GTLP6C816 GTLP/TTL 1:6 Clock Driver

General Description

The GTLP6C816 is a clock driver that provides TTL to GTLP signal level translation (and vice versa). The device provides a high speed interface between cards operating at TTL logic levels and a backplane operating at GTLP logic levels. High speed backplane operation is a direct result of GTLP's reduced output swing (<1V), reduced input threshold levels and output edge rate control. The edge rate control minimizes bus settling time. GTLP is a Fairchild Semiconductor derivative of the Gunning Transceiver logic (GTL) JEDEC standard JESD8-3.

Fairchild's GTLP has internal edge-rate control and is process, voltage, and temperature (PVT) compensated. Its function is similar to BTL and GTL but with different output levels and receiver threshold. GTLP output LOW level is typically less than 0.5V, the output level HIGH is 1.5V and the receiver threshold is 1.0V.

Functional Description

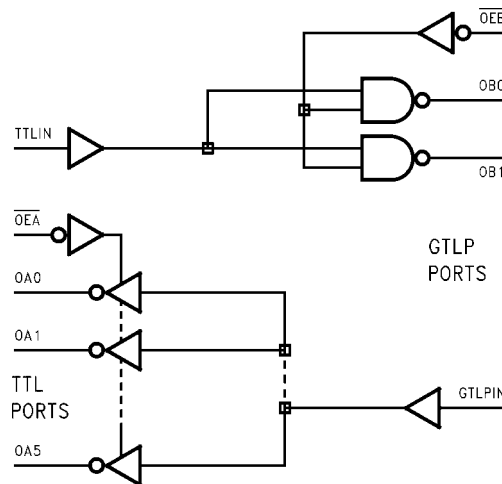

The GTLP6C816 is a clock driver providing TTL-to-GTLP clock translation, and GTLP-to-TTL clock translation in the same package. The TTL-to-GTLP direction is a 1:2 clock driver path with a single Enable pin (\overline{OEB}). For the GTLP-to-TTL direction the clock receiver path is a 1:6 buffer with a single Enable control (\overline{OEA}). Data polarity is inverting for both directions.

Note 5: GTLP V_{REF} and V_{TT} are specified to 2% tolerance since signal integrity and noise margin can be significantly degraded if these supplies are noisy. In addition, V_{TT} and R_{TERM} can be adjusted to accommodate backplane impedances other than 50Ω, within the boundaries of not exceeding the DC Absolute I_{OL} ratings. Similarly V_{REF} can be adjusted to compensate for changes in V_{TT}.
