stop bits, and the STP2 bit of the **UARTLCRH** register is ignored.

If a parity error is detected during transmission, UnRx is pulled Low during the second stop bit. In this case, the UART aborts the transmission, flushes the transmit FIFO and discards any data it contains, and raises a parity error interrupt, allowing software to detect the problem and initiate

retransmission of the affected data. Note that the UART does not support automatic retransmission in this case.

### 13.3.6 Modem Handshake Support

This section describes how to configure and use the modem flow control and status signals for UART1 when connected as a DTE (data terminal equipment) or as a DCE (data communications equipment). In general, a modem is a DCE and a computing device that connects to a modem is the DTE.

#### 13.3.6.1 Signaling

The status signals provided by UART1 differ based on whether the UART is used as a DTE or DCE. When used as a DTE, the modem flow control and status signals are defined as:

- U1CTS is Clear To Send
- U1DSR is Data Set Ready
- U1DCD is Data Carrier Detect
- U1RI is Ring Indicator
- U1RTS is Request To Send
- U1DTR is Data Terminal Ready

When used as a DCE, the the modem flow control and status signals are defined as:

- U1CTS is Request To Send
- U1DSR is Data Terminal Ready
- U1RTS is Clear To Send
- U1DTR is Data Set Ready

Note that the support for DCE functions Data Carrier Detect and Ring Indicator are not provided. If these signals are required, their function can be emulated by using a general-purpose I/O signal and providing software support.

#### 13.3.6.2 Flow Control

Flow control can be accomplished by either hardware or software. The following sections describe the different methods.

##### ***Hardware Flow Control (RTS/CTS)***

Hardware flow control between two devices is accomplished by connecting the U1RTS output to the Clear-To-Send input on the receiving device, and connecting the Request-To-Send output on the receiving device to the U1CTS input.

The U1CTS input controls the transmitter. The transmitter may only transmit data when the U1CTS input is asserted. The U1RTS output signal indicates the state of the receive FIFO. U1CTS remains asserted until the preprogrammed watermark level is reached, indicating that the Receive FIFO has no space to store additional characters.

The **UARTCTL** register bits 15 (CTSEN) and 14 (RTSEN) specify the flow control mode as shown in Table 13-3 on page 623.

**Table 13-3. Flow Control Mode**

| CTSEN | RTSEN | Description                            |
|-------|-------|----------------------------------------|
| 1     | 1     | RTS and CTS flow control enabled       |
| 1     | 0     | Only CTS flow control enabled          |
| 0     | 1     | Only RTS flow control enabled          |
| 0     | 0     | Both RTS and CTS flow control disabled |

Note that when RTSEN is 1, software cannot modify the U1RTS output value through the **UARTCTL** register Request to Send (RTS) bit, and the status of the RTS bit should be ignored.

#### **Software Flow Control (Modem Status Interrupts)**

Software flow control between two devices is accomplished by using interrupts to indicate the status of the UART. Interrupts may be generated for the U1DSR, U1DCD, U1CTS, and U1RI signals using bits 3:0 of the **UARTIM** register, respectively. The raw and masked interrupt status may be checked using the **UARTRIS** and **UARTMIS** register. These interrupts may be cleared using the **UARTICR** register.

### **13.3.7 LIN Support**

The UART module offers hardware support for the LIN protocol as either a master or a slave. The LIN mode is enabled by setting the LIN bit in the **UARTCTL** register. A LIN message is identified by the use of a Sync Break at the beginning of the message. The Sync Break is a transmission of a series of 0s. The Sync Break is followed by the Sync data field (0x55). Figure 13-4 on page 623 illustrates the structure of a LIN message.

**Figure 13-4. LIN Message**

The UART should be configured as followed to operate in LIN mode:

1. Configure the UART for 1 start bit, 8 data bits, no parity, and 1 stop bit. Enable the Transmit FIFO.
2. Set the LIN bit in the **UARTCTL** register.

When preparing to send a LIN message, the TXFIFO should contain the Sync data (0x55) at FIFO location 0 and the Identifier data at location 1, followed by the data to be transmitted, and with the checksum in the final FIFO entry.

### 13.3.7.1 LIN Master

The UART is enabled to be the LIN master by setting the MASTER bit in the **UARTLCTL** register. The length of the Sync Break is programmable using the BLEN field in the **UARTLCTL** register and can be 13-16 bits (baud clock cycles).

### 13.3.7.2 LIN Slave

The LIN UART slave is required to adjust its baud rate to that of the LIN master. In slave mode, the LIN UART recognizes the Sync Break, which must be at least 13 bits in duration. A timer is provided to capture timing data on the 1st and 5th falling edges of the Sync field so that the baud rate can be adjusted to match the master.

After detecting a Sync Break, the UART waits for the synchronization field. The first falling edge generates an interrupt using the LME1RIS bit in the **UARTRIS** register, and the timer value is captured and stored in the **UARTLSS** register (T1). On the fifth falling edge, a second interrupt is generated using the LME5RIS bit in the **UARTRIS** register, and the timer value is captured again (T2). The actual baud rate can be calculated using  $(T2-T1)/8$ , and the local baud rate should be adjusted as needed. Figure 13-5 on page 624 illustrates the synchronization field.

**Figure 13-5. LIN Synchronization Field**

## 13.3.8 FIFO Operation

The UART has two 16-entry FIFOs; one for transmit and one for receive. Both FIFOs are accessed via the **UART Data (UARTDR)** register (see page 629). Read operations of the **UARTDR** register return a 12-bit value consisting of 8 data bits and 4 error flags while write operations place 8-bit data in the transmit FIFO.

Out of reset, both FIFOs are disabled and act as 1-byte-deep holding registers. The FIFOs are enabled by setting the FEN bit in **UARTLCRH** (page 640).

FIFO status can be monitored via the **UART Flag (UARTFR)** register (see page 634) and the **UART Receive Status (UARTRSR)** register. Hardware monitors empty, full and overrun conditions. The **UARTFR** register contains empty and full flags (TXFE, TXFF, RXFE, and RXFF bits), and the **UARTRSR** register shows overrun status via the OE bit.

The trigger points at which the FIFOs generate interrupts is controlled via the **UART Interrupt FIFO Level Select (UARTIFLS)** register (see page 646). Both FIFOs can be individually configured to trigger interrupts at different levels. Available configurations include  $\frac{1}{8}$ ,  $\frac{1}{4}$ ,  $\frac{1}{2}$ ,  $\frac{3}{4}$ , and  $\frac{7}{8}$ . For example, if the  $\frac{1}{4}$  option is selected for the receive FIFO, the UART generates a receive interrupt after 4 data bytes are received. Out of reset, both FIFOs are configured to trigger an interrupt at the  $\frac{1}{2}$  mark.

### 13.3.9 Interrupts

The UART can generate interrupts when the following conditions are observed:

- Overrun Error
- Break Error
- Parity Error
- Framing Error
- Receive Timeout
- Transmit (when condition defined in the TXIFLSEL bit in the **UARTIFLS** register is met, or if the EOT bit in **UARTCTL** is set, when the last bit of all transmitted data leaves the serializer)
- Receive (when condition defined in the RXIFLSEL bit in the **UARTIFLS** register is met)

All of the interrupt events are ORed together before being sent to the interrupt controller, so the UART can only generate a single interrupt request to the controller at any given time. Software can service multiple interrupt events in a single interrupt service routine by reading the **UART Masked Interrupt Status (UARTMIS)** register (see page 655).

The interrupt events that can trigger a controller-level interrupt are defined in the **UART Interrupt Mask (UARTIM)** register (see page 648) by setting the corresponding IM bits. If interrupts are not used, the raw interrupt status is always visible via the **UART Raw Interrupt Status (UARTRIS)** register (see page 652).

Interrupts are always cleared (for both the **UARTMIS** and **UARTRIS** registers) by writing a 1 to the corresponding bit in the **UART Interrupt Clear (UARTICR)** register (see page 658).

The receive timeout interrupt is asserted when the receive FIFO is not empty, and no further data is received over a 32-bit period. The receive timeout interrupt is cleared either when the FIFO becomes empty through reading all the data (or by reading the holding register), or when a 1 is written to the corresponding bit in the **UARTICR** register.

### 13.3.10 Loopback Operation

The UART can be placed into an internal loopback mode for diagnostic or debug work by setting the LBE bit in the **UARTCTL** register (see page 642). In loopback mode, data transmitted on the UnTx output is received on the UnRx input. Note that the LBE bit should be set before the UART is enabled.

### 13.3.11 DMA Operation

The UART provides an interface to the  $\mu$ DMA controller with separate channels for transmit and receive. The DMA operation of the UART is enabled through the **UART DMA Control (UARTDMACTL)** register. When DMA operation is enabled, the UART asserts a DMA request on the receive or transmit channel when the associated FIFO can transfer data. For the receive channel, a single transfer request is asserted whenever any data is in the receive FIFO. A burst transfer request is asserted whenever the amount of data in the receive FIFO is at or above the FIFO trigger level configured in the **UARTIFLS** register. For the transmit channel, a single transfer request is asserted whenever there is at least one empty location in the transmit FIFO. The burst request is asserted whenever the transmit FIFO contains fewer characters than the FIFO trigger level. The

single and burst DMA transfer requests are handled automatically by the  $\mu$ DMA controller depending on how the DMA channel is configured.

To enable DMA operation for the receive channel, set the RXDMAE bit of the **DMA Control (UARTDMACTL)** register. To enable DMA operation for the transmit channel, set the TXDMAE bit of the **UARTDMACTL** register. The UART can also be configured to stop using DMA for the receive channel if a receive error occurs. If the DMAERR bit of the **UARTDMACR** register is set and a receive error occurs, the DMA receive requests are automatically disabled. This error condition can be cleared by clearing the appropriate UART error interrupt.

If DMA is enabled, then the  $\mu$ DMA controller triggers an interrupt when a transfer is complete. The interrupt occurs on the UART interrupt vector. Therefore, if interrupts are used for UART operation and DMA is enabled, the UART interrupt handler must be designed to handle the  $\mu$ DMA completion interrupt.

See “Micro Direct Memory Access ( $\mu$ DMA)” on page 350 for more details about programming the  $\mu$ DMA controller.

## 13.4 Initialization and Configuration

To enable and initialize the UART, the following steps are necessary:

1. The peripheral clock must be enabled by setting the UART0 or UART1 bits in the RCGC1 register (see page 257).
2. The clock to the appropriate GPIO module must be enabled via the **RCGC2** register in the System Control module (see page 266).
3. Set the GPIO AFSEL bits for the appropriate pins (see page 433). To determine which GPIOs to configure, see Table 22-4 on page 987.
4. Configure the GPIO current level and/or slew rate as specified for the mode selected (see page 435 and page 443).
5. Configure the PMCN fields in the **GPIOCTL** register to assign the UART signals to the appropriate pins (see page 450 and Table 22-5 on page 994).

To use the UART, the peripheral clock must be enabled by setting the appropriate bit in the **RCGC1** register (page 257). In addition, the clock to the appropriate GPIO module must be enabled via the **RCGC2** register (page 266) in the System Control module. To find out which GPIO port to enable, refer to Table 22-5 on page 994.

This section discusses the steps that are required to use a UART module. For this example, the UART clock is assumed to be 20 MHz, and the desired UART configuration is:

- 115200 baud rate
- Data length of 8 bits
- One stop bit
- No parity
- FIFOs disabled
- No interrupts

The first thing to consider when programming the UART is the baud-rate divisor (BRD), because the **UARTIBRD** and **UARTFBRD** registers must be written before the **UARTLCRH** register. Using the equation described in “Baud-Rate Generation” on page 619, the BRD can be calculated:

$$\text{BRD} = 20,000,000 / (16 * 115,200) = 10.8507$$

which means that the DIVINT field of the **UARTIBRD** register (see page 638) should be set to 10 decimal or 0xA. The value to be loaded into the **UARTFBRD** register (see page 639) is calculated by the equation:

$$\text{UARTFBRD}[\text{DIVFRAC}] = \text{integer}(0.8507 * 64 + 0.5) = 54$$

With the BRD values in hand, the UART configuration is written to the module in the following order:

1. Disable the UART by clearing the UARTEN bit in the **UARTCTL** register.
2. Write the integer portion of the BRD to the **UARTIBRD** register.
3. Write the fractional portion of the BRD to the **UARTFBRD** register.
4. Write the desired serial parameters to the **UARTLCRH** register (in this case, a value of 0x0000.0060).
5. Optionally, configure the  $\mu$ DMA channel (see “Micro Direct Memory Access ( $\mu$ DMA)” on page 350) and enable the DMA option(s) in the **UARTDMACTL** register.
6. Enable the UART by setting the UARTEN bit in the **UARTCTL** register.

## 13.5 Register Map

Table 13-4 on page 627 lists the UART registers. The offset listed is a hexadecimal increment to the register's address, relative to that UART's base address:

- UART0: 0x4000.C000
- UART1: 0x4000.D000

Note that the UART module clock must be enabled before the registers can be programmed (see page 257). There must be a delay of 3 system clocks after the UART module clock is enabled before any UART module registers are accessed.

**Note:** The UART must be disabled (see the UARTEN bit in the **UARTCTL** register on page 642) before any of the control registers are reprogrammed. When the UART is disabled during a TX or RX operation, the current transaction is completed prior to the UART stopping.

**Table 13-4. UART Register Map**

| Offset | Name          | Type | Reset       | Description                     | See page |

## 13.6 Register Descriptions

The remainder of this section lists and describes the UART registers, in numerical order by address offset.

## Register 1: UART Data (UARTDR), offset 0x000

**Important:** This register is read-sensitive. See the register description for details.

This register is the data register (the interface to the FIFOs).

For transmitted data, if the FIFO is enabled, data written to this location is pushed onto the transmit FIFO. If the FIFO is disabled, data is stored in the transmitter holding register (the bottom word of the transmit FIFO). A write to this register initiates a transmission from the UART.

For received data, if the FIFO is enabled, the data byte and the 4-bit status (break, frame, parity, and overrun) is pushed onto the 12-bit wide receive FIFO. If the FIFO is disabled, the data byte and status are stored in the receiving holding register (the bottom word of the receive FIFO). The received data can be retrieved by reading this register.

### UART Data (UARTDR)

UART0 base: 0x4000.C000  
 UART1 base: 0x4000.D000  
 Offset 0x000  
 Type R/W, reset 0x0000.0000

## Register 2: UART Receive Status/Error Clear (UARTRSR/UARTECR), offset 0x004

The **UARTRSR/UARTECR** register is the receive status register/error clear register.

In addition to the **UARTDR** register, receive status can also be read from the **UARTRSR** register. If the status is read from this register, then the status information corresponds to the entry read from **UARTDR** prior to reading **UARTRSR**. The status information for overrun is set immediately when an overrun condition occurs.

The **UARTRSR** register cannot be written.

A write of any value to the **UARTECR** register clears the framing, parity, break, and overrun errors. All the bits are cleared on reset.

### Read-Only Status Register

#### UART Receive Status/Error Clear (UARTRSR/UARTECR)

#### Value Description

|   |                                                                       |
|---|-----------------------------------------------------------------------|
| 1 | New data was received when the FIFO was full, resulting in data loss. |
| 0 | No data has been lost due to a FIFO overrun.                          |

This bit is cleared by a write to **UARTECR**.

The FIFO contents remain valid because no further data is written when the FIFO is full, only the contents of the shift register are overwritten. The CPU must read the data in order to empty the FIFO.

| Bit/Field | Name | Type | Reset | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

**Register 3: UART Flag (UARTFR), offset 0x018**

The **UARTFR** register is the flag register. After reset, the TXFF, RXFF, and BUSY bits are 0, and TXFE and RXFE bits are 1. The RI, DCD, DSR and CTS bits indicate the modem flow control and status. Note that the modem bits are only implemented on UART1 and are reserved on UART0.

## Register 4: UART IrDA Low-Power Register (UARTILPR), offset 0x020

The **UARTILPR** register stores the 8-bit low-power counter divisor value used to derive the low-power SIR pulse width clock by dividing down the system clock (SysClk). All the bits are cleared when reset.

The internal IrLPBaud16 clock is generated by dividing down SysClk according to the low-power divisor value written to **UARTILPR**. The duration of SIR pulses generated when low-power mode is enabled is three times the period of the IrLPBaud16 clock. The low-power divisor value is calculated as follows:

$$ILPDVSR = \text{SysClk} / F_{\text{IrLPBaud16}}$$

where  $F_{\text{IrLPBaud16}}$  is nominally 1.8432 MHz.

The divisor must be programmed such that  $1.42 \text{ MHz} < F_{\text{IrLPBaud16}} < 2.12 \text{ MHz}$ , resulting in a low-power pulse duration of 1.41–2.11  $\mu\text{s}$  (three times the period of IrLPBaud16). The minimum frequency of IrLPBaud16 ensures that pulses less than one period of IrLPBaud16 are rejected, but pulses greater than 1.4  $\mu\text{s}$  are accepted as valid pulses.

**Note:** Zero is an illegal value. Programming a zero value results in no IrLPBaud16 pulses being generated.

**Register 5: UART Integer Baud-Rate Divisor (UARTIBRD), offset 0x024**

The **UARTIBRD** register is the integer part of the baud-rate divisor value. All the bits are cleared on reset. The minimum possible divide ratio is 1 (when **UARTIBRD**=0), in which case the **UARTFBRD** register is ignored. When changing the **UARTIBRD** register, the new value does not take effect until transmission/reception of the current character is complete. Any changes to the baud-rate divisor must be followed by a write to the **UARTLCRH** register. See “Baud-Rate Generation” on page 619 for configuration details.

**Register 7: UART Line Control (UARTLCRH), offset 0x02C**

The **UARTLCRH** register is the line control register. Serial parameters such as data length, parity, and stop bit selection are implemented in this register.

When updating the baud-rate divisor (**UARTIBRD** and/or **UARTIFRD**), the **UARTLCRH** register must also be written. The write strobe for the baud-rate divisor registers is tied to the **UARTLCRH** register.

**UART Line Control (UARTLCRH)**

**Register 8: UART Control (UARTCTL), offset 0x030**

The **UARTCTL** register is the control register. All the bits are cleared on reset except for the Transmit Enable (TXE) and Receive Enable (RXE) bits, which are set.

To enable the UART module, the UARTEN bit must be set. If software requires a configuration change in the module, the UARTEN bit must be cleared before the configuration changes are written. If the UART is disabled during a transmit or receive operation, the current transaction is completed prior to the UART stopping.

Note that bits [15:14,11:10] are only implemented on UART1. These bits are reserved on UART0.

**Note:** The **UARTCTL** register should not be changed while the UART is enabled or else the results are unpredictable. The following sequence is recommended for making changes to the **UARTCTL** register.

1. Disable the UART.
2. Wait for the end of transmission or reception of the current character.
3. Flush the transmit FIFO by clearing bit 4 (FEN) in the line control register (**UARTLCRH**).
4. Reprogram the control register.
5. Enable the UART.

**UART Control (UARTCTL)**

UART0 base: 0x4000.C000

UART1 base: 0x4000.D000

Note that the UART does not support automatic retransmission on parity errors. If a parity error is detected on transmission, all further transmit operations are aborted and software must handle retransmission of the affected byte or message.</p> |

**Register 9: UART Interrupt FIFO Level Select (UARTIFLS), offset 0x034**

The **UARTIFLS** register is the interrupt FIFO level select register. You can use this register to define the FIFO level at which the TXRIS and RXRIS bits in the **UARTRIS** register are triggered.

The interrupts are generated based on a transition through a level rather than being based on the level. That is, the interrupts are generated when the fill level progresses through the trigger level. For example, if the receive trigger level is set to the half-way mark, the interrupt is triggered as the module is receiving the 9th character.

Out of reset, the TXIFLSEL and RXIFLSEL bits are configured so that the FIFOs trigger an interrupt at the half-way mark.

**UART Interrupt FIFO Level Select (UARTIFLS)**

UART0 base: 0x4000.C000  
 UART1 base: 0x4000.D000  
 Offset 0x034  
 Type R/W, reset 0x0000.0012

**Register 10: UART Interrupt Mask (UARTIM), offset 0x038**

The **UARTIM** register is the interrupt mask set/clear register.

On a read, this register gives the current value of the mask on the relevant interrupt. Setting a bit allows the corresponding raw interrupt signal to be routed to the interrupt controller. Clearing a bit prevents the raw interrupt signal from being sent to the interrupt controller.

Note that bits [3:0] are only implemented on UART1. These bits are reserved on UART0.

**UART Interrupt Mask (UARTIM)**

UART0 base: 0x4000.C000

UART1 base: 0x4000.D000

**Register 11: UART Raw Interrupt Status (UARTRIS), offset 0x03C**

The **UARTRIS** register is the raw interrupt status register. On a read, this register gives the current raw status value of the corresponding interrupt. A write has no effect.

Note that bits [3:0] are only implemented on UART1. These bits are reserved on UART0.

**UART Raw Interrupt Status (UARTRIS)**

UART0 base: 0x4000.C000

UART1 base: 0x4000.D000

Offset 0x03C

## Register 12: UART Masked Interrupt Status (UARTMIS), offset 0x040

The **UARTMIS** register is the masked interrupt status register. On a read, this register gives the current masked status value of the corresponding interrupt. A write has no effect.

Note that bits [3:0] are only implemented on UART1. These bits are reserved on UART0.

### UART Masked Interrupt Status (UARTMIS)

UART0 base: 0x4000.C000

UART1 base: 0x4000.D000

Offset 0x040

Type RO, reset 0x0000.0000

**Register 13: UART Interrupt Clear (UARTICR), offset 0x044**

The **UARTICR** register is the interrupt clear register. On a write of 1, the corresponding interrupt (both raw interrupt and masked interrupt, if enabled) is cleared. A write of 0 has no effect.

Note that bits [3:0] are only implemented on UART1. These bits are reserved on UART0.

**UART Interrupt Clear (UARTICR)**

UART0 base: 0x4000.C000

UART1 base: 0x4000.D000

Offset 0x044

Type W1C, reset 0x0000.0000

## Register 17: UART LIN Timer (UARTLTIM), offset 0x098

The **UARTLTIM** register contains the current timer value for the free-running timer that is used to calculate the baud rate when in LIN slave mode. The value in this register is used along with the value in the **UART LIN Snap Shot (UARTLSS)** register to adjust the baud rate to match that of the master.

### UART LIN Timer (UARTLTIM)

UART0 base: 0x4000.C000

UART1 base: 0x4000.D000

Offset 0x098

## 14 Synchronous Serial Interface (SSI)

The Stellaris<sup>®</sup> Synchronous Serial Interface (SSI) is a master or slave interface for synchronous serial communication with peripheral devices that have either Freescale SPI, MICROWIRE, or Texas Instruments synchronous serial interfaces.

The Stellaris LM3S8C62 controller includes one SSI module with the following features:

- Programmable interface operation for Freescale SPI, MICROWIRE, or Texas Instruments synchronous serial interfaces
- Master or slave operation
- Programmable clock bit rate and prescaler
- Separate transmit and receive FIFOs, each 16 bits wide and 8 locations deep
- Programmable data frame size from 4 to 16 bits
- Internal loopback test mode for diagnostic/debug testing
- Standard FIFO-based interrupts and End-of-Transmission interrupt
- Efficient transfers using Micro Direct Memory Access Controller ( $\mu$ DMA)
  - Separate channels for transmit and receive
  - Receive single request asserted when data is in the FIFO; burst request asserted when FIFO contains 4 entries
  - Transmit single request asserted when there is space in the FIFO; burst request asserted when FIFO contains 4 entries

## 14.1 Block Diagram

Figure 14-1. SSI Module Block Diagram

## 14.2 Signal Description

The following table lists the external signals of the SSI module and describes the function of each. The SSI signals are alternate functions for some GPIO signals and default to be GPIO signals at reset., with the exception of the **SSI0Clk**, **SSI0Fss**, **SSI0Rx**, and **SSI0Tx** pins which default to the SSI function. The column in the table below titled "Pin Mux/Pin Assignment" lists the possible GPIO pin placements for the SSI signals. The **AFSEL** bit in the **GPIO Alternate Function Select (GPIOAFSEL)** register (page 433) should be set to choose the SSI function. The number in

parentheses is the encoding that must be programmed into the PMCN field in the **GPIO Port Control (GPIOCTL)** register (page 450) to assign the SSI signal to the specified GPIO port pin. For more information on configuring GPIOs, see “General-Purpose Input/Outputs (GPIOs)” on page 410.

**Table 14-1. Signals for SSI (100LQFP)**

| Pin Name | Pin Number | Pin Mux / Pin Assignment | Pin Type | Buffer Type <sup>a</sup> | Description            |
|----------|------------|--------------------------|----------|--------------------------|------------------------|
| SSI0Clk  | 28         | PA2 (1)                  | I/O      | TTL                      | SSI module 0 clock.    |
| SSI0Fss  | 29         | PA3 (1)                  | I/O      | TTL                      | SSI module 0 frame.    |
| SSI0Rx   | 30         | PA4 (1)                  | I        | TTL                      | SSI module 0 receive.  |
| SSI0Tx   | 31         | PA5 (1)                  | O        | TTL                      | SSI module 0 transmit. |

a. The TTL designation indicates the pin has TTL-compatible voltage levels.

**Table 14-2. Signals for SSI (108BGA)**

| Pin Name | Pin Number | Pin Mux / Pin Assignment | Pin Type | Buffer Type <sup>a</sup> | Description            |
|----------|------------|--------------------------|----------|--------------------------|------------------------|
| SSI0Clk  | M4         | PA2 (1)                  | I/O      | TTL                      | SSI module 0 clock.    |
| SSI0Fss  | L4         | PA3 (1)                  | I/O      | TTL                      | SSI module 0 frame.    |
| SSI0Rx   | L5         | PA4 (1)                  | I        | TTL                      | SSI module 0 receive.  |
| SSI0Tx   | M5         | PA5 (1)                  | O        | TTL                      | SSI module 0 transmit. |

a. The TTL designation indicates the pin has TTL-compatible voltage levels.

## 14.3 Functional Description

The SSI performs serial-to-parallel conversion on data received from a peripheral device. The CPU accesses data, control, and status information. The transmit and receive paths are buffered with internal FIFO memories allowing up to eight 16-bit values to be stored independently in both transmit and receive modes. The SSI also supports the  $\mu$ DMA interface. The transmit and receive FIFOs can be programmed as destination/source addresses in the  $\mu$ DMA module.  $\mu$ DMA operation is enabled by setting the appropriate bit(s) in the **SSIDMACTL** register (see page 705).

### 14.3.1 Bit Rate Generation

The SSI includes a programmable bit rate clock divider and prescaler to generate the serial output clock. Bit rates are supported to 2 MHz and higher, although maximum bit rate is determined by peripheral devices.

The serial bit rate is derived by dividing down the input clock (SysClk). The clock is first divided by an even prescale value CPSDVSR from 2 to 254, which is programmed in the **SSI Clock Prescale (SSICPSR)** register (see page 698). The clock is further divided by a value from 1 to 256, which is  $1 + \text{SCR}$ , where SCR is the value programmed in the **SSI Control 0 (SSICR0)** register (see page 691).

The frequency of the output clock SSIClk is defined by:

$$\text{SSIClk} = \text{SysClk} / (\text{CPSDVSR} * (1 + \text{SCR}))$$

**Note:** For master mode, the system clock must be at least two times faster than the SSIClk, with the restriction that SSIClk cannot be faster than 25 MHz. For slave mode, the system clock must be at least 12 times faster than the SSIClk.

See “Synchronous Serial Interface (SSI)” on page 1038 to view SSI timing parameters.

## 14.3.2 FIFO Operation

### 14.3.2.1 Transmit FIFO

The common transmit FIFO is a 16-bit wide, 8-locations deep, first-in, first-out memory buffer. The CPU writes data to the FIFO by writing the **SSI Data (SSIDR)** register (see page 695), and data is stored in the FIFO until it is read out by the transmission logic.

When configured as a master or a slave, parallel data is written into the transmit FIFO prior to serial conversion and transmission to the attached slave or master, respectively, through the SSITx pin.

In slave mode, the SSI transmits data each time the master initiates a transaction. If the transmit FIFO is empty and the master initiates, the slave transmits the 8th most recent value in the transmit FIFO. If less than 8 values have been written to the transmit FIFO since the SSI module clock was enabled using the SSI bit in the **RGCG1** register, then 0 is transmitted. Care should be taken to ensure that valid data is in the FIFO as needed. The SSI can be configured to generate an interrupt or a  $\mu$ DMA request when the FIFO is empty.

### 14.3.2.2 Receive FIFO

The common receive FIFO is a 16-bit wide, 8-locations deep, first-in, first-out memory buffer. Received data from the serial interface is stored in the buffer until read out by the CPU, which accesses the read FIFO by reading the **SSIDR** register.

When configured as a master or slave, serial data received through the SSIRx pin is registered prior to parallel loading into the attached slave or master receive FIFO, respectively.

## 14.3.3 Interrupts

The SSI can generate interrupts when the following conditions are observed:

- Transmit FIFO service (when the transmit FIFO is half full or less)
- Receive FIFO service (when the receive FIFO is half full or more)
- Receive FIFO time-out
- Receive FIFO overrun
- End of transmission

All of the interrupt events are ORed together before being sent to the interrupt controller, so the SSI generates a single interrupt request to the controller regardless of the number of active interrupts. Each of the four individual maskable interrupts can be masked by clearing the appropriate bit in the **SSI Interrupt Mask (SSIIM)** register (see page 699). Setting the appropriate mask bit enables the interrupt.

The individual outputs, along with a combined interrupt output, allow use of either a global interrupt service routine or modular device drivers to handle interrupts. The transmit and receive dynamic dataflow interrupts have been separated from the status interrupts so that data can be read or written in response to the FIFO trigger levels. The status of the individual interrupt sources can be read from the **SSI Raw Interrupt Status (SSIRIS)** and **SSI Masked Interrupt Status (SSIMIS)** registers (see page 700 and page 702, respectively).

The receive FIFO has a time-out period that is 32 periods at the rate of SSIClk (whether or not SSIClk is currently active) and is started when the RX FIFO goes from EMPTY to not-EMPTY. If the RX FIFO is emptied before 32 clocks have passed, the time-out period is reset. As a result, the

ISR should clear the Receive FIFO Time-out Interrupt just after reading out the RX FIFO by writing a 1 to the RTIC bit in the **SSI Interrupt Clear (SSIICR)** register. The interrupt should not be cleared so late that the ISR returns before the interrupt is actually cleared, or the ISR may be re-activated unnecessarily.

The End-of-Transmission (EOT) interrupt indicates that the data has been transmitted completely. This interrupt can be used to indicate when it is safe to turn off the SSI module clock or enter sleep mode. In addition, because transmitted data and received data complete at exactly the same time, the interrupt can also indicate that read data is ready immediately, without waiting for the receive FIFO time-out period to complete.

#### 14.3.4 Frame Formats

Each data frame is between 4 and 16 bits long, depending on the size of data programmed, and is transmitted starting with the MSB. There are three basic frame types that can be selected:

- Texas Instruments synchronous serial
- Freescale SPI
- MICROWIRE

For all three formats, the serial clock (SSIClk) is held inactive while the SSI is idle, and SSIClk transitions at the programmed frequency only during active transmission or reception of data. The idle state of SSIClk is utilized to provide a receive timeout indication that occurs when the receive FIFO still contains data after a timeout period.

For Freescale SPI and MICROWIRE frame formats, the serial frame (SSIFss) pin is active Low, and is asserted (pulled down) during the entire transmission of the frame.

For Texas Instruments synchronous serial frame format, the SSIFss pin is pulsed for one serial clock period starting at its rising edge, prior to the transmission of each frame. For this frame format, both the SSI and the off-chip slave device drive their output data on the rising edge of SSIClk and latch data from the other device on the falling edge.

Unlike the full-duplex transmission of the other two frame formats, the MICROWIRE format uses a special master-slave messaging technique which operates at half-duplex. In this mode, when a frame begins, an 8-bit control message is transmitted to the off-chip slave. During this transmit, no incoming data is received by the SSI. After the message has been sent, the off-chip slave decodes it and, after waiting one serial clock after the last bit of the 8-bit control message has been sent, responds with the requested data. The returned data can be 4 to 16 bits in length, making the total frame length anywhere from 13 to 25 bits.

##### 14.3.4.1 Texas Instruments Synchronous Serial Frame Format

Figure 14-2 on page 681 shows the Texas Instruments synchronous serial frame format for a single transmitted frame.

**Figure 14-2. TI Synchronous Serial Frame Format (Single Transfer)**

In this mode, SSIClk and SSIFss are forced Low, and the transmit data line SSITx is tristated whenever the SSI is idle. Once the bottom entry of the transmit FIFO contains data, SSIFss is pulsed High for one SSIClk period. The value to be transmitted is also transferred from the transmit FIFO to the serial shift register of the transmit logic. On the next rising edge of SSIClk, the MSB of the 4 to 16-bit data frame is shifted out on the SSITx pin. Likewise, the MSB of the received data is shifted onto the SSIRx pin by the off-chip serial slave device.

Both the SSI and the off-chip serial slave device then clock each data bit into their serial shifter on each falling edge of SSIClk. The received data is transferred from the serial shifter to the receive FIFO on the first rising edge of SSIClk after the LSB has been latched.

Figure 14-3 on page 681 shows the Texas Instruments synchronous serial frame format when back-to-back frames are transmitted.

**Figure 14-3. TI Synchronous Serial Frame Format (Continuous Transfer)**

#### 14.3.4.2 Freescale SPI Frame Format

The Freescale SPI interface is a four-wire interface where the SSIFss signal behaves as a slave select. The main feature of the Freescale SPI format is that the inactive state and phase of the SSIClk signal are programmable through the SP0 and SPH bits in the **SSISCR0** control register.

##### **SPO Clock Polarity Bit**

When the SP0 clock polarity control bit is clear, it produces a steady state Low value on the SSIClk pin. If the SP0 bit is set, a steady state High value is placed on the SSIClk pin when data is not being transferred.

### SPH Phase Control Bit

The SPH phase control bit selects the clock edge that captures data and allows it to change state. The state of this bit has the most impact on the first bit transmitted by either allowing or not allowing a clock transition before the first data capture edge. When the SPH phase control bit is clear, data is captured on the first clock edge transition. If the SPH bit is set, data is captured on the second clock edge transition.

#### 14.3.4.3 Freescale SPI Frame Format with SPO=0 and SPH=0

Single and continuous transmission signal sequences for Freescale SPI format with SPO=0 and SPH=0 are shown in Figure 14-4 on page 682 and Figure 14-5 on page 682.

**Figure 14-4. Freescale SPI Format (Single Transfer) with SPO=0 and SPH=0**

**Note:** Q is undefined.

**Figure 14-5. Freescale SPI Format (Continuous Transfer) with SPO=0 and SPH=0**

In this configuration, during idle periods:

- SSIClk is forced Low
- SSIFss is forced High
- The transmit data line SSITx is arbitrarily forced Low
- When the SSI is configured as a master, it enables the SSIClk pad
- When the SSI is configured as a slave, it disables the SSIClk pad

If the SSI is enabled and valid data is in the transmit FIFO, the start of transmission is signified by the SSIFss master signal being driven Low, causing slave data to be enabled onto the SSIRx input line of the master. The master SSITx output pad is enabled.

One half SSIClk period later, valid master data is transferred to the SSITx pin. Once both the master and slave data have been set, the SSIClk master clock pin goes High after one additional half SSIClk period.

The data is now captured on the rising and propagated on the falling edges of the SSIClk signal.

In the case of a single word transmission, after all bits of the data word have been transferred, the SSIFss line is returned to its idle High state one SSIClk period after the last bit has been captured.

However, in the case of continuous back-to-back transmissions, the SSIFss signal must be pulsed High between each data word transfer because the slave select pin freezes the data in its serial peripheral register and does not allow it to be altered if the SPH bit is clear. Therefore, the master device must raise the SSIFss pin of the slave device between each data transfer to enable the serial peripheral data write. On completion of the continuous transfer, the SSIFss pin is returned to its idle state one SSIClk period after the last bit has been captured.

#### 14.3.4.4 Freescale SPI Frame Format with SPO=0 and SPH=1

The transfer signal sequence for Freescale SPI format with SPO=0 and SPH=1 is shown in Figure 14-6 on page 683, which covers both single and continuous transfers.

**Figure 14-6. Freescale SPI Frame Format with SPO=0 and SPH=1**

In this configuration, during idle periods:

- SSIClk is forced Low
- SSIFss is forced High
- The transmit data line SSITx is arbitrarily forced Low
- When the SSI is configured as a master, it enables the SSIClk pad
- When the SSI is configured as a slave, it disables the SSIClk pad

If the SSI is enabled and valid data is in the transmit FIFO, the start of transmission is signified by the SSIFss master signal being driven Low. The master SSITx output is enabled. After an additional one-half SSIClk period, both master and slave valid data are enabled onto their respective transmission lines. At the same time, the SSIClk is enabled with a rising edge transition.

Data is then captured on the falling edges and propagated on the rising edges of the SSIClk signal.

In the case of a single word transfer, after all bits have been transferred, the SSIFss line is returned to its idle High state one SSIClk period after the last bit has been captured.

For continuous back-to-back transfers, the SSIFss pin is held Low between successive data words, and termination is the same as that of the single word transfer.

#### 14.3.4.5 Freescale SPI Frame Format with SPO=1 and SPH=0

Single and continuous transmission signal sequences for Freescale SPI format with SPO=1 and SPH=0 are shown in Figure 14-7 on page 684 and Figure 14-8 on page 684.

**Figure 14-7. Freescale SPI Frame Format (Single Transfer) with SPO=1 and SPH=0**

**Figure 14-8. Freescale SPI Frame Format (Continuous Transfer) with SPO=1 and SPH=0**

In this configuration, during idle periods:

- SSIClk is forced High
- SSIFss is forced High
- The transmit data line SSITx is arbitrarily forced Low
- When the SSI is configured as a master, it enables the SSIClk pad
- When the SSI is configured as a slave, it disables the SSIClk pad

If the SSI is enabled and valid data is in the transmit FIFO, the start of transmission is signified by the SSIFss master signal being driven Low, causing slave data to be immediately transferred onto the SSIRx line of the master. The master SSITx output pad is enabled.

One-half period later, valid master data is transferred to the SSITx line. Once both the master and slave data have been set, the SSIClk master clock pin becomes Low after one additional half SSIClk period, meaning that data is captured on the falling edges and propagated on the rising edges of the SSIClk signal.

In the case of a single word transmission, after all bits of the data word are transferred, the SSIFss line is returned to its idle High state one SSIClk period after the last bit has been captured.

However, in the case of continuous back-to-back transmissions, the SSIFss signal must be pulsed High between each data word transfer because the slave select pin freezes the data in its serial peripheral register and does not allow it to be altered if the SPH bit is clear. Therefore, the master device must raise the SSIFss pin of the slave device between each data transfer to enable the serial peripheral data write. On completion of the continuous transfer, the SSIFss pin is returned to its idle state one SSIClk period after the last bit has been captured.

#### 14.3.4.6 Freescale SPI Frame Format with SPO=1 and SPH=1

The transfer signal sequence for Freescale SPI format with SPO=1 and SPH=1 is shown in Figure 14-9 on page 685, which covers both single and continuous transfers.

**Figure 14-9. Freescale SPI Frame Format with SPO=1 and SPH=1**

**Note:** Q is undefined.

In this configuration, during idle periods:

- SSIClk is forced High
- SSIFss is forced High
- The transmit data line SSITx is arbitrarily forced Low
- When the SSI is configured as a master, it enables the SSIClk pad
- When the SSI is configured as a slave, it disables the SSIClk pad

If the SSI is enabled and valid data is in the transmit FIFO, the start of transmission is signified by the SSIFss master signal being driven Low. The master SSITx output pad is enabled. After an additional one-half SSIClk period, both master and slave data are enabled onto their respective transmission lines. At the same time, SSIClk is enabled with a falling edge transition. Data is then captured on the rising edges and propagated on the falling edges of the SSIClk signal.

After all bits have been transferred, in the case of a single word transmission, the SSIFss line is returned to its idle high state one SSIClk period after the last bit has been captured.

For continuous back-to-back transmissions, the SSIFss pin remains in its active Low state until the final bit of the last word has been captured and then returns to its idle state as described above.

For continuous back-to-back transfers, the SSIFss pin is held Low between successive data words and termination is the same as that of the single word transfer.

#### 14.3.4.7 MICROWIRE Frame Format

Figure 14-10 on page 686 shows the MICROWIRE frame format for a single frame. Figure 14-11 on page 687 shows the same format when back-to-back frames are transmitted.

**Figure 14-10. MICROWIRE Frame Format (Single Frame)**

MICROWIRE format is very similar to SPI format, except that transmission is half-duplex instead of full-duplex and uses a master-slave message passing technique. Each serial transmission begins with an 8-bit control word that is transmitted from the SSI to the off-chip slave device. During this transmission, no incoming data is received by the SSI. After the message has been sent, the off-chip slave decodes it and, after waiting one serial clock after the last bit of the 8-bit control message has been sent, responds with the required data. The returned data is 4 to 16 bits in length, making the total frame length anywhere from 13 to 25 bits.

In this configuration, during idle periods:

- SSIClk is forced Low
- SSIFss is forced High
- The transmit data line SSITx is arbitrarily forced Low

A transmission is triggered by writing a control byte to the transmit FIFO. The falling edge of SSIFss causes the value contained in the bottom entry of the transmit FIFO to be transferred to the serial shift register of the transmit logic and the MSB of the 8-bit control frame to be shifted out onto the SSITx pin. SSIFss remains Low for the duration of the frame transmission. The SSIRx pin remains tristated during this transmission.

The off-chip serial slave device latches each control bit into its serial shifter on each rising edge of SSIClk. After the last bit is latched by the slave device, the control byte is decoded during a one clock wait-state, and the slave responds by transmitting data back to the SSI. Each bit is driven onto the SSIRx line on the falling edge of SSIClk. The SSI in turn latches each bit on the rising edge of SSIClk. At the end of the frame, for single transfers, the SSIFss signal is pulled High one clock period after the last bit has been latched in the receive serial shifter, causing the data to be transferred to the receive FIFO.

**Note:** The off-chip slave device can tristate the receive line either on the falling edge of SSIClk after the LSB has been latched by the receive shifter or when the SSIFss pin goes High.

For continuous transfers, data transmission begins and ends in the same manner as a single transfer. However, the SSIFss line is continuously asserted (held Low) and transmission of data occurs back-to-back. The control byte of the next frame follows directly after the LSB of the received data from the current frame. Each of the received values is transferred from the receive shifter on the falling edge of SSIClk, after the LSB of the frame has been latched into the SSI.

**Figure 14-11. MICROWIRE Frame Format (Continuous Transfer)**

In the MICROWIRE mode, the SSI slave samples the first bit of receive data on the rising edge of SSIClk after SSIFss has gone Low. Masters that drive a free-running SSIClk must ensure that the SSIFss signal has sufficient setup and hold margins with respect to the rising edge of SSIClk.

Figure 14-12 on page 687 illustrates these setup and hold time requirements. With respect to the SSIClk rising edge on which the first bit of receive data is to be sampled by the SSI slave, SSIFss must have a setup of at least two times the period of SSIClk on which the SSI operates. With respect to the SSIClk rising edge previous to this edge, SSIFss must have a hold of at least one SSIClk period.

**Figure 14-12. MICROWIRE Frame Format, SSIFss Input Setup and Hold Requirements**

### 14.3.5 DMA Operation

The SSI peripheral provides an interface to the  $\mu$ DMA controller with separate channels for transmit and receive. The  $\mu$ DMA operation of the SSI is enabled through the **SSI DMA Control (SSIDMACTL)** register. When  $\mu$ DMA operation is enabled, the SSI asserts a  $\mu$ DMA request on the receive or transmit channel when the associated FIFO can transfer data. For the receive channel, a single transfer request is asserted whenever any data is in the receive FIFO. A burst transfer request is asserted whenever the amount of data in the receive FIFO is 4 or more items. For the transmit channel, a single transfer request is asserted whenever at least one empty location is in the transmit FIFO. The burst request is asserted whenever the transmit FIFO has 4 or more empty slots. The single and burst  $\mu$ DMA transfer requests are handled automatically by the  $\mu$ DMA controller depending how the  $\mu$ DMA channel is configured. To enable  $\mu$ DMA operation for the receive channel, the RXDMAE bit of the **DMA Control (SSIDMACTL)** register should be set. To enable  $\mu$ DMA operation for the transmit channel, the TXDMAE bit of **SSIDMACTL** should be set. If  $\mu$ DMA is enabled, then the  $\mu$ DMA controller triggers an interrupt when a transfer is complete. The interrupt occurs on the SSI interrupt vector. Therefore, if interrupts are used for SSI operation and  $\mu$ DMA is enabled, the SSI interrupt handler must be designed to handle the  $\mu$ DMA completion interrupt.

See “Micro Direct Memory Access ( $\mu$ DMA)” on page 350 for more details about programming the  $\mu$ DMA controller.

## 14.4 Initialization and Configuration

To enable and initialize the SSI, the following steps are necessary:

1. Enable the SSI module by setting the SSI bit in the **RCGC1** register (see page 257).
2. Enable the clock to the appropriate GPIO module via the **RCGC2** register (see page 266). To find out which GPIO port to enable, refer to Table 22-5 on page 994.
3. Set the GPIO AFSEL bits for the appropriate pins (see page 433). To determine which GPIOs to configure, see Table 22-4 on page 987.
4. Configure the PMCN fields in the **GPIOPCTL** register to assign the SSI signals to the appropriate pins. See page 450 and Table 22-5 on page 994.

For each of the frame formats, the SSI is configured using the following steps:

1. Ensure that the SSE bit in the **SSICR1** register is clear before making any configuration changes.
2. Select whether the SSI is a master or slave:
  - a. For master operations, set the **SSICR1** register to 0x0000.0000.
  - b. For slave mode (output enabled), set the **SSICR1** register to 0x0000.0004.
  - c. For slave mode (output disabled), set the **SSICR1** register to 0x0000.000C.
3. Configure the clock prescale divisor by writing the **SSICPSR** register.
4. Write the **SSICR0** register with the following configuration:
  - Serial clock rate (SCR)
  - Desired clock phase/polarity, if using Freescale SPI mode (SPH and SPO)
  - The protocol mode: Freescale SPI, TI SSF, MICROWIRE (FRF)
  - The data size (DSS)
5. Optionally, configure the  $\mu$ DMA channel (see “Micro Direct Memory Access ( $\mu$ DMA)” on page 350) and enable the DMA option(s) in the **SSIDMACTL** register.
6. Enable the SSI by setting the SSE bit in the **SSICR1** register.

As an example, assume the SSI must be configured to operate with the following parameters:

- Master operation
- Freescale SPI mode (SPO=1, SPH=1)
- 1 Mbps bit rate
- 8 data bits

Assuming the system clock is 20 MHz, the bit rate calculation would be:

$$\begin{aligned} \text{SSIClk} &= \text{SysClk} / (\text{CPSDVSR} * (1 + \text{SCR})) \\ 1 \times 10^6 &= 20 \times 10^6 / (\text{CPSDVSR} * (1 + \text{SCR})) \end{aligned}$$

In this case, if CPSDVSR=0x2, SCR must be 0x9.

The configuration sequence would be as follows:

1. Ensure that the SSE bit in the **SSICR1** register is clear.
2. Write the **SSICR1** register with a value of 0x0000.0000.
3. Write the **SSICPSR** register with a value of 0x0000.0002.
4. Write the **SSICR0** register with a value of 0x0000.09C7.
5. The SSI is then enabled by setting the SSE bit in the **SSICR1** register.

## 14.5 Register Map

Table 14-3 on page 689 lists the SSI registers. The offset listed is a hexadecimal increment to the register's address, relative to that SSI module's base address:

- SSI0: 0x4000.8000

Note that the SSI module clock must be enabled before the registers can be programmed (see page 257). There must be a delay of 3 system clocks after the SSI module clock is enabled before any SSI module registers are accessed.

**Note:** The SSI must be disabled (see the SSE bit in the **SSICR1** register) before any of the control registers are reprogrammed.

**Table 14-3. SSI Register Map**

## 14.6 Register Descriptions

The remainder of this section lists and describes the SSI registers, in numerical order by address offset.

**Register 1: SSI Control 0 (SSICR0), offset 0x000**

The **SSICR0** register contains bit fields that control various functions within the SSI module. Functionality such as protocol mode, clock rate, and data size are configured in this register.

**SSI Control 0 (SSICR0)**

SSI0 base: 0x4000.8000

Offset 0x000

Type R/W, reset 0x0000.0000

## Register 2: SSI Control 1 (SSICR1), offset 0x004

The **SSICR1** register contains bit fields that control various functions within the SSI module. Master and slave mode functionality is controlled by this register.

### SSI Control 1 (SSICR1)

### Register 3: SSI Data (SSIDR), offset 0x008

**Important:** This register is read-sensitive. See the register description for details.

The **SSIDR** register is 16-bits wide. When the **SSIDR** register is read, the entry in the receive FIFO that is pointed to by the current FIFO read pointer is accessed. When a data value is removed by the SSI receive logic from the incoming data frame, it is placed into the entry in the receive FIFO pointed to by the current FIFO write pointer.

When the **SSIDR** register is written to, the entry in the transmit FIFO that is pointed to by the write pointer is written to. Data values are removed from the transmit FIFO one value at a time by the transmit logic. Each data value is loaded into the transmit serial shifter, then serially shifted out onto the SSITx pin at the programmed bit rate.

When a data size of less than 16 bits is selected, the user must right-justify data written to the transmit FIFO. The transmit logic ignores the unused bits. Received data less than 16 bits is automatically right-justified in the receive buffer.

When the SSI is programmed for MICROWIRE frame format, the default size for transmit data is eight bits (the most significant byte is ignored). The receive data size is controlled by the programmer. The transmit FIFO and the receive FIFO are not cleared even when the SSE bit in the **SSICR1** register is cleared, allowing the software to fill the transmit FIFO before enabling the SSI.

**Register 5: SSI Clock Prescale (SSICPSR), offset 0x010**

The **SSICPSR** register specifies the division factor which is used to derive the SSIClk from the system clock. The clock is further divided by a value from 1 to 256, which is 1 + SCR. SCR is programmed in the **SSICR0** register. The frequency of the SSIClk is defined by:

$$\text{SSIClk} = \text{SysClk} / (\text{CPSDVSR} * (1 + \text{SCR}))$$

The value programmed into this register must be an even number between 2 and 254. The least-significant bit of the programmed number is hard-coded to zero. If an odd number is written to this register, data read back from this register has the least-significant bit as zero.

## Register 6: SSI Interrupt Mask (SSIIM), offset 0x014

The **SSIIM** register is the interrupt mask set or clear register. It is a read/write register and all bits are cleared on reset.

On a read, this register gives the current value of the mask on the corresponding interrupt. Setting a bit sets the mask, preventing the interrupt from being signaled to the interrupt controller. Clearing a bit clears the corresponding mask, enabling the interrupt to be sent to the interrupt controller.

## 15 Inter-Integrated Circuit (I<sup>2</sup>C) Interface

The Inter-Integrated Circuit (I<sup>2</sup>C) bus provides bi-directional data transfer through a two-wire design (a serial data line SDA and a serial clock line SCL), and interfaces to external I<sup>2</sup>C devices such as serial memory (RAMs and ROMs), networking devices, LCDs, tone generators, and so on. The I<sup>2</sup>C bus may also be used for system testing and diagnostic purposes in product development and manufacture. The LM3S8C62 microcontroller includes one I<sup>2</sup>C module, providing the ability to interact (both transmit and receive) with other I<sup>2</sup>C devices on the bus.

The Stellaris<sup>®</sup> LM3S8C62 controller includes one I<sup>2</sup>C module with the following features:

- Devices on the I<sup>2</sup>C bus can be designated as either a master or a slave
  - Supports both transmitting and receiving data as either a master or a slave
  - Supports simultaneous master and slave operation
- Four I<sup>2</sup>C modes
  - Master transmit
  - Master receive
  - Slave transmit
  - Slave receive
- Two transmission speeds: Standard (100 Kbps) and Fast (400 Kbps)
- Master and slave interrupt generation
  - Master generates interrupts when a transmit or receive operation completes (or aborts due to an error)
  - Slave generates interrupts when data has been transferred or requested by a master or when a START or STOP condition is detected
- Master with arbitration and clock synchronization, multimaster support, and 7-bit addressing mode

## 15.1 Block Diagram

Figure 15-1. I<sup>2</sup>C Block Diagram

## 15.2 Signal Description

The following table lists the external signals of the I<sup>2</sup>C interface and describes the function of each. The I<sup>2</sup>C interface signals are alternate functions for some GPIO signals and default to be GPIO signals at reset., with the exception of the I2C0SCL and I2CSDA pins which default to the I<sup>2</sup>C function. The column in the table below titled "Pin Mux/Pin Assignment" lists the possible GPIO pin placements for the I<sup>2</sup>C signals. The AFSEL bit in the **GPIO Alternate Function Select (GPIOAFSEL)** register (page 433) should be set to choose the I<sup>2</sup>C function. The number in parentheses is the encoding that must be programmed into the PMCn field in the **GPIO Port Control (GPIOPCTL)** register (page 450) to assign the I<sup>2</sup>C signal to the specified GPIO port pin. Note that the I<sup>2</sup>C pins should be set to open drain using the **GPIO Open Drain Select (GPIOODR)** register. For more information on configuring GPIOs, see "General-Purpose Input/Outputs (GPIOs)" on page 410.

Table 15-1. Signals for I2C (100LQFP)

| Pin Name | Pin Number | Pin Mux / Pin Assignment | Pin Type | Buffer Type <sup>a</sup> | Description                      |
|----------|------------|--------------------------|----------|--------------------------|----------------------------------|
| I2C0SCL  | 70         | PB2 (1)                  | I/O      | OD                       | I <sup>2</sup> C module 0 clock. |
| I2C0SDA  | 71         | PB3 (1)                  | I/O      | OD                       | I <sup>2</sup> C module 0 data.  |

a. The TTL designation indicates the pin has TTL-compatible voltage levels.

Table 15-2. Signals for I2C (108BGA)

| Pin Name | Pin Number | Pin Mux / Pin Assignment | Pin Type | Buffer Type <sup>a</sup> | Description                      |
|----------|------------|--------------------------|----------|--------------------------|----------------------------------|
| I2C0SCL  | C11        | PB2 (1)                  | I/O      | OD                       | I <sup>2</sup> C module 0 clock. |
| I2C0SDA  | C12        | PB3 (1)                  | I/O      | OD                       | I <sup>2</sup> C module 0 data.  |

a. The TTL designation indicates the pin has TTL-compatible voltage levels.

## 15.3 Functional Description

The I<sup>2</sup>C module is comprised of both master and slave functions. For proper operation, the SDA and SCL pins must be configured as open-drain signals. A typical I<sup>2</sup>C bus configuration is shown in Figure 15-2.

See “Inter-Integrated Circuit (I<sup>2</sup>C) Interface” on page 1040 for I<sup>2</sup>C timing diagrams.

**Figure 15-2. I<sup>2</sup>C Bus Configuration**

### 15.3.1 I<sup>2</sup>C Bus Functional Overview

The I<sup>2</sup>C bus uses only two signals: SDA and SCL, named I2CSDA and I2CSCL on Stellaris microcontrollers. SDA is the bi-directional serial data line and SCL is the bi-directional serial clock line. The bus is considered idle when both lines are High.

Every transaction on the I<sup>2</sup>C bus is nine bits long, consisting of eight data bits and a single acknowledge bit. The number of bytes per transfer (defined as the time between a valid START and STOP condition, described in “START and STOP Conditions” on page 720) is unrestricted, but each byte has to be followed by an acknowledge bit, and data must be transferred MSB first. When a receiver cannot receive another complete byte, it can hold the clock line SCL Low and force the transmitter into a wait state. The data transfer continues when the receiver releases the clock SCL.

#### 15.3.1.1 START and STOP Conditions

The protocol of the I<sup>2</sup>C bus defines two states to begin and end a transaction: START and STOP. A High-to-Low transition on the SDA line while the SCL is High is defined as a START condition, and a Low-to-High transition on the SDA line while SCL is High is defined as a STOP condition. The bus is considered busy after a START condition and free after a STOP condition. See Figure 15-3.

**Figure 15-3. START and STOP Conditions**

The STOP bit determines if the cycle stops at the end of the data cycle or continues on to a repeated START condition. To generate a single transmit cycle, the **I<sup>2</sup>C Master Slave Address (I2CMSA)** register is written with the desired address, the R/S bit is cleared, and the Control register is written with ACK=X (0 or 1), STOP=1, START=1, and RUN=1 to perform the operation and stop. When the operation is completed (or aborted due an error), the interrupt pin becomes active and the data may be read from the **I<sup>2</sup>C Master Data (I2CMDR)** register. When the I<sup>2</sup>C module operates in Master receiver mode, the ACK bit is normally set causing the I<sup>2</sup>C bus controller to transmit an acknowledge automatically after each byte. This bit must be cleared when the I<sup>2</sup>C bus controller requires no further data to be transmitted from the slave transmitter.

When operating in slave mode, two bits in the **I<sup>2</sup>C Slave Raw Interrupt Status (I2CSRIS)** register indicate detection of start and stop conditions on the bus; while two bits in the **I<sup>2</sup>C Slave Masked Interrupt Status (I2CSMIS)** register allow start and stop conditions to be promoted to controller interrupts (when interrupts are enabled).

### 15.3.1.2 Data Format with 7-Bit Address

Data transfers follow the format shown in Figure 15-4. After the START condition, a slave address is transmitted. This address is 7-bits long followed by an eighth bit, which is a data direction bit (R/S bit in the **I2CMSA** register). If the R/S bit is clear, it indicates a transmit operation (send), and if it is set, it indicates a request for data (receive). A data transfer is always terminated by a STOP condition generated by the master, however, a master can initiate communications with another device on the bus by generating a repeated START condition and addressing another slave without first generating a STOP condition. Various combinations of receive/transmit formats are then possible within a single transfer.

**Figure 15-4. Complete Data Transfer with a 7-Bit Address**

The first seven bits of the first byte make up the slave address (see Figure 15-5). The eighth bit determines the direction of the message. A zero in the R/S position of the first byte means that the master transmits (sends) data to the selected slave, and a one in this position means that the master receives data from the slave.

**Figure 15-5. R/S Bit in First Byte**

### 15.3.1.3 Data Validity

The data on the SDA line must be stable during the high period of the clock, and the data line can only change when SCL is Low (see Figure 15-6).

**Figure 15-6. Data Validity During Bit Transfer on the I<sup>2</sup>C Bus**

#### 15.3.1.4 Acknowledge

All bus transactions have a required acknowledge clock cycle that is generated by the master. During the acknowledge cycle, the transmitter (which can be the master or slave) releases the SDA line. To acknowledge the transaction, the receiver must pull down SDA during the acknowledge clock cycle. The data transmitted out by the receiver during the acknowledge cycle must comply with the data validity requirements described in “Data Validity” on page 721.

When a slave receiver does not acknowledge the slave address, SDA must be left High by the slave so that the master can generate a STOP condition and abort the current transfer. If the master device is acting as a receiver during a transfer, it is responsible for acknowledging each transfer made by the slave. Because the master controls the number of bytes in the transfer, it signals the end of data to the slave transmitter by not generating an acknowledge on the last data byte. The slave transmitter must then release SDA to allow the master to generate the STOP or a repeated START condition.

#### 15.3.1.5 Arbitration

A master may start a transfer only if the bus is idle. It's possible for two or more masters to generate a START condition within minimum hold time of the START condition. In these situations, an arbitration scheme takes place on the SDA line, while SCL is High. During arbitration, the first of the competing master devices to place a '1' (High) on SDA while another master transmits a '0' (Low) switches off its data output stage and retires until the bus is idle again.

Arbitration can take place over several bits. Its first stage is a comparison of address bits, and if both masters are trying to address the same device, arbitration continues on to the comparison of data bits.

### 15.3.2 Available Speed Modes

The I<sup>2</sup>C bus can run in either Standard mode (100 kbps) or Fast mode (400 kbps). The selected mode should match the speed of the other I<sup>2</sup>C devices on the bus.

#### 15.3.2.1 Standard and Fast Modes

Standard and Fast modes are selected using a value in the **I<sup>2</sup>C Master Timer Period (I2CMTPR)** register that results in an SCL frequency of 100 kbps for Standard mode or 400 kbps for Fast mode.

The I<sup>2</sup>C clock rate is determined by the parameters *CLK\_PRD*, *TIMER\_PRD*, *SCL\_LP*, and *SCL\_HP* where:

*CLK\_PRD* is the system clock period

*SCL\_LP* is the low phase of SCL (fixed at 6)

*SCL\_HP* is the high phase of SCL (fixed at 4)

*TIMER\_PRD* is the programmed value in the **I2CMTPR** register (see page 740).

The I<sup>2</sup>C clock period is calculated as follows:

$$SCL\_PERIOD = 2 \times (1 + TIMER\_PRD) \times (SCL\_LP + SCL\_HP) \times CLK\_PRD$$

For example:

$$CLK\_PRD = 50 \text{ ns}$$

$$TIMER\_PRD = 2$$

$$SCL\_LP = 6$$

$SCL\_HP=4$

yields a SCL frequency of:

$$1/SCL\_PERIOD = 333 \text{ Khz}$$

Table 15-3 gives examples of the timer periods that should be used to generate both Standard and Fast mode SCL frequencies based on various system clock frequencies.

**Table 15-3. Examples of I<sup>2</sup>C Master Timer Period versus Speed Mode**

| System Clock | Timer Period | Standard Mode | Timer Period | Fast Mode |
|--------------|--------------|---------------|--------------|-----------|
| 4 MHz        | 0x01         | 100 Kbps      | -            | -         |
| 6 MHz        | 0x02         | 100 Kbps      | -            | -         |
| 12.5 MHz     | 0x06         | 89 Kbps       | 0x01         | 312 Kbps  |
| 16.7 MHz     | 0x08         | 93 Kbps       | 0x02         | 278 Kbps  |
| 20 MHz       | 0x09         | 100 Kbps      | 0x02         | 333 Kbps  |
| 25 MHz       | 0x0C         | 96.2 Kbps     | 0x03         | 312 Kbps  |
| 33 MHz       | 0x10         | 97.1 Kbps     | 0x04         | 330 Kbps  |
| 40 MHz       | 0x13         | 100 Kbps      | 0x04         | 400 Kbps  |
| 50 MHz       | 0x18         | 100 Kbps      | 0x06         | 357 Kbps  |
| 80 MHz       | 0x27         | 100 Kbps      | 0x09         | 400 Kbps  |

### 15.3.3 Interrupts

The I<sup>2</sup>C can generate interrupts when the following conditions are observed:

- Master transaction completed
- Master arbitration lost
- Master transaction error
- Slave transaction received
- Slave transaction requested
- Stop condition on bus detected
- Start condition on bus detected

The I<sup>2</sup>C master and I<sup>2</sup>C slave modules have separate interrupt signals. While both modules can generate interrupts for multiple conditions, only a single interrupt signal is sent to the interrupt controller.

#### 15.3.3.1 I<sup>2</sup>C Master Interrupts

The I<sup>2</sup>C master module generates an interrupt when a transaction completes (either transmit or receive), when arbitration is lost, or when an error occurs during a transaction. To enable the I<sup>2</sup>C master interrupt, software must set the IM bit in the **I<sup>2</sup>C Master Interrupt Mask (I2CMIMR)** register. When an interrupt condition is met, software must check the ERROR and ARBLST bits in the **I<sup>2</sup>C Master Control/Status (I2CMCS)** register to verify that an error didn't occur during the last transaction and to ensure that arbitration has not been lost. An error condition is asserted if the last transaction wasn't acknowledged by the slave. If an error is not detected and the master has not lost arbitration,

the application can proceed with the transfer. The interrupt is cleared by writing a 1 to the IC bit in the **I<sup>2</sup>C Master Interrupt Clear (I2CMICR)** register.

If the application doesn't require the use of interrupts, the raw interrupt status is always visible via the **I<sup>2</sup>C Master Raw Interrupt Status (I2CMRIS)** register.

#### **15.3.3.2 I<sup>2</sup>C Slave Interrupts**

The slave module can generate an interrupt when data has been received or requested. This interrupt is enabled by setting the DATAIM bit in the **I<sup>2</sup>C Slave Interrupt Mask (I2CSIMR)** register. Software determines whether the module should write (transmit) or read (receive) data from the **I<sup>2</sup>C Slave Data (I2CSDR)** register, by checking the RREQ and TREQ bits of the **I<sup>2</sup>C Slave Control/Status (I2CSCSR)** register. If the slave module is in receive mode and the first byte of a transfer is received, the FBR bit is set along with the RREQ bit. The interrupt is cleared by setting the DATAIC bit in the **I<sup>2</sup>C Slave Interrupt Clear (I2CSICR)** register.

In addition, the slave module can generate an interrupt when a start and stop condition is detected. These interrupts are enabled by setting the STARTIM and STOPIM bits of the **I<sup>2</sup>C Slave Interrupt Mask (I2CSIMR)** register and cleared by writing a 1 to the STOPIC and STARTIC bits of the **I<sup>2</sup>C Slave Interrupt Clear (I2CSICR)** register.

If the application doesn't require the use of interrupts, the raw interrupt status is always visible via the **I<sup>2</sup>C Slave Raw Interrupt Status (I2CSRIS)** register.

#### **15.3.4 Loopback Operation**

The I<sup>2</sup>C modules can be placed into an internal loopback mode for diagnostic or debug work by setting the LPBK bit in the **I<sup>2</sup>C Master Configuration (I2CMCR)** register. In loopback mode, the SDA and SCL signals from the master and slave modules are tied together.

#### **15.3.5 Command Sequence Flow Charts**

This section details the steps required to perform the various I<sup>2</sup>C transfer types in both master and slave mode.

##### **15.3.5.1 I<sup>2</sup>C Master Command Sequences**

The figures that follow show the command sequences available for the I<sup>2</sup>C master.

Figure 15-7. Master Single TRANSMIT

Figure 15-8. Master Single RECEIVE

Figure 15-9. Master TRANSMIT with Repeated START

Figure 15-10. Master RECEIVE with Repeated START

**Figure 15-12. Master TRANSMIT with Repeated START after RECEIVE with Repeated START**

### 15.3.5.2 I<sup>2</sup>C Slave Command Sequences

Figure 15-13 on page 731 presents the command sequence available for the I<sup>2</sup>C slave.

Figure 15-13. Slave Command Sequence

## 15.4 Initialization and Configuration

The following example shows how to configure the I<sup>2</sup>C module to transmit a single byte as a master. This assumes the system clock is 20 MHz.

1. Enable the I<sup>2</sup>C clock by writing a value of 0x0000.1000 to the **RCGC1** register in the System Control module (see page 257).
2. Enable the clock to the appropriate GPIO module via the **RCGC2** register in the System Control module (see page 266). To find out which GPIO port to enable, refer to Table 22-5 on page 994.
3. In the GPIO module, enable the appropriate pins for their alternate function using the **GPIOAFSEL** register (see page 433). To determine which GPIOs to configure, see Table 22-4 on page 987.
4. Enable the I<sup>2</sup>C pins for Open Drain operation. See page 438.
5. Configure the PMCN fields in the **GPIOPCTL** register to assign the I<sup>2</sup>C signals to the appropriate pins. See page 450 and Table 22-5 on page 994.
6. Initialize the I<sup>2</sup>C Master by writing the **I2CMCR** register with a value of 0x0000.0010.

7. Set the desired SCL clock speed of 100 Kbps by writing the **I2CMTPR** register with the correct value. The value written to the **I2CMTPR** register represents the number of system clock periods in one SCL clock period. The TPR value is determined by the following equation:

$$\text{TPR} = (\text{System Clock} / (2 * (\text{SCL\_LP} + \text{SCL\_HP}) * \text{SCL\_CLK})) - 1;$$

$$\text{TPR} = (20\text{MHz} / (2 * (6+4) * 1000000)) - 1;$$

$$\text{TPR} = 9$$

Write the **I2CMTPR** register with the value of 0x0000.0009.

8. Specify the slave address of the master and that the next operation is a Transmit by writing the **I2CMSA** register with a value of 0x0000.0076. This sets the slave address to 0x3B.
9. Place data (byte) to be transmitted in the data register by writing the **I2CMDR** register with the desired data.
10. Initiate a single byte transmit of the data from Master to Slave by writing the **I2CMCS** register with a value of 0x0000.0007 (STOP, START, RUN).
11. Wait until the transmission completes by polling the **I2CMCS** register's BUSBSY bit until it has been cleared.
12. Check the ERROR bit in the **I2CMCS** register to confirm the transmit was acknowledged.

## 15.5 Register Map

Table 15-4 on page 732 lists the I<sup>2</sup>C registers. All addresses given are relative to the I<sup>2</sup>C base address:

- I<sup>2</sup>C 0: 0x4002.0000

Note that the I<sup>2</sup>C module clock must be enabled before the registers can be programmed (see page 257). There must be a delay of 3 system clocks after the I<sup>2</sup>C module clock is enabled before any I<sup>2</sup>C module registers are accessed.

The hw\_i2c.h file in the StellarisWare<sup>®</sup> Driver Library uses a base address of 0x800 for the I<sup>2</sup>C slave registers. Be aware when using registers with offsets between 0x800 and 0x818 that StellarisWare uses an offset between 0x000 and 0x018 with the slave base address.

**Table 15-4. Inter-Integrated Circuit (I<sup>2</sup>C) Interface Register Map**

| Offset                       | Name    | Type | Reset       | Description                        | See page |
|------------------------------|---------|------|-------------|------------------------------------|----------|
| <b>I<sup>2</sup>C Master</b> |         |      |             |                                    |          |
| 0x000                        | I2CMSA  | R/W  | 0x0000.0000 | I2C Master Slave Address           | 734      |

## 15.6 Register Descriptions (I<sup>2</sup>C Master)

The remainder of this section lists and describes the I<sup>2</sup>C master registers, in numerical order by address offset.

**Register 1: I<sup>2</sup>C Master Slave Address (I2CMSA), offset 0x000**

This register consists of eight bits: seven address bits (A6-A0), and a Receive/Send bit, which determines if the next operation is a Receive (High), or Transmit (Low).

**I2C Master Slave Address (I2CMSA)**

I2C 0 base: 0x4002.0000

Offset 0x000

Type R/W, reset 0x0000.0000

|       | 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23  | 22  | 21  | 20  | 19  | 18  | 17  | 16  |

## Register 2: I<sup>2</sup>C Master Control/Status (I2CMCS), offset 0x004

This register accesses status bits when read and control bits when written. When read, the status register indicates the state of the I<sup>2</sup>C bus controller. When written, the control register configures the I<sup>2</sup>C controller operation.

The START bit generates the START or REPEATED START condition. The STOP bit determines if the cycle stops at the end of the data cycle or continues on to a repeated START condition. To generate a single transmit cycle, the **I<sup>2</sup>C Master Slave Address (I2CMSA)** register is written with the desired address, the R/S bit is cleared, and this register is written with ACK=X (0 or 1), STOP=1, START=1, and RUN=1 to perform the operation and stop. When the operation is completed (or aborted due an error), an interrupt becomes active and the data may be read from the **I2CMDR** register. When the I<sup>2</sup>C module operates in Master receiver mode, the ACK bit is normally set, causing the I<sup>2</sup>C bus controller to transmit an acknowledge automatically after each byte. This bit must be cleared when the I<sup>2</sup>C bus controller requires no further data to be transmitted from the slave transmitter.

|                 | All other combinations not listed are non-operations. |             |      |       |     | NOP.                                                                                                                 |

a. An X in a table cell indicates the bit can be 0 or 1.

b. In Master Receive mode, a STOP condition should be generated only after a Data Negative Acknowledge executed by the master or an Address Negative Acknowledge executed by the slave.

### Register 3: I<sup>2</sup>C Master Data (I2CMDR), offset 0x008

**Important:** This register is read-sensitive. See the register description for details.

This register contains the data to be transmitted when in the Master Transmit state and the data received when in the Master Receive state.

|-----------|----------|------|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:1      | reserved | RO   | 0     | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation. |
| 0         | RIS      | RO   | 0     | Raw Interrupt Status                                                                                                                                                                          |

**Value Description**

|   |                                |
|---|--------------------------------|
| 1 | A master interrupt is pending. |
| 0 | No interrupt.                  |

This bit is cleared by writing a 1 to the IC bit in the **I2CMICR** register.

## Register 7: I<sup>2</sup>C Master Masked Interrupt Status (I2CMMIS), offset 0x018

This register specifies whether an interrupt was signaled.

### I2C Master Masked Interrupt Status (I2CMMIS)

I2C 0 base: 0x4002.0000

Offset 0x018

Type RO, reset 0x0000.0000

## 15.7 Register Descriptions (I<sup>2</sup>C Slave)

The remainder of this section lists and describes the I<sup>2</sup>C slave registers, in numerical order by address offset.

**Register 10: I<sup>2</sup>C Slave Own Address (I2CSOAR), offset 0x800**

This register consists of seven address bits that identify the Stellaris I<sup>2</sup>C device on the I<sup>2</sup>C bus.

**I2C Slave Own Address (I2CSOAR)**

I2C 0 base: 0x4002.0000

Offset 0x800

Type R/W, reset 0x0000.0000

## Register 11: I<sup>2</sup>C Slave Control/Status (I2CSCSR), offset 0x804

This register functions as a control register when written, and a status register when read.

### Read-Only Status Register

#### I2C Slave Control/Status (I2CSCSR)

I2C 0 base: 0x4002.0000

## Register 12: I<sup>2</sup>C Slave Data (I2CSDR), offset 0x808

**Important:** This register is read-sensitive. See the register description for details.

This register contains the data to be transmitted when in the Slave Transmit state, and the data received when in the Slave Receive state.

## 16 Controller Area Network (CAN) Module

Controller Area Network (CAN) is a multicast, shared serial bus standard for connecting electronic control units (ECUs). CAN was specifically designed to be robust in electromagnetically-noisy environments and can utilize a differential balanced line like RS-485 or a more robust twisted-pair wire. Originally created for automotive purposes, it is also used in many embedded control applications (such as industrial and medical). Bit rates up to 1 Mbps are possible at network lengths less than 40 meters. Decreased bit rates allow longer network distances (for example, 125 Kbps at 500 meters).

The Stellaris<sup>®</sup> LM3S8C62 microcontroller includes one CAN unit with the following features:

- CAN protocol version 2.0 part A/B
- Bit rates up to 1 Mbps
- 32 message objects with individual identifier masks
- Maskable interrupt
- Disable Automatic Retransmission mode for Time-Triggered CAN (TTCAN) applications
- Programmable Loopback mode for self-test operation
- Programmable FIFO mode enables storage of multiple message objects
- Gluelessly attaches to an external CAN transceiver through the CANnTX and CANnRX signals

## 16.1 Block Diagram

Figure 16-1. CAN Controller Block Diagram

## 16.2 Signal Description

The following table lists the external signals of the CAN controller and describes the function of each. The CAN controller signals are alternate functions for some GPIO signals and default to be GPIO signals at reset. The column in the table below titled "Pin Mux/Pin Assignment" lists the possible GPIO pin placements for the CAN signals. The AFSEL bit in the **GPIO Alternate Function Select (GPIOAFSEL)** register (page 433) should be set to choose the CAN controller function. The number in parentheses is the encoding that must be programmed into the PMCN field in the **GPIO Port Control (GPIOPCTL)** register (page 450) to assign the CAN signal to the specified GPIO port pin. For more information on configuring GPIOs, see "General-Purpose Input/Outputs (GPIOs)" on page 410.

**Table 16-1. Signals for Controller Area Network (100LQFP)**

a. The TTL designation indicates the pin has TTL-compatible voltage levels.

## 16.3 Functional Description

The Stellaris CAN controller conforms to the CAN protocol version 2.0 (parts A and B). Message transfers that include data, remote, error, and overload frames with an 11-bit identifier (standard) or a 29-bit identifier (extended) are supported. Transfer rates can be programmed up to 1 Mbps.

The CAN module consists of three major parts:

- CAN protocol controller and message handler
- Message memory
- CAN register interface

A data frame contains data for transmission, whereas a remote frame contains no data and is used to request the transmission of a specific message object. The CAN data/remote frame is constructed as shown in Figure 16-2.

Figure 16-2. CAN Data/Remote Frame

The protocol controller transfers and receives the serial data from the CAN bus and passes the data on to the message handler. The message handler then loads this information into the appropriate message object based on the current filtering and identifiers in the message object memory. The message handler is also responsible for generating interrupts based on events on the CAN bus.

The message object memory is a set of 32 identical memory blocks that hold the current configuration, status, and actual data for each message object. These memory blocks are accessed via either of the CAN message object register interfaces.

The message memory is not directly accessible in the Stellaris memory map, so the Stellaris CAN controller provides an interface to communicate with the message memory via two CAN interface register sets for communicating with the message objects. The message object memory cannot be directly accessed, so these two interfaces must be used to read or write to each message object. The two message object interfaces allow parallel access to the CAN controller message objects when multiple objects may have new information that must be processed. In general, one interface is used for transmit data and one for receive data.

### 16.3.1 Initialization

To use the CAN controller, the peripheral clock must be enabled using the **RCGC0** register (see page 249). In addition, the clock to the appropriate GPIO module must be enabled via the **RCGC2** register (see page 266). To find out which GPIO port to enable, refer to Table 22-4 on page 987. Set the GPIO AFSEL bits for the appropriate pins (see page 433). Configure the PMCN fields in the **GPIOCTL** register to assign the CAN signals to the appropriate pins. See page 450 and Table 22-5 on page 994.

Software initialization is started by setting the INIT bit in the **CAN Control (CANCTL)** register (with software or by a hardware reset) or by going bus-off, which occurs when the transmitter's error counter exceeds a count of 255. While INIT is set, all message transfers to and from the CAN bus are stopped and the CANnTX signal is held High. Entering the initialization state does not change the configuration of the CAN controller, the message objects, or the error counters. However, some configuration registers are only accessible while in the initialization state.

To initialize the CAN controller, set the **CAN Bit Timing (CANBIT)** register and configure each message object. If a message object is not needed, label it as not valid by clearing the MSGVAL bit in the **CAN IFn Arbitration 2 (CANIFnARB2)** register. Otherwise, the whole message object must be initialized, as the fields of the message object may not have valid information, causing unexpected results. Both the INIT and CCE bits in the **CANCTL** register must be set in order to access the **CANBIT** register and the **CAN Baud Rate Prescaler Extension (CANBRPE)** register to configure the bit timing. To leave the initialization state, the INIT bit must be cleared. Afterwards, the internal Bit Stream Processor (BSP) synchronizes itself to the data transfer on the CAN bus by waiting for the occurrence of a sequence of 11 consecutive recessive bits (indicating a bus idle condition) before it takes part in bus activities and starts message transfers. Message object initialization does not require the CAN to be in the initialization state and can be done on the fly. However, message objects should all be configured to particular identifiers or set to not valid before message transfer starts. To change the configuration of a message object during normal operation, clear the MSGVAL bit in the **CANIFnARB2** register to indicate that the message object is not valid during the change. When the configuration is completed, set the MSGVAL bit again to indicate that the message object is once again valid.

### 16.3.2 Operation

Two sets of CAN Interface Registers (**CANIF1x** and **CANIF2x**) are used to access the message objects in the Message RAM. The CAN controller coordinates transfers to and from the Message RAM to and from the registers. The two sets are independent and identical and can be used to queue transactions. Generally, one interface is used to transmit data and one is used to receive data.

Once the CAN module is initialized and the INIT bit in the **CANCTL** register is cleared, the CAN module synchronizes itself to the CAN bus and starts the message transfer. As each message is received, it goes through the message handler's filtering process, and if it passes through the filter, is stored in the message object specified by the MNUM bit in the **CAN IFn Command Request (CANIFnCRQ)** register. The whole message (including all arbitration bits, data-length code, and eight data bytes) is stored in the message object. If the Identifier Mask (the MSK bits in the **CAN IFn Mask 1** and **CAN IFn Mask 2 (CANIFnMSKn)** registers) is used, the arbitration bits that are masked to "don't care" may be overwritten in the message object.

The CPU may read or write each message at any time via the CAN Interface Registers. The message handler guarantees data consistency in case of concurrent accesses.

The transmission of message objects is under the control of the software that is managing the CAN hardware. Message objects can be used for one-time data transfers or can be permanent message objects used to respond in a more periodic manner. Permanent message objects have all arbitration and control set up, and only the data bytes are updated. At the start of transmission, the appropriate TXRQST bit in the **CAN Transmission Request n (CANTXRQn)** register and the NEWDAT bit in the **CAN New Data n (CANNWDAn)** register are set. If several transmit messages are assigned to the same message object (when the number of message objects is not sufficient), the whole message object has to be configured before the transmission of this message is requested.

The transmission of any number of message objects may be requested at the same time; they are transmitted according to their internal priority, which is based on the message identifier (MNUM) for the message object, with 1 being the highest priority and 32 being the lowest priority. Messages may be updated or set to not valid any time, even when their requested transmission is still pending. The old data is discarded when a message is updated before its pending transmission has started. Depending on the configuration of the message object, the transmission of a message may be requested autonomously by the reception of a remote frame with a matching identifier.

Transmission can be automatically started by the reception of a matching remote frame. To enable this mode, set the **RMTEN** bit in the **CAN IFn Message Control (CANIFnMCTL)** register. A matching received remote frame causes the **TXRQST** bit to be set, and the message object automatically transfers its data or generates an interrupt indicating a remote frame was requested. A remote frame can be strictly a single message identifier, or it can be a range of values specified in the message object. The CAN mask registers, **CANIFnMSKn**, configure which groups of frames are identified as remote frame requests. The **UMASK** bit in the **CANIFnMCTL** register enables the **MSK** bits in the **CANIFnMSKn** register to filter which frames are identified as a remote frame request. The **MXTD** bit in the **CANIFnMSK2** register should be set if a remote frame request is expected to be triggered by 29-bit extended identifiers.

### 16.3.3 Transmitting Message Objects

If the internal transmit shift register of the CAN module is ready for loading, and if a data transfer is not occurring between the CAN Interface Registers and message RAM, the valid message object with the highest priority that has a pending transmission request is loaded into the transmit shift register by the message handler and the transmission is started. The message object's **NEWDAT** bit in the **CANNWDAn** register is cleared. After a successful transmission, and if no new data was written to the message object since the start of the transmission, the **TXRQST** bit in the **CANTXRQn** register is cleared. If the CAN controller is configured to interrupt on a successful transmission of a message object, (the **TXIE** bit in the **CAN IFn Message Control (CANIFnMCTL)** register is set), the **INTPND** bit in the **CANIFnMCTL** register is set after a successful transmission. If the CAN module has lost the arbitration or if an error occurred during the transmission, the message is re-transmitted as soon as the CAN bus is free again. If, meanwhile, the transmission of a message with higher priority has been requested, the messages are transmitted in the order of their priority.

### 16.3.4 Configuring a Transmit Message Object

The following steps illustrate how to configure a transmit message object.

1. In the **CAN IFn Command Mask (CANIFnCMASK)** register:
  - Set the **WRNRD** bit to specify a write to the **CANIFnCMASK** register; specify whether to transfer the **IDMASK**, **DIR**, and **MXTD** of the message object into the **CAN IFn** registers using the **MASK** bit
  - Specify whether to transfer the **ID**, **DIR**, **XTD**, and **MSGVAL** of the message object into the interface registers using the **ARB** bit
  - Specify whether to transfer the control bits into the interface registers using the **CONTROL** bit
  - Specify whether to clear the **INTPND** bit in the **CANIFnMCTL** register using the **CLRINTPND** bit
  - Specify whether to clear the **NEWDAT** bit in the **CANNWDAn** register using the **NEWDAT** bit
  - Specify which bits to transfer using the **DATAA** and **DATAB** bits
2. In the **CANIFnMSK1** register, use the **MSK[15:0]** bits to specify which of the bits in the 29-bit or 11-bit message identifier are used for acceptance filtering. Note that **MSK[15:0]** in this register are used for bits [15:0] of the 29-bit message identifier and are not used for an 11-bit identifier. A value of 0x00 enables all messages to pass through the acceptance filtering. Also

note that in order for these bits to be used for acceptance filtering, they must be enabled by setting the UMASK bit in the **CANIFnMCTL** register.

3. In the **CANIFnMSK2** register, use the MSK[12:0] bits to specify which of the bits in the 29-bit or 11-bit message identifier are used for acceptance filtering. Note that MSK[12:0] are used for bits [28:16] of the 29-bit message identifier; whereas MSK[12:2] are used for bits [10:0] of the 11-bit message identifier. Use the MXTD and MDIR bits to specify whether to use XTD and DIR for acceptance filtering. A value of 0x00 enables all messages to pass through the acceptance filtering. Also note that in order for these bits to be used for acceptance filtering, they must be enabled by setting the UMASK bit in the **CANIFnMCTL** register.
4. For a 29-bit identifier, configure ID[15:0] in the **CANIFnARB1** register to are used for bits [15:0] of the message identifier and ID[12:0] in the **CANIFnARB2** register to are used for bits [28:16] of the message identifier. Set the XTD bit to indicate an extended identifier; set the DIR bit to indicate transmit; and set the MSGVAL bit to indicate that the message object is valid.
5. For an 11-bit identifier, disregard the **CANIFnARB1** register and configure ID[12:2] in the **CANIFnARB2** register to are used for bits [10:0] of the message identifier. Clear the XTD bit to indicate a standard identifier; set the DIR bit to indicate transmit; and set the MSGVAL bit to indicate that the message object is valid.
6. In the **CANIFnMCTL** register:
  - Optionally set the UMASK bit to enable the mask (MSK, MXTD, and MDIR specified in the **CANIFnMSK1** and **CANIFnMSK2** registers) for acceptance filtering
  - Optionally set the TXIE bit to enable the INTPND bit to be set after a successful transmission
  - Optionally set the RMTEN bit to enable the TXRQST bit to be set on the reception of a matching remote frame allowing automatic transmission
  - Set the EOB bit for a single message object
  - Configure the DLC[3:0] field to specify the size of the data frame. Take care during this configuration not to set the NEWDAT, MSGLST, INTPND or TXRQST bits.
7. Load the data to be transmitted into the **CAN IFn Data (CANIFnDA1, CANIFnDA2, CANIFnDB1, CANIFnDB2)** registers. Byte 0 of the CAN data frame is stored in DATA[7:0] in the **CANIFnDA1** register.
8. Program the number of the message object to be transmitted in the MNUM field in the **CAN IFn Command Request (CANIFnCRQ)** register.
9. When everything is properly configured, set the TXRQST bit in the **CANIFnMCTL** register. Once this bit is set, the message object is available to be transmitted, depending on priority and bus availability. Note that setting the RMTEN bit in the **CANIFnMCTL** register can also start message transmission if a matching remote frame has been received.

### 16.3.5 Updating a Transmit Message Object

The CPU may update the data bytes of a Transmit Message Object any time via the CAN Interface Registers and neither the MSGVAL bit in the **CANIFnARB2** register nor the TXRQST bits in the **CANIFnMCTL** register have to be cleared before the update.

Even if only some of the data bytes are to be updated, all four bytes of the corresponding **CANIFnDAn/CANIFnDBn** register have to be valid before the content of that register is transferred to the message object. Either the CPU must write all four bytes into the **CANIFnDAn/CANIFnDBn** register or the message object is transferred to the **CANIFnDAn/CANIFnDBn** register before the CPU writes the new data bytes.

In order to only update the data in a message object, the WRNRD, DATAA and DATAB bits in the **CANIFnMSKn** register are set, followed by writing the updated data into **CANIFnDA1**, **CANIFnDA2**, **CANIFnDB1**, and **CANIFnDB2** registers, and then the number of the message object is written to the MNUM field in the **CAN IFn Command Request (CANIFnCRQ)** register. To begin transmission of the new data as soon as possible, set the TXRQST bit in the **CANIFnMSKn** register.

To prevent the clearing of the TXRQST bit in the **CANIFnMCTL** register at the end of a transmission that may already be in progress while the data is updated, the NEWDAT and TXRQST bits have to be set at the same time in the **CANIFnMCTL** register. When these bits are set at the same time, NEWDAT is cleared as soon as the new transmission has started.

### 16.3.6 Accepting Received Message Objects

When the arbitration and control field (the ID and XTD bits in the **CANIFnARB2** and the RMTEN and DLC[3:0] bits of the **CANIFnMCTL** register) of an incoming message is completely shifted into the CAN controller, the message handling capability of the controller starts scanning the message RAM for a matching valid message object. To scan the message RAM for a matching message object, the controller uses the acceptance filtering programmed through the mask bits in the **CANIFnMSKn** register and enabled using the UMASK bit in the **CANIFnMCTL** register. Each valid message object, starting with object 1, is compared with the incoming message to locate a matching message object in the message RAM. If a match occurs, the scanning is stopped and the message handler proceeds depending on whether it is a data frame or remote frame that was received.

### 16.3.7 Receiving a Data Frame

The message handler stores the message from the CAN controller receive shift register into the matching message object in the message RAM. The data bytes, all arbitration bits, and the DLC bits are all stored into the corresponding message object. In this manner, the data bytes are connected with the identifier even if arbitration masks are used. The NEWDAT bit of the **CANIFnMCTL** register is set to indicate that new data has been received. The CPU should clear this bit when it reads the message object to indicate to the controller that the message has been received, and the buffer is free to receive more messages. If the CAN controller receives a message and the NEWDAT bit is already set, the MSGST bit in the **CANIFnMCTL** register is set to indicate that the previous data was lost. If the system requires an interrupt on successful reception of a frame, the RXIE bit of the **CANIFnMCTL** register should be set. In this case, the INTPND bit of the same register is set, causing the **CANINT** register to point to the message object that just received a message. The TXRQST bit of this message object should be cleared to prevent the transmission of a remote frame.

### 16.3.8 Receiving a Remote Frame

A remote frame contains no data, but instead specifies which object should be transmitted. When a remote frame is received, three different configurations of the matching message object have to be considered:

Table 16-3. Message Object Configurations

| Configuration in CANIFnMCTL                                                                                                                                                                                                                                                                                                                                       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <ul style="list-style-type: none"> <li>■ DIR = 1 (direction = transmit); programmed in the <b>CANIFnARB2</b> register</li> <li>■ RMTEN = 1 (set the TXRQST bit of the <b>CANIFnMCTL</b> register at reception of the frame to enable transmission)</li> <li>■ UMASK = 1 or 0</li> </ul>                                                                           | At the reception of a matching remote frame, the TXRQST bit of this message object is set. The rest of the message object remains unchanged, and the controller automatically transfers the data in the message object as soon as possible.                                                                                                                                                                                                                                                                                                                                                                                   |
| <ul style="list-style-type: none"> <li>■ DIR = 1 (direction = transmit); programmed in the <b>CANIFnARB2</b> register</li> <li>■ RMTEN = 0 (do not change the TXRQST bit of the <b>CANIFnMCTL</b> register at reception of the frame)</li> <li>■ UMASK = 0 (ignore mask in the <b>CANIFnMSKn</b> register)</li> </ul>                                             | At the reception of a matching remote frame, the TXRQST bit of this message object remains unchanged, and the remote frame is ignored. This remote frame is disabled, the data is not transferred and nothing indicates that the remote frame ever happened.                                                                                                                                                                                                                                                                                                                                                                  |
| <ul style="list-style-type: none"> <li>■ DIR = 1 (direction = transmit); programmed in the <b>CANIFnARB2</b> register</li> <li>■ RMTEN = 0 (do not change the TXRQST bit of the <b>CANIFnMCTL</b> register at reception of the frame)</li> <li>■ UMASK = 1 (use mask (MSK, MXTD, and MDIR in the <b>CANIFnMSKn</b> register) for acceptance filtering)</li> </ul> | At the reception of a matching remote frame, the TXRQST bit of this message object is cleared. The arbitration and control field (ID + XTD + RMTEN + DLC) from the shift register is stored into the message object in the message RAM, and the NEWDAT bit of this message object is set. The data field of the message object remains unchanged; the remote frame is treated similar to a received data frame. This mode is useful for a remote data request from another CAN device for which the Stellaris controller does not have readily available data. The software must fill the data and answer the frame manually. |

### 16.3.9 Receive/Transmit Priority

The receive/transmit priority for the message objects is controlled by the message number. Message object 1 has the highest priority, while message object 32 has the lowest priority. If more than one transmission request is pending, the message objects are transmitted in order based on the message object with the lowest message number. This prioritization is separate from that of the message identifier which is enforced by the CAN bus. As a result, if message object 1 and message object 2 both have valid messages to be transmitted, message object 1 is always transmitted first regardless of the message identifier in the message object itself.

### 16.3.10 Configuring a Receive Message Object

The following steps illustrate how to configure a receive message object.

1. Program the **CAN IFn Command Mask (CANIFnCMASK)** register as described in the “Configuring a Transmit Message Object” on page 759 section, except that the WRNRD bit is set to specify a write to the message RAM.
2. Program the **CANIFnMSK1** and **CANIFnMSK2** registers as described in the “Configuring a Transmit Message Object” on page 759 section to configure which bits are used for acceptance filtering. Note that in order for these bits to be used for acceptance filtering, they must be enabled by setting the UMASK bit in the **CANIFnMCTL** register.
3. In the **CANIFnMSK2** register, use the MSK[12:0] bits to specify which of the bits in the 29-bit or 11-bit message identifier are used for acceptance filtering. Note that MSK[12:0] are used for bits [28:16] of the 29-bit message identifier; whereas MSK[12:2] are used for bits [10:0] of the 11-bit message identifier. Use the MXTD and MDIR bits to specify whether to use XTD and

DIR for acceptance filtering. A value of 0x00 enables all messages to pass through the acceptance filtering. Also note that in order for these bits to be used for acceptance filtering, they must be enabled by setting the UMASK bit in the **CANIFnMCTL** register.

4. Program the **CANIFnARB1** and **CANIFnARB2** registers as described in the “Configuring a Transmit Message Object” on page 759 section to program XTD and ID bits for the message identifier to be received; set the MSGVAL bit to indicate a valid message; and clear the DIR bit to specify receive.
5. In the **CANIFnMCTL** register:
  - Optionally set the UMASK bit to enable the mask (MSK, MXTD, and MDIR specified in the **CANIFnMSK1** and **CANIFnMSK2** registers) for acceptance filtering
  - Optionally set the RXIE bit to enable the INTPND bit to be set after a successful reception
  - Clear the RMTEN bit to leave the TXRQST bit unchanged
  - Set the EOB bit for a single message object
  - Configure the DLC[3:0] field to specify the size of the data frame

Take care during this configuration not to set the NEWDAT, MSGLST, INTPND or TXRQST bits.
6. Program the number of the message object to be received in the MNUM field in the **CAN IFn Command Request (CANIFnCRQ)** register. Reception of the message object begins as soon as a matching frame is available on the CAN bus.

When the message handler stores a data frame in the message object, it stores the received Data Length Code and eight data bytes in the **CANIFnDA1**, **CANIFnDA2**, **CANIFnDB1**, and **CANIFnDB2** register. Byte 0 of the CAN data frame is stored in DATA[7:0] in the **CANIFnDA1** register. If the Data Length Code is less than 8, the remaining bytes of the message object are overwritten by unspecified values.

The CAN mask registers can be used to allow groups of data frames to be received by a message object. The CAN mask registers, **CANIFnMSKn**, configure which groups of frames are received by a message object. The UMASK bit in the **CANIFnMCTL** register enables the MSK bits in the **CANIFnMSKn** register to filter which frames are received. The MXTD bit in the **CANIFnMSK2** register should be set if only 29-bit extended identifiers are expected by this message object.

### 16.3.11 Handling of Received Message Objects

The CPU may read a received message any time via the CAN Interface registers because the data consistency is guaranteed by the message handler state machine.

Typically, the CPU first writes 0x007F to the **CANIFnCMSGK** register and then writes the number of the message object to the **CANIFnCRQ** register. That combination transfers the whole received message from the message RAM into the Message Buffer registers (**CANIFnMSKn**, **CANIFnARBn**, and **CANIFnMCTL**). Additionally, the NEWDAT and INTPND bits are cleared in the message RAM, acknowledging that the message has been read and clearing the pending interrupt generated by this message object.

If the message object uses masks for acceptance filtering, the **CANIFnARBn** registers show the full, unmasked ID for the received message.

The NEWDAT bit in the **CANIFnMCTL** register shows whether a new message has been received since the last time this message object was read. The MSGLST bit in the **CANIFnMCTL** register shows whether more than one message has been received since the last time this message object was read. MSGLST is not automatically cleared, and should be cleared by software after reading its status.

Using a remote frame, the CPU may request new data from another CAN node on the CAN bus. Setting the TXRQST bit of a receive object causes the transmission of a remote frame with the receive object's identifier. This remote frame triggers the other CAN node to start the transmission of the matching data frame. If the matching data frame is received before the remote frame could be transmitted, the TXRQST bit is automatically reset. This prevents the possible loss of data when the other device on the CAN bus has already transmitted the data slightly earlier than expected.

#### 16.3.11.1 Configuration of a FIFO Buffer

With the exception of the EOB bit in the **CANIFnMCTL** register, the configuration of receive message objects belonging to a FIFO buffer is the same as the configuration of a single receive message object (see "Configuring a Receive Message Object" on page 762). To concatenate two or more message objects into a FIFO buffer, the identifiers and masks (if used) of these message objects have to be programmed to matching values. Due to the implicit priority of the message objects, the message object with the lowest message object number is the first message object in a FIFO buffer. The EOB bit of all message objects of a FIFO buffer except the last one must be cleared. The EOB bit of the last message object of a FIFO buffer is set, indicating it is the last entry in the buffer.

#### 16.3.11.2 Reception of Messages with FIFO Buffers

Received messages with identifiers matching to a FIFO buffer are stored starting with the message object with the lowest message number. When a message is stored into a message object of a FIFO buffer, the NEWDAT of the **CANIFnMCTL** register bit of this message object is set. By setting NEWDAT while EOB is clear, the message object is locked and cannot be written to by the message handler until the CPU has cleared the NEWDAT bit. Messages are stored into a FIFO buffer until the last message object of this FIFO buffer is reached. Until all of the preceding message objects have been released by clearing the NEWDAT bit, all further messages for this FIFO buffer are written into the last message object of the FIFO buffer and therefore overwrite previous messages.

#### 16.3.11.3 Reading from a FIFO Buffer

When the CPU transfers the contents of a message object from a FIFO buffer by writing its number to the **CANIFnCRQ** register, the TXRQST and CLRINTPND bits in the **CANIFnCMSK** register should be set such that the NEWDAT and INTPEND bits in the **CANIFnMCTL** register are cleared after the read. The values of these bits in the **CANIFnMCTL** register always reflect the status of the message object before the bits are cleared. To assure the correct function of a FIFO buffer, the CPU should read out the message objects starting with the message object with the lowest message number. When reading from the FIFO buffer, the user should be aware that a new received message could be placed in the location of any message object for which the NEWDAT bit of the **CANIFnMCTL** register is clear. As a result, the order of the received messages in the FIFO is not guaranteed. Figure 16-3 on page 765 shows how a set of message objects which are concatenated to a FIFO Buffer can be handled by the CPU.

Figure 16-3. Message Objects in a FIFO Buffer

### 16.3.12 Handling of Interrupts

If several interrupts are pending, the **CAN Interrupt (CANINT)** register points to the pending interrupt with the highest priority, disregarding their chronological order. The status interrupt has the highest

priority. Among the message interrupts, the message object's interrupt with the lowest message number has the highest priority. A message interrupt is cleared by clearing the message object's INTPND bit in the **CANIFnMCTL** register or by reading the **CAN Status (CANSTS)** register. The status Interrupt is cleared by reading the **CANSTS** register.

The interrupt identifier INTID in the **CANINT** register indicates the cause of the interrupt. When no interrupt is pending, the register reads as 0x0000. If the value of the INTID field is different from 0, then an interrupt is pending. If the IE bit is set in the **CANCTL** register, the interrupt line to the interrupt controller is active. The interrupt line remains active until the INTID field is 0, meaning that all interrupt sources have been cleared (the cause of the interrupt is reset), or until IE is cleared, which disables interrupts from the CAN controller.

The INTID field of the **CANINT** register points to the pending message interrupt with the highest interrupt priority. The SIE bit in the **CANCTL** register controls whether a change of the RXOK, TXOK, and LEC bits in the **CANSTS** register can cause an interrupt. The EIE bit in the **CANCTL** register controls whether a change of the BOFF and EWARN bits in the **CANSTS** register can cause an interrupt. The IE bit in the **CANCTL** register controls whether any interrupt from the CAN controller actually generates an interrupt to the interrupt controller. The **CANINT** register is updated even when the IE bit in the **CANCTL** register is clear, but the interrupt is not indicated to the CPU.

A value of 0x8000 in the **CANINT** register indicates that an interrupt is pending because the CAN module has updated, but not necessarily changed, the **CANSTS** register, indicating that either an error or status interrupt has been generated. A write access to the **CANSTS** register can clear the RXOK, TXOK, and LEC bits in that same register; however, the only way to clear the source of a status interrupt is to read the **CANSTS** register.

The source of an interrupt can be determined in two ways during interrupt handling. The first is to read the INTID bit in the **CANINT** register to determine the highest priority interrupt that is pending, and the second is to read the **CAN Message Interrupt Pending (CANMSGnINT)** register to see all of the message objects that have pending interrupts.

An interrupt service routine reading the message that is the source of the interrupt may read the message and clear the message object's INTPND bit at the same time by setting the CLRINTPND bit in the **CANIFnCMSK** register. Once the INTPND bit has been cleared, the **CANINT** register contains the message number for the next message object with a pending interrupt.

### 16.3.13 Test Mode

A Test Mode is provided which allows various diagnostics to be performed. Test Mode is entered by setting the TEST bit in the **CANCTL** register. Once in Test Mode, the TX[1:0], LBACK, SILENT and BASIC bits in the **CAN Test (CANTST)** register can be used to put the CAN controller into the various diagnostic modes. The RX bit in the **CANTST** register allows monitoring of the CANnRX signal. All **CANTST** register functions are disabled when the TEST bit is cleared.

#### 16.3.13.1 Silent Mode

Silent Mode can be used to analyze the traffic on a CAN bus without affecting it by the transmission of dominant bits (Acknowledge Bits, Error Frames). The CAN Controller is put in Silent Mode setting the SILENT bit in the **CANTST** register. In Silent Mode, the CAN controller is able to receive valid data frames and valid remote frames, but it sends only recessive bits on the CAN bus and cannot start a transmission. If the CAN Controller is required to send a dominant bit (ACK bit, overload flag, or active error flag), the bit is rerouted internally so that the CAN Controller monitors this dominant bit, although the CAN bus remains in recessive state.

### 16.3.13.2 Loopback Mode

Loopback mode is useful for self-test functions. In Loopback Mode, the CAN Controller internally routes the CANnTX signal on to the CANnRX signal and treats its own transmitted messages as received messages and stores them (if they pass acceptance filtering) into the message buffer. The CAN Controller is put in Loopback Mode by setting the LBACK bit in the **CANTST** register. To be independent from external stimulation, the CAN Controller ignores acknowledge errors (a recessive bit sampled in the acknowledge slot of a data/remote frame) in Loopback Mode. The actual value of the CANnRX signal is disregarded by the CAN Controller. The transmitted messages can be monitored on the CANnTX signal.

### 16.3.13.3 Loopback Combined with Silent Mode

Loopback Mode and Silent Mode can be combined to allow the CAN Controller to be tested without affecting a running CAN system connected to the CANnTX and CANnRX signals. In this mode, the CANnRX signal is disconnected from the CAN Controller and the CANnTX signal is held recessive. This mode is enabled by setting both the LBACK and SILENT bits in the **CANTST** register.

### 16.3.13.4 Basic Mode

Basic Mode allows the CAN Controller to be operated without the Message RAM. In Basic Mode, The CANIF1 registers are used as the transmit buffer. The transmission of the contents of the IF1 registers is requested by setting the BUSY bit of the **CANIF1CRQ** register. The CANIF1 registers are locked while the BUSY bit is set. The BUSY bit indicates that a transmission is pending. As soon the CAN bus is idle, the CANIF1 registers are loaded into the shift register of the CAN Controller and transmission is started. When the transmission has completed, the BUSY bit is cleared and the locked CANIF1 registers are released. A pending transmission can be aborted at any time by clearing the BUSY bit in the **CANIF1CRQ** register while the CANIF1 registers are locked. If the CPU has cleared the BUSY bit, a possible retransmission in case of lost arbitration or an error is disabled.

The CANIF2 Registers are used as a receive buffer. After the reception of a message, the contents of the shift register are stored in the CANIF2 registers, without any acceptance filtering. Additionally, the actual contents of the shift register can be monitored during the message transfer. Each time a read message object is initiated by setting the BUSY bit of the **CANIF2CRQ** register, the contents of the shift register are stored into the CANIF2 registers.

In Basic Mode, all message-object-related control and status bits and of the control bits of the **CANIFnCMSK** registers are not evaluated. The message number of the **CANIFnCRQ** registers is also not evaluated. In the **CANIF2MCTL** register, the NEWDAT and MSGLST bits retain their function, the DLC[3:0] field shows the received DLC, the other control bits are cleared.

Basic Mode is enabled by setting the BASIC bit in the **CANTST** register.

### 16.3.13.5 Transmit Control

Software can directly override control of the CANnTX signal in four different ways.

- CANnTX is controlled by the CAN Controller
- The sample point is driven on the CANnTX signal to monitor the bit timing
- CANnTX drives a low value
- CANnTX drives a high value

The last two functions, combined with the readable CAN receive pin CANnRX, can be used to check the physical layer of the CAN bus.

The Transmit Control function is enabled by programming the TX[1:0] field in the **CANTST** register. The three test functions for the CANnTX signal interfere with all CAN protocol functions. TX[1:0] must be cleared when CAN message transfer or Loopback Mode, Silent Mode, or Basic Mode are selected.

### 16.3.14 Bit Timing Configuration Error Considerations

Even if minor errors in the configuration of the CAN bit timing do not result in immediate failure, the performance of a CAN network can be reduced significantly. In many cases, the CAN bit synchronization amends a faulty configuration of the CAN bit timing to such a degree that only occasionally an error frame is generated. In the case of arbitration, however, when two or more CAN nodes simultaneously try to transmit a frame, a misplaced sample point may cause one of the transmitters to become error passive. The analysis of such sporadic errors requires a detailed knowledge of the CAN bit synchronization inside a CAN node and of the CAN nodes' interaction on the CAN bus.

### 16.3.15 Bit Time and Bit Rate

The CAN system supports bit rates in the range of lower than 1 Kbps up to 1000 Kbps. Each member of the CAN network has its own clock generator. The timing parameter of the bit time can be configured individually for each CAN node, creating a common bit rate even though the CAN nodes' oscillator periods may be different.

Because of small variations in frequency caused by changes in temperature or voltage and by deteriorating components, these oscillators are not absolutely stable. As long as the variations remain inside a specific oscillator's tolerance range, the CAN nodes are able to compensate for the different bit rates by periodically resynchronizing to the bit stream.

According to the CAN specification, the bit time is divided into four segments (see Figure 16-4 on page 769): the Synchronization Segment, the Propagation Time Segment, the Phase Buffer Segment 1, and the Phase Buffer Segment 2. Each segment consists of a specific, programmable number of time quanta (see Table 16-4 on page 769). The length of the time quantum ( $t_q$ ), which is the basic time unit of the bit time, is defined by the CAN controller's input clock ( $f_{sys}$ ) and the Baud Rate Prescaler (BRP):

$$t_q = \text{BRP} / f_{sys}$$

The  $f_{sys}$  input clock is the system clock frequency as configured by the **RCC** or **RCC2** registers (see page 208 or page 215).

The Synchronization Segment Sync is that part of the bit time where edges of the CAN bus level are expected to occur; the distance between an edge that occurs outside of Sync and the Sync is called the phase error of that edge.

The Propagation Time Segment Prop is intended to compensate for the physical delay times within the CAN network.

The Phase Buffer Segments Phase1 and Phase2 surround the Sample Point.

The (Re-)Synchronization Jump Width (SJW) defines how far a resynchronization may move the Sample Point inside the limits defined by the Phase Buffer Segments to compensate for edge phase errors.

A given bit rate may be met by different bit-time configurations, but for the proper function of the CAN network, the physical delay times and the oscillator's tolerance range have to be considered.

Figure 16-4. CAN Bit Time

Table 16-4. CAN Protocol Ranges<sup>a</sup>

| Parameter | Range          | Remark                                                                                                              |
|-----------|----------------|---------------------------------------------------------------------------------------------------------------------|
| BRP       | [1 .. 64]      | Defines the length of the time quantum $t_q$ . The <b>CANBRPE</b> register can be used to extend the range to 1024. |
| Sync      | 1 $t_q$        | Fixed length, synchronization of bus input to system clock                                                          |
| Prop      | [1 .. 8] $t_q$ | Compensates for the physical delay times                                                                            |
| Phase1    | [1 .. 8] $t_q$ | May be lengthened temporarily by synchronization                                                                    |
| Phase2    | [1 .. 8] $t_q$ | May be shortened temporarily by synchronization                                                                     |
| SJW       | [1 .. 4] $t_q$ | May not be longer than either Phase Buffer Segment                                                                  |

a. This table describes the minimum programmable ranges required by the CAN protocol.

The bit timing configuration is programmed in two register bytes in the **CANBIT** register. In the **CANBIT** register, the four components TSEG2, TSEG1, SJW, and BRP have to be programmed to a numerical value that is one less than its functional value; so instead of values in the range of [1..n], values in the range of [0..n-1] are programmed. That way, for example, SJW (functional range of [1..4]) is represented by only two bits in the SJW bit field. Table 16-5 shows the relationship between the **CANBIT** register values and the parameters.

Table 16-5. CANBIT Register Values

| CANBIT Register Field | Setting           |
|-----------------------|-------------------|
| TSEG2                 | Phase2 - 1        |
| TSEG1                 | Prop + Phase1 - 1 |
| SJW                   | SJW - 1           |
| BRP                   | BRP               |

Therefore, the length of the bit time is (programmed values):

$$[TSEG1 + TSEG2 + 3] \times t_q$$

or (functional values):

$$[Sync + Prop + Phase1 + Phase2] \times t_q$$

The data in the **CANBIT** register is the configuration input of the CAN protocol controller. The baud rate prescaler (configured by the BRP field) defines the length of the time quantum, the basic time

unit of the bit time; the bit timing logic (configured by TSEG1, TSEG2, and SJW) defines the number of time quanta in the bit time.

The processing of the bit time, the calculation of the position of the sample point, and occasional synchronizations are controlled by the CAN controller and are evaluated once per time quantum.

The CAN controller translates messages to and from frames. In addition, the controller generates and discards the enclosing fixed format bits, inserts and extracts stuff bits, calculates and checks the CRC code, performs the error management, and decides which type of synchronization is to be used. The bit value is received or transmitted at the sample point. The information processing time (IPT) is the time after the sample point needed to calculate the next bit to be transmitted on the CAN bus. The IPT includes any of the following: retrieving the next data bit, handling a CRC bit, determining if bit stuffing is required, generating an error flag or simply going idle.

The IPT is application-specific but may not be longer than  $2 t_q$ ; the CAN's IPT is  $0 t_q$ . Its length is the lower limit of the programmed length of Phase2. In case of synchronization, Phase2 may be shortened to a value less than IPT, which does not affect bus timing.

### 16.3.16 Calculating the Bit Timing Parameters

Usually, the calculation of the bit timing configuration starts with a required bit rate or bit time. The resulting bit time (1/bit rate) must be an integer multiple of the system clock period.

The bit time may consist of 4 to 25 time quanta. Several combinations may lead to the required bit time, allowing iterations of the following steps.

The first part of the bit time to be defined is Prop. Its length depends on the delay times measured in the system. A maximum bus length as well as a maximum node delay has to be defined for expandable CAN bus systems. The resulting time for Prop is converted into time quanta (rounded up to the nearest integer multiple of  $t_q$ ).

Sync is  $1 t_q$  long (fixed), which leaves  $(\text{bit time} - \text{Prop} - 1) t_q$  for the two Phase Buffer Segments. If the number of remaining  $t_q$  is even, the Phase Buffer Segments have the same length, that is,  $\text{Phase2} = \text{Phase1}$ , else  $\text{Phase2} = \text{Phase1} + 1$ .

The minimum nominal length of Phase2 has to be regarded as well. Phase2 may not be shorter than the CAN controller's Information Processing Time, which is, depending on the actual implementation, in the range of  $[0..2] t_q$ .

The length of the synchronization jump width is set to the least of 4, Phase1 or Phase2.

The oscillator tolerance range necessary for the resulting configuration is calculated by the formula given below:

$$(1 - df) \times f_{nom} \leq f_{osc} \leq (1 + df) \times f_{nom}$$

where:

- $df$  = Maximum tolerance of oscillator frequency
- $f_{osc}$  = Actual oscillator frequency
- $f_{nom}$  = Nominal oscillator frequency

Maximum frequency tolerance must take into account the following formulas:

$$df \leq \frac{(Phase\_seg1, Phase\_seg2) \min}{2 \times (13 \times t_{bit} - Phase\_Seg2)}$$

$$df_{max} = 2 \times df \times f_{nom}$$

where:

- Phase1 and Phase2 are from Table 16-4 on page 769
- $t_{bit}$  = Bit Time
- $df_{max}$  = Maximum difference between two oscillators

If more than one configuration is possible, that configuration allowing the highest oscillator tolerance range should be chosen.

CAN nodes with different system clocks require different configurations to come to the same bit rate. The calculation of the propagation time in the CAN network, based on the nodes with the longest delay times, is done once for the whole network.

The CAN system's oscillator tolerance range is limited by the node with the lowest tolerance range.

The calculation may show that bus length or bit rate have to be decreased or that the oscillator frequencies' stability has to be increased in order to find a protocol-compliant configuration of the CAN bit timing.

### 16.3.16.1 Example for Bit Timing at High Baud Rate

In this example, the frequency of CAN clock is 25 MHz, and the bit rate is 1 Mbps.

$$\text{bit time} = 1 \mu\text{s} = n * t_q = 5 * t_q$$

$$t_q = 200 \text{ ns}$$

$$t_q = (\text{Baud rate Prescaler}) / \text{CAN Clock}$$

$$\text{Baud rate Prescaler} = t_q * \text{CAN Clock}$$

$$\text{Baud rate Prescaler} = 200\text{E}-9 * 25\text{E}6 = 5$$

$$t_{\text{Sync}} = 1 * t_q = 200 \text{ ns}$$

\\fixed at 1 time quanta

delay of bus driver 50 ns

delay of receiver circuit 30 ns

delay of bus line (40m) 220 ns

$$t_{\text{Prop}} 400 \text{ ns} = 2 * t_q$$

\\400 is next integer multiple of  $t_q$

$$\text{bit time} = t_{\text{Sync}} + t_{\text{TSeg1}} + t_{\text{TSeg2}} = 5 * t_q$$

$$\text{bit time} = t_{\text{Sync}} + t_{\text{Prop}} + t_{\text{Phase 1}} + t_{\text{Phase 2}}$$

$$t_{\text{Phase 1}} + t_{\text{Phase 2}} = \text{bit time} - t_{\text{Sync}} - t_{\text{Prop}}$$

$$t_{\text{Phase 1}} + t_{\text{Phase 2}} = (5 * t_q) - (1 * t_q) - (2 * t_q)$$

$$t_{\text{Phase 1}} + t_{\text{Phase 2}} = 2 * t_q$$

$$t_{\text{Phase1}} = 1 * t_q$$

$$t_{\text{Phase2}} = 1 * t_q$$

\\tPhase2 = tPhase1

$$tTSeg1 = tProp + tPhase1$$

$$tTSeg1 = (2 * t_q) + (1 * t_q)$$

$$tTSeg1 = 3 * t_q$$

$$tTSeg2 = tPhase2$$

$$tTSeg2 = (\text{Information Processing Time} + 1) * t_q$$

$$tTSeg2 = 1 * t_q \quad \backslash\backslash \text{Assumes IPT}=0$$

$$tSJW = 1 * t_q \quad \backslash\backslash \text{Least of 4, Phase1 and Phase2}$$

In the above example, the bit field values for the **CANBIT** register are:

|       |                                           |
|-------|-------------------------------------------|
| TSEG2 | = TSeg2 -1<br>= 1-1<br>= 0                |
| TSEG1 | = TSeg1 -1<br>= 3-1<br>= 2                |
| SJW   | = SJW -1<br>= 1-1<br>= 0                  |
| BRP   | = Baud rate prescaler - 1<br>= 5-1<br>= 4 |

The final value programmed into the **CANBIT** register = 0x0204.

### 16.3.16.2 Example for Bit Timing at Low Baud Rate

In this example, the frequency of the CAN clock is 50 MHz, and the bit rate is 100 Kbps.

$$\text{bit time} = 10 \mu\text{s} = n * t_q = 10 * t_q$$

$$t_q = 1 \mu\text{s}$$

$$t_q = (\text{Baud rate Prescaler}) / \text{CAN Clock}$$

$$\text{Baud rate Prescaler} = t_q * \text{CAN Clock}$$

$$\text{Baud rate Prescaler} = 1\text{E-}6 * 50\text{E}6 = 50$$

$$tSync = 1 * t_q = 1 \mu\text{s} \quad \backslash\backslash \text{fixed at 1 time quanta}$$

$$\text{delay of bus driver } 200 \text{ ns}$$

$$\text{delay of receiver circuit } 80 \text{ ns}$$

$$\text{delay of bus line (40m) } 220 \text{ ns}$$

$$tProp 1 \mu\text{s} = 1 * t_q \quad \backslash\backslash 1 \mu\text{s is next integer multiple of } t_q$$

$$\text{bit time} = tSync + tTSeg1 + tTSeg2 = 10 * t_q$$

$$\text{bit time} = tSync + tProp + tPhase 1 + tPhase2$$

$$tPhase 1 + tPhase2 = \text{bit time} - tSync - tProp$$

$$tPhase 1 + tPhase2 = (10 * t_q) - (1 * t_q) - (1 * t_q)$$

$$tPhase 1 + tPhase2 = 8 * t_q$$

$$tPhase1 = 4 * t_q$$

$$tPhase2 = 4 * t_q \quad \backslash\backslash tPhase1 = tPhase2$$

|       |                                            |
|-------|--------------------------------------------|
| TSEG2 | = TSeg2 -1<br>= 4-1<br>= 3                 |
| TSEG1 | = TSeg1 -1<br>= 5-1<br>= 4                 |
| SJW   | = SJW -1<br>= 4-1<br>= 3                   |
| BRP   | = Baud rate prescaler - 1<br>= 50-1<br>=49 |

## 16.4 Register Map

Note that the CAN controller clock must be enabled before the registers can be programmed (see page 249). There must be a delay of 3 system clocks after the CAN module clock is enabled before any CAN module registers are accessed.

| Offset | Name       | Type | Reset       | Description                       | See page |

## 16.5 CAN Register Descriptions

The remainder of this section lists and describes the CAN registers, in numerical order by address offset. There are two sets of Interface Registers that are used to access the Message Objects in the Message RAM: **CANIF1x** and **CANIF2x**. The function of the two sets are identical and are used to queue transactions.

## Register 1: CAN Control (CANCTL), offset 0x000

This control register initializes the module and enables test mode and interrupts.

The bus-off recovery sequence (see CAN Specification Rev. 2.0) cannot be shortened by setting or clearing INIT. If the device goes bus-off, it sets INIT, stopping all bus activities. Once INIT has been cleared by the CPU, the device then waits for 129 occurrences of Bus Idle (129 \* 11 consecutive High bits) before resuming normal operations. At the end of the bus-off recovery sequence, the Error Management Counters are reset.

During the waiting time after INIT is cleared, each time a sequence of 11 High bits has been monitored, a BITERROR0 code is written to the **CANSTS** register (the LEC field = 0x5), enabling the CPU to readily check whether the CAN bus is stuck Low or continuously disturbed, and to monitor the proceeding of the bus-off recovery sequence.

## Register 2: CAN Status (CANSTS), offset 0x004

**Important:** This register is read-sensitive. See the register description for details.

The status register contains information for interrupt servicing such as Bus-Off, error count threshold, and error types.

The LEC field holds the code that indicates the type of the last error to occur on the CAN bus. This field is cleared when a message has been transferred (reception or transmission) without error. The unused error code 0x7 may be written by the CPU to manually set this field to an invalid error so that it can be checked for a change later.

An error interrupt is generated by the BOFF and EWARN bits, and a status interrupt is generated by the RXOK, TXOK, and LEC bits, if the corresponding enable bits in the **CAN Control (CANCTL)** register are set. A change of the EPASS bit or a write to the RXOK, TXOK, or LEC bits does not generate an interrupt.

Reading the **CAN Status (CANSTS)** register clears the **CAN Interrupt (CANINT)** register, if it is pending.

### CAN Status (CANSTS)

CAN0 base: 0x4004.0000

Offset 0x004

Type R/W, reset 0x0000.0000

When the arbitration field is transmitted, data conflicts are a part of the arbitration protocol. When other frame fields are transmitted, data conflicts are considered errors. |  | A Bit 1 Error indicates that the device wanted to send a High level (logical 1) but the monitored bus value was Low (logical 0). | 0x5 | Bit 0 Error |  | A Bit 0 Error indicates that the device wanted to send a Low level (logical 0), but the monitored bus value was High (logical 1). |  | During bus-off recovery, this status is set each time a sequence of 11 High bits has been monitored. By checking for this status, software can monitor the proceeding of the bus-off recovery sequence without any disturbances to the bus. | 0x6 | CRC Error |  | The CRC checksum was incorrect in the received message, indicating that the calculated value received did not match the calculated CRC of the data. | 0x7 | No Event |  | When the LEC bit shows this value, no CAN bus event was detected since this value was written to the LEC field. |
| Value     | Description                                                                                                                                                                                                                                                                         |      |       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |       |             |     |          |     |             |  |                                                                                                               |     |              |  |                                                                 |     |           |  |                                                               |     |             |  |                                                                                                                                                                                                                                                                                     |  |                                                                                                                                  |     |             |  |                                                                                                                                   |  |                                                                                                                                                                                                                                             |     |           |  |                                                                                                                                                     |     |          |  |                                                                                                                 |

|           | When a message is transmitted, the CAN controller monitors the data lines to detect any conflicts. When the arbitration field is transmitted, data conflicts are a part of the arbitration protocol. When other frame fields are transmitted, data conflicts are considered errors. |      |       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |       |             |     |          |     |             |  |                                                                                                               |     |              |  |                                                                 |     |           |  |                                                               |     |             |  |                                                                                                                                                                                                                                                                                     |  |                                                                                                                                  |     |             |  |                                                                                                                                   |  |                                                                                                                                                                                                                                             |     |           |  |                                                                                                                                                     |     |          |  |                                                                                                                 |
|           | A Bit 1 Error indicates that the device wanted to send a High level (logical 1) but the monitored bus value was Low (logical 0).                                                                                                                                                    |      |       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |       |             |     |          |     |             |  |                                                                                                               |     |              |  |                                                                 |     |           |  |                                                               |     |             |  |                                                                                                                                                                                                                                                                                     |  |                                                                                                                                  |     |             |  |                                                                                                                                   |  |                                                                                                                                                                                                                                             |     |           |  |                                                                                                                                                     |     |          |  |                                                                                                                 |

|           | A Bit 0 Error indicates that the device wanted to send a Low level (logical 0), but the monitored bus value was High (logical 1).                                                                                                                                                   |      |       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |       |             |     |          |     |             |  |                                                                                                               |     |              |  |                                                                 |     |           |  |                                                               |     |             |  |                                                                                                                                                                                                                                                                                     |  |                                                                                                                                  |     |             |  |                                                                                                                                   |  |                                                                                                                                                                                                                                             |     |           |  |                                                                                                                                                     |     |          |  |                                                                                                                 |
|           | During bus-off recovery, this status is set each time a sequence of 11 High bits has been monitored. By checking for this status, software can monitor the proceeding of the bus-off recovery sequence without any disturbances to the bus.                                         |      |       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |       |             |     |          |     |             |  |                                                                                                               |     |              |  |                                                                 |     |           |  |                                                               |     |             |  |                                                                                                                                                                                                                                                                                     |  |                                                                                                                                  |     |             |  |                                                                                                                                   |  |                                                                                                                                                                                                                                             |     |           |  |                                                                                                                                                     |     |          |  |                                                                                                                 |

**Register 3: CAN Error Counter (CANERR), offset 0x008**

This register contains the error counter values, which can be used to analyze the cause of an error.

**CAN Error Counter (CANERR)**

CAN0 base: 0x4004.0000

Offset 0x008

Type RO, reset 0x0000.0000

## Register 4: CAN Bit Timing (CANBIT), offset 0x00C

This register is used to program the bit width and bit quantum. Values are programmed to the system clock frequency. This register is write-enabled by setting the CCE and INIT bits in the **CANCTL** register. See “Bit Time and Bit Rate” on page 768 for more information.

| 31:15     | reserved | RO   | 0x0000 | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.                                                                                                                                                                                                                                                                                                                             |
| 14:12     | TSEG2    | R/W  | 0x2    | Time Segment after Sample Point<br>0x00-0x07: The actual interpretation by the hardware of this value is such that one more than the value programmed here is used.<br>So, for example, the reset value of 0x2 means that 3 (2+1) bit time quanta are defined for Phase2 (see Figure 16-4 on page 769). The bit time quanta is defined by the BRP field.                                                                                                                                                                  |
| 11:8      | TSEG1    | R/W  | 0x3    | Time Segment Before Sample Point<br>0x00-0x0F: The actual interpretation by the hardware of this value is such that one more than the value programmed here is used.<br>So, for example, the reset value of 0x3 means that 4 (3+1) bit time quanta are defined for Phase1 (see Figure 16-4 on page 769). The bit time quanta is defined by the BRP field.                                                                                                                                                                 |
| 7:6       | SJW      | R/W  | 0x0    | (Re)Synchronization Jump Width<br>0x00-0x03: The actual interpretation by the hardware of this value is such that one more than the value programmed here is used.<br>During the start of frame (SOF), if the CAN controller detects a phase error (misalignment), it can adjust the length of TSEG2 or TSEG1 by the value in SJW. So the reset value of 0 adjusts the length by 1 bit time quanta.                                                                                                                       |
| 5:0       | BRP      | R/W  | 0x1    | Baud Rate Prescaler<br>The value by which the oscillator frequency is divided for generating the bit time quanta. The bit time is built up from a multiple of this quantum.<br>0x00-0x03F: The actual interpretation by the hardware of this value is such that one more than the value programmed here is used.<br>BRP defines the number of CAN clock periods that make up 1 bit time quanta, so the reset value is 2 bit time quanta (1+1).<br>The <b>CANBRPE</b> register can be used to further divide the bit time. |

**Register 5: CAN Interrupt (CANINT), offset 0x010**

This register indicates the source of the interrupt.

If several interrupts are pending, the **CAN Interrupt (CANINT)** register points to the pending interrupt with the highest priority, disregarding the order in which the interrupts occurred. An interrupt remains pending until the CPU has cleared it. If the INTID field is not 0x0000 (the default) and the IE bit in the **CANCTL** register is set, the interrupt is active. The interrupt line remains active until the INTID field is cleared by reading the **CANSTS** register, or until the IE bit in the **CANCTL** register is cleared.

**Note:** Reading the **CAN Status (CANSTS)** register clears the **CAN Interrupt (CANINT)** register, if it is pending.

## Register 6: CAN Test (CANTST), offset 0x014

This register is used for self-test and external pin access. It is write-enabled by setting the TEST bit in the **CANCTL** register. Different test functions may be combined, however, CAN transfers are affected if the TX bits in this register are not zero.

**Register 8: CAN IF1 Command Request (CANIF1CRQ), offset 0x020****Register 9: CAN IF2 Command Request (CANIF2CRQ), offset 0x080**

A message transfer is started as soon as there is a write of the message object number to the MNUM field when the TXRQST bit in the **CANIF1MCTL** register is set. With this write operation, the BUSY bit is automatically set to indicate that a transfer between the CAN Interface Registers and the internal message RAM is in progress. After a wait time of 3 to 6 CAN\_CLK periods, the transfer between the interface register and the message RAM completes, which then clears the BUSY bit.

**Register 10: CAN IF1 Command Mask (CANIF1CMSK), offset 0x024****Register 11: CAN IF2 Command Mask (CANIF2CMSK), offset 0x084**

Reading the Command Mask registers provides status for various functions. Writing to the Command Mask registers specifies the transfer direction and selects which buffer registers are the source or target of the data transfer.

Note that when a read from the message object buffer occurs when the WRNRD bit is clear and the CLRINTPND and/or NEWDAT bits are set, the interrupt pending and/or new data flags in the message object buffer are cleared.

**CAN IF1 Command Mask (CANIF1CMSK)**

CAN0 base: 0x4004.0000

Offset 0x024

Type R/W, reset 0x0000.0000

Register 12: CAN IF1 Mask 1 (CANIF1MSK1), offset 0x028

Register 13: CAN IF2 Mask 1 (CANIF2MSK1), offset 0x088

The mask information provided in this register accompanies the data (**CANIFnDAn**), arbitration information (**CANIFnARBn**), and control information (**CANIFnMCTL**) to the message object in the message RAM. The mask is used with the ID bit in the **CANIFnARBn** register for acceptance filtering. Additional mask information is contained in the **CANIFnMSK2** register.

CAN IF1 Mask 1 (CANIF1MSK1)

CAN0 base: 0x4004.0000  
Offset 0x028  
Type R/W, reset 0x0000.FFFF

These registers contain the data to be sent or that has been received. In a CAN data frame, data byte 0 is the first byte to be transmitted or received and data byte 7 is the last byte to be transmitted or received. In CAN's serial bit stream, the MSB of each byte is transmitted first.

**Register 30: CAN Transmission Request 1 (CANTXRQ1), offset 0x100****Register 31: CAN Transmission Request 2 (CANTXRQ2), offset 0x104**

The **CANTXRQ1** and **CANTXRQ2** registers hold the TXRQST bits of the 32 message objects. By reading out these bits, the CPU can check which message object has a transmission request pending. The TXRQST bit of a specific message object can be changed by three sources: (1) the CPU via the **CANIFnMCTL** register, (2) the message handler state machine after the reception of a remote frame, or (3) the message handler state machine after a successful transmission.

The **CANTXRQ1** register contains the TXRQST bits of the first 16 message objects in the message RAM; the **CANTXRQ2** register contains the TXRQST bits of the second 16 message objects.

**CAN Transmission Request 1 (CANTXRQ1)**

**Register 34: CAN Message 1 Interrupt Pending (CANMSG1INT), offset 0x140****Register 35: CAN Message 2 Interrupt Pending (CANMSG2INT), offset 0x144**

The **CANMSG1INT** and **CANMSG2INT** registers hold the INTPND bits of the 32 message objects. By reading these bits, the CPU can check which message object has an interrupt pending. The INTPND bit of a specific message object can be changed through two sources: (1) the CPU via the **CANIFnMCTL** register, or (2) the message handler state machine after the reception or transmission of a frame.

This field is also encoded in the **CANINT** register.

The **CANMSG1INT** register contains the INTPND bits of the first 16 message objects in the message RAM; the **CANMSG2INT** register contains the INTPND bits of the second 16 message objects.

## 17 Ethernet Controller

The Stellaris<sup>®</sup> Ethernet Controller consists of a fully integrated media access controller (MAC) and network physical (PHY) interface. The Ethernet Controller conforms to *IEEE 802.3* specifications and fully supports 10BASE-T and 100BASE-TX standards.

The Stellaris Ethernet Controller module has the following features:

- Conforms to the *IEEE 802.3-2002 specification*
  - 10BASE-T/100BASE-TX IEEE-802.3 compliant. Requires only a dual 1:1 isolation transformer interface to the line
  - 10BASE-T/100BASE-TX ENDEC, 100BASE-TX scrambler/descrambler
  - Full-featured auto-negotiation
- Multiple operational modes
  - Full- and half-duplex 100 Mbps
  - Full- and half-duplex 10 Mbps
  - Power-saving and power-down modes
- Highly configurable
  - Programmable MAC address
  - LED activity selection
  - Promiscuous mode support
  - CRC error-rejection control
  - User-configurable interrupts
- Physical media manipulation
  - MDI/MDI-X cross-over support through software assist
  - Register-programmable transmit amplitude
  - Automatic polarity correction and 10BASE-T signal reception
- Efficient transfers using Micro Direct Memory Access Controller ( $\mu$ DMA)
  - Separate channels for transmit and receive
  - Receive channel request asserted on packet receipt
  - Transmit channel request asserted on empty transmit FIFO

## 17.1 Block Diagram

As shown in Figure 17-1 on page 805, the Ethernet Controller is functionally divided into two layers: the Media Access Controller (MAC) layer and the Network Physical (PHY) layer. These layers correspond to the OSI model layers 2 and 1, respectively. The CPU accesses the Ethernet Controller via the MAC layer. The MAC layer provides transmit and receive processing for Ethernet frames. The MAC layer also provides the interface to the PHY layer via an internal Media Independent Interface (MII). The PHY layer communicates with the Ethernet bus.

**Figure 17-1. Ethernet Controller**

Figure 17-2 on page 805 shows more detail of the internal structure of the Ethernet Controller and how the register set relates to various functions.

**Figure 17-2. Ethernet Controller Block Diagram**

## 17.2 Signal Description

The following table lists the external signals of the Ethernet Controller and describes the function of each. The Ethernet LED signals are alternate functions for GPIO signals and default to be GPIO signals at reset. The column in the table below titled "Pin Mux/Pin Assignment" lists the GPIO pin placement for the LED signals. The AFSEL bit in the **GPIO Alternate Function Select (GPIOAFSEL)** register (page 433) should be set to choose the LED function. The number in parentheses is the encoding that must be programmed into the PMCN field in the **GPIO Port Control (GPIOPTCL)** register (page 450) to assign the LED0 and LED1 signals to the specified GPIO port pins. For more information on configuring GPIOs, see "General-Purpose Input/Outputs (GPIOs)" on page 410. The remaining signals (with the word "fixed" in the Pin Mux/Pin Assignment column) have a fixed pin assignment and function.

**Table 17-1. Signals for Ethernet (100LQFP)**

| Pin Name | Pin Number | Pin Mux / Pin Assignment | Pin Type | Buffer Type <sup>a</sup> | Description                                                       |
|----------|------------|--------------------------|----------|--------------------------|-------------------------------------------------------------------|

| LED1     | J11        | PF2 (1)                  | O        | TTL                      | Ethernet LED 1.                                                   |
| MDIO     | L9         | fixed                    | I/O      | OD                       | MDIO of the Ethernet PHY.                                         |
| RXIN     | L7         | fixed                    | I        | Analog                   | RXIN of the Ethernet PHY.                                         |
| RXIP     | M7         | fixed                    | I        | Analog                   | RXIP of the Ethernet PHY.                                         |
| TXON     | L8         | fixed                    | O        | TTL                      | TXON of the Ethernet PHY.                                         |
| TXOP     | M8         | fixed                    | O        | TTL                      | TXOP of the Ethernet PHY.                                         |
| XTALNPHY | J1         | fixed                    | O        | Analog                   | Ethernet PHY XTALN 25-MHz oscillator crystal output.              |
| XTALPPHY | J2         | fixed                    | I        | Analog                   | Ethernet PHY XTALP 25-MHz oscillator crystal input.               |

a. The TTL designation indicates the pin has TTL-compatible voltage levels.

## 17.3 Functional Description

**Note:** A 12.4-kΩ resistor should be connected between the ERBIAS and ground. The 12.4-kΩ resistor should have a 1% tolerance and should be located in close proximity to the ERBIAS pin. Power dissipation in the resistor is low, so a chip resistor of any geometry may be used.

The functional description of the Ethernet Controller is discussed in the following sections.

### 17.3.1 MAC Operation

The following sections describe the operation of the MAC layer, including an overview of the Ethernet frame format, the MAC layer FIFOs, Ethernet transmission and reception options, and LED indicators.

#### 17.3.1.1 Ethernet Frame Format

Ethernet data is carried by Ethernet frames. The basic frame format is shown in Figure 17-3 on page 807.

**Figure 17-3. Ethernet Frame**

|            |           |                     |                |                 |                    |            |
|------------|-----------|---------------------|----------------|-----------------|--------------------|------------|
| Preamble   | SFD       | Destination Address | Source Address | Length/<br>Type | Data               | FCS        |
| 7<br>Bytes | 1<br>Byte | 6<br>Bytes          | 6<br>Bytes     | 2<br>Bytes      | 46 - 1500<br>Bytes | 4<br>Bytes |

The seven fields of the frame are transmitted from left to right. The bits within the frame are transmitted from least to most significant bit.

- Preamble

The Preamble field is used to synchronize with the received frame's timing. The preamble is 7 octets long.

- Start Frame Delimiter (SFD)

The SFD field follows the preamble pattern and indicates the start of the frame. Its value is 1010.1011b.

- Destination Address (DA)

This field specifies destination addresses for which the frame is intended. The LSB (bit 16 of DA oct 1 in the frame, see Table 17-3 on page 809) of the DA determines whether the address is an individual (0), or group/multicast (1) address.

- Source Address (SA)

The source address field identifies the station from which the frame was initiated.

- Length/Type Field

The meaning of this field depends on its numeric value. This field can be interpreted as length or type code. The maximum length of the data field is 1500 octets. If the value of the Length/Type field is less than or equal to 1500 decimal, it indicates the number of MAC client data octets. If the value of this field is greater than or equal to 1536 decimal, then it encodes the type interpretation. The meaning of the Length/Type field when the value is between 1500 and 1536 decimal is unspecified by the IEEE 802.3 standard. However, the Ethernet Controller assumes type interpretation if the value of the Length/Type field is greater than 1500 decimal. The definition

of the Type field is specified in the IEEE 802.3 standard. The first of the two octets in this field is most significant.

- Data

The data field is a sequence of octets that is at least 46 in length, up to 1500 in length. Full data transparency is provided so any values can appear in this field. A minimum frame size of 46 octets is required to meet the IEEE standard. If the frame size is too small, the Ethernet Controller automatically appends extra bits (a pad), thus the pad can have a size of 0 to 46 octets. Data padding can be disabled by clearing the PADEN bit in the **Ethernet MAC Transmit Control (MACTCTL)** register.

For the Ethernet Controller, data sent/received can be larger than 1500 bytes without causing a Frame Too Long error. Instead, a FIFO overrun error is reported using the FOV bit in the **Ethernet MAC Raw Interrupt Status (MACRIS)** register when the frame received is too large to fit into the Ethernet Controller's 2K RAM.

- Frame Check Sequence (FCS)

The frame check sequence carries the cyclic redundancy check (CRC) value. The CRC is computed over the destination address, source address, length/type, and data (including pad) fields using the CRC-32 algorithm. The Ethernet Controller computes the FCS value one nibble at a time. For transmitted frames, this field is automatically inserted by the MAC layer, unless disabled by clearing the CRC bit in the **MACTCTL** register. For received frames, this field is automatically checked. If the FCS does not pass, the frame is not placed in the RX FIFO, unless the FCS check is disabled by clearing the BADCRC bit in the **MACRCTL** register.

### 17.3.1.2 MAC Layer FIFOs

The Ethernet Controller is capable of simultaneous transmission and reception. This feature is enabled by setting the DUPLEX bit in the **MACTCTL** register.

For Ethernet frame transmission, a 2-KB transmit FIFO is provided that can be used to store a single frame. While the *IEEE 802.3 specification* limits the size of an Ethernet frame's payload section to 1500 Bytes, the Ethernet Controller places no such limit. The full buffer can be used for a payload of up to 2032 bytes (as the first 16 bytes in the FIFO are reserved for destination address, source address and length/type information).

For Ethernet frame reception, a 2-KB receive FIFO is provided that can be used to store multiple frames, up to a maximum of 31 frames. If a frame is received, and there is insufficient space in the RX FIFO, an overflow error is indicated using the FOV bit in the **MACRIS** register.

For details regarding the TX and RX FIFO layout, refer to Table 17-3 on page 809. Please note the following difference between TX and RX FIFO layout. For the TX FIFO, the Data Length field in the first FIFO word refers to the Ethernet frame data payload, as shown in the 5th to nth FIFO positions. For the RX FIFO, the Frame Length field is the total length of the received Ethernet frame, including the Length/Type bytes and the FCS bits.

If FCS generation is disabled by clearing the CRC bit in the **MACTCTL** register, the last word in the TX FIFO must contain the FCS bytes for the frame that has been written to the FIFO.

Also note that if the length of the data payload section is not a multiple of 4, the FCS field is not aligned on a word boundary in the FIFO. However, for the RX FIFO, the beginning of the next frame is always on a word boundary.

Table 17-3. TX &amp; RX FIFO Organization

| FIFO Word Read/Write Sequence | Word Bit Fields | TX FIFO (Write)                    | RX FIFO (Read)                      |
|-------------------------------|-----------------|------------------------------------|-------------------------------------|
| 1st                           | 7:0             | Data Length Least Significant Byte | Frame Length Least Significant Byte |
|                               | 15:8            | Data Length Most Significant Byte  | Frame Length Most Significant Byte  |
|                               | 23:16           | DA oct 1                           |                                     |
|                               | 31:24           | DA oct 2                           |                                     |
| 2nd                           | 7:0             | DA oct 3                           |                                     |
|                               | 15:8            | DA oct 4                           |                                     |
|                               | 23:16           | DA oct 5                           |                                     |
|                               | 31:24           | DA oct 6                           |                                     |
| 3rd                           | 7:0             | SA oct 1                           |                                     |
|                               | 15:8            | SA oct 2                           |                                     |
|                               | 23:16           | SA oct 3                           |                                     |
|                               | 31:24           | SA oct 4                           |                                     |

a. If the CRC bit in the **MACTCTL** register is clear, the FCS bytes must be written with the correct CRC. If the CRC bit is set, the Ethernet Controller automatically writes the FCS bytes.

### 17.3.1.3 Ethernet Transmission Options

At the MAC layer, the transmitter can be configured for both full-duplex and half-duplex operation by using the DUPLEX bit in the **MACTCTL** register. Note that in 10BASE-T half-duplex mode, the transmitted data is looped back on the receive path.

The Ethernet Controller automatically generates and inserts the Frame Check Sequence (FCS) at the end of the transmit frame when the CRC bit in the **MACTCTL** register is set. However, for test purposes, this feature can be disabled in order to generate a frame with an invalid CRC by clearing the CRC bit.

The *IEEE 802.3 specification* requires that the Ethernet frame payload section be a minimum of 46 bytes. The Ethernet Controller automatically pads the data section if the payload data section loaded into the FIFO is less than the minimum 46 bytes when the PADEN bit in the **MACTCTL** register is set. This feature can be disabled by clearing the PADEN bit.

The transmitter must be enabled by setting the TXEN bit in the **MACTCTL** register.

#### 17.3.1.4 Ethernet Reception Options

The Ethernet Controller RX FIFO should be cleared during software initialization. The receiver should first be disabled by clearing the RXEN bit in the **Ethernet MAC Receive Control (MACRCTL)** register, then the FIFO can be cleared by setting the RSTFIFO bit in the **MACRCTL** register.

The receiver automatically rejects frames that contain bad CRC values in the FCS field. In this case, a Receive Error interrupt is generated and the receive data is lost. To accept all frames, clear the BADCRC bit in the **MACRCTL** register.

In normal operating mode, the receiver accepts only those frames that have a destination address that matches the address programmed into the **Ethernet MAC Individual Address 0 (MACIA0)** and **Ethernet MAC Individual Address 1 (MACIA1)** registers. However, the Ethernet receiver can also be configured for Promiscuous and Multicast modes by setting the PRMS and AMUL bits in the **MACRCTL** register.

#### 17.3.1.5 LED Indicators

The Ethernet Controller supports two LED signals that can be used to indicate various states of operation. These signals are mapped to the LED0 and LED1 pins. By default, these pins are configured as GPIO signals (PF3 and PF2). For the Ethernet Controller to drive these signals, they must be reconfigured to their hardware function. See “General-Purpose Input/Outputs (GPIOs)” on page 410 for additional details. The function of these pins is programmable using the **Ethernet MAC LED Encoding (MACLED)** register. Refer to page 840 for additional details on how to program these LED functions.

#### 17.3.2 Internal MII Operation

For the MII management interface to function properly, the MDIO signal must be connected through a 10 k $\Omega$  pull-up resistor to the +3.3 V supply. Failure to connect this pull-up resistor prevents management transactions on this internal MII to function. Note that it is possible for data transmission across the MII to still function since the PHY layer auto-negotiates the link parameters by default.

For the MII management interface to function properly, the internal clock must be divided down from the system clock to a frequency no greater than 2.5 MHz. The **Ethernet MAC Management Divider (MACMDV)** register contains the divider used for scaling down the system clock. See page 835 for more details about the use of this register.

#### 17.3.3 PHY Operation

The Physical Layer (PHY) in the Ethernet Controller includes integrated ENDECs, scrambler/descrambler, dual-speed clock recovery, and full-featured auto-negotiation functions. The transmitter includes an on-chip pulse shaper and a low-power line driver. The receiver has an adaptive equalizer and a baseline restoration circuit required for accurate clock and data recovery. The transceiver interfaces to Category-5 unshielded twisted pair (Cat-5 UTP) cabling for 100BASE-TX applications, and Category-3 unshielded twisted pair (Cat-3 UTP) for 10BASE-T applications. The Ethernet Controller is connected to the line media via dual 1:1 isolation transformers. No external filter is required.

##### 17.3.3.1 Clock Selection

The Ethernet Controller can be clocked from an on-chip crystal oscillator which can also be driven by an external oscillator. When using the on-chip crystal oscillator, a 25-MHz crystal should be connected between the XTALPPHY and XTALNPY pins. Alternatively, an external 25-MHz clock input can be connected to the XTALPPHY pin. In this mode of operation, a crystal is not required and the XTALNPY pin should be left unconnected. The Ethernet oscillator is powered down when

the EPHY0 bit in the **Run Mode Clock Gating Control Register 2 (RCGC2)** register is clear. After setting the EPHY0 bit, software must wait 3.5 ms before accessing any of the MII Management registers. See “Ethernet Controller” on page 1041 for more information regarding the specifications of the Ethernet Controller.

### 17.3.3.2 Auto-Negotiation

The Ethernet Controller supports the auto-negotiation functions of Clause 28 of the *IEEE 802.3* standard for 10/100 Mbps operation over copper wiring. This function is controlled via register settings. The auto-negotiation function is turned on by default, and the ANEGEN bit in the **Ethernet PHY Management Register 0 - Control (MR0)** is set after reset. Software can disable the auto-negotiation function by clearing the ANEGEN bit. The contents of the **Ethernet PHY Management Register - Auto-Negotiation Advertisement (MR4)** are reflected to the Ethernet Controller's link partner during auto-negotiation via fast-link pulse coding.

Once auto-negotiation is complete, the SPEED bit in the **Ethernet PHY Management Register 31 - PHY Special Control/Status (MR31)** register reflects the actual speed. The AUTODONE bit in **MR31** is set to indicate that auto-negotiation is complete. Setting the RANEG bit in the **MR0** register also causes auto-negotiation to restart.

### 17.3.3.3 Polarity Correction

The Ethernet Controller is capable of automatic polarity reversal for 10BASE-T and auto-negotiation functions. The XPOL bit in the **Ethernet PHY Management Register 27 -Special Control/Status (MR27)** register is set to indicate the polarity has automatically been reversed.

### 17.3.3.4 MDI/MDI-X Configuration

The Ethernet Controller supports the MDI/MDI-X configuration as defined in *IEEE 802.3-2002 specification* through software assistance. The MDI/MDI-X configuration eliminates the need for cross-over cables when connecting to another device, such as a hub. Software can implement the MDI/MDI-X configuration using a function outlined by the pseudo code below. This code should be called periodically using one of the available timer resources on the Stellaris microcontroller such as the System Tick Timer or one of the General Purpose timers. The following code refers to the LINK bit in the **Ethernet PHY Management Register 1 - Status (MR1)**, the ENON bit in the **Ethernet PHY Management Register 17 - Mode Control/Status (MR17)**, and the EN bit of the **Ethernet PHY MDIX (MDIX)** register.

```
//
// Entry Point for MDI/MDI-X configuration.
//

//
// Increment the Link Active and Energy Detect Timers using the elapsed time
// since the last call to this function. If using a periodic timer, the
// elapsed time should be a constant (the programmed period of the timer).
//
Increment Link Active Timer
Increment Energy Detect Timer

//
if(No Ethernet Link Active)
{
    //
    // If energy has been detected on the link, reset the Energy Detect Timer.
```

```
// If it is a "new" energy detect, reset the link detect timer also.
//
if(Ethernet Energy Detected)
{
    Reset Energy Detect Timer

    if(New Energy Detect)
    {
        Reset Link Detect Timer
    }
}

//
// If the Energy or Link Detect timer has expired, toggle the MDI/MDI-X
// mode. Typically, the Energy Detect Timer would be ~62ms, while the
// Link Detect Timer would be ~2s
//
if((Energy Detect Timer Expired) or
   (Link Detect Timer Expired))
{
    Reset Energy Detect Timer

    if(Random Event)
    {
        Reset Link Detect Timer
        Toggle MDI/MDI-X Mode
    }
}

//
// Here, if an Ethernet Link has been detected, simply reset the timers
// for the next time around.
//
else
{
    Reset Link Detect Timer
    Reset Energy Detect Timer
}
```

### 17.3.3.5 Power Management

The PHY has two power-saving modes:

- Power-Down
- Energy Detect Power-Down

Power-down mode is activated by setting the PWRDN bit in the **MR0** register. When the PHY is in power-down mode, it consumes minimum power. When the PWRDN bit is cleared, the PHY powers up and is automatically reset.

The energy detect power-down mode is activated by setting the EDPD bit in the **MR17** register. In this mode of operation, when no energy is present on the line, the PHY is powered down, except

for the management interface, the SQUELCH circuit and the ENERGYON logic. The ENERGYON logic is used to detect the presence of valid energy from 100BASE-T, 10BASE-T, or auto-negotiation signals. While the PHY is powered down, nothing is transmitted. When link pulses or packets are received, the PHY powers-up. The PHY automatically resets itself into the state it had prior to power down and sets the EONIS bit in the **MR29** register. The first and possibly the second packet to activate the ENERGYON mode may be lost.

### 17.3.4 Interrupts

The Ethernet Controller can generate an interrupt for one or more of the following conditions:

- A frame has been received into an empty RX FIFO
- A frame transmission error has occurred
- A frame has been transmitted successfully
- A frame has been received with inadequate room in the RX FIFO (overflow)
- A frame has been received with one or more error conditions (for example, FCS failed)
- An MII management transaction between the MAC and PHY layers has completed
- One or more of the following PHY layer conditions occurs:
  - Auto-Negotiate Complete
  - Remote Fault
  - Link Partner Acknowledge
  - Parallel Detect Fault
  - Page Received

Refer to **Ethernet PHY Management Register 29 - Interrupt Source Flags (MR29)** (see page 858) for additional details regarding PHY interrupts.

### 17.3.5 DMA Operation

The Ethernet peripheral provides request signals to the  $\mu$ DMA controller and has a dedicated channel for transmit and one for receive. The request is a single type for both channels. Burst requests are not supported. The RX channel request is asserted when a packet is received while the TX channel request is asserted when the transmit FIFO becomes empty.

No special configuration is needed to enable the Ethernet peripheral for use with the  $\mu$ DMA controller.

Because the size of a received packet is not known until the header is examined, it is best to set up the initial  $\mu$ DMA transfer to copy the first 4 words including the packet length plus the Ethernet header from the RX FIFO when the RX request occurs. The  $\mu$ DMA causes an interrupt when this transfer is complete. Upon entering the interrupt handler, the packet length in the FIFO and the Ethernet header are in a buffer and can be examined. Once the packet length is known, then another  $\mu$ DMA transfer can be set up to transfer the remaining received packet payload from the FIFO into a buffer. This transfer should be initiated by software. Another interrupt occurs when this transfer is done.

Even though the TX channel generates a TX empty request, the recommended way to handle  $\mu$ DMA transfers for transmitting packets is to set up the transfer from the buffer containing the packet to the transmit FIFO, and then to initiate the transfer with a software request. An interrupt occurs when this transfer is complete. For both channels, the "auto-request" transfer mode should be used. See "Micro Direct Memory Access ( $\mu$ DMA)" on page 350 for more details about programming the  $\mu$ DMA controller.

## 17.4 Initialization and Configuration

The following sections describe the hardware and software configuration required to set up the Ethernet Controller.

### 17.4.1 Hardware Configuration

Figure 17-4 on page 814 shows the proper method for interfacing the Ethernet Controller to a 10/100BASE-T Ethernet jack.

**Figure 17-4. Interface to an Ethernet Jack**

The following isolation transformers have been tested and are known to successfully interface to the Ethernet PHY layer.

- Isolation Transformers
  - TDK TLA-6T103
  - TDK TLA-6T118
  - Bel-Fuse S558-5999-46
  - Halo TG22-3506ND
  - Halo TG110-S050
  - PCA EPF8023G
  - Pulse PE-68515
  - Valor ST6118
  - YCL 20PMT04
- Isolation transformers with integrated RJ45 connector

- TDK TLA-6T704
- Delta RJS-1A08T089A
- Isolation transformers with integrated RJ45 connector, LEDs and termination resistors
  - Pulse J0011D21B/E
  - Pulse J3011G21DNL

## 17.4.2 Software Configuration

To use the Ethernet Controller, it must be enabled by setting the EPHY0 and EMAC0 bits in the **RCGC2** register (see page 266). In addition, the clock to the appropriate GPIO module must be enabled via the **RCGC2** register in the System Control module. See page 266. To find out which GPIO port to enable, refer to Table 22-4 on page 987. Configure the PMCN fields in the **GPIOPCTL** register to assign the Ethernet signals to the appropriate pins. See page 450 and Table 22-5 on page 994.

The following steps can then be used to configure the Ethernet Controller for basic operation.

1. Program the **MACDIV** register to obtain a 2.5 MHz clock (or less) on the internal MII. Assuming a 20-MHz system clock, the **MACDIV** value should be 0x03 or greater.
2. Program the **MACIA0** and **MACIA1** register for address filtering.
3. Program the **MACTCTL** register for Auto CRC generation, padding, and full-duplex operation using a value of 0x16.
4. Program the **MACRCTL** register to flush the receive FIFO and reject frames with bad FCS using a value of 0x18.
5. Enable both the Transmitter and Receive by setting the LSB in both the **MACTCTL** and **MACRCTL** registers.
6. To transmit a frame, write the frame into the TX FIFO using the **Ethernet MAC Data (MACDATA)** register. Then set the NEWTX bit in the **Ethernet Mac Transmission Request (MACTR)** register to initiate the transmit process. When the NEWTX bit has been cleared, the TX FIFO is available for the next transmit frame.
7. To receive a frame, wait for the NPR field in the **Ethernet MAC Number of Packets (MACNP)** register to be non-zero. Then begin reading the frame from the RX FIFO by using the **MACDATA** register. To ensure that the entire packet is received, either use the DriverLib EthernetPacketGet() API or compare the number of bytes received to the Length field from the frame to determine when the packet has been completely read.

## 17.5 Register Map

Table 17-4 on page 816 lists the Ethernet MAC and MII Management registers. The MAC register addresses given are relative to the Ethernet base address of 0x4004.8000. The MII Management registers are accessed using the **MACMCTL** register. Note that the Ethernet controller clocks must be enabled before the registers can be programmed (see page 266). There must be a delay of 3 system clocks after the Ethernet module clock is enabled before any Ethernet module registers are accessed. In addition, the Ethernet oscillator is powered down when the EPHY0 bit in the **Run Mode Clock Gating Control Register 2 (RCGC2)** register is clear. After setting the EPHY0 bit, software must wait 3.5 ms before accessing any of the MII Management registers.

The *IEEE 802.3* standard specifies a register set for controlling and gathering status from the PHY layer. The registers are collectively known as the MII Management registers and are detailed in Section 22.2.4 of the *IEEE 802.3 specification*. Table 17-4 on page 816 also lists these MII Management registers. All addresses given are absolute and are written directly to the REGADR field of the **Ethernet MAC Management Control (MACMCTL)** register. The format of registers 0 to 15 are defined by the IEEE specification and are common to all PHY layer implementations. The only variance allowed is for features that may or may not be supported by a specific PHY implementation. Registers 16 to 31 are vendor-specific registers, used to support features that are specific to a vendor's PHY implementation.

**Table 17-4. Ethernet Register Map**

| Offset                                                        | Name           | Type  | Reset       | Description                                                         | See page |
|---------------------------------------------------------------|----------------|-------|-------------|---------------------------------------------------------------------|----------|
| <b>Ethernet MAC (Ethernet Offset)</b>                         |                |       |             |                                                                     |          |
| 0x000                                                         | MACRIS/MACIACK | R/W1C | 0x0000.0000 | Ethernet MAC Raw Interrupt Status/Acknowledge                       | 818      |

## 17.6 Ethernet MAC Register Descriptions

The remainder of this section lists and describes the Ethernet MAC registers, in numerical order by address offset. Also see “MII Management Register Descriptions” on page 842.

## Register 1: Ethernet MAC Raw Interrupt Status/Acknowledge (MACRIS/MACIACK), offset 0x000

The **MACRIS/MACIACK** register is the interrupt status and acknowledge register. On a read, this register gives the current status value of the corresponding interrupt prior to masking. On a write, setting any bit clears the corresponding interrupt status bit.

### Ethernet MAC Raw Interrupt Status/Acknowledge (MACRIS/MACIACK)

## Register 2: Ethernet MAC Interrupt Mask (MACIM), offset 0x004

This register allows software to enable/disable Ethernet MAC interrupts. Clearing a bit disables the interrupt, while setting the bit enables it.

### Ethernet MAC Interrupt Mask (MACIM)

### Register 3: Ethernet MAC Receive Control (MACRCTL), offset 0x008

This register configures the receiver and controls the types of frames that are received.

It is important to note that when the receiver is enabled, all valid frames with a broadcast address of FF-FF-FF-FF-FF-FF in the Destination Address field are received and stored in the RX FIFO, even if the AMUL bit is not set.

#### Ethernet MAC Receive Control (MACRCTL)

Base 0x4004.8000  
Offset 0x008  
Type R/W, reset 0x0000.0008

## Register 5: Ethernet MAC Data (MACDATA), offset 0x010

**Important:** This register is read-sensitive. See the register description for details.

This register enables software to access the TX and RX FIFOs.

Reads from this register return the data stored in the RX FIFO from the location indicated by the read pointer. The read pointer is then auto incremented to the next RX FIFO location. Reading from the RX FIFO when a frame has not been received or is in the process of being received returns indeterminate data and does not increment the read pointer.

Writes to this register store the data in the TX FIFO at the location indicated by the write pointer. The write pointer is then auto incremented to the next TX FIFO location. Writing more data into the TX FIFO than indicated in the length field results in the data being lost. Writing less data into the TX FIFO than indicated in the length field results in indeterminate data being appended to the end of the frame to achieve the indicated length. Attempting to write the next frame into the TX FIFO before transmission of the first has completed results in the data being lost.

Bytes may not be randomly accessed in either the RX or TX FIFOs. Data must be read from the RX FIFO sequentially and stored in a buffer for further processing. Once a read has been performed, the data in the FIFO cannot be re-read. Data must be written to the TX FIFO sequentially. If an error is made in placing the frame into the TX FIFO, the write pointer can be reset to the start of the TX FIFO by writing the TXER bit of the **MACIACK** register and then the data re-written.

## Register 8: Ethernet MAC Threshold (MACTHR), offset 0x01C

In order to increase the transmission rate, it is possible to program the Ethernet Controller to begin transmission of the next frame prior to the completion of the transmission of the current frame.

**Caution – Extreme care must be used when implementing this function. Software must be able to guarantee that the complete frame is able to be stored in the transmission FIFO prior to the completion of the transmission frame.**

This register enables software to set the threshold level at which the transmission of the frame begins. If the THRESH bits are set to 0x3F, which is the reset value, the early transmission feature is disabled, and transmission does not start until the NEWTX bit is set in the **MACTR** register.

Writing the THRESH field to any value besides 0x3F enables the early transmission feature. Once the byte count of data in the TX FIFO reaches the value derived from the THRESH bits as shown below, transmission of the frame begins. When the THRESH field is clear, transmission of the frame begins after 4 bytes (a single write) are stored in the TX FIFO. Each increment of the THRESH bit field waits for an additional 32 bytes of data (eight writes) to be stored in the TX FIFO. Therefore, a value of 0x01 causes the transmitter to wait for 36 bytes of data to be written while a value of 0x02 makes the wait equal to 68 bytes of written data. In general, early transmission starts when:

$$\text{Number of Bytes} \geq 4 ((\text{THRESH} \times 8) + 1)$$

Reaching the threshold level has the same effect as setting the NEWTX bit in the **MACTR** register. Transmission of the frame begins, and then the number of bytes indicated by the Data Length field is transmitted. Because underrun checking is not performed, if any event, such as an interrupt, delays the filling of the FIFO, the tail pointer may reach and pass the write pointer in the TX FIFO. In this event, indeterminate values are transmitted rather than the end of the frame. Therefore, sufficient bus bandwidth for writing to the TX FIFO must be guaranteed by the software.

If a frame smaller than the threshold level must be sent, the NEWTX bit in the **MACTR** register must be set with an explicit write, which initiates the transmission of the frame even though the threshold limit has not been reached.

If the threshold level is set too small, it is possible for the transmitter to underrun. If this occurs, the transmit frame is aborted, and a transmit error occurs. Note that in this case, the TXER bit in the **MACRIS** is not set, meaning that the CPU receives no indication that a transmit error happened.

**Register 9: Ethernet MAC Management Control (MACMCTL), offset 0x020**

This register enables software to control the transfer of data to and from the MII Management registers in the Ethernet PHY layer. The address, name, type, reset configuration, and functional description of each of these registers can be found in Table 17-4 on page 816 and in “MII Management Register Descriptions” on page 842.

In order to initiate a *read* transaction from the MII Management registers, the WRITE bit must be cleared during the same cycle that the START bit is set.

In order to initiate a *write* transaction to the MII Management registers, the WRITE bit must be set during the same cycle that the START bit is set.

**Register 10: Ethernet MAC Management Divider (MACMDV), offset 0x024**

This register enables software to set the clock divider for the Management Data Clock (MDC). This clock is used to synchronize read and write transactions between the system and the MII Management registers. The frequency of the MDC clock can be calculated from the following formula:

$$F_{mdc} = \frac{F_{ipclk}}{2 \times (\text{MACMDV} + 1)}$$

The clock divider must be written with a value that ensures that the MDC clock does not exceed a frequency of 2.5 MHz.

**Register 13: Ethernet MAC Number of Packets (MACNP), offset 0x034**

This register holds the number of frames that are currently in the RX FIFO. When NPR is 0, there are no frames in the RX FIFO, and the RXINT bit is clear. When NPR is any other value, at least one frame is in the RX FIFO, and the RXINT bit in the **MACRIS** register is set.

**Note:** The FCS bytes are not included in the NPR value. As a result, the NPR value could be zero before the FCS bytes are read from the FIFO. In addition, a new packet could be received before the NPR value reaches zero. To ensure that the entire packet is received, either use the DriverLib EthernetPacketGet() API or compare the number of bytes received to the Length field from the frame to determine when the packet has been completely read.

| 5:0       | NPR      | RO   | 0x00      | Number of Packets in Receive FIFO<br>The NPR bits represent the number of packets stored in the RX FIFO. While the NPR field is greater than 0, the RXINT interrupt in the <b>MACRIS</b> register is set. |

**Register 14: Ethernet MAC Transmission Request (MACTR), offset 0x038**

This register enables software to initiate the transmission of the frame currently located in the TX FIFO. Once the frame has been transmitted from the TX FIFO or a transmission error has been encountered, the NEWTX bit is automatically cleared.

## Register 16: Ethernet PHY MDIX (MDIX), offset 0x044

This register enables the transmit and receive lines to be reversed in order to implement the MDI/MDI-X functionality. Software can implement the MDI/MDI-X configuration by using any available timer resource such as SysTick (see “System Timer (SysTick)” on page 100 for more information) to implement this functionality. Once the Ethernet Controller has been configured and enabled, software should check to see if the LINK bit in the **MR1** register has been set within approximately 1 s; if not, set the EN bit of the **MDIX** register to switch the reverse the transmit and receive lines to the PHY layer. Software should check the LINK bit again after approximately another 1 s and if no link has been established, the EN bit should be cleared. Software must continue to change the termination back and forth by setting and clearing the EN bit every 1 s until a link is established.

## 17.7 MII Management Register Descriptions

The *IEEE 802.3 standard* specifies a register set for controlling and gathering status from the PHY layer. The registers are collectively known as the MII Management registers. The **Ethernet MAC Management Control (MACMCTL)** register is used to access the MII Management registers, see page 833. All addresses given are absolute. Addresses not listed are reserved; these addresses should not be written to and any data read should be ignored. Also see “Ethernet MAC Register Descriptions” on page 817.

## Register 17: Ethernet PHY Management Register 0 – Control (MR0), address 0x00

This register enables software to configure the operation of the PHY layer. The default settings of these registers are designed to initialize the Ethernet Controller to a normal operational mode without configuration.

## Register 18: Ethernet PHY Management Register 1 – Status (MR1), address 0x01

This register enables software to determine the capabilities of the PHY layer and perform its initialization and operation appropriately.

### Ethernet PHY Management Register 1 – Status (MR1)

Base 0x4004.8000

Address 0x01

Type RO, reset 0x7809

## Register 21: Ethernet PHY Management Register 4 – Auto-Negotiation Advertisement (MR4), address 0x04

This register provides the advertised abilities of the Ethernet Controller used during auto-negotiation. Bits 8:5 represent the Technology Ability Field bits. This field can be overwritten by software to auto-negotiate to an alternate common technology. Writing to this register has no effect until auto-negotiation is re-initiated by setting the RANEG bit in the **MR0** register.

## Register 27: Ethernet PHY Management Register 29 – Interrupt Status (MR29), address 0x1D

This register contains information about the source of PHY layer interrupts. Reading this register clears any bits that are set. The PHYINT bit is set in the **MACRIS/MACIACK** register whenever any of the bits in this register are set.

## 18 Analog Comparators

An analog comparator is a peripheral that compares two analog voltages and provides a logical output that signals the comparison result.

**Note:** Not all comparators have the option to drive an output pin. See “Signal Description” on page 864 for more information.

The comparator can provide its output to a device pin, acting as a replacement for an analog comparator on the board. In addition, the comparator can signal the application via interrupts or trigger the start of a sample sequence in the ADC. The interrupt generation and ADC triggering logic is separate and independent. This flexibility means, for example, that an interrupt can be generated on a rising edge and the ADC triggered on a falling edge.

The Stellaris® LM3S8C62 microcontroller provides two independent integrated analog comparators with the following functions:

- Compare external pin input to external pin input or to internal programmable voltage reference
- Compare a test voltage against any one of the following voltages:
  - An individual external reference voltage
  - A shared single external reference voltage
  - A shared internal reference voltage

### 18.1 Block Diagram

**Figure 18-1. Analog Comparator Module Block Diagram**

## 18.2 Signal Description

The following table lists the external signals of the Analog Comparators and describes the function of each. The Analog Comparator output signals are alternate functions for some GPIO signals and default to be GPIO signals at reset. The column in the table below titled "Pin Mux/Pin Assignment" lists the possible GPIO pin placements for the Analog Comparator signals. The AFSEL bit in the **GPIO Alternate Function Select (GPIOAFSEL)** register (page 433) should be set to choose the Analog Comparator function. The number in parentheses is the encoding that must be programmed into the PMCN field in the **GPIO Port Control (GPIOCTL)** register (page 450) to assign the Analog Comparator signal to the specified GPIO port pin. The positive and negative input signals are configured by clearing the DEN bit in the **GPIO Digital Enable (GPIODEN)** register. For more information on configuring GPIOs, see "General-Purpose Input/Outputs (GPIOs)" on page 410.

a. The TTL designation indicates the pin has TTL-compatible voltage levels.

## 18.3 Functional Description

The comparator compares the VIN- and VIN+ inputs to produce an output, VOUT.

$VIN- < VIN+, VOUT = 1$

$VIN- > VIN+, VOUT = 0$

As shown in Figure 18-2 on page 865, the input source for VIN- is an external input, Cn-. In addition to an external input, Cn+, input sources for VIN+ can be the C0+ or an internal reference,  $V_{IREF}$ .

**Figure 18-2. Structure of Comparator Unit**

A comparator is configured through two status/control registers, **Analog Comparator Control (ACCTL)** and **Analog Comparator Status (ACSTAT)**. The internal reference is configured through one control register, **Analog Comparator Reference Voltage Control (ACREFCTL)**. Interrupt status and control are configured through three registers, **Analog Comparator Masked Interrupt Status (ACMIS)**, **Analog Comparator Raw Interrupt Status (ACRIS)**, and **Analog Comparator Interrupt Enable (ACINTEN)**.

Typically, the comparator output is used internally to generate an interrupt as controlled by the ISEN bit in the **ACCTL** register. The output may also be used to drive an external pin, Co or generate an analog-to-digital converter (ADC) trigger.

**Important:** The ASRCP bits in the **ACCTL** register must be set before using the analog comparators.

### 18.3.1 Internal Reference Programming

The structure of the internal reference is shown in Figure 18-3 on page 865. The internal reference is controlled by a single configuration register (**ACREFCTL**). Table 18-3 on page 866 shows the programming options to develop specific internal reference values, to compare an external voltage against a particular voltage generated internally ( $V_{IREF}$ ).

**Figure 18-3. Comparator Internal Reference Structure**

Table 18-3. Internal Reference Voltage and ACREFCTL Field Values

| ACREFCTL Register |               | Output Reference Voltage Based on VREF Field Value                                                                                                                                                                                                       |
|-------------------|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| EN Bit Value      | RNG Bit Value |                                                                                                                                                                                                                                                          |
| EN=0              | RNG=X         | 0 V (GND) for any value of VREF; however, it is recommended that RNG=1 and VREF=0 for the least noisy ground reference.                                                                                                                                  |
| EN=1              | RNG=0         | <p>Total resistance in ladder is 31 R.</p> $V_{IREF} = V_{DDA} \times \frac{R_{VREF}}{R_T}$ $V_{IREF} = V_{DDA} \times \frac{(VREF + 8)}{31}$ $V_{IREF} = 0.85 + 0.106 \times VREF$ <p>The range of internal reference in this mode is 0.85-2.448 V.</p> |
|                   | RNG=1         | <p>Total resistance in ladder is 23 R.</p> $V_{IREF} = V_{DDA} \times \frac{R_{VREF}}{R_T}$ $V_{IREF} = V_{DDA} \times \frac{VREF}{23}$ $V_{IREF} = 0.143 \times VREF$ <p>The range of internal reference for this mode is 0-2.152 V.</p>                |

## 18.4 Initialization and Configuration

The following example shows how to configure an analog comparator to read back its output value from an internal register.

1. Enable the analog comparator clock by writing a value of 0x0010.0000 to the **RCGC1** register in the System Control module (see page 257).
2. Enable the clock to the appropriate GPIO modules via the **RCGC2** register (see page 266). To find out which GPIO ports to enable, refer to Table 22-5 on page 994.
3. In the GPIO module, enable the GPIO port/pin associated with the input signals as GPIO inputs. To determine which GPIO to configure, see Table 22-4 on page 987.

4. Configure the PMCN fields in the **GPIOPCTL** register to assign the analog comparator output signals to the appropriate pins (see page 450 and Table 22-5 on page 994).
5. Configure the internal voltage reference to 1.65 V by writing the **ACREFCTL** register with the value 0x0000.030C.
6. Configure the comparator to use the internal voltage reference and to *not* invert the output by writing the **ACCTLn** register with the value of 0x0000.040C.
7. Delay for 10  $\mu$ s.
8. Read the comparator output value by reading the **ACSTATn** register's OVAL value.

Change the level of the comparator negative input signal C- to see the OVAL value change.

## 18.5 Register Map

Table 18-4 on page 867 lists the comparator registers. The offset listed is a hexadecimal increment to the register's address, relative to the Analog Comparator base address of 0x4003.C000. Note that the analog comparator clock must be enabled before the registers can be programmed (see page 257). There must be a delay of 3 system clocks after the analog comparator module clock is enabled before any analog comparator module registers are accessed.

**Table 18-4. Analog Comparators Register Map**

| Offset | Name     | Type  | Reset       | Description                                 | See page |
|--------|----------|-------|-------------|---------------------------------------------|----------|

| 0x004  | ACRIS    | RO    | 0x0000.0000 | Analog Comparator Raw Interrupt Status      | 869      |
| 0x008  | ACINTEN  | R/W   | 0x0000.0000 | Analog Comparator Interrupt Enable          | 870      |
| 0x010  | ACREFCTL | R/W   | 0x0000.0000 | Analog Comparator Reference Voltage Control | 871      |
| 0x020  | ACSTAT0  | RO    | 0x0000.0000 | Analog Comparator Status 0                  | 872      |
| 0x024  | ACCTL0   | R/W   | 0x0000.0000 | Analog Comparator Control 0                 | 873      |
| 0x040  | ACSTAT1  | RO    | 0x0000.0000 | Analog Comparator Status 1                  | 872      |
| 0x044  | ACCTL1   | R/W   | 0x0000.0000 | Analog Comparator Control 1                 | 873      |

## 18.6 Register Descriptions

The remainder of this section lists and describes the Analog Comparator registers, in numerical order by address offset.

## Register 1: Analog Comparator Masked Interrupt Status (ACMIS), offset 0x000

This register provides a summary of the interrupt status (masked) of the comparators.

### Analog Comparator Masked Interrupt Status (ACMIS)

Base 0x4003.C000

Offset 0x000

Type R/W1C, reset 0x0000.0000

## Register 4: Analog Comparator Reference Voltage Control (ACREFCTL), offset 0x010

This register specifies whether the resistor ladder is powered on as well as the range and tap.

### Analog Comparator Reference Voltage Control (ACREFCTL)

Base 0x4003.C000

Offset 0x010

Type R/W, reset 0x0000.0000

To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.                                                                                                                                                                                                            |       |             |     |                                                            |     |                                                                                |     |             |     |             |

## 19 Pulse Width Modulator (PWM)

Pulse width modulation (PWM) is a powerful technique for digitally encoding analog signal levels. High-resolution counters are used to generate a square wave, and the duty cycle of the square wave is modulated to encode an analog signal. Typical applications include switching power supplies and motor control.

The Stellaris® microcontroller contains one PWM module, with three PWM generator blocks and a control block, for a total of 6 PWM outputs. The control block determines the polarity of the PWM signals, and which signals are passed through to the pins.

Each PWM generator block produces two PWM signals that share the same timer and frequency and can either be programmed with independent actions or as a single pair of complementary signals with dead-band delays inserted. The output signals, `pwmA'` and `pwmB'`, of the PWM generation blocks are managed by the output control block before being passed to the device pins as `PWM0` and `PWM1` or `PWM2` and `PWM3`, and so on.

The Stellaris PWM module provides a great deal of flexibility and can generate simple PWM signals, such as those required by a simple charge pump as well as paired PWM signals with dead-band delays, such as those required by a half-H bridge driver.

Each PWM generator block has the following features:

- Four fault-condition handling inputs to quickly provide low-latency shutdown and prevent damage to the motor being controlled
- One 16-bit counter
  - Runs in Down or Up/Down mode
  - Output frequency controlled by a 16-bit load value
  - Load value updates can be synchronized
  - Produces output signals at zero and load value
- Two PWM comparators
  - Comparator value updates can be synchronized
  - Produces output signals on match
- PWM signal generator
  - Output PWM signal is constructed based on actions taken as a result of the counter and PWM comparator output signals
  - Produces two independent PWM signals
- Dead-band generator
  - Produces two PWM signals with programmable dead-band delays suitable for driving a half-H bridge
  - Can be bypassed, leaving input PWM signals unmodified

- Can initiate an ADC sample sequence

The control block determines the polarity of the PWM signals and which signals are passed through to the pins. The output of the PWM generation blocks are managed by the output control block before being passed to the device pins. The PWM control block has the following options:

- PWM output enable of each PWM signal
- Optional output inversion of each PWM signal (polarity control)
- Optional fault handling for each PWM signal
- Synchronization of timers in the PWM generator blocks
- Synchronization of timer/comparator updates across the PWM generator blocks
- Synchronization of PWM output enables across the PWM generator blocks
- Interrupt status summary of the PWM generator blocks
- Extended PWM fault handling, with multiple fault signals, programmable polarities, and filtering
- PWM generators can be operated independently or synchronized with other generators

## **19.1 Block Diagram**

Figure 19-1 on page 877 provides the Stellaris PWM module diagram and Figure 19-2 on page 877 provides a more detailed diagram of a Stellaris PWM generator. The LM3S8C62 controller contains three generator blocks that generate six independent PWM signals or three paired PWM signals with dead-band delays inserted.

## 19.2 Signal Description

The following table lists the external signals of the PWM module and describes the function of each. The PWM controller signals are alternate functions for some GPIO signals and default to be GPIO

signals at reset. The column in the table below titled "Pin Mux/Pin Assignment" lists the possible GPIO pin placements for these PWM signals. The AFSEL bit in the **GPIO Alternate Function Select (GPIOAFSEL)** register (page 433) should be set to choose the PWM function. The number in parentheses is the encoding that must be programmed into the PMCN field in the **GPIO Port Control (GPIOCTL)** register (page 450) to assign the PWM signal to the specified GPIO port pin. For more information on configuring GPIOs, see "General-Purpose Input/Outputs (GPIOs)" on page 410.

**Table 19-1. Signals for PWM (100LQFP)**

| Pin Name | Pin Number                      | Pin Mux / Pin Assignment                                       | Pin Type | Buffer Type <sup>a</sup> | Description                                          |

## 19.3 Functional Description

### 19.3.1 PWM Timer

The timer in each PWM generator runs in one of two modes: Count-Down mode or Count-Up/Down mode. In Count-Down mode, the timer counts from the load value to zero, goes back to the load value, and continues counting down. In Count-Up/Down mode, the timer counts from zero up to the load value, back down to zero, back up to the load value, and so on. Generally, Count-Down mode is used for generating left- or right-aligned PWM signals, while the Count-Up/Down mode is used for generating center-aligned PWM signals.

The timers output three signals that are used in the PWM generation process: the direction signal (this is always Low in Count-Down mode, but alternates between Low and High in Count-Up/Down mode), a single-clock-cycle-width High pulse when the counter is zero, and a single-clock-cycle-width High pulse when the counter is equal to the load value. Note that in Count-Down mode, the zero pulse is immediately followed by the load pulse. In the figures in this chapter, these signals are labelled "dir," "zero," and "load."

### 19.3.2 PWM Comparators

Each PWM generator has two comparators that monitor the value of the counter; when either comparator matches the counter, they output a single-clock-cycle-width High pulse, labelled "cmpA"

and "cmpB" in the figures in this chapter. When in Count-Up/Down mode, these comparators match both when counting up and when counting down, and thus are qualified by the counter direction signal. These qualified pulses are used in the PWM generation process. If either comparator match value is greater than the counter load value, then that comparator never outputs a High pulse.

Figure 19-3 on page 880 shows the behavior of the counter and the relationship of these pulses when the counter is in Count-Down mode. Figure 19-4 on page 881 shows the behavior of the counter and the relationship of these pulses when the counter is in Count-Up/Down mode. In these figures, the following definitions apply:

- LOAD is the value in the **PWMnLOAD** register
- COMPA is the value in the **PWMnCMPA** register
- COMPB is the value in the **PWMnCMPB** register
- 0 is the value zero
- load is the internal signal that has a single-clock-cycle-width High pulse when the counter is equal to the load value
- zero is the internal signal that has a single-clock-cycle-width High pulse when the counter is zero
- cmpA is the internal signal that has a single-clock-cycle-width High pulse when the counter is equal to COMPA
- cmpB is the internal signal that has a single-clock-cycle-width High pulse when the counter is equal to COMPB
- dir is the internal signal that indicates the count direction

**Figure 19-3. PWM Count-Down Mode**

**Figure 19-4. PWM Count-Up/Down Mode**

### 19.3.3 PWM Signal Generator

Each PWM generator takes the load, zero, cmpA, and cmpB pulses (qualified by the dir signal) and generates two internal PWM signals, pwmA and pwmB. In Count-Down mode, there are four events that can affect these signals: zero, load, match A down, and match B down. In Count-Up/Down mode, there are six events that can affect these signals: zero, load, match A down, match A up, match B down, and match B up. The match A or match B events are ignored when they coincide with the zero or load events. If the match A and match B events coincide, the first signal, pwmA, is generated based only on the match A event, and the second signal, pwmB, is generated based only on the match B event.

For each event, the effect on each output PWM signal is programmable: it can be left alone (ignoring the event), it can be toggled, it can be driven Low, or it can be driven High. These actions can be used to generate a pair of PWM signals of various positions and duty cycles, which do or do not overlap. Figure 19-5 on page 881 shows the use of Count-Up/Down mode to generate a pair of center-aligned, overlapped PWM signals that have different duty cycles. This figure shows the pwmA and pwmB signals before they have passed through the dead-band generator.

**Figure 19-5. PWM Generation Example In Count-Up/Down Mode**

In this example, the first generator is set to drive High on match A up, drive Low on match A down, and ignore the other four events. The second generator is set to drive High on match B up, drive Low on match B down, and ignore the other four events. Changing the value of comparator A changes the duty cycle of the pwmA signal, and changing the value of comparator B changes the duty cycle of the pwmB signal.

### 19.3.4 Dead-Band Generator

The pwmA and pwmB signals produced by each PWM generator are passed to the dead-band generator. If the dead-band generator is disabled, the PWM signals simply pass through to the pwmA' and pwmB' signals unmodified. If the dead-band generator is enabled, the pwmB signal is lost and two PWM signals are generated based on the pwmA signal. The first output PWM signal, pwmA' is the pwmA signal with the rising edge delayed by a programmable amount. The second output PWM signal, pwmB', is the inversion of the pwmA signal with a programmable delay added between the falling edge of the pwmA signal and the rising edge of the pwmB' signal.

The resulting signals are a pair of active High signals where one is always High, except for a programmable amount of time at transitions where both are Low. These signals are therefore suitable for driving a half-H bridge, with the dead-band delays preventing shoot-through current from damaging the power electronics. Figure 19-6 on page 882 shows the effect of the dead-band generator on the pwmA signal and the resulting pwmA' and pwmB' signals that are transmitted to the output control block.

**Figure 19-6. PWM Dead-Band Generator**

### 19.3.5 Interrupt/ADC-Trigger Selector

Each PWM generator also takes the same four (or six) counter events and uses them to generate an interrupt or an ADC trigger. Any of these events or a set of these events can be selected as a source for an interrupt; when any of the selected events occur, an interrupt is generated. Additionally, the same event, a different event, the same set of events, or a different set of events can be selected as a source for an ADC trigger; when any of these selected events occur, an ADC trigger pulse is generated. The selection of events allows the interrupt or ADC trigger to occur at a specific position within the pwmA or pwmB signal. Note that interrupts and ADC triggers are based on the raw events; delays in the PWM signal edges caused by the dead-band generator are not taken into account.

### 19.3.6 Synchronization Methods

The PWM module provides three PWM generators, each providing two PWM outputs that may be used in a wide variety of applications. Generally speaking, the PWM is used in one of two categories of operation:

- **Unsynchronized.** The PWM generator and its two output signals are used alone, independent of other PWM generators.
- **Synchronized.** The PWM generator and its two outputs signals are used in conjunction with other PWM generators using a common, unified time base. If multiple PWM generators are configured with the same counter load value, synchronization can be used to guarantee that they also have the same count value (the PWM generators must be configured before they are synchronized). With this feature, more than two PWMn signals can be produced with a known relationship between the edges of those signals because the counters always have the same values. Other states in the module provide mechanisms to maintain the common time base and mutual synchronization.

The counter in a PWM generator can be reset to zero by writing the **PWM Time Base Sync (PWMSYNC)** register and setting the SYNCn bit associated with the generator. Multiple PWM generators can be synchronized together by setting all necessary SYNCn bits in one access. For example, setting the SYNC0 and SYNC1 bits in the **PWMSYNC** register causes the counters in PWM generators 0 and 1 to reset together.

Additional synchronization can occur between multiple PWM generators by updating register contents in one of the following three ways:

- **Immediately.** The write value has immediate effect, and the hardware reacts immediately.
- **Locally Synchronized.** The write value does not affect the logic until the counter reaches the value zero at the end of the PWM cycle. In this case, the effect of the write is deferred, providing a guaranteed defined behavior and preventing overly short or overly long output PWM pulses.
- **Globally Synchronized.** The write value does not affect the logic until two sequential events have occurred: (1) the Update mode for the generator function is programmed for global synchronization in the **PWMnCTL** register, and (2) the counter reaches zero at the end of the PWM cycle. In this case, the effect of the write is deferred until the end of the PWM cycle following the end of all updates. This mode allows multiple items in multiple PWM generators to be updated simultaneously without odd effects during the update; everything runs from the old values until a point at which they all run from the new values. The Update mode of the load and comparator match values can be individually configured in each PWM generator block. It typically makes sense to use the synchronous update mechanism across PWM generator blocks when the timers in those blocks are synchronized, although this is not required in order for this mechanism to function properly.

The following registers provide either local or global synchronization based on the state of various Update mode bits and fields in the **PWMnCTL** register (LOADUPD; CMPAUPD; CMPBUPD):

- Generator Registers: **PWMnLOAD**, **PWMnCMPA**, and **PWMnCMPB**

The following registers default to immediate update, but are provided with the optional functionality of synchronously updating rather than having all updates take immediate effect:

- Module-Level Register: **PWMENABLE** (based on the state of the ENUPDn bits in the PWMENUPD register).
- Generator Register: **PWMnGENA**, **PWMnGENB**, **PWMnDBCTL**, **PWMnDBRISE**, and **PWMnDBFALL** (based on the state of various Update mode bits and fields in the **PWMnCTL** register (GENAUPD; GENBUPD; DBCTLUPD; DBRISEUPD; DBFALLUPD)).

All other registers are considered statically provisioned for the execution of an application or are used dynamically for purposes unrelated to maintaining synchronization and therefore do not need synchronous update functionality.

### 19.3.7 Fault Conditions

A fault condition is one in which the controller must be signaled to stop normal PWM function and then set the PWMn signals to a safe state. Two basic situations cause fault conditions:

- The microcontroller is stalled and cannot perform the necessary computation in the time required for motion control
- An external error or event is detected

The PWM generator can use the following inputs to generate a fault condition, including:

- FAULTn pin assertion
- A stall of the controller generated by the debugger
- The trigger of an ADC digital comparator

Fault conditions are calculated on a per-PWM generator basis. Each PWM generator configures the necessary conditions to indicate a fault condition exists. This method allows the development of applications with dependent and independent control.

Four fault input pins (FAULT0-FAULT3). These inputs may be used with circuits that generate an active High or active Low signal to indicate an error condition. A FAULTn pins may be individually programmed for the appropriate logic sense using the **PWMnFLTSSEN** register.

The PWM generator's mode control, including fault condition handling, is provided in the **PWMnCTL** register. This register determines whether the input or a combination of FAULTn input signals and/or digital comparator triggers (as configured by the **PWMnFLTSRC0** and **PWMnFLTSRC1** registers) is used to generate a fault condition. The **PWMnCTL** register also selects whether the fault condition is maintained as long as the external condition lasts or if it is latched until the fault condition until cleared by software. Finally, this register also enables a counter that may be used to extend the period of a fault condition for external events to assure that the duration is a minimum length. The minimum fault period count is specified in the **PWMnMINFLTPER** register.

Status regarding the specific fault cause is provided in the **PWMnFLTSTAT0** and **PWMnFLTSTAT1** registers.

PWM generator fault conditions may be promoted to a controller interrupt using the **PWMINTEN** register.

### 19.3.8 Output Control Block

The output control block takes care of the final conditioning of the pwmA' and pwmB' signals before they go to the pins as the PWMn signals. Via a single register, the **PWM Output Enable (PWENABLE)** register, the set of PWM signals that are actually enabled to the pins can be modified. This function can be used, for example, to perform commutation of a brushless DC motor with a single register write (and without modifying the individual PWM generators, which are modified by the feedback control loop). In addition, the updating of the bits in the **PWENABLE** register can be configured to be immediate or locally or globally synchronized to the next synchronous update using the **PWM Enable Update (PWMENUPD)** register.

During fault conditions, the PWM output signals, PWMn, usually must be driven to safe values so that external equipment may be safely controlled. The **PWMFAULT** register specifies whether during a fault condition, the generated signal continues to be passed driven or to an encoding specified in the **PWMFAULTVAL** register.

A final inversion can be applied to any of the PWMn signals, making them active Low instead of the default active High using the **PWM Output Inversion (PWMINVERT)**. The inversion is applied even if a value has been enabled in the **PWMFAULT** register and specified in the **PWMFAULTVAL** register. In other words, if a bit is set in the **PWMFAULT**, **PWMFAULTVAL**, and **PWMINVERT** registers, the output on the PWMn signal is 0, not 1 as specified in the **PWMFAULTVAL** register.

## 19.4 Initialization and Configuration

The following example shows how to initialize PWM Generator 0 with a 25-kHz frequency, a 25% duty cycle on the PWM0 pin, and a 75% duty cycle on the PWM1 pin. This example assumes the system clock is 20 MHz.

1. Enable the PWM clock by writing a value of 0x0010.0000 to the **RCGC0** register in the System Control module (see page 249).
2. Enable the clock to the appropriate GPIO module via the **RCGC2** register in the System Control module (see page 266).
3. In the GPIO module, enable the appropriate pins for their alternate function using the **GPIOAFSEL** register. To determine which GPIOs to configure, see Table 22-4 on page 987.
4. Configure the PMCN fields in the **GPIOPCTL** register to assign the PWM signals to the appropriate pins (see page 450 and Table 22-5 on page 994).
5. Configure the **Run-Mode Clock Configuration (RCC)** register in the System Control module to use the PWM divide (USEPWMDIV) and set the divider (PWMDIV) to divide by 2 (000).
6. Configure the PWM generator for countdown mode with immediate updates to the parameters.
  - Write the **PWM0CTL** register with a value of 0x0000.0000.
  - Write the **PWM0GENA** register with a value of 0x0000.008C.
  - Write the **PWM0GENB** register with a value of 0x0000.080C.
7. Set the period. For a 25-KHz frequency, the period = 1/25,000, or 40 microseconds. The PWM clock source is 10 MHz; the system clock divided by 2. Thus there are 400 clock ticks per period. Use this value to set the **PWM0LOAD** register. In Count-Down mode, set the LOAD field in the **PWM0LOAD** register to the requested period minus one.
  - Write the **PWM0LOAD** register with a value of 0x0000.018F.
8. Set the pulse width of the PWM0 pin for a 25% duty cycle.
  - Write the **PWM0CMPA** register with a value of 0x0000.012B.
9. Set the pulse width of the PWM1 pin for a 75% duty cycle.
  - Write the **PWM0CMPB** register with a value of 0x0000.0063.
10. Start the timers in PWM generator 0.
  - Write the **PWM0CTL** register with a value of 0x0000.0001.
11. Enable PWM outputs.
  - Write the **PWMENABLE** register with a value of 0x0000.0003.

## 19.5 Register Map

Table 19-3 on page 886 lists the PWM registers. The offset listed is a hexadecimal increment to the register's address, relative to the PWM module's base address:

## ■ PWM0: 0x4002.8000

Note that the PWM module clock must be enabled before the registers can be programmed (see page 249). There must be a delay of 3 system clocks after the PWM module clock is enabled before any PWM module registers are accessed.

**Table 19-3. PWM Register Map**

| Offset | Name          | Type  | Reset       | Description                       | See page |
|--------|---------------|-------|-------------|-----------------------------------|----------|
| 0x000  | PWMCTL        | R/W   | 0x0000.0000 | PWM Master Control                | 889      |

## 19.6 Register Descriptions

The remainder of this section lists and describes the PWM registers, in numerical order by address offset.

## Register 1: PWM Master Control (PWMCTL), offset 0x000

This register provides master control over the PWM generation blocks.

### PWM Master Control (PWMCTL)

PWM0 base: 0x4002.8000

Offset 0x000

Type R/W, reset 0x0000.0000

|       | 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19          | 18          | 17          | 16  |
|-------|----------|----|----|----|----|----|----|----|----|----|----|----|-------------|-------------|-------------|-----|
|       | reserved |    |    |    |    |    |    |    |    |    |    |    |             |             |             |     |
| Type  | RO       | RO | RO | RO | RO | RO | RO | RO | RO | RO | RO | RO | RO          | RO          | RO          | RO  |

**Register 2: PWM Time Base Sync (PWMSYNC), offset 0x004**

This register provides a method to perform synchronization of the counters in the PWM generation blocks. Setting a bit in this register causes the specified counter to reset back to 0; setting multiple bits resets multiple counters simultaneously. The bits auto-clear after the reset has occurred; reading them back as zero indicates that the synchronization has completed.

**PWM Time Base Sync (PWMSYNC)**

PWM0 base: 0x4002.8000

Offset 0x004

### Register 3: PWM Output Enable (PWMENABLE), offset 0x008

This register provides a master control of which generated pwmA' and pwmB' signals are output to the PWMn pins. By disabling a PWM output, the generation process can continue (for example, when the time bases are synchronized) without driving PWM signals to the pins. When bits in this register are set, the corresponding pwmA' or pwmB' signal is passed through to the output stage. When bits are clear, the pwmA' or pwmB' signal is replaced by a zero value which is also passed to the output stage. The **PWMINVERT** register controls the output stage, so if the corresponding bit is set in that register, the value seen on the PWMn signal is inverted from what is configured by the bits in this register. Updates to the bits in this register can be immediate or locally or globally synchronized to the next synchronous update as controlled by the ENUPDn fields in the **PWMENUPD** register.

## Register 4: PWM Output Inversion (PWMINVERT), offset 0x00C

This register provides a master control of the polarity of the PWMn signals on the device pins. The pwmA' and pwmB' signals generated by the PWM generator are active High; but can be made active Low via this register. Disabled PWM channels are also passed through the output inverter (if so configured) so that inactive signals can be High. In addition, if the **PWMFAULT** register enables a specific value to be placed on the PWMn signals during a fault condition, that value is inverted if the corresponding bit in this register is set.

## Register 5: PWM Output Fault (PWMFAULT), offset 0x010

This register controls the behavior of the PWMn outputs in the presence of fault conditions. Both the fault inputs (FAULTn pins and digital comparator outputs) and debug events are considered fault conditions. On a fault condition, each pwmA' or pwmB' signal can be passed through unmodified or driven to the value specified by the corresponding bit in the **PWMFAULTVAL** register. For outputs that are configured for pass-through, the debug event handling on the corresponding PWM generator also determines if the pwmA' or pwmB' signal continues to be generated.

Fault condition control occurs before the output inverter, so PWM signals driven to a specified value on fault are inverted if the channel is configured for inversion (therefore, the pin is driven to the logical complement of the specified value on a fault condition).

## Register 6: PWM Interrupt Enable (PWMINTEN), offset 0x014

This register controls the global interrupt generation capabilities of the PWM module. The events that can cause an interrupt are the fault input and the individual interrupts from the PWM generators.

## Register 7: PWM Raw Interrupt Status (PWMRIS), offset 0x018

This register provides the current set of interrupt sources that are asserted, regardless of whether they are enabled to cause an interrupt to be asserted to the interrupt controller. The fault interrupt is asserted based on the fault condition source that is specified by the **PWMnCTL**, **PWMnFLTSRC0** and **PWMnFLTSRC1** registers. The fault interrupt is latched on detection and must be cleared through the **PWM Interrupt Status and Clear (PWMISC)** register. The actual value of the FAULTn signals can be observed using the **PWMSTATUS** register.

The PWM generator interrupts simply reflect the status of the PWM generators and are cleared via the interrupt status register in the PWM generator blocks. If a bit is set, the event is active; if a bit is clear the event is not active.

## Register 8: PWM Interrupt Status and Clear (PWMISC), offset 0x01C

This register provides a summary of the interrupt status of the individual PWM generator blocks. If a fault interrupt is set, the corresponding FAULTn input has caused an interrupt. For the fault interrupt, a write of 1 to that bit position clears the latched interrupt status. If an block interrupt bit is set, the corresponding generator block is asserting an interrupt. The individual interrupt status registers, **PWMnISC**, in each block must be consulted to determine the reason for the interrupt and used to clear the interrupt.

## Register 10: PWM Fault Condition Value (PWMFAULTVAL), offset 0x024

This register specifies the output value driven on the PWMn signals during a fault condition if enabled by the corresponding bit in the **PWMFAULT** register. Note that if the corresponding bit in the **PWMINVERT** register is set, the output value is driven to the logical NOT of the bit value in this register.

### PWM Fault Condition Value (PWMFAULTVAL)

PWM0 base: 0x4002.8000

**Register 11: PWM Enable Update (PWMENUPD), offset 0x028**

This register specifies when updates to the PWMnEN bit in the **PWMENABLE** register are performed. The PWMnEN bit enables the pwmA' or pwmB' output to be passed to the microcontroller's pin. Updates can be immediate or locally or globally synchronized to the next synchronous update.

**PWM Enable Update (PWMENUPD)**

PWM0 base: 0x4002.8000

Offset 0x028

Type R/W, reset 0x0000.0000

**Register 12: PWM0 Control (PWM0CTL), offset 0x040****Register 13: PWM1 Control (PWM1CTL), offset 0x080****Register 14: PWM2 Control (PWM2CTL), offset 0x0C0**

These registers configure the PWM signal generation blocks (PWM0CTL controls the PWM generator 0 block, and so on). The Register Update mode, Debug mode, Counting mode, and Block Enable mode are all controlled via these registers. The blocks produce the PWM signals, which can be either two independent PWM signals (from the same counter), or a paired set of PWM signals with dead-band delays added.

The PWM0 block produces the PWM0 and PWM1 outputs, the PWM1 block produces the PWM2 and PWM3 outputs, and the PWM2 block produces the PWM4 and PWM5 outputs.

**PWM0 Control (PWM0CTL)**

|           |          |      |       | A fault condition is in effect for as long as the generating source is asserting.                                                                                                                         |
|           |          |      |       | 1 Fault Condition Latched                                                                                                                                                                                 |
|           |          |      |       | A fault condition is set as the result of the assertion of the faulting source and is held (latched) while the <b>PWMISC</b> INTFAULTn bit is set. Clearing the INTFAULTn bit clears the fault condition. |

| Bit/Field | Name      | Type | Reset | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-----------|-----------|------|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 17        | MINFLTPER | R/W  | 0     | <p>Minimum Fault Period</p> <p>This bit specifies that the PWM generator enables a one-shot counter to provide a minimum fault condition period.</p> <p>The timer begins counting on the rising edge of the fault condition to extend the condition for a minimum duration of the count value. The timer ignores the state of the fault condition while counting.</p> <p>The minimum fault delay is in effect only when the MINFLTPER bit is set. If a detected fault is in the process of being extended when the MINFLTPER bit is cleared, the fault condition extension is aborted.</p> <p>The delay time is specified by the <b>PWMnMINFLTPER</b> register MFP field value. The effect of this is to pulse stretch the fault condition input.</p> <p>The delay value is defined by the PWM clock period. Because the fault input is not synchronized to the PWM clock, the period of the time is <math>PWMClock * (MFP \text{ value} + 1)</math> or <math>PWMClock * (MFP \text{ value} + 2)</math>.</p> <p>The delay function makes sense only if the fault source is unlatched. A latched fault source makes the fault condition appear asserted until cleared by software and negates the utility of the extend feature. It applies to all fault condition sources as specified in the FLTSRC field.</p> <p>Value Description</p> <p>0 The FAULT input deassertion is unaffected.</p> <p>1 The <b>PWMnMINFLTPER</b> one-shot counter is active and extends the period of the fault condition to a minimum period.</p> |
| 16        | FLTSRC    | R/W  | 0     | <p>Fault Condition Source</p> <p>Value Description</p> <p>0 The Fault condition is determined by the Fault0 input.</p> <p>1 The Fault condition is determined by the configuration of the <b>PWMnFLTSRC0</b> and <b>PWMnFLTSRC1</b> registers.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

**Register 15: PWM0 Interrupt and Trigger Enable (PWM0INTEN), offset 0x044****Register 16: PWM1 Interrupt and Trigger Enable (PWM1INTEN), offset 0x084****Register 17: PWM2 Interrupt and Trigger Enable (PWM2INTEN), offset 0x0C4**

These registers control the interrupt and ADC trigger generation capabilities of the PWM generators (**PWM0INTEN** controls the PWM generator 0 block, and so on). The events that can cause an interrupt or an ADC trigger are:

- The counter being equal to the load register
- The counter being equal to zero
- The counter being equal to the **PWMnCMPA** register while counting up
- The counter being equal to the **PWMnCMPA** register while counting down
- The counter being equal to the **PWMnCMPB** register while counting up
- The counter being equal to the **PWMnCMPB** register while counting down

Any combination of these events can generate either an interrupt or an ADC trigger, though no determination can be made as to the actual event that caused an ADC trigger if more than one is specified. The **PWMnRIS** register provides information about which events have caused raw interrupts.

**PWM0 Interrupt and Trigger Enable (PWM0INTEN)**

PWM0 base: 0x4002.8000

Offset 0x044

Type R/W, reset 0x0000.0000

**Register 18: PWM0 Raw Interrupt Status (PWM0RIS), offset 0x048****Register 19: PWM1 Raw Interrupt Status (PWM1RIS), offset 0x088****Register 20: PWM2 Raw Interrupt Status (PWM2RIS), offset 0x0C8**

These registers provide the current set of interrupt sources that are asserted, regardless of whether they cause an interrupt to be asserted to the controller (**PWM0RIS** controls the PWM generator 0 block, and so on). If a bit is set, the event has occurred; if a bit is clear, the event has not occurred. Bits in this register are cleared by writing a 1 to the corresponding bit in the **PWMnISC** register.

**PWM0 Raw Interrupt Status (PWM0RIS)**

PWM0 base: 0x4002.8000

Offset 0x048

Type RO, reset 0x0000.0000

**Register 21: PWM0 Interrupt Status and Clear (PWM0ISC), offset 0x04C****Register 22: PWM1 Interrupt Status and Clear (PWM1ISC), offset 0x08C****Register 23: PWM2 Interrupt Status and Clear (PWM2ISC), offset 0x0CC**

These registers provide the current set of interrupt sources that are asserted to the interrupt controller (**PWM0ISC** controls the PWM generator 0 block, and so on). A bit is set if the event has occurred and is enabled in the **PWMnINTEN** register; if a bit is clear, the event has not occurred or is not enabled. These are R/W1C registers; writing a 1 to a bit position clears the corresponding interrupt reason.

**PWM0 Interrupt Status and Clear (PWM0ISC)**

**Register 24: PWM0 Load (PWM0LOAD), offset 0x050****Register 25: PWM1 Load (PWM1LOAD), offset 0x090****Register 26: PWM2 Load (PWM2LOAD), offset 0x0D0**

These registers contain the load value for the PWM counter (**PWM0LOAD** controls the PWM generator 0 block, and so on). Based on the counter mode configured by the **MODE** bit in the **PWMnCTL** register, this value is either loaded into the counter after it reaches zero or is the limit of up-counting after which the counter decrements back to zero. When this value matches the counter, a pulse is output which can be configured to drive the generation of the pwmA and/or pwmB signal (via the **PWMnGENA/PWMnGENB** register) or drive an interruptor ADC trigger (via the **PWMnINTEN** register).

If the Load Value Update mode is locally synchronized (based on the **LOADUPD** field encoding in the **PWMnCTL** register), the 16-bit **LOAD** value is used the next time the counter reaches zero. If the update mode is globally synchronized, it is used the next time the counter reaches zero after a synchronous update has been requested through the **PWM Master Control (PWMCTL)** register (see page 889). If this register is re-written before the actual update occurs, the previous value is never used and is lost.

**Register 36: PWM0 Generator A Control (PWM0GENA), offset 0x060****Register 37: PWM1 Generator A Control (PWM1GENA), offset 0x0A0****Register 38: PWM2 Generator A Control (PWM2GENA), offset 0x0E0**

These registers control the generation of the pwmA signal based on the load and zero output pulses from the counter, as well as the compare A and compare B pulses from the comparators (**PWM0GENA** controls the PWM generator 0 block, and so on). When the counter is running in Count-Down mode, only four of these events occur; when running in Count-Up/Down mode, all six occur. These events provide great flexibility in the positioning and duty cycle of the resulting PWM signal.

The **PWM0GENA** register controls generation of the pwm0A signal; **PWM1GENA**, the pwm1A signal; and **PWM2GENA**, the pwm2A signal.

If a zero or load event coincides with a compare A or compare B event, the zero or load action is taken and the compare A or compare B action is ignored. If a compare A event coincides with a compare B event, the compare A action is taken and the compare B action is ignored.

If the Generator A update mode is immediate (based on the GENAUPD field encoding in the **PWMnCTL** register), the ACTCMPBD, ACTCMPBU, ACTCMPAD, ACTCMPAU, ACTLOAD, and ACTZERO values are used immediately. If the update mode is locally synchronized, these values are used the next time the counter reaches zero. If the update mode is globally synchronized, these values are used the next time the counter reaches zero after a synchronous update has been requested through the **PWM Master Control (PWMCTL)** register (see page 889). If this register is rewritten before the actual update occurs, the previous value is never used and is lost.

**PWM0 Generator A Control (PWM0GENA)**

**Register 39: PWM0 Generator B Control (PWM0GENB), offset 0x064****Register 40: PWM1 Generator B Control (PWM1GENB), offset 0x0A4****Register 41: PWM2 Generator B Control (PWM2GENB), offset 0x0E4**

These registers control the generation of the pwmB signal based on the load and zero output pulses from the counter, as well as the compare A and compare B pulses from the comparators (**PWM0GENB** controls the PWM generator 0 block, and so on). When the counter is running in Count-Down mode, only four of these events occur; when running in Count-Up/Down mode, all six occur. These events provide great flexibility in the positioning and duty cycle of the resulting PWM signal.

The **PWM0GENB** register controls generation of the pwm0B signal; **PWM1GENB**, the pwm1B signal; and **PWM2GENB**, the pwm2B signal.

If a zero or load event coincides with a compare A or compare B event, the zero or load action is taken and the compare A or compare B action is ignored. If a compare A event coincides with a compare B event, the compare B action is taken and the compare A action is ignored.

If the Generator B update mode is immediate (based on the GENBUPD field encoding in the **PWMnCTL** register), the ACTCMPBD, ACTCMPBU, ACTCMPAD, ACTCMPAU, ACTLOAD, and ACTZERO values are used immediately. If the update mode is locally synchronized, these values are used the next time the counter reaches zero. If the update mode is globally synchronized, these values are used the next time the counter reaches zero after a synchronous update has been requested through the **PWM Master Control (PWMCTL)** register (see page 889). If this register is rewritten before the actual update occurs, the previous value is never used and is lost.

**PWM0 Generator B Control (PWM0GENB)**

**Register 42: PWM0 Dead-Band Control (PWM0DBCTL), offset 0x068****Register 43: PWM1 Dead-Band Control (PWM1DBCTL), offset 0x0A8****Register 44: PWM2 Dead-Band Control (PWM2DBCTL), offset 0x0E8**

The **PWMnDBCTL** register controls the dead-band generator, which produces the PWMn signals based on the pwmA and pwmB signals. When disabled, the pwmA signal passes through to the pwmA' signal and the pwmB signal passes through to the pwmB' signal. When dead-band control is enabled, the pwmB signal is ignored, the pwmA' signal is generated by delaying the rising edge(s) of the pwmA signal by the value in the **PWMnDBRISE** register (see page 933), and the pwmB' signal is generated by inverting the pwmA signal and delaying the falling edge(s) of the pwmA signal by the value in the **PWMnDBFALL** register (see page 934). The Output Control block outputs the pwm0A' signal on the PWM0 signal and the pwm0B' signal on the PWM1 signal. In a similar manner, PWM2 and PWM3 are produced from the pwm1A' and pwm1B' signals, and PWM4 and PWM5 are produced from the pwm2A' and pwm2B' signals.

If the Dead-Band Control mode is immediate (based on the DBCTLUPD field encoding in the **PWMnCTL** register), the ENABLE bit value is used immediately. If the update mode is locally synchronized, this value is used the next time the counter reaches zero. If the update mode is globally synchronized, this value is used the next time the counter reaches zero after a synchronous update has been requested through the **PWM Master Control (PWMCTL)** register (see page 889). If this register is rewritten before the actual update occurs, the previous value is never used and is lost.

**PWM0 Dead-Band Control (PWM0DBCTL)**

PWM0 base: 0x4002.8000  
Offset 0x068  
Type R/W, reset 0x0000.0000

**Register 45: PWM0 Dead-Band Rising-Edge Delay (PWM0DBRISE), offset 0x06C****Register 46: PWM1 Dead-Band Rising-Edge Delay (PWM1DBRISE), offset 0x0AC****Register 47: PWM2 Dead-Band Rising-Edge Delay (PWM2DBRISE), offset 0x0EC**

The **PWMnDBRISE** register contains the number of clock cycles to delay the rising edge of the pwmA signal when generating the pwmA' signal. If the dead-band generator is disabled through the **PWMnDBCTL** register, this register is ignored. If the value of this register is larger than the width of a High pulse on the pwmA signal, the rising-edge delay consumes the entire High time of the signal, resulting in no High time on the output. Care must be taken to ensure that the pwmA High time always exceeds the rising-edge delay.

If the Dead-Band Rising-Edge Delay mode is immediate (based on the DBRISEUPD field encoding in the **PWMnCTL** register), the 12-bit RISEDELAY value is used immediately. If the update mode is locally synchronized, this value is used the next time the counter reaches zero. If the update mode is globally synchronized, this value is used the next time the counter reaches zero after a synchronous update has been requested through the **PWM Master Control (PWMCTL)** register (see page 889). If this register is rewritten before the actual update occurs, the previous value is never used and is lost.

**PWM0 Dead-Band Rising-Edge Delay (PWM0DBRISE)**

**Register 51: PWM0 Fault Source 0 (PWM0FLTSRC0), offset 0x074****Register 52: PWM1 Fault Source 0 (PWM1FLTSRC0), offset 0x0B4****Register 53: PWM2 Fault Source 0 (PWM2FLTSRC0), offset 0x0F4**

This register specifies which fault pin inputs are used to generate a fault condition. Each bit in the following register indicates whether the corresponding fault pin is included in the fault condition. All enabled fault pins are ORed together to form the **PWMnFLTSRC0** portion of the fault condition. The **PWMnFLTSRC0** fault condition is then ORed with the **PWMnFLTSRC1** fault condition to generate the final fault condition for the PWM generator.

If the FLTSRC bit in the **PWMnCTL** register (see page 910) is clear, only the Fault0 signal affects the fault condition generated. Otherwise, sources defined in **PWMnFLTSRC0** and **PWMnFLTSRC1** affect the fault condition generated.

**Register 57: PWM0 Minimum Fault Period (PWM0MINFLTPER), offset 0x07C****Register 58: PWM1 Minimum Fault Period (PWM1MINFLTPER), offset 0x0BC****Register 59: PWM2 Minimum Fault Period (PWM2MINFLTPER), offset 0x0FC**

If the MINFLTPER bit in the **PWMnCTL** register is set, this register specifies the 16-bit time-extension value to be used in extending the fault condition. The value is loaded into a 16-bit down counter, and the counter value is used to extend the fault condition. The fault condition is released in the clock immediately after the counter value reaches 0. The fault condition is asynchronous to the PWM clock; and the delay value is the product of the PWM clock period and the (MFP field value + 1) or (MFP field value + 2) depending on when the fault condition asserts with respect to the PWM clock. The counter decrements at the PWM clock rate, without pause or condition.

**Register 64: PWM0 Fault Status 0 (PWM0FLTSTAT0), offset 0x804****Register 65: PWM1 Fault Status 0 (PWM1FLTSTAT0), offset 0x884****Register 66: PWM2 Fault Status 0 (PWM2FLTSTAT0), offset 0x904**

Along with the **PWMnFLTSTAT1** register, this register provides status regarding the fault condition inputs.

If the LATCH bit in the **PWMnCTL** register is clear, the contents of the **PWMnFLTSTAT0** register are read-only (RO) and provide the current state of the FAULTn inputs.

If the LATCH bit in the **PWMnCTL** register is set, the contents of the **PWMnFLTSTAT0** register are read / write 1 to clear (R/W1C) and provide a latched version of the FAULTn inputs. In this mode, the register bits are cleared by writing a 1 to a set bit. The FAULTn inputs are recorded after their sense is adjusted in the generator.

The contents of this register can only be written if the fault source extensions are enabled (the FLTSRC bit in the **PWMnCTL** register is set).

**PWM0 Fault Status 0 (PWM0FLTSTAT0)**

**Register 67: PWM0 Fault Status 1 (PWM0FLTSTAT1), offset 0x808****Register 68: PWM1 Fault Status 1 (PWM1FLTSTAT1), offset 0x888****Register 69: PWM2 Fault Status 1 (PWM2FLTSTAT1), offset 0x908**

Along with the **PWMnFLTSTAT0** register, this register provides status regarding the fault condition inputs.

If the LATCH bit in the **PWMnCTL** register is clear, the contents of the **PWMnFLTSTAT1** register are read-only (RO) and provide the current state of the digital comparator triggers.

If the LATCH bit in the **PWMnCTL** register is set, the contents of the **PWMnFLTSTAT1** register are read / write 1 to clear (R/W1C) and provide a latched version of the digital comparator triggers. In this mode, the register bits are cleared by writing a 1 to a set bit. The contents of this register can only be written if the fault source extensions are enabled (the FLTSRC bit in the **PWMnCTL** register is set).

**PWM0 Fault Status 1 (PWM0FLTSTAT1)**

PWM0 base: 0x4002.8000

## 20 Quadrature Encoder Interface (QEI)

A quadrature encoder, also known as a 2-channel incremental encoder, converts linear displacement into a pulse signal. By monitoring both the number of pulses and the relative phase of the two signals, you can track the position, direction of rotation, and speed. In addition, a third channel, or index signal, can be used to reset the position counter.

The LM3S8C62 microcontroller includes two quadrature encoder interface (QEI) modules. Each QEI module interprets the code produced by a quadrature encoder wheel to integrate position over time and determine direction of rotation. In addition, it can capture a running estimate of the velocity of the encoder wheel.

The Stellaris® LM3S8C62 microcontroller includes two QEI modules providing control of two motors at the same time with the following features:

- Position integrator that tracks the encoder position
- Programmable noise filter on the inputs
- Velocity capture using built-in timer
- The input frequency of the QEI inputs may be as high as 1/4 of the processor frequency (for example, 12.5 MHz for a 50-MHz system)
- Interrupt generation on:
  - Index pulse
  - Velocity-timer expiration
  - Direction change
  - Quadrature error detection

### 20.1 Block Diagram

Figure 20-1 on page 948 provides a block diagram of a Stellaris QEI module.

Figure 20-1. QEI Block Diagram

## 20.2 Signal Description

The following table lists the external signals of the QEI module and describes the function of each. The QEI signals are alternate functions for some GPIO signals and default to be GPIO signals at reset. The column in the table below titled "Pin Mux/Pin Assignment" lists the possible GPIO pin placements for these QEI signals. The AFSEL bit in the **GPIO Alternate Function Select (GPIOAFSEL)** register (page 433) should be set to choose the QEI function. The number in parentheses is the encoding that must be programmed into the PMCN field in the **GPIO Port Control (GPIOPCTL)** register (page 450) to assign the QEI signal to the specified GPIO port pin. For more information on configuring GPIOs, see "General-Purpose Input/Outputs (GPIOs)" on page 410.

Table 20-1. Signals for QEI (100LQFP)

a. The TTL designation indicates the pin has TTL-compatible voltage levels.

## 20.3 Functional Description

The QE1 module interprets the two-bit gray code produced by a quadrature encoder wheel to integrate position over time and determine direction of rotation. In addition, it can capture a running estimate of the velocity of the encoder wheel.

The position integrator and velocity capture can be independently enabled, though the position integrator must be enabled before the velocity capture can be enabled. The two phase signals, PhA and PhB, can be swapped before being interpreted by the QE1 module to change the meaning of forward and backward and to correct for miswiring of the system. Alternatively, the phase signals can be interpreted as a clock and direction signal as output by some encoders.

The QE1 module input signals have a digital noise filter on them that can be enabled to prevent spurious operation. The noise filter requires that the inputs be stable for a specified number of consecutive clock cycles before updating the edge detector. The filter is enabled by the FILTEN bit in the **QE1 Control (QEICTL)** register. The frequency of the input update is programmable using the FILTCNT bit field in the **QEICTL** register.

The QE1 module supports two modes of signal operation: quadrature phase mode and clock/direction mode. In quadrature phase mode, the encoder produces two clocks that are 90 degrees out of phase; the edge relationship is used to determine the direction of rotation. In clock/direction mode, the encoder produces a clock signal to indicate steps and a direction signal to indicate the direction of rotation. This mode is determined by the SIGMODE bit of the **QEICTL** register (see page 954).

When the QE1 module is set to use the quadrature phase mode (SIGMODE bit is clear), the capture mode for the position integrator can be set to update the position counter on every edge of the PhA

signal or to update on every edge of both PhA and PhB. Updating the position counter on every PhA and PhB edge provides more positional resolution at the cost of less range in the positional counter.

When edges on PhA lead edges on PhB, the position counter is incremented. When edges on PhB lead edges on PhA, the position counter is decremented. When a rising and falling edge pair is seen on one of the phases without any edges on the other, the direction of rotation has changed.

The positional counter is automatically reset on one of two conditions: sensing the index pulse or reaching the maximum position value. The reset mode is determined by the RESMODE bit of the **QEICTL** register.

When RESMODE is set, the positional counter is reset when the index pulse is sensed. This mode limits the positional counter to the values [0:N-1], where N is the number of phase edges in a full revolution of the encoder wheel. The **QEI Maximum Position (QEIMAXPOS)** register must be programmed with N-1 so that the reverse direction from position 0 can move the position counter to N-1. In this mode, the position register contains the absolute position of the encoder relative to the index (or home) position once an index pulse has been seen.

When RESMODE is clear, the positional counter is constrained to the range [0:M], where M is the programmable maximum value. The index pulse is ignored by the positional counter in this mode.

Velocity capture uses a configurable timer and a count register. The timer counts the number of phase edges (using the same configuration as for the position integrator) in a given time period. The edge count from the previous time period is available to the controller via the **QE1 Velocity (QESPEED)** register, while the edge count for the current time period is being accumulated in the **QE1 Velocity Counter (QEICOUNT)** register. As soon as the current time period is complete, the total number of edges counted in that time period is made available in the **QESPEED** register (overwriting the previous value), the **QEICOUNT** register is cleared, and counting commences on a new time period. The number of edges counted in a given time period is directly proportional to the velocity of the encoder.

Figure 20-2 on page 950 shows how the Stellaris quadrature encoder converts the phase input signals into clock pulses, the direction signal, and how the velocity predivider operates (in Divide by 4 mode).

### Figure 20-2. Quadrature Encoder and Velocity Predivider Operation

The period of the timer is configurable by specifying the load value for the timer in the **QEI Timer Load (QEILOAD)** register. When the timer reaches zero, an interrupt can be triggered, and the hardware reloads the timer with the **QEILOAD** value and continues to count down. At lower encoder speeds, a longer timer period is required to be able to capture enough edges to have a meaningful result. At higher encoder speeds, both a shorter timer period and/or the velocity predivider can be used.

The following equation converts the velocity counter value into an rpm value:

```
rpm = (clock * (2 ^ VELDIV) * SPEED * 60) ÷ (LOAD * ppr * edges)
```

where:

cLock is the controller clock rate

ppr is the number of pulses per revolution of the physical encoder

edges is 2 or 4, based on the capture mode set in the **QIECTL** register (2 for CAPMODE clear and 4 for CAPMODE set)

For example, consider a motor running at 600 rpm. A 2048 pulse per revolution quadrature encoder is attached to the motor, producing 8192 phase edges per revolution. With a velocity predivider of ÷1 (VELDIV is clear) and clocking on both PhA and PhB edges, this results in 81,920 pulses per second (the motor turns 10 times per second). If the timer were clocked at 10,000 Hz, and the load value was 2,500 (¼ of a second), it would count 20,480 pulses per update. Using the above equation:

$$\text{rpm} = (10000 * 1 * 20480 * 60) \div (2500 * 2048 * 4) = 600 \text{ rpm}$$

Now, consider that the motor is sped up to 3000 rpm. This results in 409,600 pulses per second, or 102,400 every ¼ of a second. Again, the above equation gives:

$$\text{rpm} = (10000 * 1 * 102400 * 60) \div (2500 * 2048 * 4) = 3000 \text{ rpm}$$

Care must be taken when evaluating this equation because intermediate values may exceed the capacity of a 32-bit integer. In the above examples, the clock is 10,000 and the divider is 2,500; both could be predivided by 100 (at compile time if they are constants) and therefore be 100 and 25. In fact, if they were compile-time constants, they could also be reduced to a simple multiply by 4, cancelled by the ÷4 for the edge-count factor.

---

**Important:** Reducing constant factors at compile time is the best way to control the intermediate values of this equation and reduce the processing requirement of computing this equation.

---

The division can be avoided by selecting a timer load value such that the divisor is a power of 2; a simple shift can therefore be done in place of the division. For encoders with a power of 2 pulses per revolution, the load value can be a power of 2. For other encoders, a load value must be selected such that the product is very close to a power of 2. For example, a 100 pulse-per-revolution encoder could use a load value of 82, resulting in 32,800 as the divisor, which is 0.09% above  $2^{14}$ . In this case a shift by 15 would be an adequate approximation of the divide in most cases. If absolute accuracy were required, the microcontroller's divide instruction could be used.

The QEI module can produce a controller interrupt on several events: phase error, direction change, reception of the index pulse, and expiration of the velocity timer. Standard masking, raw interrupt status, interrupt status, and interrupt clear capabilities are provided.

## 20.4 Initialization and Configuration

The following example shows how to configure the Quadrature Encoder module to read back an absolute position:

1. Enable the QEI clock by writing a value of 0x0000.0100 to the **RCGC1** register in the System Control module (see page 257).
2. Enable the clock to the appropriate GPIO module via the **RCGC2** register in the System Control module (see page 266).
3. In the GPIO module, enable the appropriate pins for their alternate function using the **GPIOAFSEL** register. To determine which GPIOs to configure, see Table 22-4 on page 987.

4. Configure the PMCN fields in the **GPIOPCTL** register to assign the QEI signals to the appropriate pins (see page 450 and Table 22-5 on page 994).
5. Configure the quadrature encoder to capture edges on both signals and maintain an absolute position by resetting on index pulses. A 1000-line encoder with four edges per line, results in 4000 pulses per revolution; therefore, set the maximum position to 3999 (0xF9F) as the count is zero-based.
  - Write the **QEICTL** register with the value of 0x0000.0018.
  - Write the **QEIMAXPOS** register with the value of 0x0000.0F9F.
6. Enable the quadrature encoder by setting bit 0 of the **QEICTL** register.
7. Delay until the encoder position is required.
8. Read the encoder position by reading the **QEI Position (QEIPOS)** register value.

## 20.5 Register Map

Table 20-3 on page 952 lists the QEI registers. The offset listed is a hexadecimal increment to the register's address, relative to the module's base address:

- QEIO: 0x4002.C000
- QEI1: 0x4002.D000

Note that the QEI module clock must be enabled before the registers can be programmed (see page 257). There must be a delay of 3 system clocks after the QEI module clock is enabled before any QEI module registers are accessed.

**Table 20-3. QEI Register Map**

| Offset | Name      | Type  | Reset       | Description                    | See page |

## 20.6 Register Descriptions

The remainder of this section lists and describes the QEI registers, in numerical order by address offset.

## Register 1: QEI Control (QEICTL), offset 0x000

This register contains the configuration of the QEI module. Separate enables are provided for the quadrature encoder and the velocity capture blocks; the quadrature encoder must be enabled in order to capture the velocity, but the velocity does not need to be captured in applications that do not need it. The phase signal interpretation, phase swap, Position Update mode, Position Reset mode, and velocity predivider are all set via this register.

### QEI Control (QEICTL)

Register 5: QEI Timer Load (QEILOAD), offset 0x010

This register contains the load value for the velocity timer. Because this value is loaded into the timer on the clock cycle after the timer is zero, this value should be one less than the number of clocks in the desired period. So, for example, to have 2000 decimal clocks per timer period, this register should contain 1999 decimal.

QEI Timer Load (QEILOAD)

QEI0 base: 0x4002.C000  
QEI1 base: 0x4002.D000  
Offset 0x010  
Type R/W, reset 0x0000.0000

|       |      |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |

|-----------|------|------|-------------|---------------------------------------------------------------------|
| 31:0      | LOAD | R/W  | 0x0000.0000 | Velocity Timer Load Value<br>The load value for the velocity timer. |

Register 6: QEI Timer (QEITIME), offset 0x014

This register contains the current value of the velocity timer. This counter does not increment when the VELEN bit in the QEICTL register is clear.

QEI Timer (QEITIME)

QEI0 base: 0x4002.C000  
QEI1 base: 0x4002.D000  
Offset 0x014  
Type RO, reset 0x0000.0000

| Bit/Field | Name | Type | Reset       | Description                                                              |
|-----------|------|------|-------------|--------------------------------------------------------------------------|
| 31:0      | TIME | RO   | 0x0000.0000 | Velocity Timer Current Value<br>The current value of the velocity timer. |

Register 7: QEI Velocity Counter (QEICOUNT), offset 0x018

This register contains the running count of velocity pulses for the current time period. Because this count is a running total, the time period to which it applies cannot be known with precision (that is, a read of this register does not necessarily correspond to the time returned by the **QEITIME** register because there is a small window of time between the two reads, during which either value may have changed). The **QEISPEED** register should be used to determine the actual encoder velocity; this register is provided for information purposes only. This counter does not increment when the VELEN bit in the **QEICTL** register is clear.

QEI Velocity Counter (QEICOUNT)

QEI0 base: 0x4002.C000  
 QEI1 base: 0x4002.D000  
 Offset 0x018  
 Type RO, reset 0x0000.0000

| Bit/Field | Name  | Type | Reset       | Description                                                                                    |
|-----------|-------|------|-------------|------------------------------------------------------------------------------------------------|
| 31:0      | COUNT | RO   | 0x0000.0000 | Velocity Pulse Count<br>The running total of encoder pulses during this velocity timer period. |

Register 8: QEI Velocity (QEISPEED), offset 0x01C

This register contains the most recently measured velocity of the quadrature encoder. This value corresponds to the number of velocity pulses counted in the previous velocity timer period. This register does not update when the VELEN bit in the **QEICTL** register is clear.

QEI Velocity (QEISPEED)

QEI0 base: 0x4002.C000  
QEI1 base: 0x4002.D000  
Offset 0x01C  
Type RO, reset 0x0000.0000

| Bit/Field | Name  | Type | Reset       | Description                                                                    |
|-----------|-------|------|-------------|--------------------------------------------------------------------------------|
| 31:0      | SPEED | RO   | 0x0000.0000 | Velocity<br>The measured speed of the quadrature encoder in pulses per period. |

## Register 9: QEI Interrupt Enable (QEIINTEN), offset 0x020

This register contains enables for each of the QEI module interrupts. An interrupt is asserted to the interrupt controller if the corresponding bit in this register is set.

### QEI Interrupt Enable (QEIINTEN)

QEI0 base: 0x4002.C000

## Register 10: QEI Raw Interrupt Status (QEIRIS), offset 0x024

This register provides the current set of interrupt sources that are asserted, regardless of whether they cause an interrupt to be asserted to the controller (configured through the **QEINTEN** register). If a bit is set, the latched event has occurred; if a bit is clear, the event in question has not occurred.

## Register 11: QEI Interrupt Status and Clear (QEIISC), offset 0x028

This register provides the current set of interrupt sources that are asserted to the controller. If a bit is set, the latched event has occurred and is enabled to generate an interrupt; if a bit is clear the event in question has not occurred or is not enabled to generate an interrupt. This register is R/W1C; writing a 1 to a bit position clears the bit and the corresponding interrupt reason.

### QEI Interrupt Status and Clear (QEIISC)

## 21 Pin Diagram

The LM3S8C62 microcontroller pin diagram is shown below.

Each GPIO signal is identified by its GPIO port unless it defaults to an alternate function on reset. In this case, the GPIO port name is followed by the default alternate function. To see a complete list of possible functions for each pin, see Table 22-5 on page 994.

**Figure 21-1. 100-Pin LQFP Package Pin Diagram**

**Figure 21-2. 108-Ball BGA Package Pin Diagram (Top View)**

## 22 Signal Tables

The following tables list the signals available for each pin. Signals are configured as GPIOs on reset, except for those noted below. Use the **GPIOAMSEL** register (see page 449) to select analog mode. For a GPIO pin to be used for an alternate digital function, the corresponding bit in the **GPIOAFSEL** register (see page 433) must be set. Further pin muxing options are provided through the PMCx bit field in the **GPIOPCTL** register (see page 450), which selects one of several available peripheral functions for that GPIO.

**Important:** All GPIO pins are configured as GPIOs by default with the exception of the pins shown in the table below. A Power-On-Reset (POR) or asserting RST puts the pins back to their default state.

**Table 22-1. GPIO Pins With Default Alternate Functions**

| GPIO Pin | Default State     | GPIOAFSEL Bit | GPIOPCTL PMCx Bit Field |
|----------|-------------------|---------------|-------------------------|
| PA[1:0]  | UART0             | 0             | 0x1                     |
| PA[5:2]  | SSI0              | 0             | 0x1                     |
| PB[3:2]  | I <sup>2</sup> C0 | 0             | 0x1                     |
| PC[3:0]  | JTAG/SWD          | 1             | 0x3                     |

Table 22-2 on page 973 shows the pin-to-signal-name mapping, including functional characteristics of the signals. Each possible alternate analog and digital function is listed for each pin.

Table 22-3 on page 980 lists the signals in alphabetical order by signal name. If it is possible for a signal to be on multiple pins, each possible pin assignment is listed. The "Pin Mux" column indicates the GPIO and the encoding needed in the PMCx bit field in the **GPIOPCTL** register.

Table 22-4 on page 987 groups the signals by functionality, except for GPIOs. If it is possible for a signal to be on multiple pins, each possible pin assignment is listed.

Table 22-5 on page 994 lists the GPIO pins and their analog and digital alternate functions. The AINx and VREFx analog signals are not 5-V tolerant and go through an isolation circuit before reaching their circuitry. These signals are configured by clearing the corresponding DEN bit in the **GPIO Digital Enable (GPIODEN)** register and setting the corresponding AMSEL bit in the **GPIO Analog Mode Select (GPIOAMSEL)** register. Other analog signals are 5-V tolerant and are connected directly to their circuitry (C0-, C0+, C1-, C1+). These signals are configured by clearing the DEN bit in the **GPIO Digital Enable (GPIODEN)** register. The digital signals are enabled by setting the appropriate bit in the **GPIO Alternate Function Select (GPIOAFSEL)** and **GPIODEN** registers and configuring the PMCx bit field in the **GPIO Port Control (GPIOPCTL)** register to the numeric encoding shown in the table below. Table entries that are shaded gray are the default values for the corresponding GPIO pin.

Table 22-6 on page 996 lists the signals based on number of possible pin assignments. This table can be used to plan how to configure the pins for a particular functionality. Application Note AN01274 Configuring Stellaris® Microcontrollers with Pin Multiplexing provides an overview of the pin muxing implementation, an explanation of how a system designer defines a pin configuration, and examples of the pin configuration process.

**Note:** All digital inputs are Schmitt triggered.

## 22.1 100-Pin LQFP Package Pin Tables

Table 22-2. Signals by Pin Number

| Pin Number | Pin Name | Pin Type | Buffer Type <sup>a</sup> | Description                                                                                                                                                                                                                                                                                                    |
|------------|----------|----------|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1          | PE7      | I/O      | TTL                      | GPIO port E bit 7.                                                                                                                                                                                                                                                                                             |
|            | AIN0     | I        | Analog                   | Analog-to-digital converter input 0.                                                                                                                                                                                                                                                                           |
|            | PWM5     | O        | TTL                      | PWM 5. This signal is controlled by PWM Generator 2.                                                                                                                                                                                                                                                           |
| 2          | PE6      | I/O      | TTL                      | GPIO port E bit 6.                                                                                                                                                                                                                                                                                             |
|            | AIN1     | I        | Analog                   | Analog-to-digital converter input 1.                                                                                                                                                                                                                                                                           |
|            | C10      | O        | TTL                      | Analog comparator 1 output.                                                                                                                                                                                                                                                                                    |
|            | PWM4     | O        | TTL                      | PWM 4. This signal is controlled by PWM Generator 2.                                                                                                                                                                                                                                                           |
| 3          | VDDA     | -        | Power                    | The positive supply (3.3 V) for the analog circuits (ADC, Analog Comparators, etc.). These are separated from VDD to minimize the electrical noise contained on VDD from affecting the analog functions. VDDA pins must be connected to 3.3 V, regardless of system implementation.                            |
| 4          | GNDA     | -        | Power                    | The ground reference for the analog circuits (ADC, Analog Comparators, etc.). These are separated from GND to minimize the electrical noise contained on VDD from affecting the analog functions.                                                                                                              |
| 5          | PE5      | I/O      | TTL                      | GPIO port E bit 5.                                                                                                                                                                                                                                                                                             |
|            | AIN2     | I        | Analog                   | Analog-to-digital converter input 2.                                                                                                                                                                                                                                                                           |
|            | CCP5     | I/O      | TTL                      | Capture/Compare/PWM 5.                                                                                                                                                                                                                                                                                         |
| 6          | PE4      | I/O      | TTL                      | GPIO port E bit 4.                                                                                                                                                                                                                                                                                             |
|            | AIN3     | I        | Analog                   | Analog-to-digital converter input 3.                                                                                                                                                                                                                                                                           |
|            | CCP2     | I/O      | TTL                      | Capture/Compare/PWM 2.                                                                                                                                                                                                                                                                                         |
|            | CCP3     | I/O      | TTL                      | Capture/Compare/PWM 3.                                                                                                                                                                                                                                                                                         |
|            | Fault0   | I        | TTL                      | PWM Fault 0.                                                                                                                                                                                                                                                                                                   |
| 7          | LDO      | -        | Power                    | Low drop-out regulator output voltage. This pin requires an external capacitor between the pin and GND of 1 $\mu$ F or greater. When the on-chip LDO is used to provide power to the logic, the LDO pin must also be connected to the VDDC pins at the board level in addition to the decoupling capacitor(s). |
| 8          | VDD      | -        | Power                    | Positive supply for I/O and some logic.                                                                                                                                                                                                                                                                        |
| 9          | GND      | -        | Power                    | Ground reference for logic and I/O pins.                                                                                                                                                                                                                                                                       |
| 10         | PD0      | I/O      | TTL                      | GPIO port D bit 0.                                                                                                                                                                                                                                                                                             |
|            | AIN15    | I        | Analog                   | Analog-to-digital converter input 15.                                                                                                                                                                                                                                                                          |
|            | CAN0Rx   | I        | TTL                      | CAN module 0 receive.                                                                                                                                                                                                                                                                                          |

Table 22-2. Signals by Pin Number (continued)

| Pin Number | Pin Name | Pin Type | Buffer Type <sup>a</sup> | Description                                                                                        |
|------------|----------|----------|--------------------------|----------------------------------------------------------------------------------------------------|
| 11         | PD1      | I/O      | TTL                      | GPIO port D bit 1.                                                                                 |
|            | AIN14    | I        | Analog                   | Analog-to-digital converter input 14.                                                              |
|            | CAN0Tx   | O        | TTL                      | CAN module 0 transmit.                                                                             |
|            | CCP2     | I/O      | TTL                      | Capture/Compare/PWM 2.                                                                             |
|            | CCP7     | I/O      | TTL                      | Capture/Compare/PWM 7.                                                                             |
|            | PWM1     | O        | TTL                      | PWM 1. This signal is controlled by PWM Generator 0.                                               |
|            | PhA0     | I        | TTL                      | QEI module 0 phase A.                                                                              |
|            | PhB1     | I        | TTL                      | QEI module 1 phase B.                                                                              |
| 12         | U1Tx     | O        | TTL                      | UART module 1 transmit. When in IrDA mode, this signal has IrDA modulation.                        |
|            | PD2      | I/O      | TTL                      | GPIO port D bit 2.                                                                                 |
|            | AIN13    | I        | Analog                   | Analog-to-digital converter input 13.                                                              |
|            | CCP5     | I/O      | TTL                      | Capture/Compare/PWM 5.                                                                             |
|            | CCP6     | I/O      | TTL                      | Capture/Compare/PWM 6.                                                                             |
|            | PWM2     | O        | TTL                      | PWM 2. This signal is controlled by PWM Generator 1.                                               |
| 13         | U1Rx     | I        | TTL                      | UART module 1 receive. When in IrDA mode, this signal has IrDA modulation.                         |
|            | PD3      | I/O      | TTL                      | GPIO port D bit 3.                                                                                 |
|            | AIN12    | I        | Analog                   | Analog-to-digital converter input 12.                                                              |
|            | CCP0     | I/O      | TTL                      | Capture/Compare/PWM 0.                                                                             |
|            | CCP7     | I/O      | TTL                      | Capture/Compare/PWM 7.                                                                             |
|            | PWM3     | O        | TTL                      | PWM 3. This signal is controlled by PWM Generator 1.                                               |
| 14         | U1Tx     | O        | TTL                      | UART module 1 transmit. When in IrDA mode, this signal has IrDA modulation.                        |
|            | VDDC     | -        | Power                    | Positive supply for most of the logic function, including the processor core and most peripherals. |
|            | GND      | -        | Power                    | Ground reference for logic and I/O pins.                                                           |
| 15         | XTALPPHY | I        | Analog                   | Ethernet PHY XTALP 25-MHz oscillator crystal input.                                                |
| 16         | XTALNPHY | O        | Analog                   | Ethernet PHY XTALN 25-MHz oscillator crystal output.                                               |
| 17         | PG1      | I/O      | TTL                      | GPIO port G bit 1.                                                                                 |
|            | PWM1     | O        | TTL                      | PWM 1. This signal is controlled by PWM Generator 0.                                               |
|            | PWM5     | O        | TTL                      | PWM 5. This signal is controlled by PWM Generator 2.                                               |
| 18         | PG0      | I/O      | TTL                      | GPIO port G bit 0.                                                                                 |
|            | PWM0     | O        | TTL                      | PWM 0. This signal is controlled by PWM Generator 0.                                               |
|            | PWM4     | O        | TTL                      | PWM 4. This signal is controlled by PWM Generator 2.                                               |
| 19         | VDD      | -        | Power                    | Positive supply for I/O and some logic.                                                            |
| 20         | GND      | -        | Power                    | Ground reference for logic and I/O pins.                                                           |
| 21         |          |          |                          |                                                                                                    |

Table 22-2. Signals by Pin Number (continued)

| Pin Number | Pin Name | Pin Type | Buffer Type <sup>a</sup> | Description                                                                 |
|------------|----------|----------|--------------------------|-----------------------------------------------------------------------------|
| 22         | PC7      | I/O      | TTL                      | GPIO port C bit 7.                                                          |
|            | C10      | O        | TTL                      | Analog comparator 1 output.                                                 |
|            | CCP0     | I/O      | TTL                      | Capture/Compare/PWM 0.                                                      |
|            | CCP4     | I/O      | TTL                      | Capture/Compare/PWM 4.                                                      |
|            | PhB0     | I        | TTL                      | QEI module 0 phase B.                                                       |
|            | U1Tx     | O        | TTL                      | UART module 1 transmit. When in IrDA mode, this signal has IrDA modulation. |
| 23         | PC6      | I/O      | TTL                      | GPIO port C bit 6.                                                          |
|            | CCP0     | I/O      | TTL                      | Capture/Compare/PWM 0.                                                      |
|            | CCP3     | I/O      | TTL                      | Capture/Compare/PWM 3.                                                      |
|            | PhB0     | I        | TTL                      | QEI module 0 phase B.                                                       |
|            | U1Rx     | I        | TTL                      | UART module 1 receive. When in IrDA mode, this signal has IrDA modulation.  |
| 24         | PC5      | I/O      | TTL                      | GPIO port C bit 5.                                                          |
|            | C00      | O        | TTL                      | Analog comparator 0 output.                                                 |
|            | C1+      | I        | Analog                   | Analog comparator 1 positive input.                                         |
|            | C10      | O        | TTL                      | Analog comparator 1 output.                                                 |
|            | CCP1     | I/O      | TTL                      | Capture/Compare/PWM 1.                                                      |
|            | CCP3     | I/O      | TTL                      | Capture/Compare/PWM 3.                                                      |
|            | Fault2   | I        | TTL                      | PWM Fault 2.                                                                |
| 25         | PC4      | I/O      | TTL                      | GPIO port C bit 4.                                                          |
|            | CCP1     | I/O      | TTL                      | Capture/Compare/PWM 1.                                                      |
|            | CCP2     | I/O      | TTL                      | Capture/Compare/PWM 2.                                                      |
|            | CCP4     | I/O      | TTL                      | Capture/Compare/PWM 4.                                                      |
|            | CCP5     | I/O      | TTL                      | Capture/Compare/PWM 5.                                                      |
|            | PhA0     | I        | TTL                      | QEI module 0 phase A.                                                       |
| 26         | PA0      | I/O      | TTL                      | GPIO port A bit 0.                                                          |
|            | U0Rx     | I        | TTL                      | UART module 0 receive. When in IrDA mode, this signal has IrDA modulation.  |
|            | U1Rx     | I        | TTL                      | UART module 1 receive. When in IrDA mode, this signal has IrDA modulation.  |
| 27         | PA1      | I/O      | TTL                      | GPIO port A bit 1.                                                          |
|            | U0Tx     | O        | TTL                      | UART module 0 transmit. When in IrDA mode, this signal has IrDA modulation. |
|            | U1Tx     | O        | TTL                      | UART module 1 transmit. When in IrDA mode, this signal has IrDA modulation. |
| 28         | PA2      | I/O      | TTL                      | GPIO port A bit 2.                                                          |
|            | PwM4     | O        | TTL                      | PWM 4. This signal is controlled by PWM Generator 2.                        |
|            | SSI0C1k  | I/O      | TTL                      | SSI module 0 clock.                                                         |
| 29         | PA3      | I/O      | TTL                      | GPIO port A bit 3.                                                          |
|            | PwM5     | O        | TTL                      | PWM 5. This signal is controlled by PWM Generator 2.                        |
|            | SSI0Fss  | I/O      | TTL                      | SSI module 0 frame.                                                         |

Table 22-2. Signals by Pin Number (continued)

| Pin Number | Pin Name | Pin Type | Buffer Type <sup>a</sup> | Description                                                                                        |
|------------|----------|----------|--------------------------|----------------------------------------------------------------------------------------------------|
| 30         | PA4      | I/O      | TTL                      | GPIO port A bit 4.                                                                                 |
|            | CAN0Rx   | I        | TTL                      | CAN module 0 receive.                                                                              |
|            | SSI0Rx   | I        | TTL                      | SSI module 0 receive.                                                                              |
| 31         | PA5      | I/O      | TTL                      | GPIO port A bit 5.                                                                                 |
|            | CAN0Tx   | O        | TTL                      | CAN module 0 transmit.                                                                             |
|            | SSI0Tx   | O        | TTL                      | SSI module 0 transmit.                                                                             |
| 32         | VDD      | -        | Power                    | Positive supply for I/O and some logic.                                                            |
| 33         | GND      | -        | Power                    | Ground reference for logic and I/O pins.                                                           |
| 34         | PA6      | I/O      | TTL                      | GPIO port A bit 6.                                                                                 |
|            | CAN0Rx   | I        | TTL                      | CAN module 0 receive.                                                                              |
|            | CCP1     | I/O      | TTL                      | Capture/Compare/PWM 1.                                                                             |
|            | PWM0     | O        | TTL                      | PWM 0. This signal is controlled by PWM Generator 0.                                               |
|            | PWM4     | O        | TTL                      | PWM 4. This signal is controlled by PWM Generator 2.                                               |
| 35         | PA7      | I/O      | TTL                      | GPIO port A bit 7.                                                                                 |
|            | CAN0Tx   | O        | TTL                      | CAN module 0 transmit.                                                                             |
|            | CCP3     | I/O      | TTL                      | Capture/Compare/PWM 3.                                                                             |
|            | CCP4     | I/O      | TTL                      | Capture/Compare/PWM 4.                                                                             |
|            | PWM1     | O        | TTL                      | PWM 1. This signal is controlled by PWM Generator 0.                                               |
|            | PWM5     | O        | TTL                      | PWM 5. This signal is controlled by PWM Generator 2.                                               |
| 36         | VDD      | -        | Power                    | Positive supply for I/O and some logic.                                                            |
| 37         | RXIN     | I        | Analog                   | RXIN of the Ethernet PHY.                                                                          |
| 38         | VDDC     | -        | Power                    | Positive supply for most of the logic function, including the processor core and most peripherals. |
| 39         | GND      | -        | Power                    | Ground reference for logic and I/O pins.                                                           |
| 40         | RXIP     | I        | Analog                   | RXIP of the Ethernet PHY.                                                                          |
| 41         | ERBIAS   | O        | Analog                   | 12.4-kΩ resistor (1% precision) used internally for Ethernet PHY.                                  |
| 42         | GND      | -        | Power                    | Ground reference for logic and I/O pins.                                                           |
| 43         | TXOP     | O        | TTL                      | TXOP of the Ethernet PHY.                                                                          |
| 44         | VDD      | -        | Power                    | Positive supply for I/O and some logic.                                                            |
| 45         | GND      | -        | Power                    | Ground reference for logic and I/O pins.                                                           |
| 46         | TXON     | O        | TTL                      | TXON of the Ethernet PHY.                                                                          |
| 47         | PF0      | I/O      | TTL                      | GPIO port F bit 0.                                                                                 |
|            | PWM0     | O        | TTL                      | PWM 0. This signal is controlled by PWM Generator 0.                                               |
|            | PhB0     | I        | TTL                      | QEI module 0 phase B.                                                                              |
|            | U1DSR    | I        | TTL                      | UART module 1 Data Set Ready modem output control line.                                            |
| 48         | OSC0     | I        | Analog                   | Main oscillator crystal input or an external clock reference input.                                |
| 49         | OSC1     | O        | Analog                   | Main oscillator crystal output. Leave unconnected when using a single-ended clock source.          |
| 50         | WAKE     | I        | TTL                      | An external input that brings the processor out of Hibernate mode when asserted.                   |
| 51         | HIB      | O        | OD                       | An output that indicates the processor is in Hibernate mode.                                       |

Table 22-2. Signals by Pin Number (continued)

| Pin Number | Pin Name | Pin Type | Buffer Type <sup>a</sup> | Description                                                                                                                                                                                                                                    |
|------------|----------|----------|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 52         | XOSC0    | I        | Analog                   | Hibernation module oscillator crystal input or an external clock reference input. Note that this is either a 4.194304-MHz crystal or a 32.768-kHz oscillator for the Hibernation module RTC. See the CLKSEL bit in the <b>HIBCTL</b> register. |
| 53         | XOSC1    | O        | Analog                   | Hibernation module oscillator crystal output. Leave unconnected when using a single-ended clock source.                                                                                                                                        |
| 54         | GND      | -        | Power                    | Ground reference for logic and I/O pins.                                                                                                                                                                                                       |
| 55         | VBAT     | -        | Power                    | Power source for the Hibernation module. It is normally connected to the positive terminal of a battery and serves as the battery backup/Hibernation module power-source supply.                                                               |
| 56         | VDD      | -        | Power                    | Positive supply for I/O and some logic.                                                                                                                                                                                                        |

|            | U1Tx     | O        | TTL                      | UART module 1 transmit. When in IrDA mode, this signal has IrDA modulation.                                                                                                                                                                    |
| 68         | VDD      | -        | Power                    | Positive supply for I/O and some logic.                                                                                                                                                                                                        |
| 69         | GND      | -        | Power                    | Ground reference for logic and I/O pins.                                                                                                                                                                                                       |

Table 22-2. Signals by Pin Number (*continued*)

| Pin Number | Pin Name | Pin Type | Buffer Type <sup>a</sup> | Description                                                                        |
|------------|----------|----------|--------------------------|------------------------------------------------------------------------------------|
| 70         | PB2      | I/O      | TTL                      | GPIO port B bit 2.                                                                 |
|            | CCP0     | I/O      | TTL                      | Capture/Compare/PWM 0.                                                             |
|            | CCP3     | I/O      | TTL                      | Capture/Compare/PWM 3.                                                             |
|            | I2C0SCL  | I/O      | OD                       | I <sup>2</sup> C module 0 clock.                                                   |
|            | IDX0     | I        | TTL                      | QEI module 0 index.                                                                |
| 71         | PB3      | I/O      | TTL                      | GPIO port B bit 3.                                                                 |
|            | Fault0   | I        | TTL                      | PWM Fault 0.                                                                       |
|            | Fault3   | I        | TTL                      | PWM Fault 3.                                                                       |
|            | I2C0SDA  | I/O      | OD                       | I <sup>2</sup> C module 0 data.                                                    |
| 72         | PE0      | I/O      | TTL                      | GPIO port E bit 0.                                                                 |
|            | CCP3     | I/O      | TTL                      | Capture/Compare/PWM 3.                                                             |
|            | PWM4     | O        | TTL                      | PWM 4. This signal is controlled by PWM Generator 2.                               |
| 73         | PE1      | I/O      | TTL                      | GPIO port E bit 1.                                                                 |
|            | CCP2     | I/O      | TTL                      | Capture/Compare/PWM 2.                                                             |
|            | CCP6     | I/O      | TTL                      | Capture/Compare/PWM 6.                                                             |
|            | Fault0   | I        | TTL                      | PWM Fault 0.                                                                       |
|            | PWM5     | O        | TTL                      | PWM 5. This signal is controlled by PWM Generator 2.                               |
| 74         | PE2      | I/O      | TTL                      | GPIO port E bit 2.                                                                 |
|            | AIN9     | I        | Analog                   | Analog-to-digital converter input 9.                                               |
|            | CCP2     | I/O      | TTL                      | Capture/Compare/PWM 2.                                                             |
|            | CCP4     | I/O      | TTL                      | Capture/Compare/PWM 4.                                                             |
|            | PhA0     | I        | TTL                      | QEI module 0 phase A.                                                              |
|            | PhB1     | I        | TTL                      | QEI module 1 phase B.                                                              |
| 75         | PE3      | I/O      | TTL                      | GPIO port E bit 3.                                                                 |
|            | AIN8     | I        | Analog                   | Analog-to-digital converter input 8.                                               |
|            | CCP1     | I/O      | TTL                      | Capture/Compare/PWM 1.                                                             |
|            | CCP7     | I/O      | TTL                      | Capture/Compare/PWM 7.                                                             |
|            | PhA1     | I        | TTL                      | QEI module 1 phase A.                                                              |
|            | PhB0     | I        | TTL                      | QEI module 0 phase B.                                                              |
| 76         | CMOD1    | I        | TTL                      | CPU Mode bit 1. Input must be set to logic 0 (grounded); other encodings reserved. |
| 77         | PC3      | I/O      | TTL                      | GPIO port C bit 3.                                                                 |
|            | SW0      | O        | TTL                      | JTAG TDO and SWO.                                                                  |
|            | TD0      | O        | TTL                      | JTAG TDO and SWO.                                                                  |
| 78         | PC2      | I/O      | TTL                      | GPIO port C bit 2.                                                                 |
|            | TDI      | I        | TTL                      | JTAG TDI.                                                                          |
| 79         | PC1      | I/O      | TTL                      | GPIO port C bit 1.                                                                 |
|            | SWDIO    | I/O      | TTL                      | JTAG TMS and SWDIO.                                                                |
|            | TMS      | I        | TTL                      | JTAG TMS and SWDIO.                                                                |

Table 22-2. Signals by Pin Number (continued)

| Pin Number | Pin Name | Pin Type | Buffer Type <sup>a</sup> | Description                                                                                                                                                                                                                                                                                                                |
|------------|----------|----------|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 80         | PC0      | I/O      | TTL                      | GPIO port C bit 0.                                                                                                                                                                                                                                                                                                         |
|            | SWCLK    | I        | TTL                      | JTAG/SWD CLK.                                                                                                                                                                                                                                                                                                              |
|            | TCK      | I        | TTL                      | JTAG/SWD CLK.                                                                                                                                                                                                                                                                                                              |
| 81         | VDD      | -        | Power                    | Positive supply for I/O and some logic.                                                                                                                                                                                                                                                                                    |

When in IrDA mode, this signal has IrDA modulation.                                                                                                                                                                                                                                                |

Table 22-2. Signals by Pin Number (continued)

| Pin Number | Pin Name | Pin Type | Buffer Type <sup>a</sup> | Description                                                                                                                                                                                                                                                                         |
|------------|----------|----------|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 92         | PB4      | I/O      | TTL                      | GPIO port B bit 4.                                                                                                                                                                                                                                                                  |
|            | AIN10    | I        | Analog                   | Analog-to-digital converter input 10.                                                                                                                                                                                                                                               |
|            | C0-      | I        | Analog                   | Analog comparator 0 negative input.                                                                                                                                                                                                                                                 |
|            | CAN0RX   | I        | TTL                      | CAN module 0 receive.                                                                                                                                                                                                                                                               |
|            | IDX0     | I        | TTL                      | QEI module 0 index.                                                                                                                                                                                                                                                                 |
|            | U1Rx     | I        | TTL                      | UART module 1 receive. When in IrDA mode, this signal has IrDA modulation.                                                                                                                                                                                                          |
| 93         | VDD      | -        | Power                    | Positive supply for I/O and some logic.                                                                                                                                                                                                                                             |
| 94         | GND      | -        | Power                    | Ground reference for logic and I/O pins.                                                                                                                                                                                                                                            |
| 95         | PD4      | I/O      | TTL                      | GPIO port D bit 4.                                                                                                                                                                                                                                                                  |
|            | AIN7     | I        | Analog                   | Analog-to-digital converter input 7.                                                                                                                                                                                                                                                |
|            | CCP0     | I/O      | TTL                      | Capture/Compare/PWM 0.                                                                                                                                                                                                                                                              |
|            | CCP3     | I/O      | TTL                      | Capture/Compare/PWM 3.                                                                                                                                                                                                                                                              |
| 96         | PD5      | I/O      | TTL                      | GPIO port D bit 5.                                                                                                                                                                                                                                                                  |
|            | AIN6     | I        | Analog                   | Analog-to-digital converter input 6.                                                                                                                                                                                                                                                |
|            | CCP2     | I/O      | TTL                      | Capture/Compare/PWM 2.                                                                                                                                                                                                                                                              |
|            | CCP4     | I/O      | TTL                      | Capture/Compare/PWM 4.                                                                                                                                                                                                                                                              |
| 97         | GNDA     | -        | Power                    | The ground reference for the analog circuits (ADC, Analog Comparators, etc.). These are separated from GND to minimize the electrical noise contained on VDD from affecting the analog functions.                                                                                   |
| 98         | VDDA     | -        | Power                    | The positive supply (3.3 V) for the analog circuits (ADC, Analog Comparators, etc.). These are separated from VDD to minimize the electrical noise contained on VDD from affecting the analog functions. VDDA pins must be connected to 3.3 V, regardless of system implementation. |
| 99         | PD6      | I/O      | TTL                      | GPIO port D bit 6.                                                                                                                                                                                                                                                                  |

| VDDA     | 3<br>98                                                       | fixed                                                          | -        | Power                    | The positive supply (3.3 V) for the analog circuits (ADC, Analog Comparators, etc.). These are separated from VDD to minimize the electrical noise contained on VDD from affecting the analog functions. VDDA pins must be connected to 3.3 V, regardless of system implementation.                                        |
| VDDC     | 14<br>38<br>62<br>88                                          | fixed                                                          | -        | Power                    | Positive supply for most of the logic function, including the processor core and most peripherals.                                                                                                                                                                                                                         |
| VREFA    | 90                                                            | PB6                                                            | I        | Analog                   | This input provides a reference voltage used to specify the input voltage at which the ADC converts to a maximum value. In other words, the voltage that is applied to VREFA is the voltage with which an AINn signal is converted to 4095. The VREFA input is limited to the range specified in Table 24-22 on page 1038. |

Table 22-3. Signals by Signal Name (*continued*)

| Pin Name | Pin Number | Pin Mux / Pin Assignment | Pin Type | Buffer Type <sup>a</sup> | Description                                                                                                                                                                                                                                    |
|----------|------------|--------------------------|----------|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| WAKE     | 50         | fixed                    | I        | TTL                      | An external input that brings the processor out of Hibernate mode when asserted.                                                                                                                                                               |
| XOSC0    | 52         | fixed                    | I        | Analog                   | Hibernation module oscillator crystal input or an external clock reference input. Note that this is either a 4.194304-MHz crystal or a 32.768-kHz oscillator for the Hibernation module RTC. See the CLKSEL bit in the <b>HIBCTL</b> register. |
| XOSC1    | 53         | fixed                    | O        | Analog                   | Hibernation module oscillator crystal output. Leave unconnected when using a single-ended clock source.                                                                                                                                        |
| XTALNPHY | 17         | fixed                    | O        | Analog                   | Ethernet PHY XTALN 25-MHz oscillator crystal output.                                                                                                                                                                                           |
| XTALPPHY | 16         | fixed                    | I        | Analog                   | Ethernet PHY XTALP 25-MHz oscillator crystal input.                                                                                                                                                                                            |

a. The TTL designation indicates the pin has TTL-compatible voltage levels.

Table 22-4. Signals by Function, Except for GPIO

| Function | Pin Name | Pin Number | Pin Type | Buffer Type <sup>a</sup> | Description                                                                                                                                                                                                                                                                                                                |

|          | VREFA    | 90         | I        | Analog                   | This input provides a reference voltage used to specify the input voltage at which the ADC converts to a maximum value. In other words, the voltage that is applied to VREFA is the voltage with which an AINn signal is converted to 4095. The VREFA input is limited to the range specified in Table 24-22 on page 1038. |

Table 22-4. Signals by Function, Except for GPIO (*continued*)

|            | VREFA    | I        | Analog                   | This input provides a reference voltage used to specify the input voltage at which the ADC converts to a maximum value. In other words, the voltage that is applied to VREFA is the voltage with which an AINn signal is converted to 4095. The VREFA input is limited to the range specified in Table 24-22 on page 1038. |

|            | I2C0SDA  | I/O      | OD                       | I <sup>2</sup> C module 0 data.                                                                                                                                                                                                                                                     |

Table 22-7. Signals by Pin Number (continued)

| Pin Number | Pin Name | Pin Type | Buffer Type <sup>a</sup> | Description                                                                                                                                                                                                                                                                                               |
|------------|----------|----------|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| D1         | NC       | -        | -                        | No connect. Leave the pin electrically unconnected/isolated.                                                                                                                                                                                                                                              |
| D2         | NC       | -        | -                        | No connect. Leave the pin electrically unconnected/isolated.                                                                                                                                                                                                                                              |
| D3         | VDDC     | -        | Power                    | Positive supply for most of the logic function, including the processor core and most peripherals.                                                                                                                                                                                                        |
| D10        | VDD      | -        | Power                    | Positive supply for I/O and some logic.                                                                                                                                                                                                                                                                   |
| D11        | VDD      | -        | Power                    | Positive supply for I/O and some logic.                                                                                                                                                                                                                                                                   |
| D12        | PB1      | I/O      | TTL                      | GPIO port B bit 1. This pin is not 5-V tolerant.                                                                                                                                                                                                                                                          |
|            | CCP1     | I/O      | TTL                      | Capture/Compare/PWM 1.                                                                                                                                                                                                                                                                                    |
|            | CCP2     | I/O      | TTL                      | Capture/Compare/PWM 2.                                                                                                                                                                                                                                                                                    |
|            | PWM3     | O        | TTL                      | PWM 3. This signal is controlled by PWM Generator 1.                                                                                                                                                                                                                                                      |
|            | U1Tx     | O        | TTL                      | UART module 1 transmit. When in IrDA mode, this signal has IrDA modulation.                                                                                                                                                                                                                               |
| E1         | NC       | -        | -                        | No connect. Leave the pin electrically unconnected/isolated.                                                                                                                                                                                                                                              |
| E2         | NC       | -        | -                        | No connect. Leave the pin electrically unconnected/isolated.                                                                                                                                                                                                                                              |
| E3         | LDO      | -        | Power                    | Low drop-out regulator output voltage. This pin requires an external capacitor between the pin and GND of 1 µF or greater. When the on-chip LDO is used to provide power to the logic, the LDO pin must also be connected to the VDDC pins at the board level in addition to the decoupling capacitor(s). |
| E10        | VDD      | -        | Power                    | Positive supply for I/O and some logic.                                                                                                                                                                                                                                                                   |
| E11        | CMOD0    | I        | TTL                      | CPU Mode bit 0. Input must be set to logic 0 (grounded); other encodings reserved.                                                                                                                                                                                                                        |
| E12        | PB0      | I/O      | TTL                      | GPIO port B bit 0. This pin is not 5-V tolerant.                                                                                                                                                                                                                                                          |
|            | CCP0     | I/O      | TTL                      | Capture/Compare/PWM 0.                                                                                                                                                                                                                                                                                    |
|            | PWM2     | O        | TTL                      | PWM 2. This signal is controlled by PWM Generator 1.                                                                                                                                                                                                                                                      |
|            | U1Rx     | I        | TTL                      | UART module 1 receive. When in IrDA mode, this signal has IrDA modulation.                                                                                                                                                                                                                                |
| F1         | NC       | -        | -                        | No connect. Leave the pin electrically unconnected/isolated.                                                                                                                                                                                                                                              |
| F2         | NC       | -        | -                        | No connect. Leave the pin electrically unconnected/isolated.                                                                                                                                                                                                                                              |
| F3         | VDDC     | -        | Power                    | Positive supply for most of the logic function, including the processor core and most peripherals.                                                                                                                                                                                                        |

|            | IDX0     | I        | TTL                      | QEI module 0 index.                                                                                                                                                                                                                                                                                       |
|            | PWM0     | O        | TTL                      | PWM 0. This signal is controlled by PWM Generator 0.                                                                                                                                                                                                                                                      |
|            | U1Rx     | I        | TTL                      | UART module 1 receive. When in IrDA mode, this signal has IrDA modulation.                                                                                                                                                                                                                                |

Table 22-7. Signals by Pin Number (continued)

| Pin Number | Pin Name | Pin Type | Buffer Type <sup>a</sup> | Description                                                                                        |
|------------|----------|----------|--------------------------|----------------------------------------------------------------------------------------------------|
| G2         | PD1      | I/O      | TTL                      | GPIO port D bit 1.                                                                                 |
|            | AIN14    | I        | Analog                   | Analog-to-digital converter input 14.                                                              |
|            | CAN0Tx   | O        | TTL                      | CAN module 0 transmit.                                                                             |
|            | CCP2     | I/O      | TTL                      | Capture/Compare/PWM 2.                                                                             |
|            | CCP7     | I/O      | TTL                      | Capture/Compare/PWM 7.                                                                             |
|            | PWM1     | O        | TTL                      | PWM 1. This signal is controlled by PWM Generator 0.                                               |
|            | PhA0     | I        | TTL                      | QEI module 0 phase A.                                                                              |
|            | PhB1     | I        | TTL                      | QEI module 1 phase B.                                                                              |
|            | U1Tx     | O        | TTL                      | UART module 1 transmit. When in IrDA mode, this signal has IrDA modulation.                        |
| G3         | VDDC     | -        | Power                    | Positive supply for most of the logic function, including the processor core and most peripherals. |
| G10        | VDD      | -        | Power                    | Positive supply for I/O and some logic.                                                            |
| G11        | VDD      | -        | Power                    | Positive supply for I/O and some logic.                                                            |
| G12        | VDD      | -        | Power                    | Positive supply for I/O and some logic.                                                            |
| H1         | PD3      | I/O      | TTL                      | GPIO port D bit 3.                                                                                 |
|            | AIN12    | I        | Analog                   | Analog-to-digital converter input 12.                                                              |
|            | CCP0     | I/O      | TTL                      | Capture/Compare/PWM 0.                                                                             |
|            | CCP7     | I/O      | TTL                      | Capture/Compare/PWM 7.                                                                             |
|            | PWM3     | O        | TTL                      | PWM 3. This signal is controlled by PWM Generator 1.                                               |
|            | U1Tx     | O        | TTL                      | UART module 1 transmit. When in IrDA mode, this signal has IrDA modulation.                        |
| H2         | PD2      | I/O      | TTL                      | GPIO port D bit 2.                                                                                 |
|            | AIN13    | I        | Analog                   | Analog-to-digital converter input 13.                                                              |
|            | CCP5     | I/O      | TTL                      | Capture/Compare/PWM 5.                                                                             |
|            | CCP6     | I/O      | TTL                      | Capture/Compare/PWM 6.                                                                             |
|            | PWM2     | O        | TTL                      | PWM 2. This signal is controlled by PWM Generator 1.                                               |
|            | U1Rx     | I        | TTL                      | UART module 1 receive. When in IrDA mode, this signal has IrDA modulation.                         |
| H3         | GND      | -        | Power                    | Ground reference for logic and I/O pins.                                                           |
| H10        | VDD      | -        | Power                    | Positive supply for I/O and some logic.                                                            |
| H11        | RST      | I        | TTL                      | System reset input.                                                                                |
| H12        | PF1      | I/O      | TTL                      | GPIO port F bit 1.                                                                                 |
|            | CCP3     | I/O      | TTL                      | Capture/Compare/PWM 3.                                                                             |
|            | IDX1     | I        | TTL                      | QEI module 1 index.                                                                                |
|            | PWM1     | O        | TTL                      | PWM 1. This signal is controlled by PWM Generator 0.                                               |
| J1         | XTALNPHY | O        | Analog                   | Ethernet PHY XTALN 25-MHz oscillator crystal output.                                               |
| J2         | XTALPPHY | I        | Analog                   | Ethernet PHY XTALP 25-MHz oscillator crystal input.                                                |
| J3         | GND      | -        | Power                    | Ground reference for logic and I/O pins.                                                           |
| J10        | GND      | -        | Power                    | Ground reference for logic and I/O pins.                                                           |

Table 22-7. Signals by Pin Number (continued)

| Pin Number | Pin Name | Pin Type | Buffer Type <sup>a</sup> | Description                                                                                                                                                                                                                                    |
|------------|----------|----------|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| J11        | PF2      | I/O      | TTL                      | GPIO port F bit 2.                                                                                                                                                                                                                             |
|            | LED1     | O        | TTL                      | Ethernet LED 1.                                                                                                                                                                                                                                |
|            | PWM2     | O        | TTL                      | PWM 2. This signal is controlled by PWM Generator 1.                                                                                                                                                                                           |
|            | PWM4     | O        | TTL                      | PWM 4. This signal is controlled by PWM Generator 2.                                                                                                                                                                                           |
| J12        | PF3      | I/O      | TTL                      | GPIO port F bit 3.                                                                                                                                                                                                                             |
|            | LED0     | O        | TTL                      | Ethernet LED 0.                                                                                                                                                                                                                                |
|            | PWM3     | O        | TTL                      | PWM 3. This signal is controlled by PWM Generator 1.                                                                                                                                                                                           |
|            | PWM5     | O        | TTL                      | PWM 5. This signal is controlled by PWM Generator 2.                                                                                                                                                                                           |
| K1         | PG0      | I/O      | TTL                      | GPIO port G bit 0.                                                                                                                                                                                                                             |
|            | PWM0     | O        | TTL                      | PWM 0. This signal is controlled by PWM Generator 0.                                                                                                                                                                                           |
|            | PWM4     | O        | TTL                      | PWM 4. This signal is controlled by PWM Generator 2.                                                                                                                                                                                           |
| K2         | PG1      | I/O      | TTL                      | GPIO port G bit 1.                                                                                                                                                                                                                             |
|            | PWM1     | O        | TTL                      | PWM 1. This signal is controlled by PWM Generator 0.                                                                                                                                                                                           |
|            | PWM5     | O        | TTL                      | PWM 5. This signal is controlled by PWM Generator 2.                                                                                                                                                                                           |
| K3         | ERBIAS   | O        | Analog                   | 12.4-kΩ resistor (1% precision) used internally for Ethernet PHY.                                                                                                                                                                              |
| K4         | GND      | -        | Power                    | Ground reference for logic and I/O pins.                                                                                                                                                                                                       |
| K5         | GND      | -        | Power                    | Ground reference for logic and I/O pins.                                                                                                                                                                                                       |
| K6         | GND      | -        | Power                    | Ground reference for logic and I/O pins.                                                                                                                                                                                                       |
| K7         | VDD      | -        | Power                    | Positive supply for I/O and some logic.                                                                                                                                                                                                        |
| K8         | VDD      | -        | Power                    | Positive supply for I/O and some logic.                                                                                                                                                                                                        |
| K9         | VDD      | -        | Power                    | Positive supply for I/O and some logic.                                                                                                                                                                                                        |
| K10        | GND      | -        | Power                    | Ground reference for logic and I/O pins.                                                                                                                                                                                                       |
| K11        | XOSC0    | I        | Analog                   | Hibernation module oscillator crystal input or an external clock reference input. Note that this is either a 4.194304-MHz crystal or a 32.768-kHz oscillator for the Hibernation module RTC. See the CLKSEL bit in the <b>HIBCTL</b> register. |
| K12        | XOSC1    | O        | Analog                   | Hibernation module oscillator crystal output. Leave unconnected when using a single-ended clock source.                                                                                                                                        |
| L1         | PC4      | I/O      | TTL                      | GPIO port C bit 4.                                                                                                                                                                                                                             |
|            | CCP1     | I/O      | TTL                      | Capture/Compare/PWM 1.                                                                                                                                                                                                                         |

|            | CCP0     | I/O      | TTL                      | Capture/Compare/PWM 0.                                                                                                                                                                                                                         |
|            | CCP4     | I/O      | TTL                      | Capture/Compare/PWM 4.                                                                                                                                                                                                                         |
|            | PhB0     | I        | TTL                      | QEI module 0 phase B.                                                                                                                                                                                                                          |
|            | U1Tx     | O        | TTL                      | UART module 1 transmit. When in IrDA mode, this signal has IrDA modulation.                                                                                                                                                                    |

Table 22-7. Signals by Pin Number (continued)

| Pin Number | Pin Name | Pin Type | Buffer Type <sup>a</sup> | Description                                                                                                                                                                      |
|------------|----------|----------|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| L3         | PA0      | I/O      | TTL                      | GPIO port A bit 0.                                                                                                                                                               |
|            | U0Rx     | I        | TTL                      | UART module 0 receive. When in IrDA mode, this signal has IrDA modulation.                                                                                                       |
|            | U1Rx     | I        | TTL                      | UART module 1 receive. When in IrDA mode, this signal has IrDA modulation.                                                                                                       |
| L4         | PA3      | I/O      | TTL                      | GPIO port A bit 3.                                                                                                                                                               |
|            | PWM5     | O        | TTL                      | PWM 5. This signal is controlled by PWM Generator 2.                                                                                                                             |
|            | SSI0Fss  | I/O      | TTL                      | SSI module 0 frame.                                                                                                                                                              |
| L5         | PA4      | I/O      | TTL                      | GPIO port A bit 4.                                                                                                                                                               |
|            | CAN0Rx   | I        | TTL                      | CAN module 0 receive.                                                                                                                                                            |
|            | SSI0Rx   | I        | TTL                      | SSI module 0 receive.                                                                                                                                                            |
| L6         | PA6      | I/O      | TTL                      | GPIO port A bit 6.                                                                                                                                                               |
|            | CAN0Rx   | I        | TTL                      | CAN module 0 receive.                                                                                                                                                            |
|            | CCP1     | I/O      | TTL                      | Capture/Compare/PWM 1.                                                                                                                                                           |
|            | PWM0     | O        | TTL                      | PWM 0. This signal is controlled by PWM Generator 0.                                                                                                                             |
|            | PWM4     | O        | TTL                      | PWM 4. This signal is controlled by PWM Generator 2.                                                                                                                             |
| L7         | RXIN     | I        | Analog                   | RXIN of the Ethernet PHY.                                                                                                                                                        |
| L8         | TXON     | O        | TTL                      | TXON of the Ethernet PHY.                                                                                                                                                        |
| L9         | MDIO     | I/O      | OD                       | MDIO of the Ethernet PHY.                                                                                                                                                        |
| L10        | GND      | -        | Power                    | Ground reference for logic and I/O pins.                                                                                                                                         |
| L11        | OSC0     | I        | Analog                   | Main oscillator crystal input or an external clock reference input.                                                                                                              |
| L12        | VBAT     | -        | Power                    | Power source for the Hibernation module. It is normally connected to the positive terminal of a battery and serves as the battery backup/Hibernation module power-source supply. |
| M1         | PC5      | I/O      | TTL                      | GPIO port C bit 5.                                                                                                                                                               |
|            | C0o      | O        | TTL                      | Analog comparator 0 output.                                                                                                                                                      |
|            | C1+      | I        | Analog                   | Analog comparator 1 positive input.                                                                                                                                              |

Table 22-7. Signals by Pin Number (continued)

| Pin Number | Pin Name | Pin Type | Buffer Type <sup>a</sup> | Description                                                                               |
|------------|----------|----------|--------------------------|-------------------------------------------------------------------------------------------|
| M4         | PA2      | I/O      | TTL                      | GPIO port A bit 2.                                                                        |
|            | PWM4     | O        | TTL                      | PWM 4. This signal is controlled by PWM Generator 2.                                      |
|            | SSI0C1k  | I/O      | TTL                      | SSI module 0 clock.                                                                       |
| M5         | PA5      | I/O      | TTL                      | GPIO port A bit 5.                                                                        |
|            | CAN0Tx   | O        | TTL                      | CAN module 0 transmit.                                                                    |
|            | SSI0Tx   | O        | TTL                      | SSI module 0 transmit.                                                                    |
| M6         | PA7      | I/O      | TTL                      | GPIO port A bit 7.                                                                        |
|            | CAN0Tx   | O        | TTL                      | CAN module 0 transmit.                                                                    |
|            | CCP3     | I/O      | TTL                      | Capture/Compare/PWM 3.                                                                    |
|            | CCP4     | I/O      | TTL                      | Capture/Compare/PWM 4.                                                                    |
|            | PWM1     | O        | TTL                      | PWM 1. This signal is controlled by PWM Generator 0.                                      |
|            | PWM5     | O        | TTL                      | PWM 5. This signal is controlled by PWM Generator 2.                                      |
| M7         | RXIP     | I        | Analog                   | RXIP of the Ethernet PHY.                                                                 |
| M8         | TX0P     | O        | TTL                      | TX0P of the Ethernet PHY.                                                                 |
| M9         | PF0      | I/O      | TTL                      | GPIO port F bit 0.                                                                        |
|            | PWM0     | O        | TTL                      | PWM 0. This signal is controlled by PWM Generator 0.                                      |
|            | PhB0     | I        | TTL                      | QEI module 0 phase B.                                                                     |
|            | U1DSR    | I        | TTL                      | UART module 1 Data Set Ready modem output control line.                                   |
| M10        | WAKE     | I        | TTL                      | An external input that brings the processor out of Hibernate mode when asserted.          |
| M11        | OSC1     | O        | Analog                   | Main oscillator crystal output. Leave unconnected when using a single-ended clock source. |
| M12        | HIB      | O        | OD                       | An output that indicates the processor is in Hibernate mode.                              |

a. The TTL designation indicates the pin has TTL-compatible voltage levels.

Table 22-8. Signals by Signal Name

| Pin Name | Pin Number | Pin Mux / Pin Assignment | Pin Type | Buffer Type <sup>a</sup> | Description                           |
|----------|------------|--------------------------|----------|--------------------------|---------------------------------------|
| AIN0     | B1         | PE7                      | I        | Analog                   | Analog-to-digital converter input 0.  |
| AIN1     | A1         | PE6                      | I        | Analog                   | Analog-to-digital converter input 1.  |
| AIN2     | B3         | PE5                      | I        | Analog                   | Analog-to-digital converter input 2.  |
| AIN3     | B2         | PE4                      | I        | Analog                   | Analog-to-digital converter input 3.  |
| AIN4     | A2         | PD7                      | I        | Analog                   | Analog-to-digital converter input 4.  |
| AIN5     | A3         | PD6                      | I        | Analog                   | Analog-to-digital converter input 5.  |
| AIN6     | B4         | PD5                      | I        | Analog                   | Analog-to-digital converter input 6.  |
| AIN7     | A4         | PD4                      | I        | Analog                   | Analog-to-digital converter input 7.  |
| AIN8     | A12        | PE3                      | I        | Analog                   | Analog-to-digital converter input 8.  |
| AIN9     | B11        | PE2                      | I        | Analog                   | Analog-to-digital converter input 9.  |
| AIN10    | A6         | PB4                      | I        | Analog                   | Analog-to-digital converter input 10. |
| AIN11    | B7         | PB5                      | I        | Analog                   | Analog-to-digital converter input 11. |
| AIN12    | H1         | PD3                      | I        | Analog                   | Analog-to-digital converter input 12. |
| AIN13    | H2         | PD2                      | I        | Analog                   | Analog-to-digital converter input 13. |

Table 22-8. Signals by Signal Name (*continued*)

| Pin Name | Pin Number                                      | Pin Mux / Pin Assignment                                                              | Pin Type | Buffer Type <sup>a</sup> | Description                           |

These are separated from VDD to minimize the electrical noise contained on VDD from affecting the analog functions. VDDA pins must be connected to 3.3 V, regardless of system implementation.                                        |
| VDDC     | F3<br>D3<br>G3<br>C3                                                   | fixed                                                          | -        | Power                    | Positive supply for most of the logic function, including the processor core and most peripherals.                                                                                                                                                                                                                         |
| VREFA    | A7                                                                     | PB6                                                            | I        | Analog                   | This input provides a reference voltage used to specify the input voltage at which the ADC converts to a maximum value. In other words, the voltage that is applied to VREFA is the voltage with which an AINn signal is converted to 4095. The VREFA input is limited to the range specified in Table 24-22 on page 1038. |
| WAKE     | M10                                                                    | fixed                                                          | I        | TTL                      | An external input that brings the processor out of Hibernate mode when asserted.                                                                                                                                                                                                                                           |
| XOSC0    | K11                                                                    | fixed                                                          | I        | Analog                   | Hibernation module oscillator crystal input or an external clock reference input. Note that this is either a 4.194304-MHz crystal or a 32.768-kHz oscillator for the Hibernation module RTC. See the CLKSEL bit in the <b>HIBCTL</b> register.                                                                             |
| XOSC1    | K12                                                                    | fixed                                                          | O        | Analog                   | Hibernation module oscillator crystal output. Leave unconnected when using a single-ended clock source.                                                                                                                                                                                                                    |

Table 22-8. Signals by Signal Name (continued)

| Pin Name | Pin Number | Pin Mux / Pin Assignment | Pin Type | Buffer Type <sup>a</sup> | Description                                          |
|----------|------------|--------------------------|----------|--------------------------|------------------------------------------------------|
| XTALNPHY | J1         | fixed                    | O        | Analog                   | Ethernet PHY XTALN 25-MHz oscillator crystal output. |
| XTALPPHY | J2         | fixed                    | I        | Analog                   | Ethernet PHY XTALP 25-MHz oscillator crystal input.  |

a. The TTL designation indicates the pin has TTL-compatible voltage levels.

Table 22-9. Signals by Function, Except for GPIO

| Function           | Pin Name | Pin Number           | Pin Type | Buffer Type <sup>a</sup> | Description                                                                                                                                                                                                                                                                                                                |

## 22.3 Connections for Unused Signals

Table 22-12 on page 1023 show how to handle signals for functions that are not used in a particular system implementation for devices that are in a 100-pin LQFP package. Two options are shown in the table: an acceptable practice and a preferred practice for reduced power consumption and improved EMC characteristics. If a module is not used in a system, and its inputs are grounded, it is important that the clock to the module is never enabled by setting the corresponding bit in the **RCGCx** register.

**Table 22-12. Connections for Unused Signals (100-Pin LQFP)**

| Function       | Signal Name           | Pin Number                             | Acceptable Practice                        | Preferred Practice                                             |
|----------------|-----------------------|----------------------------------------|--------------------------------------------|----------------------------------------------------------------|
| Ethernet       | ERBIAS                | 33                                     | Connect to GND through 12.4-kΩ resistor.   | Connect to GND through 12.4-kΩ resistor.                       |
|                | RXIN                  | 37                                     | NC                                         | GND                                                            |
|                | RXIP                  | 40                                     | NC                                         | GND                                                            |

| System Control | OSC0                  | 48                                     | NC                                         | GND                                                            |
|                | OSC1                  | 49                                     | NC                                         | NC                                                             |
|                | RST                   | 64                                     | Pull up as shown in Figure 5-1 on page 181 | Connect through a capacitor to GND as close to pin as possible |
| USB0RBIAS      | 73                    | Connect to GND through 10-kΩ resistor. | Connect to GND through 10-kΩ resistor.     |                                                                |

a. Note that the Ethernet PHY is powered up by default. The PHY cannot be powered down unless a clock source is provided and the MDIO pin is pulled up through a 10-kΩ resistor.

Table 22-13 on page 1023 show how to handle signals for functions that are not used in a particular system implementation for devices that are in a 108-ball BGA package. Two options are shown in the table: an acceptable practice and a preferred practice for reduced power consumption and improved EMC characteristics. If a module is not used in a system, and its inputs are grounded, it is important that the clock to the module is never enabled by setting the corresponding bit in the **RCGCx** register.

**Table 22-13. Connections for Unused Signals (108-Ball BGA)**

| Function | Signal Name           | Pin Number | Acceptable Practice                      | Preferred Practice                       |
|----------|-----------------------|------------|------------------------------------------|------------------------------------------|
| Ethernet | ERBIAS                | J3         | Connect to GND through 12.4-kΩ resistor. | Connect to GND through 12.4-kΩ resistor. |
|          | RXIN                  | L7         | NC                                       | GND                                      |

|                | XOSC1       | K12        | NC                                         | NC                                                             |
| No Connects    | NC          | -          | NC                                         | NC                                                             |
| System Control | OSC0        | L11        | NC                                         | GND                                                            |
|                | OSC1        | M11        | NC                                         | NC                                                             |
|                | RST         | H11        | Pull up as shown in Figure 5-1 on page 181 | Connect through a capacitor to GND as close to pin as possible |

a. Note that the Ethernet PHY is powered up by default. The PHY cannot be powered down unless a clock source is provided and the MDIO pin is pulled up through a 10-k $\Omega$  resistor.

## 23 Operating Characteristics

**Table 23-1. Temperature Characteristics**

| Characteristic                         | Symbol | Value       | Unit |
|----------------------------------------|--------|-------------|------|
| Industrial operating temperature range | $T_A$  | -40 to +85  | °C   |
| Unpowered storage temperature range    | $T_S$  | -65 to +150 | °C   |

**Table 23-2. Thermal Characteristics**

| Characteristic                                        | Symbol        | Value                         | Unit |
|-------------------------------------------------------|---------------|-------------------------------|------|
| Thermal resistance (junction to ambient) <sup>a</sup> | $\Theta_{JA}$ | 33 (100LQFP)<br>31 (108BGA)   | °C/W |
| Junction temperature, -40 to +125 <sup>b</sup>        | $T_J$         | $T_A + (P \cdot \Theta_{JA})$ | °C   |

a. Junction to ambient thermal resistance  $\Theta_{JA}$  numbers are determined by a package simulator.

b. Power dissipation is a function of temperature.

**Table 23-3. ESD Absolute Maximum Ratings<sup>a</sup>**

| Parameter Name | Min | Nom | Max | Unit |
|----------------|-----|-----|-----|------|
| $V_{ESDHBM}$   | -   | -   | 2.0 | kV   |
| $V_{ESDCDM}$   | -   | -   | 500 | V    |

a. All Stellaris® parts are ESD tested following the JEDEC standard.

## 24 Electrical Characteristics

### 24.1 Maximum Ratings

The maximum ratings are the limits to which the device can be subjected without permanently damaging the device.

**Note:** The device is not guaranteed to operate properly at the maximum ratings.

**Table 24-1. Maximum Ratings**

| Parameter        | Parameter Name <sup>a</sup>                                                    | Value |                       | Unit |
|------------------|--------------------------------------------------------------------------------|-------|-----------------------|------|
|                  |                                                                                | Min   | Max                   |      |
| V <sub>DD</sub>  | V <sub>DD</sub> supply voltage                                                 | 0     | 4                     | V    |
| V <sub>DDA</sub> | V <sub>DDA</sub> supply voltage                                                | 0     | 4                     | V    |
| V <sub>BAT</sub> | V <sub>BAT</sub> battery supply voltage                                        | 0     | 4                     | V    |
| V <sub>IN</sub>  | Input voltage                                                                  | -0.3  | 5.5                   | V    |
|                  | Input voltage for a GPIO configured as an analog input                         | -0.3  | V <sub>DD</sub> + 0.3 | V    |
|                  | Input voltage for PB0 and PB1 when configured as GPIO                          | -0.3  | V <sub>DD</sub> + 0.3 | V    |
| I                | Maximum current per output pin                                                 | -     | 25                    | mA   |
| V <sub>NON</sub> | Maximum input voltage on a non-power pin when the microcontroller is unpowered | -     | 300                   | mV   |

a. Voltages are measured with respect to GND.

**Important:** This device contains circuitry to protect the inputs against damage due to high-static voltages or electric fields; however, it is advised that normal precautions be taken to avoid application of any voltage higher than maximum-rated voltages to this high-impedance circuit. Reliability of operation is enhanced if unused inputs are connected to an appropriate logic voltage level (see “Connections for Unused Signals” on page 1022).

### 24.2 Recommended Operating Conditions

For special high-current applications, the GPIO output buffers may be used with the following restrictions. With the GPIO pins configured as 8-mA output drivers, a total of four GPIO outputs may be used to sink current loads up to 18 mA each. At 18-mA sink current loading, the V<sub>OL</sub> value is specified as 1.2 V. The high-current GPIO package pins must be selected such that there are only a maximum of two per side of the physical package or BGA pin group with the total number of high-current GPIO outputs not exceeding four for the entire package.

**Table 24-2. Recommended DC Operating Conditions**

| Parameter                    | Parameter Name                  | Min   | Nom | Max   | Unit |
|------------------------------|---------------------------------|-------|-----|-------|------|
| V <sub>DD</sub>              | V <sub>DD</sub> supply voltage  | 3.0   | 3.3 | 3.6   | V    |
| V <sub>DDA</sub>             | V <sub>DDA</sub> supply voltage | 3.0   | 3.3 | 3.6   | V    |
| V <sub>DDC</sub>             | V <sub>DDC</sub> supply voltage | 1.235 | 1.3 | 1.365 | V    |
| V <sub>IH</sub>              | High-level input voltage        | 2.1   | -   | 5.0   | V    |
| V <sub>IL</sub>              | Low-level input voltage         | -0.3  | -   | 1.2   | V    |
| V <sub>OH</sub> <sup>a</sup> | High-level output voltage       | 2.4   | -   | -     | V    |

**Table 24-2. Recommended DC Operating Conditions (continued)**

| Parameter  | Parameter Name                            | Min | Nom | Max | Unit |
|------------|-------------------------------------------|-----|-----|-----|------|
| $V_{OL}^a$ | Low-level output voltage                  | -   | -   | 0.4 | V    |
| $I_{OH}$   | High-level source current, $V_{OH}=2.4$ V |     |     |     |      |
|            | 2-mA Drive                                | 2.0 | -   | -   | mA   |
|            | 4-mA Drive                                | 4.0 | -   | -   | mA   |
|            | 8-mA Drive                                | 8.0 | -   | -   | mA   |
| $I_{OL}$   | Low-level sink current, $V_{OL}=0.4$ V    |     |     |     |      |
|            | 2-mA Drive                                | 2.0 | -   | -   | mA   |
|            | 4-mA Drive                                | 4.0 | -   | -   | mA   |
|            | 8-mA Drive                                | 8.0 | -   | -   | mA   |
| $I_{OHC}$  | High-current sink, $V_{OL}=1.2$ V         | 18  | -   | -   | mA   |

a.  $V_{OL}$  and  $V_{OH}$  shift to 1.2 V when using high-current GPIOs.

## 24.3 Load Conditions

Unless otherwise specified, the following conditions are true for all timing measurements.

**Figure 24-1. Load Conditions**

## 24.4 JTAG and Boundary Scan

**Table 24-3. JTAG Characteristics**

| Parameter No. | Parameter       | Parameter Name                               | Min | Nom       | Max | Unit |
|---------------|-----------------|----------------------------------------------|-----|-----------|-----|------|
| J1            | $F_{TCK}$       | TCK operational clock frequency <sup>a</sup> | 0   | -         | 10  | MHz  |
| J2            | $T_{TCK}$       | TCK operational clock period                 | 100 | -         | -   | ns   |
| J3            | $T_{TCK\_LOW}$  | TCK clock Low time                           | -   | $t_{TCK}$ | -   | ns   |
| J4            | $T_{TCK\_HIGH}$ | TCK clock High time                          | -   | $t_{TCK}$ | -   | ns   |
| J5            | $T_{TCK\_R}$    | TCK rise time                                | 0   | -         | 10  | ns   |
| J6            | $T_{TCK\_F}$    | TCK fall time                                | 0   | -         | 10  | ns   |
| J7            | $T_{TMS\_SU}$   | TMS setup time to TCK rise                   | 20  | -         | -   | ns   |
| J8            | $T_{TMS\_HLD}$  | TMS hold time from TCK rise                  | 20  | -         | -   | ns   |
| J9            | $T_{TDI\_SU}$   | TDI setup time to TCK rise                   | 25  | -         | -   | ns   |
| J10           | $T_{TDI\_HLD}$  | TDI hold time from TCK rise                  | 25  | -         | -   | ns   |

**Table 24-3. JTAG Characteristics (continued)**

| Parameter No. | Parameter      | Parameter Name                                                            | Min | Nom | Max | Unit |
|---------------|----------------|---------------------------------------------------------------------------|-----|-----|-----|------|
| J11           | $T_{TDO\_ZDV}$ | TCK fall to Data Valid from High-Z, 2-mA drive                            | -   | 23  | 35  | ns   |
|               |                | TCK fall to Data Valid from High-Z, 4-mA drive                            |     | 15  | 26  | ns   |
|               |                | TCK fall to Data Valid from High-Z, 8-mA drive                            |     | 14  | 25  | ns   |
|               |                | TCK fall to Data Valid from High-Z, 8-mA drive with slew rate control     |     | 18  | 29  | ns   |
| J12           | $T_{TDO\_DV}$  | TCK fall to Data Valid from Data Valid, 2-mA drive                        | -   | 21  | 35  | ns   |
|               |                | TCK fall to Data Valid from Data Valid, 4-mA drive                        |     | 14  | 25  | ns   |
|               |                | TCK fall to Data Valid from Data Valid, 8-mA drive                        |     | 13  | 24  | ns   |
|               |                | TCK fall to Data Valid from Data Valid, 8-mA drive with slew rate control |     | 18  | 28  | ns   |
| J13           | $T_{TDO\_DVZ}$ | TCK fall to High-Z from Data Valid, 2-mA drive                            | -   | 9   | 11  | ns   |
|               |                | TCK fall to High-Z from Data Valid, 4-mA drive                            |     | 7   | 9   | ns   |
|               |                | TCK fall to High-Z from Data Valid, 8-mA drive                            |     | 6   | 8   | ns   |
|               |                | TCK fall to High-Z from Data Valid, 8-mA drive with slew rate control     |     | 7   | 9   | ns   |

a. A ratio of at least 8:1 must be kept between the system clock and TCK.

## 24.5 Power and Brown-out

Table 24-4. Power Characteristics

| Parameter No. | Parameter     | Parameter Name                                    | Min  | Nom | Max  | Unit    |
|---------------|---------------|---------------------------------------------------|------|-----|------|---------|
| P1            | $V_{TH}$      | Power-On Reset threshold                          | -    | 2   | -    | V       |
| P2            | $V_{BTH}$     | Brown-Out Reset threshold                         | 2.85 | 2.9 | 2.95 | V       |
| P3            | $T_{POR}$     | Power-On Reset timeout                            | 6    | -   | 18   | ms      |
| P4            | $T_{BOR}$     | Brown-Out timeout                                 | -    | 500 | -    | $\mu$ s |
| P5            | $T_{IRPOR}$   | Internal reset timeout after POR                  | -    | -   | 2    | ms      |
| P6            | $T_{IRBOR}$   | Internal reset timeout after BOR                  | -    | -   | 2    | ms      |
| P7            | $T_{VDDRISE}$ | Supply voltage ( $V_{DD}$ ) rise time (0V-3.0V)   | -    | -   | 10   | ms      |
| P8            | $T_{VDD2\_3}$ | Supply voltage ( $V_{DD}$ ) rise time (2.0V-3.0V) | -    | -   | 6    | ms      |

## 24.6 Reset

Table 24-5. Reset Characteristics

| Parameter No. | Parameter   | Parameter Name                                               | Min | Nom | Max | Unit    |
|---------------|-------------|--------------------------------------------------------------|-----|-----|-----|---------|
| R1            | $T_{IRHWR}$ | Internal reset timeout after hardware reset (RST pin)        | -   | -   | 2   | ms      |
| R2            | $T_{IRSWR}$ | Internal reset timeout after software-initiated system reset | -   | -   | 2   | ms      |
| R3            | $T_{IRWDR}$ | Internal reset timeout after watchdog reset                  | -   | -   | 2   | ms      |
| R4            | $T_{IRMFR}$ | Internal reset timeout after MOSC failure reset              | -   | -   | 2   | ms      |
| R5            | $T_{MIN}$   | Minimum RST pulse width <sup>a</sup>                         | 2   | -   | -   | $\mu$ s |

a. This specification must be met in order to guarantee proper reset operation.

Figure 24-7. External Reset Timing ( $\overline{\text{RST}}$ )

Figure 24-8. Software Reset Timing

**Figure 24-9. Watchdog Reset Timing****Figure 24-10. MOSC Failure Reset Timing**

## 24.7 On-Chip Low Drop-Out (LDO) Regulator

**Table 24-6. LDO Regulator Characteristics**

| Parameter        | Parameter Name                                           | Min   | Nom | Max   | Unit |
|------------------|----------------------------------------------------------|-------|-----|-------|------|
| C <sub>LDO</sub> | External filter capacitor size for internal power supply | 1.0   | -   | 3.0   | μF   |
| V <sub>LDO</sub> | LDO output voltage                                       | 1.235 | 1.3 | 1.365 | V    |

## 24.8 Clocks

The following sections provide specifications on the various clock sources and mode.

### 24.8.1 PLL Specifications

The following tables provide specifications for using the PLL.

**Table 24-7. Phase Locked Loop (PLL) Characteristics**

| Parameter             | Parameter Name                        | Min                | Nom | Max               | Unit |
|-----------------------|---------------------------------------|--------------------|-----|-------------------|------|
| F <sub>REF_XTAL</sub> | Crystal reference <sup>a</sup>        | 3.579545           | -   | 16.384            | MHz  |
| F <sub>REF_EXT</sub>  | External clock reference <sup>a</sup> | 3.579545           | -   | 16.384            | MHz  |
| F <sub>PLL</sub>      | PLL frequency <sup>b</sup>            | -                  | 400 | -                 | MHz  |
| T <sub>READY</sub>    | PLL lock time                         | 0.562 <sup>c</sup> | -   | 1.38 <sup>d</sup> | ms   |

a. The exact value is determined by the crystal value programmed into the XTAL field of the **Run-Mode Clock Configuration (RCC)** register.

b. PLL frequency is automatically calculated by the hardware based on the XTAL field of the **RCC** register.

c. Using a 16.384-MHz crystal

d. Using 3.5795-MHz crystal

Table 24-8 on page 1032 shows the actual frequency of the PLL based on the crystal frequency used (defined by the XTAL field in the **RCC** register).

Table 24-8. Actual PLL Frequency

| XTAL | Crystal Frequency (MHz) | PLL Frequency (MHz) | Error   |
|------|-------------------------|---------------------|---------|
| 0x04 | 3.5795                  | 400.904             | 0.0023% |
| 0x05 | 3.6864                  | 398.1312            | 0.0047% |
| 0x06 | 4.0                     | 400                 | -       |
| 0x07 | 4.096                   | 401.408             | 0.0035% |
| 0x08 | 4.9152                  | 398.1312            | 0.0047% |
| 0x09 | 5.0                     | 400                 | -       |
| 0x0A | 5.12                    | 399.36              | 0.0016% |
| 0x0B | 6.0                     | 400                 | -       |
| 0x0C | 6.144                   | 399.36              | 0.0016% |
| 0x0D | 7.3728                  | 398.1312            | 0.0047% |
| 0x0E | 8.0                     | 400                 | -       |
| 0x0F | 8.192                   | 398.6773333         | 0.0033% |
| 0x10 | 10.0                    | 400                 | -       |
| 0x11 | 12.0                    | 400                 | -       |
| 0x12 | 12.288                  | 401.408             | 0.0035% |
| 0x13 | 13.56                   | 397.76              | 0.0056% |
| 0x14 | 14.318                  | 400.90904           | 0.0023% |
| 0x15 | 16.0                    | 400                 | -       |
| 0x16 | 16.384                  | 404.1386667         | 0.010%  |

## 24.8.2 PIOSC Specifications

Table 24-9. PIOSC Clock Characteristics

| Parameter              | Parameter Name                                                                                                           | Min | Nom    | Max | Unit |
|------------------------|--------------------------------------------------------------------------------------------------------------------------|-----|--------|-----|------|
| F <sub>PIOSC25</sub>   | Internal 16-MHz precision oscillator frequency variance, factory calibrated at 25 °C                                     | -   | ±0.25% | ±1% | -    |
| F <sub>PIOSCT</sub>    | Internal 16-MHz precision oscillator frequency variance, factory calibrated at 25 °C, across specified temperature range | -   | -      | ±3% | -    |
| F <sub>PIOSCUCAL</sub> | Internal 16-MHz precision oscillator frequency variance, user calibrated at a chosen temperature                         | -   | ±0.25% | ±1% | -    |

## 24.8.3 Internal 30-kHz Oscillator Specifications

Table 24-10. 30-kHz Clock Characteristics

| Parameter              | Parameter Name                       | Min | Nom | Max | Unit |
|------------------------|--------------------------------------|-----|-----|-----|------|
| F <sub>IOSC30KHZ</sub> | Internal 30-KHz oscillator frequency | 15  | 30  | 45  | KHz  |

## 24.8.4 Hibernation Clock Source Specifications

Table 24-11. Hibernation Clock Characteristics

| Parameter                | Parameter Name                               | Min | Nom      | Max | Unit |
|--------------------------|----------------------------------------------|-----|----------|-----|------|
| F <sub>HIBOSC</sub>      | Hibernation module oscillator frequency      | -   | 4.194304 | -   | MHz  |
| F <sub>HIBOSC_XTAL</sub> | Crystal reference for hibernation oscillator | -   | 4.194304 | -   | MHz  |

**Table 24-11. Hibernation Clock Characteristics (continued)**

| Parameter                 | Parameter Name                                   | Min | Nom    | Max | Unit |
|---------------------------|--------------------------------------------------|-----|--------|-----|------|
| T <sub>HIBOSC_START</sub> | Hibernation oscillator startup time <sup>a</sup> | -   | -      | 10  | ms   |
| F <sub>HIBOSC_EXT</sub>   | External clock reference for hibernation module  | -   | 32.768 | -   | KHz  |
| DC <sub>HIBOSC_EXT</sub>  | External clock reference duty cycle              | 45  | -      | 55  | %    |

a. This parameter is highly sensitive to PCB layout and trace lengths, which may make this parameter time longer. Care must be taken in PCB design to minimize trace lengths and RLC (resistance, inductance, capacitance).

**Table 24-12. HIB Oscillator Input Characteristics**

| Parameter             | Parameter Name                             | Min | Nom                                          | Max | Unit |
|-----------------------|--------------------------------------------|-----|----------------------------------------------|-----|------|
| F <sub>HIBOSC</sub>   | Hibernation module oscillator frequency    | -   | 4.194304                                     | -   | MHz  |
| TOL <sub>HIBOSC</sub> | Hibernation oscillator frequency tolerance | -   | Defined by customer application requirements | -   | PPM  |

## 24.8.5 Main Oscillator Specifications

**Table 24-13. Main Oscillator Clock Characteristics**

| Parameter                    | Parameter Name                                                                | Min  | Nom | Max    | Unit |
|------------------------------|-------------------------------------------------------------------------------|------|-----|--------|------|
| F <sub>MOSC</sub>            | Main oscillator frequency                                                     | 1    | -   | 16.384 | MHz  |
| T <sub>MOSC_PER</sub>        | Main oscillator period                                                        | 61   | -   | 1000   | ns   |
| T <sub>MOSC_SETTLE</sub>     | Main oscillator settling time <sup>a</sup>                                    | 17.5 | -   | 20     | ms   |
| T <sub>REF_XTAL_BYPASS</sub> | Crystal reference using the main oscillator (PLL in BYPASS mode) <sup>b</sup> | 1    | -   | 16.384 | MHz  |
| F <sub>REF_EXT_BYPASS</sub>  | External clock reference (PLL in BYPASS mode) <sup>b</sup>                    | 0    | -   | 50     | MHz  |
| DC <sub>MOSC_EXT</sub>       | External clock reference duty cycle                                           | 45   | -   | 55     | %    |

a. This parameter is highly sensitive to PCB layout and trace lengths, which may make this parameter time longer. Care must be taken in PCB design to minimize trace lengths and RLC (resistance, inductance, capacitance).

b. If the ADC is used, the crystal reference must be 16 MHz ± .03% when the PLL is bypassed.

**Table 24-14. Supported MOSC Crystal Frequencies**

| Crystal Frequency (MHz) Not Using the PLL | Crystal Frequency (MHz) Using the PLL |
|-------------------------------------------|---------------------------------------|
| 1.000 MHz                                 | reserved                              |
| 1.8432 MHz                                | reserved                              |
| 2.000 MHz                                 | reserved                              |
| 2.4576 MHz                                | reserved                              |
| 3.579545 MHz                              |                                       |
| 3.6864 MHz                                |                                       |
| 4 MHz                                     |                                       |
| 4.096 MHz                                 |                                       |
| 4.9152 MHz                                |                                       |
| 5 MHz                                     |                                       |
| 5.12 MHz                                  |                                       |
| 6 MHz (reset value)                       |                                       |

Table 24-14. Supported MOSC Crystal Frequencies (continued)

| Crystal Frequency (MHz) Not Using the PLL | Crystal Frequency (MHz) Using the PLL |
|-------------------------------------------|---------------------------------------|
| 6.144 MHz                                 |                                       |
| 7.3728 MHz                                |                                       |
| 8 MHz                                     |                                       |
| 8.192 MHz                                 |                                       |
| 10.0 MHz                                  |                                       |
| 12.0 MHz                                  |                                       |
| 12.288 MHz                                |                                       |
| 13.56 MHz                                 |                                       |
| 14.31818 MHz                              |                                       |
| 16.0 MHz                                  |                                       |
| 16.384 MHz                                |                                       |

## 24.8.6 System Clock Specification with ADC Operation

Table 24-15. System Clock Characteristics with ADC Operation

| Parameter           | Parameter Name                                                                 | Min     | Nom | Max     | Unit |
|---------------------|--------------------------------------------------------------------------------|---------|-----|---------|------|
| F <sub>sysadc</sub> | System clock frequency when the ADC module is operating (when PLL is bypassed) | 15.9952 | 16  | 16.0048 | MHz  |

## 24.9 Sleep Modes

Table 24-16. Sleep Modes AC Characteristics<sup>a</sup>

| Parameter No | Parameter               | Parameter Name                                                             | Min | Nom | Max                | Unit          |
|--------------|-------------------------|----------------------------------------------------------------------------|-----|-----|--------------------|---------------|
| D1           | T <sub>WAKE_S</sub>     | Time to wake from interrupt in sleep or deep-sleep mode, not using the PLL | -   | -   | 7                  | system clocks |
| D2           | T <sub>WAKE_PLL_S</sub> | Time to wake from interrupt in sleep or deep-sleep mode when using the PLL | -   | -   | T <sub>READY</sub> | ms            |
| D3           | T <sub>ENTER_DS</sub>   | Time to enter deep-sleep mode from sleep request                           | -   | 0   | 35 <sup>b</sup>    | ms            |

a. Values in this table assume the IOSC is the clock source during sleep or deep-sleep mode.

b. Nominal specification occurs 99.9995% of the time.

## 24.10 Hibernation Module

The Hibernation module requires special system implementation considerations because it is intended to power down all other sections of its host device, refer to “Hibernation Module” on page 278.

Table 24-17. Hibernation Module Battery Characteristics

| Parameter           | Parameter Name             | Min | Nominal | Max | Unit |
|---------------------|----------------------------|-----|---------|-----|------|
| V <sub>BAT</sub>    | Battery supply voltage     | 2.4 | 3.0     | 3.6 | V    |
| V <sub>LOWBAT</sub> | Low battery detect voltage | 1.8 | -       | 2.2 | V    |

**Table 24-18. Hibernation Module AC Characteristics**

| Parameter No | Parameter              | Parameter Name                                                                                                       | Min | Nom | Max             | Unit    |
|--------------|------------------------|----------------------------------------------------------------------------------------------------------------------|-----|-----|-----------------|---------|
| H1           | $T_{HIB\_LOW}$         | Internal 32.768 KHz clock reference rising edge to HIB asserted                                                      | 20  | -   | -               | $\mu s$ |
| H2           | $T_{HIB\_HIGH}$        | Internal 32.768 KHz clock reference rising edge to HIB deasserted                                                    | -   | 30  | -               | $\mu s$ |
| H3           | $T_{WAKE\_TO\_HIB}$    | WAKE assert to HIB desassert (wake up time), internal Hibernation oscillator running during hibernation <sup>a</sup> | 62  | -   | 124             | $\mu s$ |
| H4           | $T_{WAKE\_TO\_HIB}$    | WAKE assert to HIB desassert (wake up time), internal Hibernation oscillator stopped during hibernation <sup>a</sup> | -   | -   | 10              | ms      |
| H5           | $T_{WAKE\_CLOCK}$      | WAKE assertion time, internal Hibernation oscillator running during hibernation                                      | 62  | -   | -               | $\mu s$ |
| H6           | $T_{WAKE\_NOCLOCK}$    | WAKE assertion time, internal Hibernation oscillator stopped during hibernation <sup>b</sup>                         | 10  | -   | -               | ms      |
| H7           | $T_{HIB\_REG\_ACCESS}$ | Time required for a write to a non-volatile register in the HIB module to complete                                   | 92  | -   | -               | $\mu s$ |
| H8           | $T_{HIB\_TO\_HIB}$     | HIB high time between assertions                                                                                     | 100 | -   | -               | ms      |
| H9           | $T_{ENTER\_HIB}$       | Time to enter hibernation mode from hibernation request                                                              | -   | 0   | 35 <sup>c</sup> | ms      |

a. Code begins executing after the time period specified by  $T_{IRPOR}$  following the deassertion of HIB.

b. This mode is used when the PINWEN bit is set and the RTCEN bit is clear in the HIBCTL register.

c. Nominal specification occurs 99.998% of the time.

**Figure 24-11. Hibernation Module Timing with Internal Oscillator Running in Hibernation****Figure 24-12. Hibernation Module Timing with Internal Oscillator Stopped in Hibernation**

## 24.11 Flash Memory

**Table 24-19. Flash Memory Characteristics**

| Parameter          | Parameter Name                                                        | Min    | Nom | Max | Unit   |
|--------------------|-----------------------------------------------------------------------|--------|-----|-----|--------|
| PE <sub>CYC</sub>  | Number of guaranteed program/erase cycles before failure <sup>a</sup> | 15,000 | -   | -   | cycles |
| T <sub>RET</sub>   | Data retention, -40°C to +85°C                                        | 10     | -   | -   | years  |
| T <sub>PROG</sub>  | Word program time                                                     | -      | -   | 1   | ms     |
| T <sub>BPROG</sub> | Buffer program time                                                   | -      | -   | 1   | ms     |
| T <sub>ERASE</sub> | Page erase time                                                       | -      | -   | 12  | ms     |
| T <sub>ME</sub>    | Mass erase time                                                       | -      | -   | 16  | ms     |

a. A program/erase cycle is defined as switching the bits from 1-> 0 -> 1.

## 24.12 GPIO Module

**Note:** All GPIOs are 5-V tolerant, except PB0 and PB1. See “Signal Description” on page 410 for more information on GPIO configuration.

**Table 24-20. GPIO Module Characteristics**

| Parameter           | Parameter Name                                                 | Min | Nom | Max | Unit |
|---------------------|----------------------------------------------------------------|-----|-----|-----|------|
| R <sub>GPIOPU</sub> | GPIO internal pull-up resistor                                 | 100 | -   | 300 | kΩ   |
| R <sub>GPIOPD</sub> | GPIO internal pull-down resistor                               | 200 | -   | 500 | kΩ   |
| I <sub>LKG</sub>    | GPIO input leakage current <sup>a</sup>                        | -   | -   | 2   | μA   |
| T <sub>GPIOR</sub>  | GPIO Rise Time, 2-mA drive <sup>b</sup>                        | -   | 14  | 20  | ns   |
|                     | GPIO Rise Time, 4-mA drive <sup>b</sup>                        |     | 7   | 10  | ns   |
|                     | GPIO Rise Time, 8-mA drive <sup>b</sup>                        |     | 4   | 5   | ns   |
|                     | GPIO Rise Time, 8-mA drive with slew rate control <sup>b</sup> |     | 6   | 8   | ns   |
| T <sub>GPIOF</sub>  | GPIO Fall Time, 2-mA drive <sup>c</sup>                        | -   | 14  | 21  | ns   |
|                     | GPIO Fall Time, 4-mA drive <sup>c</sup>                        |     | 7   | 11  | ns   |
|                     | GPIO Fall Time, 8-mA drive <sup>c</sup>                        |     | 4   | 6   | ns   |
|                     | GPIO Fall Time, 8-mA drive with slew rate control <sup>c</sup> |     | 6   | 8   | ns   |

a. The leakage current is measured with GND or VDD applied to the corresponding pin(s). The leakage of digital port pins is measured individually. The port pin is configured as an input and the pullup/pulldown resistor is disabled.

b. Time measured from 20% to 80% of V<sub>DD</sub>.

c. Time measured from 80% to 20% of V<sub>DD</sub>.

## 24.13 Analog-to-Digital Converter (ADC)

Table 24-21. ADC Characteristics<sup>a</sup>

| Parameter            | Parameter Name                                                                  | Min     | Nom | Max                 | Unit          |
|----------------------|---------------------------------------------------------------------------------|---------|-----|---------------------|---------------|
| $V_{\text{ADCIN}}$   | Maximum single-ended, full-scale analog input voltage, using internal reference | -       | -   | 3.0                 | V             |
|                      | Maximum single-ended, full-scale analog input voltage, using external reference | -       | -   | $V_{\text{REFA}}$   | V             |
|                      | Minimum single-ended, full-scale analog input voltage                           | 0.0     | -   | -                   | V             |
|                      | Maximum differential, full-scale analog input voltage, using internal reference | -       | -   | 1.5                 | V             |
|                      | Maximum differential, full-scale analog input voltage, using external reference | -       | -   | $V_{\text{REFA}}/2$ | V             |
|                      | Minimum differential, full-scale analog input voltage                           | 0.0     | -   | -                   | V             |
| N                    | Resolution                                                                      | 12      |     |                     | bits          |
| $F_{\text{ADC}}$     | ADC internal clock frequency <sup>b</sup>                                       | 15.9952 | 16  | 16.0048             | MHz           |
| $T_{\text{ADCCONV}}$ | Conversion time <sup>c</sup>                                                    | 1       |     |                     | μs            |
| $F_{\text{ADCCONV}}$ | Conversion rate <sup>c</sup>                                                    | 1000    |     |                     | k samples/s   |
| $T_{\text{ADCSAMP}}$ | Sample time                                                                     | 125     | -   | -                   | ns            |
| $T_{\text{LT}}$      | Latency from trigger to start of conversion                                     | -       | 2   | -                   | system clocks |
| $I_{\text{L}}$       | ADC input leakage                                                               | -       | -   | 2.0                 | μA            |
| $R_{\text{ADC}}$     | ADC equivalent resistance                                                       | -       | -   | 10                  | kΩ            |
| $C_{\text{ADC}}$     | ADC equivalent capacitance                                                      | 0.9     | 1.0 | 1.1                 | pF            |
| $E_{\text{L}}$       | Integral nonlinearity (INL) error, 12-bit mode                                  | -       | -   | ±8                  | LSB           |
|                      | Integral nonlinearity (INL) error, 10-bit mode                                  | -       | -   | ±2                  | LSB           |
| $E_{\text{D}}$       | Differential nonlinearity (DNL) error, 12-bit mode                              | -       | -   | ±4                  | LSB           |
|                      | Differential nonlinearity (DNL) error, 10-bit mode                              | -       | -   | ±2                  | LSB           |
| $E_{\text{O}}$       | Offset error, 12-bit mode                                                       | -       | -   | ±40                 | LSB           |
|                      | Offset error, 10-bit mode                                                       | -       | -   | ±10                 | LSB           |
| $E_{\text{G}}$       | Full-scale gain error, 12-bit mode                                              | -       | -   | ±100                | LSB           |
|                      | Full-scale gain error, 10-bit mode                                              | -       | -   | ±25                 | LSB           |
| $E_{\text{TS}}$      | Temperature sensor accuracy <sup>d</sup>                                        | -       | -   | ±5                  | °C            |

a. The ADC reference voltage is 3.0 V. This reference voltage is internally generated from the 3.3 VDDA supply by a band gap circuit.

b. The ADC must be clocked from the PLL or directly from an external clock source to operate properly.

c. The conversion time and rate scale from the specified number if the ADC internal clock frequency is any value other than 16 MHz.

d. Note that this parameter does not include ADC error.

Figure 24-13. ADC Input Equivalency Diagram

Table 24-22. ADC Module External Reference Characteristics<sup>a</sup>

| Parameter  | Parameter Name                                                                                            | Min  | Nom | Max  | Unit    |
|------------|-----------------------------------------------------------------------------------------------------------|------|-----|------|---------|
| $V_{REFA}$ | External voltage reference for ADC, when the VREF field in the <b>ADCCTL</b> register is 0x1 <sup>b</sup> | 2.97 | -   | 3.03 | V       |
|            | External voltage reference for ADC, when the VREF field in the <b>ADCCTL</b> register is 0x3 <sup>c</sup> | 0.99 | -   | 1.01 | V       |
| $I_L$      | External voltage reference leakage current                                                                | -    | -   | 2.0  | $\mu A$ |

a. Care must be taken to supply a reference voltage of acceptable quality.

b. Ground is always used as the reference level for the minimum conversion value.

c. Ground is always used as the reference level for the minimum conversion value.

Table 24-23. ADC Module Internal Reference Characteristics

| Parameter  | Parameter Name                     | Min | Nom | Max | Unit |
|------------|------------------------------------|-----|-----|-----|------|
| $V_{REFI}$ | Internal voltage reference for ADC | -   | 3.0 | -   | V    |

## 24.14 Synchronous Serial Interface (SSI)

Table 24-24. SSI Characteristics

| Parameter No. | Parameter       | Parameter Name                     | Min | Nom | Max | Unit          |
|---------------|-----------------|------------------------------------|-----|-----|-----|---------------|
| S1            | $T_{CLK\_PER}$  | SSIClk cycle time <sup>a</sup>     | 100 | -   | -   | ns            |
| S2            | $T_{CLK\_HIGH}$ | SSIClk high time                   | -   | 0.5 | -   | t clk_per     |
| S3            | $T_{CLK\_LOW}$  | SSIClk low time                    | -   | 0.5 | -   | t clk_per     |
| S4            | $T_{CLKRF}$     | SSIClk rise/fall time <sup>b</sup> | -   | 4   | 6   | ns            |
| S5            | $T_{DMD}$       | Data from master valid delay time  | 0   | -   | 1   | system clocks |
| S6            | $T_{DMS}$       | Data from master setup time        | 1   | -   | -   | system clocks |
| S7            | $T_{DMH}$       | Data from master hold time         | 2   | -   | -   | system clocks |
| S8            | $T_{DSS}$       | Data from slave setup time         | 1   | -   | -   | system clocks |

**Table 24-24. SSI Characteristics (continued)**

| Parameter No. | Parameter | Parameter Name            | Min | Nom | Max | Unit          |
|---------------|-----------|---------------------------|-----|-----|-----|---------------|
| S9            | $T_{DSH}$ | Data from slave hold time | 2   | -   | -   | system clocks |

a. In master mode, the system clock must be at least twice as fast as the SSIClk; in slave mode, the system clock must be at least 12 times faster than the SSIClk.

b. Note that the delays shown are using 8-mA drive strength.

## 24.15 Inter-Integrated Circuit (I<sup>2</sup>C) Interface

**Table 24-25. I<sup>2</sup>C Characteristics**

| Parameter No.   | Parameter         | Parameter Name                                                               | Min | Nom | Max          | Unit          |
|-----------------|-------------------|------------------------------------------------------------------------------|-----|-----|--------------|---------------|
| 11 <sup>a</sup> | T <sub>SCH</sub>  | Start condition hold time                                                    | 36  | -   | -            | system clocks |
| 12 <sup>a</sup> | T <sub>LP</sub>   | Clock Low period                                                             | 36  | -   | -            | system clocks |
| 13 <sup>b</sup> | T <sub>SRT</sub>  | I2CSCL/I2CSDA rise time (V <sub>IL</sub> = 0.5 V to V <sub>IH</sub> = 2.4 V) | -   | -   | (see note b) | ns            |
| 14 <sup>a</sup> | T <sub>DH</sub>   | Data hold time                                                               | 2   | -   | -            | system clocks |
| 15 <sup>c</sup> | T <sub>SFT</sub>  | I2CSCL/I2CSDA fall time (V <sub>IH</sub> = 2.4 V to V <sub>IL</sub> = 0.5 V) | -   | 9   | 10           | ns            |
| 16 <sup>a</sup> | T <sub>HT</sub>   | Clock High time                                                              | 24  | -   | -            | system clocks |
| 17 <sup>a</sup> | T <sub>DS</sub>   | Data setup time                                                              | 18  | -   | -            | system clocks |
| 18 <sup>a</sup> | T <sub>SCSR</sub> | Start condition setup time (for repeated start condition only)               | 36  | -   | -            | system clocks |
| 19 <sup>a</sup> | T <sub>SCS</sub>  | Stop condition setup time                                                    | 24  | -   | -            | system clocks |

a. Values depend on the value programmed into the TPR bit in the **I<sup>2</sup>C Master Timer Period (I2CMTPR)** register; a TPR programmed for the maximum I2CSCL frequency (TPR=0x2) results in a minimum output timing as shown in the table above. The I<sup>2</sup>C interface is designed to scale the actual data transition time to move it to the middle of the I2CSCL Low period. The actual position is affected by the value programmed into the TPR; however, the numbers given in the above values are minimum values.

b. Because I2CSCL and I2CSDA are open-drain-type outputs, which the controller can only actively drive Low, the time I2CSCL or I2CSDA takes to reach a high level depends on external signal capacitance and pull-up resistor values.

c. Specified at a nominal 50 pF load.

Figure 24-17. I<sup>2</sup>C Timing

## 24.16 Ethernet Controller

Table 24-26. Ethernet Controller DC Characteristics

| Parameter          | Parameter Name                                    | Value       | Unit |
|--------------------|---------------------------------------------------|-------------|------|
| R <sub>EBIAS</sub> | Value of the pull-down resistor on the ERBIAS pin | 12.4K ± 1 % | Ω    |

Table 24-27. 100BASE-TX Transmitter Characteristics<sup>a</sup>

| Parameter Name            | Min | Nom | Max  | Unit |
|---------------------------|-----|-----|------|------|
| Peak output amplitude     | 950 | -   | 1050 | mVpk |
| Output amplitude symmetry | 98  | -   | 102  | %    |
| Output overshoot          | -   | -   | 5    | %    |
| Rise/Fall time            | 3   | -   | 5    | ns   |
| Rise/Fall time imbalance  | -   | -   | 500  | ps   |
| Duty cycle distortion     | -   | -   | ±250 | ps   |
| Jitter                    | -   | -   | 1.4  | ns   |

a. Measured at the line side of the transformer.

Table 24-28. 100BASE-TX Transmitter Characteristics (informative)<sup>a</sup>

| Parameter Name          | Min | Nom | Max | Unit |
|-------------------------|-----|-----|-----|------|
| Return loss             | 16  | -   | -   | dB   |
| Open-circuit inductance | 350 | -   | -   | μH   |

a. The specifications in this table are included for information only. They are mainly a function of the external transformer and termination resistors used for measurements.

Table 24-29. 100BASE-TX Receiver Characteristics

| Parameter Name                       | Min | Nom | Max  | Unit  |
|--------------------------------------|-----|-----|------|-------|
| Signal detect assertion threshold    | 600 | 700 | -    | mVppd |
| Signal detect de-assertion threshold | 350 | 425 | -    | mVppd |
| Differential input resistance        | -   | 3.6 | -    | kΩ    |
| Jitter tolerance (pk-pk)             | 4   | -   | -    | ns    |
| Baseline wander tracking             | -80 | -   | +80  | %     |
| Signal detect assertion time         | -   | -   | 1000 | μs    |
| Signal detect de-assertion time      | -   | -   | 4    | μs    |

**Table 24-30. 10BASE-T Transmitter Characteristics<sup>a</sup>**

| Parameter Name                        | Min | Nom | Max | Unit |
|---------------------------------------|-----|-----|-----|------|
| Peak differential output signal       | 2.2 | -   | 2.7 | V    |
| Harmonic content                      | 27  | -   | -   | dB   |
| Link pulse width                      | -   | 100 | -   | ns   |
| Start-of-idle pulse width, Last bit 0 | -   | 300 | -   | ns   |
| Start-of-idle pulse width, Last bit 1 | -   | 350 | -   | ns   |

a. The Manchester-encoded data pulses, the link pulse and the start-of-idle pulse are tested against the templates and using the procedures found in Clause 14 of *IEEE 802.3*.

**Table 24-31. 10BASE-T Transmitter Characteristics (informative)<sup>a</sup>**

| Parameter Name                  | Min                 | Nom | Max | Unit |
|---------------------------------|---------------------|-----|-----|------|
| Output return loss              | 15                  | -   | -   | dB   |
| Output impedance balance        | $29 - 17\log(f/10)$ | -   | -   | dB   |
| Peak common-mode output voltage | -                   | -   | 50  | mV   |
| Common-mode rejection           | -                   | -   | 100 | mV   |
| Common-mode rejection jitter    | -                   | -   | 1   | ns   |

a. The specifications in this table are included for information only. They are mainly a function of the external transformer and termination resistors used for measurements.

**Table 24-32. 10BASE-T Receiver Characteristics**

| Parameter Name                | Min | Nom | Max | Unit       |
|-------------------------------|-----|-----|-----|------------|
| Jitter tolerance (pk-pk)      | 30  | 26  | -   | ns         |
| Input squelched threshold     | 340 | 440 | 540 | mVppd      |
| Differential input resistance | -   | 3.6 | -   | k $\Omega$ |
| Common-mode rejection         | 25  | -   | -   | V          |

**Table 24-33. Isolation Transformers<sup>a</sup>**

| Name                      | Value              | Condition       |
|---------------------------|--------------------|-----------------|
| Turns ratio               | 1 CT : 1 CT        | +/- 5%          |
| Open-circuit inductance   | 350 $\mu$ H (min)  | @ 10 mV, 10 kHz |
| Leakage inductance        | 0.40 $\mu$ H (max) | @ 1 MHz (min)   |
| Inter-winding capacitance | 25 pF (max)        |                 |
| DC resistance             | 0.9 Ohm (max)      |                 |
| Insertion loss            | 0.4 dB (typ)       | 0-65 MHz        |
| HIPOT                     | 1500               | Vrms            |

a. Two simple 1:1 isolation transformers are required at the line interface. Transformers with integrated common-mode chokes are recommended for exceeding FCC requirements. This table gives the recommended line transformer characteristics.

**Note:** The 100Base-TX amplitude specifications assume a transformer loss of 0.4 dB.

**Table 24-34. Ethernet Reference Crystal**

| Parameter               | Parameter Name                    | Min | Nom | Max | Unit |

## 24.18 Current Consumption

This section provides information on typical and maximum power consumption under various conditions. Unless otherwise indicated, current consumption numbers include use of the on-chip LDO regulator and therefore include I<sub>DDC</sub>.

### 24.18.1 Nominal Power Consumption

The following table provides nominal figures for current consumption.

Table 24-38. Nominal Power Consumption

| Parameter                 | Parameter Name                                                              | Conditions                                                                                                                                              | Nom                                  | Unit |
|---------------------------|-----------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------|------|
| I <sub>DD_RUN</sub>       | Run mode 1 (Flash loop)                                                     | V <sub>DD</sub> = 3.3 V<br>Code= while(1){} executed out of Flash<br>Peripherals = All ON<br>System Clock = 80 MHz (with PLL)<br>Temp = 25°C            | 101 <sup>a</sup><br>159 <sup>b</sup> | mA   |
| I <sub>DD_DEEPSLEEP</sub> | Deep-sleep mode                                                             | Peripherals = All OFF<br>System Clock = IOS30KHZ/64<br>Temp = 25°C                                                                                      | 550                                  | μA   |
| I <sub>HIB_NORTC</sub>    | Hibernate mode (external wake, RTC disabled, I/O not powered <sup>c</sup> ) | V <sub>BAT</sub> = 3.0 V<br>V <sub>DD</sub> = 0 V<br>V <sub>DDA</sub> = 0 V<br>Peripherals = All OFF<br>System Clock = OFF<br>Hibernate Module = 0 kHz  | 30                                   | μA   |
| I <sub>HIB_RTC</sub>      | Hibernate mode (RTC enabled, I/O not powered <sup>c</sup> )                 | V <sub>BAT</sub> = 3.0 V<br>V <sub>DD</sub> = 0 V<br>V <sub>DDA</sub> = 0 V<br>Peripherals = All OFF<br>System Clock = OFF<br>Hibernate Module = 32 kHz | 44                                   | μA   |

a. Ethernet MAC and PHY powered down by software.

b. Auto-negotiate enabled. If an Ethernet cable is attached to the connector, the consumption increases by 7-10 mA.

c. The VDD3ON mode must be disabled for the I/O ring to be unpowered.

### 24.18.2 Maximum Current Consumption

The current measurements specified in the table that follows are maximum values under the following conditions:

- V<sub>DD</sub> = 3.6 V

- $V_{DDC} = 1.3\text{ V}$
- $V_{BAT} = 3.25\text{ V}$
- $V_{DDA} = 3.6\text{ V}$
- Temperature = 25°C
- Clock source (MOSC) = 3.579545-MHz crystal oscillator

**Table 24-39. Detailed Current Specifications**

| Parameter           | Parameter Name          | Conditions                                                                                                                                          | Max                                  | Unit |
|---------------------|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------|------|
| $I_{DD\_RUN}$       | Run mode 1 (Flash loop) | $V_{DD} = 3.6\text{ V}$<br>Code= while(1){} executed out of Flash<br>Peripherals = All ON<br>System Clock = 80 MHz (with PLL)<br>Temperature = 25°C | 210 <sup>a</sup><br>138 <sup>b</sup> | mA   |

## B Ordering and Contact Information

### B.1 Ordering Information

**Table B-1. Part Ordering Information**

| Orderable Part Number | Description                                                                          |
|-----------------------|--------------------------------------------------------------------------------------|
| LM3S8C62-IQC80-A2     | Stellaris® LM3S8C62 Microcontroller Industrial Temperature 100-pin LQFP              |
| LM3S8C62-IBZ80-A2     | Stellaris LM3S8C62 Microcontroller Industrial Temperature 108-ball BGA               |
| LM3S8C62-IQC80-A2T    | Stellaris LM3S8C62 Microcontroller Industrial Temperature 100-pin LQFP Tape-and-reel |
| LM3S8C62-IBZ80-A2T    | Stellaris LM3S8C62 Microcontroller Industrial Temperature 108-ball BGA Tape-and-reel |

### B.2 Part Markings

The Stellaris microcontrollers are marked with an identifying number. This code contains the following information:

- The first line indicates the part number. In the example figure below, this is the LM3S9B90.
- In the second line, the first seven characters indicate the temperature, package, speed, and revision. In the example below, this is an Industrial temperature (I), 100-pin LQFP package (QC), 80-MHz (80), revision C0 (C0) device.
- The remaining characters contain internal tracking numbers.

## B.3 Kits

The Stellaris Family provides the hardware and software tools that engineers need to begin development quickly.

- Reference Design Kits accelerate product development by providing ready-to-run hardware and comprehensive documentation including hardware design files
- Evaluation Kits provide a low-cost and effective means of evaluating Stellaris microcontrollers before purchase
- Development Kits provide you with all the tools you need to develop and prototype embedded applications right out of the box

See the website at [www.ti.com/stellaris](http://www.ti.com/stellaris) for the latest tools available, or ask your distributor.

## B.4 Support Information

For support on Stellaris products, contact the TI Worldwide Product Information Center nearest you: <http://www-k.ext.ti.com/sc/technical-support/product-information-centers.htm>.

## C Package Information

### C.1 100-Pin LQFP Package

#### C.1.1 Package Dimensions

Figure C-1. 100-Pin LQFP Package Dimensions

**Note:** The following notes apply to the package drawing.

1. All dimensions shown in mm.
2. Dimensions shown are nominal with tolerances indicated.
3. Foot length 'L' is measured at gage plane 0.25 mm above seating plane.

| Body +2.00 mm Footprint, 1.4 mm package thickness |             |                     |
|---------------------------------------------------|-------------|---------------------|
| Symbols                                           | Leads       | 100L                |
| A                                                 | Max.        | 1.60                |
| A <sub>1</sub>                                    | -           | 0.05 Min./0.15 Max. |
| A <sub>2</sub>                                    | ±0.05       | 1.40                |
| D                                                 | ±0.20       | 16.00               |
| D <sub>1</sub>                                    | ±0.05       | 14.00               |
| E                                                 | ±0.20       | 16.00               |
| E <sub>1</sub>                                    | ±0.05       | 14.00               |
| L                                                 | +0.15/-0.10 | 0.60                |
| e                                                 | Basic       | 0.50                |
| b                                                 | +0.05       | 0.22                |
| θ                                                 | -           | 0°-7°               |
| ddd                                               | Max.        | 0.08                |
| ccc                                               | Max.        | 0.08                |
| JEDEC Reference Drawing                           |             | MS-026              |
| Variation Designator                              |             | BED                 |

C.1.2 Tray Dimensions

Figure C-2. 100-Pin LQFP Tray Dimensions

C.1.3 Tape and Reel Dimensions

Note: In the figure that follows, pin 1 is located in the top right corner of the device.

Figure C-3. 100-Pin LQFP Tape and Reel Dimensions

## C.2 108-Ball BGA Package

### C.2.1 Package Dimensions

Figure C-4. 108-Ball BGA Package Dimensions

**Note:** The following notes apply to the package drawing.

1. ALL DIMENSIONS ARE IN MILLIMETERS.
2. 'e' REPRESENTS THE BASIC SOLDER BALL GRID PITCH.
3. 'M' REPRESENTS THE BASIC SOLDER BALL MATRIX SIZE.  
AND SYMBOL 'N' IS THE NUMBER OF BALLS AFTER DEPOPULATING.
4. 'b' IS MEASURABLE AT THE MAXIMUM SOLDER BALL DIAMETER AFTER REFLOW  
PARALLEL TO PRIMARY DATUM [C].
5. DIMENSION 'ccc' IS MEASURED PARALLEL TO PRIMARY DATUM [C].
6. PRIMARY DATUM [C] AND SEATING PLANE ARE DEFINED BY THE SPHERICAL  
CROWNS OF THE SOLDER BALLS.
7. PACKAGE SURFACE SHALL BE MATTE FINISH CHARMILLES 24 TO 27.
8. SUBSTRATE MATERIAL BASE IS BT RESIN.
9. THE OVERALL PACKAGE THICKNESS "A" ALREADY CONSIDERS COLLAPSE BALLS
10. DIMENSIONING AND TOLERANCING PER ASME Y14.5M 1994.
11. EXCEPT DIMENSION b.

| Symbols            | MIN      | NOM   | MAX   |

<sup>(1)</sup> The marketing status values are defined as follows:

**ACTIVE:** Product device recommended for new designs.

**LIFEBUY:** TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.

**NRND:** Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.

**PREVIEW:** Device has been announced but is not in production. Samples may or may not be available.

**OBSOLETE:** TI has discontinued the production of the device.

<sup>(2)</sup> Eco Plan - The planned eco-friendly classification: Pb-Free (RoHS), Pb-Free (RoHS Exempt), or Green (RoHS & no Sb/Br) - please check <http://www.ti.com/productcontent> for the latest availability information and additional product content details.

**TBD:** The Pb-Free/Green conversion plan has not been defined.

**Pb-Free (RoHS):** TI's terms "Lead-Free" or "Pb-Free" mean semiconductor products that are compatible with the current RoHS requirements for all 6 substances, including the requirement that lead not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, TI Pb-Free products are suitable for use in specified lead-free processes.

**Pb-Free (RoHS Exempt):** This component has a RoHS exemption for either 1) lead-based flip-chip solder bumps used between the die and package, or 2) lead-based die adhesive used between the die and leadframe. The component is otherwise considered Pb-Free (RoHS compatible) as defined above.

**Green (RoHS & no Sb/Br):** TI defines "Green" to mean Pb-Free (RoHS compatible), and free of Bromine (Br) and Antimony (Sb) based flame retardants (Br or Sb do not exceed 0.1% by weight in homogeneous material)

<sup>(3)</sup> MSL, Peak Temp. -- The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

**Important Information and Disclaimer:** The information provided on this page represents TI's knowledge and belief as of the date that it is provided. TI bases its knowledge and belief on information provided by third parties, and makes no representation or warranty as to the accuracy of such information. Efforts are underway to better integrate information from third parties. TI has taken and continues to take reasonable steps to provide representative and accurate information but may not have conducted destructive testing or chemical analysis on incoming materials and chemicals. TI and TI suppliers consider certain information to be proprietary, and thus CAS numbers and other limited information may not be available for release.

In no event shall TI's liability arising out of such information exceed the total purchase price of the TI part(s) at issue in this document sold by TI to Customer on an annual basis.

## IMPORTANT NOTICE

Texas Instruments Incorporated and its subsidiaries (TI) reserve the right to make corrections, modifications, enhancements, improvements, and other changes to its products and services at any time and to discontinue any product or service without notice. Customers should obtain the latest relevant information before placing orders and should verify that such information is current and complete. All products are sold subject to TI's terms and conditions of sale supplied at the time of order acknowledgment.

TI warrants performance of its hardware products to the specifications applicable at the time of sale in accordance with TI's standard warranty. Testing and other quality control techniques are used to the extent TI deems necessary to support this warranty. Except where mandated by government requirements, testing of all parameters of each product is not necessarily performed.

TI assumes no liability for applications assistance or customer product design. Customers are responsible for their products and applications using TI components. To minimize the risks associated with customer products and applications, customers should provide adequate design and operating safeguards.

TI does not warrant or represent that any license, either express or implied, is granted under any TI patent right, copyright, mask work right, or other TI intellectual property right relating to any combination, machine, or process in which TI products or services are used. Information published by TI regarding third-party products or services does not constitute a license from TI to use such products or services or a warranty or endorsement thereof. Use of such information may require a license from a third party under the patents or other intellectual property of the third party, or a license from TI under the patents or other intellectual property of TI.

Reproduction of TI information in TI data books or data sheets is permissible only if reproduction is without alteration and is accompanied by all associated warranties, conditions, limitations, and notices. Reproduction of this information with alteration is an unfair and deceptive business practice. TI is not responsible or liable for such altered documentation. Information of third parties may be subject to additional restrictions.

Resale of TI products or services with statements different from or beyond the parameters stated by TI for that product or service voids all express and any implied warranties for the associated TI product or service and is an unfair and deceptive business practice. TI is not responsible or liable for any such statements.

TI products are not authorized for use in safety-critical applications (such as life support) where a failure of the TI product would reasonably be expected to cause severe personal injury or death, unless officers of the parties have executed an agreement specifically governing such use. Buyers represent that they have all necessary expertise in the safety and regulatory ramifications of their applications, and acknowledge and agree that they are solely responsible for all legal, regulatory and safety-related requirements concerning their products and any use of TI products in such safety-critical applications, notwithstanding any applications-related information or support that may be provided by TI. Further, Buyers must fully indemnify TI and its representatives against any damages arising out of the use of TI products in such safety-critical applications.

TI products are neither designed nor intended for use in military/aerospace applications or environments unless the TI products are specifically designated by TI as military-grade or "enhanced plastic." Only products designated by TI as military-grade meet military specifications. Buyers acknowledge and agree that any such use of TI products which TI has not designated as military-grade is solely at the Buyer's risk, and that they are solely responsible for compliance with all legal and regulatory requirements in connection with such use.

TI products are neither designed nor intended for use in automotive applications or environments unless the specific TI products are designated by TI as compliant with ISO/TS 16949 requirements. Buyers acknowledge and agree that, if they use any non-designated products in automotive applications, TI will not be responsible for any failure to meet such requirements.
