

# THE DATASHEET OF LMP7702MMX/NOPB

## LMP770x Precision, CMOS Input, RRIO, Wide Supply Range Amplifiers

### 1 Features

- Unless Otherwise Noted, Typical Values at  $V_S = 5\text{ V}$
- Input Offset Voltage (LMP7701):  $\pm 200\text{-}\mu\text{V}$  (Maximum)
- Input Offset Voltage (LMP7702/LMP7704):  $\pm 220\text{-}\mu\text{V}$  (Maximum)
- Input Bias Current:  $\pm 200\text{ fA}$
- Input Bias Current:  $\pm 200\text{ fA}$
- Input Voltage Noise:  $9\text{ nV}/\sqrt{\text{Hz}}$
- CMRR: 130 dB
- Open-Loop Gain: 130 dB
- Temperature Range:  $-40^\circ\text{C}$  to  $125^\circ\text{C}$
- Unity-Gain Bandwidth: 2.5 MHz
- Supply Current (LMP7701):  $715\text{ }\mu\text{A}$
- Supply Current (LMP7702): 1.5 mA
- Supply Current (LMP7704): 2.9 mA
- Supply Voltage Range: 2.7 V to 12 V
- Rail-to-Rail Input and Output

### 2 Applications

- High Impedance Sensor Interface
- Battery-Powered Instrumentation
- High Gain Amplifiers
- DAC Buffer
- Instrumentation Amplifier
- Active Filters

### 3 Description

The LMP770x are single, dual, and quad low-offset voltage, rail-to-rail input and output precision amplifiers, each with a CMOS input stage and a wide supply voltage range. The LMP770x are part of the LMP™ precision amplifier family and are ideal for sensor interface and other instrumentation applications.

The specified low-offset voltage of less than  $\pm 200\text{ }\mu\text{V}$ , along with the specified low input bias current of less than  $\pm 1\text{ pA}$ , make the LMP7701 ideal for precision applications. The LMP770x are built using VIP50 technology, which allows the combination of a CMOS input stage and a 12-V common-mode and supply voltage range. This makes the LMP770x ideal for applications where conventional CMOS parts cannot operate under the desired voltage conditions.

#### Device Information<sup>(1)</sup>

PART NUMBER	PACKAGE	BODY SIZE (NOM)
LMP7701	SOT-23 (5)	1.60 mm x 2.90 mm
	SOIC (8)	3.91 mm x 4.90 mm
LMP7702	VSSOP (8)	3.00 mm x 3.00 mm
	SOIC (8)	3.91 mm x 4.90 mm
LMP7704	TSSOP (14)	4.40 mm x 5.00 mm
	SOIC (14)	3.91 mm x 8.65 mm

(1) For all available packages, see the orderable addendum at the end of the data sheet.

## 5 Description (continued)

The LMP770x each have a rail-to-rail input stage that significantly reduces the CMRR glitch commonly associated with rail-to-rail input amplifiers. This is achieved by trimming both sides of the complimentary input stage, thereby reducing the difference between the NMOS and PMOS offsets. The output of the LMP770x swings within 40 mV of either rail to maximize the signal dynamic range in applications requiring low supply voltage.

The LMP7701 is offered in the space-saving 5-Pin SOT-23 and 8-Pin SOIC package. The LMP7702 is offered in the 8-Pin SOIC and 8-Pin VSSOP package. The quad LMP7704 is offered in the 14-Pin SOIC and 14-Pin TSSOP package. These small packages are ideal solutions for area constrained PC boards and portable electronics.

## 6 Pin Configuration and Functions

## 7 Specifications

### 7.1 Absolute Maximum Ratings

 See <sup>(1)(2)</sup>

	MIN	MAX	UNIT
V <sub>IN</sub> differential		±300	mV
Supply voltage (V <sub>S</sub> = V <sup>+</sup> – V <sup>–</sup> )		13.2	V
Voltage at input/output pins		V <sup>+</sup> + 0.3, V <sup>–</sup> – 0.3	V
Input current		10	mA
Junction temperature <sup>(3)</sup>		+150	°C
Soldering information	Infrared or convection (20 sec)	235	°C
	Wave soldering lead temp. (10 sec)	260	°C
Storage temperature, T <sub>stg</sub>	–65	150	°C

- (1) Stresses beyond those listed under *Absolute Maximum Ratings* may cause permanent damage to the device. These are stress ratings only, which do not imply functional operation of the device at these or any other conditions beyond those indicated under *Recommended Operating Conditions*. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.
- (2) If Military/Aerospace specified devices are required, contact the TI Sales Office/ Distributors for availability and specifications.
- (3) The maximum power dissipation is a function of T<sub>J(MAX)</sub>, θ<sub>JA</sub>. The maximum allowable power dissipation at any ambient temperature is P<sub>D</sub> = (T<sub>J(MAX)</sub> – T<sub>A</sub>) / θ<sub>JA</sub>. All numbers apply for packages soldered directly onto a PC Board.

### 7.2 ESD Ratings

	VALUE	UNIT
V <sub>(ESD)</sub> Electrostatic discharge	Human body model (HBM), per ANSI/ESDA/JEDEC JS-001 <sup>(1)(2)</sup>	±2000
	Charged-device model (CDM), per JEDEC specification JESD22-C101 <sup>(3)</sup>	±1000
	Machine Model (MM)	±200

- (1) JEDEC document JEP155 states that 500-V HBM allows safe manufacturing with a standard ESD control process.
- (2) Human Body Model, applicable std. MIL-STD-883, Method 3015.7. Machine Model, applicable std. JESD22-A115-A (ESD MM std. of JEDEC) Field-Induced Charge-Device Model, applicable std. JESD22-C101-C (ESD FICDM std. of JEDEC).
- (3) JEDEC document JEP157 states that 250-V CDM allows safe manufacturing with a standard ESD control process.

### 7.3 Recommended Operating Conditions

	MIN	NOM	MAX	UNIT
Temperature range <sup>(1)</sup>	-40		125	°C
Supply voltage ( $V_S = V^+ - V^-$ )	2.7		12	V

(1) The maximum power dissipation is a function of  $T_{J(MAX)}$ ,  $\theta_{JA}$ . The maximum allowable power dissipation at any ambient temperature is  $P_D = (T_{J(MAX)} - T_A) / \theta_{JA}$ . All numbers apply for packages soldered directly onto a PC Board.

### 7.4 Thermal Information

THERMAL METRIC <sup>(1)</sup>		LMP7701	LMP7701, LMP7702	LMP7702	LMP7704		UNIT
		DBV (SOT-23)	D (SOIC)	DGK (VSSOP)	D (SOIC)	PW (TSSOP)	
		5 PINS	8 PINS	8 PINS	14 PINS	14 PINS	
$R_{\theta JA}$	Junction-to-ambient thermal resistance <sup>(2)</sup>	122.9	114.3	167.5	79.9	107.5	°C/W
$R_{\theta JC(top)}$	Junction-to-case (top) thermal resistance	69.3	59.5	58.7	36.9	33.0	°C/W
$R_{\theta JB}$	Junction-to-board thermal resistance	63.3	54.8	87.5	34.7	50.4	°C/W
$\Psi_{JT}$	Junction-to-top characterization parameter	19.4	12.1	6.6	5.5	1.8	°C/W
$\Psi_{JB}$	Junction-to-board characterization parameter	62.8	54.2	86.1	34.4	49.7	°C/W

(1) For more information about traditional and new thermal metrics, see the *Semiconductor and IC Package Thermal Metrics* application report (SPRA953).

(2) The maximum power dissipation is a function of  $T_{J(MAX)}$ ,  $\theta_{JA}$ . The maximum allowable power dissipation at any ambient temperature is  $P_D = (T_{J(MAX)} - T_A) / \theta_{JA}$ . All numbers apply for packages soldered directly onto a PC Board.

### 7.5 Electrical Characteristics 3-V

Unless otherwise specified, all limits are ensured for  $T_A = 25^\circ\text{C}$ ,  $V^+ = 3\text{ V}$ ,  $V^- = 0\text{ V}$ ,  $V_{CM} = V^+/2$ , and  $R_L > 10\text{ k}\Omega$  to  $V^+/2$ .<sup>(1)</sup>

PARAMETER	TEST CONDITIONS	MIN <sup>(2)</sup>	TYP <sup>(3)</sup>	MAX <sup>(2)</sup>	UNIT
$V_{OS}$ Input Offset Voltage	LMP7701		±37	±200	μV
		at the temperature extremes		±500	
	LMP7702/LMP7704		±56	±220	
		at the temperature extremes		±520	
$TCV_{OS}$ Input Offset Voltage Temperature Drift	See <sup>(4)</sup>		±1		μV/°C
		at the temperature extremes		±5	
$I_B$ Input Bias Current	See <sup>(4)</sup> <sup>(5)</sup> -40°C ≤ $T_A$ ≤ 85°C		±0.2	±1	pA
		at the temperature extremes		±50	
	See <sup>(4)</sup> <sup>(5)</sup> -40°C ≤ $T_A$ ≤ 125°C		±0.2	±1	
		at the temperature extremes		±400	
$I_{OS}$ Input Offset Current			40		fA

(1) Electrical Table values apply only for factory testing conditions at the temperature indicated. Factory testing conditions result in very limited self-heating of the device such that  $T_J = T_A$ . No specification of parametric performance is indicated in the electrical tables under conditions of internal self-heating where  $T_J > T_A$ .

(2) Limits are 100% production tested at 25°C. Limits over the operating temperature range are specified through correlations using the Statistical Quality Control (SQC) method.

(3) Typical values represent the most likely parametric norm as determined at the time of characterization. Actual typical values may vary over time and will also depend on the application and configuration. The typical values are not tested and are not specified on shipped production material.

(4) This parameter is specified by design and/or characterization and is not tested in production.

(5) Positive current corresponds to current flowing into the device.

**Electrical Characteristics 3-V (continued)**

 Unless otherwise specified, all limits are ensured for  $T_A = 25^\circ\text{C}$ ,  $V^+ = 3\text{ V}$ ,  $V^- = 0\text{ V}$ ,  $V_{CM} = V^+/2$ , and  $R_L > 10\text{ k}\Omega$  to  $V^+/2$ .<sup>(1)</sup>

$i_n$	Input Referred Current Noise Density	$f = 100\text{ kHz}$		1		fA/ $\sqrt{\text{Hz}}$

(6) The maximum power dissipation is a function of  $T_{\text{J}(\text{MAX})}$ ,  $\theta_{\text{JA}}$ . The maximum allowable power dissipation at any ambient temperature is  $P_D = (T_{\text{J}(\text{MAX})} - T_A) / \theta_{\text{JA}}$ . All numbers apply for packages soldered directly onto a PC Board.

(7) The short circuit test is a momentary test.

(8) The number specified is the slower of positive and negative slew rates.

## 7.6 Electrical Characteristics 5-V

Unless otherwise specified, all limits are ensured for  $T_A = 25^\circ\text{C}$ ,  $V^+ = 5\text{ V}$ ,  $V^- = 0\text{ V}$ ,  $V_{CM} = V^+/2$ , and  $R_L > 10\text{ k}\Omega$  to  $V^+/2$ .<sup>(1)</sup>

(1) Electrical Table values apply only for factory testing conditions at the temperature indicated. Factory testing conditions result in very limited self-heating of the device such that  $T_J = T_A$ . No specification of parametric performance is indicated in the electrical tables under conditions of internal self-heating where  $T_J > T_A$ .

(2) Limits are 100% production tested at  $25^\circ\text{C}$ . Limits over the operating temperature range are specified through correlations using the Statistical Quality Control (SQC) method.

(3) Typical values represent the most likely parametric norm as determined at the time of characterization. Actual typical values may vary over time and will also depend on the application and configuration. The typical values are not tested and are not ensured on shipped production material.

(4) This parameter is specified by design and/or characterization and is not tested in production.

(5) Positive current corresponds to current flowing into the device.

## 8 Detailed Description

### 8.1 Overview

The LMP770x are single, dual, and quad low offset voltage, rail-to-rail input and output precision amplifiers each with a CMOS input stage and wide supply voltage range of 2.7V to 12V. The LMP770x have a very low input bias current of only  $\pm 200$  fA at room temperature.

The wide supply voltage range of 2.7V to 12V over the extensive temperature range of  $-40^{\circ}\text{C}$  to  $125^{\circ}\text{C}$  makes the LMP770x excellent choices for low voltage precision applications with extensive temperature requirements.

The LMP770x have only  $\pm 37$   $\mu\text{V}$  of typical input referred offset voltage and this offset is specified to be less than  $\pm 500$   $\mu\text{V}$  for the single and  $\pm 520$   $\mu\text{V}$  for the dual and quad, over temperature. This minimal offset voltage allows more accurate signal detection and amplification in precision applications.

The low input bias current of only  $\pm 200$  fA along with the low input referred voltage noise of  $9\text{ nV}/\sqrt{\text{Hz}}$  gives the LMP770x superiority for use in sensor applications. Lower levels of noise from the LMP770x mean of better signal fidelity and a higher signal-to-noise ratio.

Texas Instruments is heavily committed to precision amplifiers and the market segment they serve. Technical support and extensive characterization data is available for sensitive applications or applications with a constrained error budget.

The LMP7701 is offered in the space saving 5-Pin SOT-23 and 8-Pin SOIC package. The LMP7702 comes in the 8-Pin SOIC and 8-Pin VSSOP package. The LMP7704 is offered in the 14-Pin SOIC and 14-Pin TSSOP package. These small packages are ideal solutions for area constrained PC boards and portable electronics.

### 8.2 Functional Block Diagram

**Figure 40. Functional Block Diagram (LMP7701)**

### 8.3 Feature Description

#### 8.3.1 Capacitive Load

The LMP770x can each be connected as a non-inverting unity gain follower. This configuration is the most sensitive to capacitive loading.

The combination of a capacitive load placed on the output of an amplifier along with the amplifier's output impedance creates a phase lag which in turn reduces the phase margin of the amplifier. If the phase margin is significantly reduced, the response will be either underdamped or it will oscillate.

To drive heavier capacitive loads, an isolation resistor,  $R_{\text{ISO}}$ , in [Figure 41](#) should be used. By using this isolation resistor, the capacitive load is isolated from the amplifier's output, and hence, the pole caused by  $C_L$  is no longer in the feedback loop. The larger the value of  $R_{\text{ISO}}$ , the more stable the output voltage will be. If values of  $R_{\text{ISO}}$  are sufficiently large, the feedback loop will be stable, independent of the value of  $C_L$ . However, larger values of  $R_{\text{ISO}}$  result in reduced output swing and reduced output current drive.

**Feature Description (continued)**

**Figure 41. Isolating Capacitive Load**
**8.3.2 Input Capacitance**

CMOS input stages inherently have low input bias current and higher input referred voltage noise. The LMP770x enhance this performance by having the low input bias current of only  $\pm 200$  fA, as well as, a very low input referred voltage noise of 9 nV/ $\sqrt{\text{Hz}}$ . To achieve this a larger input stage has been used. This larger input stage increases the input capacitance of the LMP770x. The typical value of this input capacitance,  $C_{\text{IN}}$ , for the LMP770x is 25 pF. The input capacitance will interact with other impedances such as gain and feedback resistors, which are seen on the inputs of the amplifier, to form a pole. This pole will have little or no effect on the output of the amplifier at low frequencies and DC conditions, but will play a bigger role as the frequency increases. At higher frequencies, the presence of this pole will decrease phase margin and will also cause gain peaking. To compensate for the input capacitance, care must be taken in choosing the feedback resistors. In addition to being selective in picking values for the feedback resistor, a capacitor can be added to the feedback path to increase stability.

The DC gain of the circuit shown in [Figure 42](#) is simply  $-R_2/R_1$ .

**Figure 42. Compensating for Input Capacitance**

For the time being, ignore  $C_F$ . The AC gain of the circuit in [Figure 42](#) can be calculated as follows:

$$\frac{V_{\text{OUT}}}{V_{\text{IN}}}(s) = \frac{-R_2/R_1}{\left[ 1 + \frac{s}{\left( \frac{A_0 R_1}{R_1 + R_2} \right)} + \frac{s^2}{\left( \frac{A_0}{C_{\text{IN}} R_2} \right)} \right]} \quad (1)$$

This equation is rearranged to find the location of the two poles:

$$P_{1,2} = \frac{-1}{2C_{\text{IN}}} \left[ \frac{1}{R_1} + \frac{1}{R_2} \pm \sqrt{\left( \frac{1}{R_1} + \frac{1}{R_2} \right)^2 - \frac{4 A_0 C_{\text{IN}}}{R_2}} \right] \quad (2)$$

### Feature Description (continued)

As shown in Equation 2, as values of  $R_1$  and  $R_2$  are increased, the magnitude of the poles is reduced, which in turn decreases the bandwidth of the amplifier. Whenever possible, it is best to choose smaller feedback resistors. Figure 43 shows the effect of the feedback resistor on the bandwidth of the LMP770x.

Figure 43. Closed-Loop Gain vs Frequency

Equation 2 has two poles. In most cases, it is the presence of pairs of poles that causes gain peaking. To eliminate this effect, the poles should be placed in Butterworth position, because poles in Butterworth position do not cause gain peaking. To achieve a Butterworth pair, the quantity under the square root in Equation 2 should be set to equal  $-1$ . Using this fact and the relation between  $R_1$  and  $R_2$ ,  $R_2 = -A_V R_1$ , the optimum value for  $R_1$  can be found. This is shown in Equation 3. If  $R_1$  is chosen to be larger than this optimum value, gain peaking will occur.

$$R_1 < \frac{(1 - A_V)^2}{2A_0A_VC_{IN}} \quad (3)$$

In Figure 42,  $C_F$  is added to compensate for input capacitance and to increase stability. Additionally,  $C_F$  reduces or eliminates the gain peaking that can be caused by having a larger feedback resistor. Figure 44 shows how  $C_F$  reduces gain peaking.

Figure 44. Closed-Loop Gain vs Frequency With Compensation

## Feature Description (continued)

### 8.3.3 Diodes Between the Inputs

The LMP770x have a set of anti-parallel diodes between the input pins, as shown in [Figure 45](#). These diodes are present to protect the input stage of the amplifier. At the same time, they limit the amount of differential input voltage that is allowed on the input pins. A differential signal larger than one diode voltage drop might damage the diodes. The differential signal between the inputs needs to be limited to  $\pm 300$  mV or the input current needs to be limited to  $\pm 10$  mA.

**Figure 45. Input of LMP7701**

## 8.4 Device Functional Modes

### 8.4.1 Precision Current Source

The LMP770x can each be used as a precision current source in many different applications. Figure 46 shows a typical precision current source. This circuit implements a precision voltage controlled current source. Amplifier A1 is a differential amplifier that uses the voltage drop across  $R_S$  as the feedback signal. Amplifier A2 is a buffer that eliminates the error current from the load side of the  $R_S$  resistor that would flow in the feedback resistor if it were connected to the load side of the  $R_S$  resistor. In general, the circuit is stable as long as the closed loop bandwidth of amplifier A2 is greater than the closed loop bandwidth of amplifier A1. If A1 and A2 are the same type of amplifiers, then the feedback around A1 will reduce its bandwidth compared to A2.

**Figure 46. Precision Current Source**

The equation for output current can be derived as shown in Equation 4.

$$\frac{V_2 R}{R + R} + \frac{(V_0 - I R_S) R}{R + R} = \frac{V_1 R}{R + R} + \frac{V_0 R}{R + R} \quad (4)$$

Solving for the current I results in the Equation 5.

$$I = \frac{V_2 - V_1}{R_S} \quad (5)$$

## 9 Application and Implementation

### NOTE

Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI's customers are responsible for determining suitability of components for their purposes. Customers should validate and test their design implementation to confirm system functionality.

### 9.1 Application Information

#### 9.1.1 Low Input Voltage Noise

The LMP770x have the very low input voltage noise of  $9 \text{ nV}/\sqrt{\text{Hz}}$ . This input voltage noise can be further reduced by placing N amplifiers in parallel as shown in Figure 47. The total voltage noise on the output of this circuit is divided by the square root of the number of amplifiers used in this parallel combination. This is because each individual amplifier acts as an independent noise source, and the average noise of independent sources is the quadrature sum of the independent sources divided by the number of sources. For N identical amplifiers, this means:

**Application Information (continued)**

$$\begin{aligned} \text{REDUCED INPUT VOLTAGE NOISE} &= \frac{1}{N} \sqrt{e_{n1}^2 + e_{n2}^2 + \dots + e_{nN}^2} \\ &= \frac{1}{N} \sqrt{N e_n^2} = \frac{\sqrt{N}}{N} e_n \\ &= \frac{1}{\sqrt{N}} e_n \end{aligned}$$

(6)

Figure 47 shows a schematic of this input voltage noise reduction circuit. Typical resistor values are:

$R_G = 10\Omega$ ,  $R_F = 1\text{ k}\Omega$ , and  $R_O = 1\text{ k}\Omega$ .

**Figure 47. Noise Reduction Circuit**

**9.1.2 Total Noise Contribution**

The LMP770x have very low input bias current, very low input current noise, and very low input voltage noise. As a result, these amplifiers are ideal choices for circuits with high impedance sensor applications.

Figure 48 shows the typical input noise of the LMP770x as a function of source resistance where:

$e_n$  denotes the input referred voltage noise

$e_i$  is the voltage drop across source resistance due to input referred current noise or  $e_i = R_S * i_n$

$e_t$  shows the thermal noise of the source resistance

$e_{ni}$  shows the total noise on the input.

Where:

$$e_{ni} = \sqrt{e_n^2 + e_i^2 + e_t^2}$$

## Typical Application (continued)

### 9.2.1 Design Requirements

pH electrodes are very high impedance sensors. As their name indicates, they are used to measure the pH of a solution. They usually do this by generating an output voltage which is proportional to the pH of the solution. pH electrodes are calibrated so that they have zero output for a neutral solution, pH = 7, and positive and negative voltages for acidic or alkaline solutions. This means that the output of a pH electrode is bipolar and must be level shifted to be used in a single supply system. The rate of change of this voltage is usually shown in mV/pH and is different for different pH sensors. Temperature is also an important factor in a pH electrode reading. The output voltage of the sensor will change with temperature.

### 9.2.2 Detailed Design Procedure

Many sensors have high source impedances that may range up to 10 MΩ. The output signal of sensors often needs to be amplified or otherwise conditioned by means of an amplifier. The input bias current of this amplifier can load the sensor's output and cause a voltage drop across the source resistance as shown in Figure 50, where  $V_{IN+} = V_S - I_{BIAS} * R_S$

The last term,  $I_{BIAS} * R_S$ , shows the voltage drop across  $R_S$ . To prevent errors introduced to the system due to this voltage, an op amp with very low input bias current must be used with high impedance sensors. This is to keep the error contribution by  $I_{BIAS} * R_S$  less than the input voltage noise of the amplifier, so that it will not become the dominant noise factor.

Figure 50. Noise Due to  $I_{BIAS}$

Figure 51 shows a typical output voltage spectrum of a pH electrode. The exact values of output voltage will be different for different sensors. In this example, the pH electrode has an output voltage of 59.15 mV/pH at 25°C.

Figure 51. Output Voltage of a pH Electrode

The temperature dependence of a typical pH electrode is shown in Figure 52. As is evident, the output voltage changes with changes in temperature.

The schematic shown in Figure 49 is a typical circuit which can be used for pH measurement. The LM35 is a precision integrated circuit temperature sensor. This sensor is differentiated from similar products because it has an output voltage linearly proportional to Celsius measurement, without converting the temperature to Kelvin. The LM35 is used to measure the temperature of the solution and feeds this reading to the Analog to Digital Converter, ADC. This information is used by the ADC to calculate the temperature effects on the pH readings. The LM35 needs to have a resistor,  $R_T$  in Figure 49, to  $-V^+$  to be able to read temperatures less than 0°C.  $R_T$  is not needed if temperatures are not expected to be less than zero.

### Typical Application (continued)

The output of pH electrodes is usually large enough that it does not require much amplification; however, due to the very high impedance, the output of a pH electrode needs to be buffered before it can go to an ADC. Because most ADCs are operated on single supply, the output of the pH electrode also needs to be level shifted. Amplifier A1 buffers the output of the pH electrode with a moderate gain of +2, while A2 provides the level shifting.  $V_{OUT}$  at the output of A2 is given by:  $V_{OUT} = -2V_{pH} + 1.024V$ .

The LM4140A is a precision, low noise, voltage reference used to provide the level shift needed. The ADC used in this application is the ADC12032 which is a 12-bit, 2 channel converter with multiplexers on the inputs and a serial output. The 12-bit ADC enables users to measure pH with an accuracy of 0.003 of a pH unit. Adequate power supply bypassing and grounding is extremely important for ADCs. Recommended bypass capacitors are shown in Figure 49. It is common to share power supplies between different components in a circuit. To minimize the effects of power supply ripples caused by other components, the op amps must have bypass capacitors on the supply pins. Using the same value capacitors as those used with the ADC are ideal. The combination of these three values of capacitors ensures that AC noise present on the power supply line is grounded and does not interfere with the amplifiers' signal.

### 9.2.3 Application Curves

**Figure 52. Temperature Dependence of a pH Electrode**

## 10 Power Supply Recommendations

For proper operation, the power supplies must be decoupled. For supply decoupling, TI recommends placing 10-nF to 1- $\mu$ F capacitors as close as possible to the operational-amplifier power supply pins. For single supply configurations, place a capacitor between the  $V^+$  and  $V^-$  supply pins. For dual supply configurations, place one capacitor between  $V^+$  and ground, and place a second capacitor between  $V^-$  and ground. Bypass capacitors must have a low ESR of less than 0.1  $\Omega$ .

## 11 Layout

### 11.1 Layout Guidelines

Take care to minimize the loop area formed by the bypass capacitor connection between supply pins and ground. A ground plane underneath the device is recommended; any bypass components to ground should have a nearby via to the ground plane. The optimum bypass capacitor placement is closest to the corresponding supply pin. Use of thicker traces from the bypass capacitors to the corresponding supply pins will lower the power supply inductance and provide a more stable power supply.

The feedback components should be placed as close to the device as possible to minimize stray parasitics.

### 11.2 Layout Example

Figure 53. LMP7701 Example Layout

## 12 Device and Documentation Support

### 12.1 Related Links

The table below lists quick access links. Categories include technical documents, support and community resources, tools and software, and quick access to sample or buy.

(1) The marketing status values are defined as follows:  
**ACTIVE:** Product device recommended for new designs.

**LIFEBUY:** TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.

**NRND:** Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.

**PREVIEW:** Device has been announced but is not in production. Samples may or may not be available.

**OBSELETE:** TI has discontinued the production of the device.

<sup>(2)</sup> **RoHS:** TI defines "RoHS" to mean semiconductor products that are compliant with the current EU RoHS requirements for all 10 RoHS substances, including the requirement that RoHS substance do not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, "RoHS" products are suitable for use in specified lead-free processes. TI may reference these types of products as "Pb-Free".

**RoHS Exempt:** TI defines "RoHS Exempt" to mean products that contain lead but are compliant with EU RoHS pursuant to a specific EU RoHS exemption.

**Green:** TI defines "Green" to mean the content of Chlorine (Cl) and Bromine (Br) based flame retardants meet JS709B low halogen requirements of <=1000ppm threshold. Antimony trioxide based flame retardants must also meet the <=1000ppm threshold requirement.

<sup>(3)</sup> MSL, Peak Temp. - The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

<sup>(4)</sup> There may be additional marking, which relates to the logo, the lot trace code information, or the environmental category on the device.

<sup>(5)</sup> Multiple Device Markings will be inside parentheses. Only one Device Marking contained in parentheses and separated by a "~" will appear on a device. If a line is indented then it is a continuation of the previous line and the two combined represent the entire Device Marking for that device.

<sup>(6)</sup> Lead finish/Ball material - Orderable Devices may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead finish/Ball material values may wrap to two lines if the finish value exceeds the maximum column width.
