TPT29539Q-TS5R-S**

Automotive I²C to 16-bit GPIO Expander with Interrupt and Reset

Features

- I²C-bus to 16-bit GPIO Expander
- Operating Power Supply Voltage from 1.65 V to 3.6 V
- Low Standby Current Consumption:
 - 1.5 μ A (typical at 3.3 V V_{CC})
- 400-kHz Fast-mode I²C-bus
- 5-V Tolerant I/Os
- Internal Power-on Reset
- Open-drain Active LOW Interrupt Output (\overline{INT})
- Configurable Slave Address with 2 Address Pins
- Latch-Up Performance exceeds 200 mA per JESD 78
- ESD Protection Exceeds JESD 22
 - \pm 4000-V Human Body Model
 - \pm 1500-V Charged Device Model
- AEC Q100: Automotive Grade 1

Applications

- Automotive ASAS, Infotainment,
- Automotive Body Electronics, EV/HEV
- Servers/Storages/Routers (Telecom Switching Equipment)
- Personal Computers

Description

The TPT29539Q is a 16-bit GPIO expander with interrupt and weak pull-up resistors for I²C-bus applications. The power supplier voltage ranges from 1.65 V to 3.6 V, allowing for the TPT29539Q to interconnect with 1.8-V microcontrollers.

The TPT29539Q contains 16-bit Input and Output. The open-drain interrupt (\overline{INT}) output is changeable when any input state changes from its related register state. The device is used to indicate the system master that an input state has changed. (\overline{INT}) can be connected to the interrupt input of a microcontroller. The TPT29539Q can remain a simple slave device. The power-on reset sets the registers to their default values and initializes the device state machine. The TPT29539Q also has a hardware \overline{INT} pin to reset the device to its default state.

All input/output pins do not have internal pull-up resistors, thus the device can save power consumption as communicating with external I/Os. Two hardware pins (A0, A1) select the fixed I²C-bus address and allow up to eight devices to share the same I²C-bus.

The TPT29539Q is available in the TSSOP24 package, and is characterized from -40°C to $+125^{\circ}\text{C}$ to meet automotive application requirements.

Feature Description

Device Address

Following a START condition, the bus master must output the address of the slave it is accessing. All input/output pins have internal weak pull-up resistors to remove external components. Two hardware pins (A0, A1) select the fixed I²C-bus address and allow up to eight devices to share the same I²C-bus. To conserve power, address pins (A0, A1) must be pulled HIGH or LOW. The address of the TPT29539Q is shown below.

Figure 7. Slave Device Address

Control Register

Command Byte

The command byte is the first byte to follow the address byte during a write transmission. It is used as a pointer to determine which of the following registers will be written or read.

Table 2. Command Byte Description

Register 0 and 1: Input port registers

This register is an input-only port, which means the incoming logic levels of the pins, regardless of whether the pin is defined as an input or an output by Register 3 (output port 1), and writes to this register have no effect.

The default value 'X' is determined by the externally logic level.

Register 2 and 3: Output port registers

This register is an output-only port, which means the outcoming logic levels of the pins are defined as outputs by Register 6 (Configuration port 0) and 7 (Configuration port 1). Bit values in this register have no effect on pins defined as inputs. In fact, the value reading from this register is in the flip-flop controlling the output selection, not the actual pin value.

Register 4 and 5: Polarity Inversion registers

This register allows the user to invert the polarity of the input port register data. If a bit in this register is set (written with '1'), the input port data polarity is inverted. If a bit in this register is cleared (written with '0'), the input port data polarity is retained.

Automotive I²C to 16-bit GPIO Expander with Interrupt and Reset**Register 6 and 7: Configuration registers**

This register configures the directions of the I/O pins. If a bit in this register is set (written with '1'), the corresponding port pin is enabled as an input with a high-impedance output driver. If a bit in this register is cleared (written with '0'), the corresponding port pin is enabled as an output. Note that there is a high-value resistor tied to V_{DD} at each pin. At reset, the device's ports are inputs with a pull-up to V_{DD}.

Application and Implementation

Note

Information in the following application sections is not part of the 3PEAK's component specification and 3PEAK does not warrant its accuracy or completeness. 3PEAK's customers are responsible for determining suitability of components for their purposes. Customers should validate and test their design implementation to confirm system functionality.

Application Information

The TPT29539Q builds in 16-bit input and output, and interrupt $\overline{\text{INT}}$ can be connected to the interrupt input of a microcontroller, then the interrupt $\overline{\text{INT}}$ output will response to any input state change.

IO Configuration Requirements

To make sure the TPT29539Q can support the different application, the device is requested to set all GPIOs a default value after or before powering up the device. Or the backup method, after powering up the TPT29539Q, registers are reset to a default value by digital circuit while GPIOs status are not yet stable, because there is no pull-up/pull-down resistors inside. The digital circuit is monitoring and comparing the GPIOs status to the default value of the registers in real time and when they are not matched, during the unstable period, the $\overline{\text{INT}}$ is locked. This has been confirmed in lab testing by adding time delay in seconds after powering up the TPT29539Q (for GPIOs status to reach a stable status). After seconds, the $\overline{\text{INT}}$ function is ready to work, and the performance is exactly as designed. The delay time will depend on the different capacitance on board.

Typical Application

One application of the TPT29539Q device is used as below.

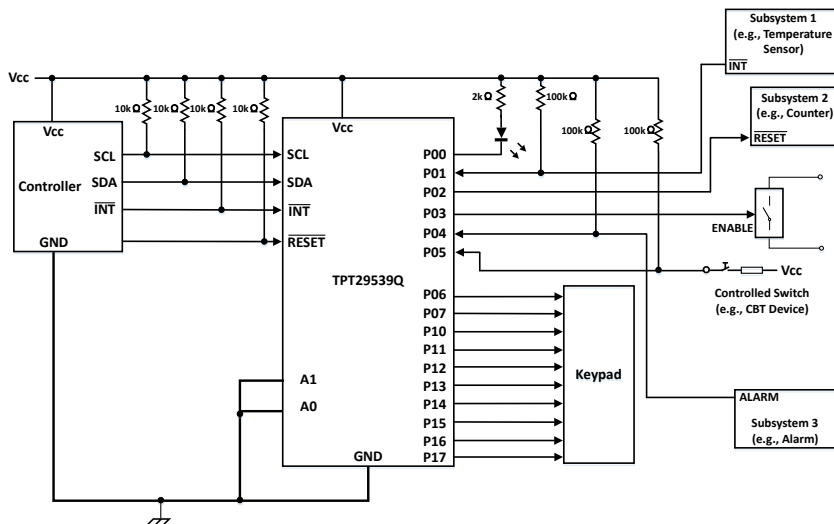

Figure 8. Typical Application Reference Circuit

Layout

Layout Guideline

Reflections and matching are closely related to loop antenna theory, but different enough to warrant their own discussion. When a PCB trace turns a corner at a 90° angle, a reflection can occur. This is primarily due to the change in the width of the trace. At the apex of the turn, the trace width is increased to 1.414 times its width. This change in width upsets the transmission line characteristics, especially the distributed capacitance and self-inductance of the trace, thus resulting in the reflection. Not all PCB traces can be straight, so they will have to turn corners. Figure 9 shows progressively better techniques of rounding corners. Only the last example (BEST) maintains constant trace width and minimizes reflections.

Figure 9. Trace Example

Route high-speed signals using a minimum of vias and corners which reduces signal reflections and impedance changes. When a via must be used, increase the clearance size around it to minimize its capacitance. Each via introduces discontinuities in the signal's transmission line and increases the chance of picking up interference from the other layers of the board. Be careful when designing test points, through-hole pins are not recommended at high frequencies.

Layout Example

Figure 10 illustrates an example of a PCB layout with the TPT29539Q. Some key considerations are as follows:

- Decouple the VDD pin with a 0.1- μ F capacitor, placed it as close to the pin as possible. Make sure that the capacitor voltage rating is sufficient for the VDD supply.
- Keep the input lines as short as possible.
- Use a solid ground plane to help reduce electromagnetic interference (EMI) noise pickup.
- Do not run sensitive analog traces in parallel with digital traces. Avoid crossing digital and analog traces if possible, and only make perpendicular crossings when necessary.
