MAX1444

General Description

The MAX1444 10-bit, 3V analog-to-digital converter (ADC) features a pipelined 10-stage ADC architecture with fully differential wideband track-and-hold (T/H) input and digital error correction incorporating a fully differential signal path. This ADC is optimized for low-power, high dynamic performance applications in imaging and digital communications. The MAX1444 operates from a single 2.7V to 3.6V supply, consuming only 57mW while delivering a 59.5dB signal-to-noise ratio (SNR) at a 20MHz input frequency. The fully differential input stage has a 400MHz -3dB bandwidth and may be operated with single-ended inputs. In addition to low operating power, the MAX1444 features a 5 μ A power-down mode for idle periods.

An internal 2.048V precision bandgap reference is used to set the ADC full-scale range. A flexible reference structure allows the user to supply a buffered, direct, or externally derived reference for applications requiring increased accuracy or a different input voltage range.

Higher speed, pin-compatible versions of the MAX1444 are also available. Please refer to the MAX1446 data sheet (60Msps) and the MAX1448 data sheet (80Msps).

The MAX1444 has parallel, offset binary, CMOS-compatible three-state outputs that can be operated from 1.7V to 3.6V to allow flexible interfacing. The device is available in a 5x5mm 32-pin TQFP package and is specified over the extended industrial (-40°C to +85°C) temperature range.

Applications

- Ultrasound Imaging
- CCD Imaging
- Baseband and IF Digitization
- Digital Set-Top Boxes
- Video Digitizing Applications

Functional Diagram appears at end of data sheet.

Features

- ◆ Single 3.0V Operation
- ◆ Excellent Dynamic Performance
 - 59.5dB SNR at $f_{IN} = 20\text{MHz}$
 - 74dBc SFDR at $f_{IN} = 20\text{MHz}$
- ◆ Low Power
 - 19mA (Normal Operation)
 - 5 μ A (Shutdown Mode)
- ◆ Fully Differential Analog Input
- ◆ Wide 2V_{p-p} Differential Input Voltage Range
- ◆ 400MHz -3dB Input Bandwidth
- ◆ On-Chip 2.048V Precision Bandgap Reference
- ◆ CMOS-Compatible Three-State Outputs
- ◆ 32-Pin TQFP Package
- ◆ Evaluation Kit Available

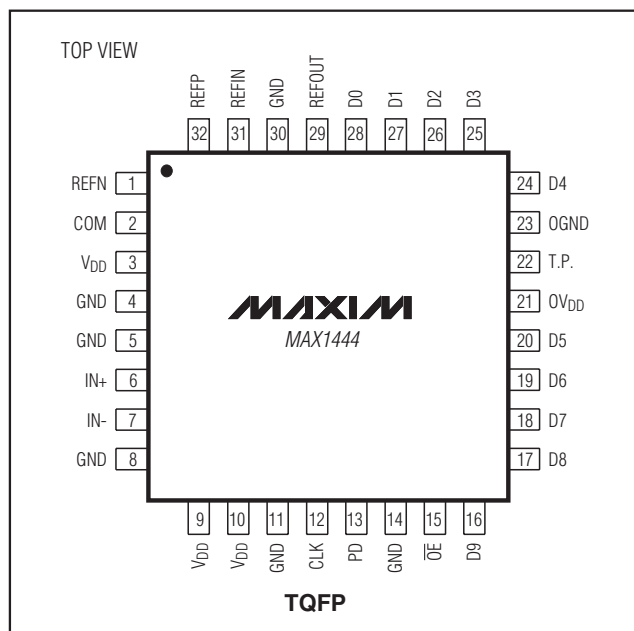

Ordering Information

PART	TEMP RANGE	PIN-PACKAGE
MAX1444EHJ	-40°C to +85°C	32 TQFP
MAX1444EHJ/V+	-40°C to +85°C	32 TQFP

V Denotes an automotive qualified part.

+ Denotes a lead(Pb)-free/RoHS-compliant package.

Pin Configuration

10-Bit, 40Msps, 3.0V, Low-Power ADC with Internal Reference

ABSOLUTE MAXIMUM RATINGS

V _{DD} , OV _{DD} to GND	-0.3V to +3.6V
OGND to GND	-0.3V to +0.3V
IN+, IN- to GND	-0.3V to V _{DD}
REFIN, REFOUT, REFP, REFN, and COM to GND	-0.3V to (V _{DD} + 0.3V)
OE, PD, CLK to GND	-0.3V to (V _{DD} + 0.3V)
D9–D0 to GND	-0.3V to (OV _{DD} + 0.3V)

Continuous Power Dissipation (T _A = +70°C)	32-Pin TQFP (derate 18.7mW/°C above +70°C)	1495.3mW
Operating Temperature Range		-40°C to +85°C
Storage Temperature Range		-60°C to +150°C
Lead Temperature (soldering, 10s)		+300°C
Soldering Temperature (reflow)		+260°C

Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

Pin Description

PIN	NAME	FUNCTION
1	REFN	Lower Reference. Conversion range is $\pm(V_{REFP} - V_{REFN})$. Bypass to GND with a $> 0.1\mu\text{F}$ capacitor.
2	COM	Common-Mode Voltage Output. Bypass to GND with a $> 0.1\mu\text{F}$ capacitor.
3, 9, 10	V _{DD}	Analog Supply Voltage. Bypass to GND with a capacitor combination of $2.2\mu\text{F}$ in parallel with $0.1\mu\text{F}$.
4, 5, 8, 11, 14, 30	GND	Analog Ground
6	IN+	Positive Analog Input. For single-ended operation, connect signal source to IN+.
7	IN-	Negative Analog Input. For single-ended operation, connect IN- to COM.
12	CLK	Conversion Clock Input
13	PD	Power Down Input. High: Power-down mode. Low: Normal operation.
15	OE	Output Enable Input. High: Digital outputs disabled. Low: Digital outputs enabled.
16–20	D9–D5	Three-State Digital Outputs D9–D5. D9 is the MSB.
21	OV _{DD}	Output Driver Supply Voltage. Bypass to GND with a capacitor combination of $2.2\mu\text{F}$ in parallel with $0.1\mu\text{F}$.
22	T.P.	Test Point. Do not connect.
23	OGND	Output Driver Ground
24–28	D4–D0	Three-State Digital Outputs D4–D0. D0 is the LSB.
29	REFOUT	Internal Reference Voltage Output. May be connected to REFIN through a resistor or a resistor-divider.
31	REFIN	Reference Input. $V_{REFIN} = 2 \times (V_{REFP} - V_{REFN})$. Bypass to GND with a $> 0.1\mu\text{F}$ capacitor.
32	REFP	Upper Reference. Conversion range is $\pm(V_{REFP} - V_{REFN})$. Bypass to GND with a $> 0.1\mu\text{F}$ capacitor.

10-Bit, 40Mps, 3.0V, Low-Power ADC with Internal Reference

Detailed Description

The MAX1444 uses a 10-stage, fully differential, pipelined architecture (Figure 1) that allows for high-speed conversion while minimizing power consumption. Each sample moves through a pipeline stage every half-clock cycle. Counting the delay through the output latch, the clock-cycle latency is 5.5.

A 1.5-bit (2-comparator) flash ADC converts the held input voltage into a digital code. The following digital-to-analog converter (DAC) converts the digitized result back into an analog voltage, which is then subtracted from the original held input signal. The resulting error signal is then multiplied by two, and the product is passed along to the next pipeline stage where the process is repeated until the signal has been processed by all 10 stages. Each stage provides a 1-bit resolution.

Input Track-and-Hold Circuit

Figure 2 displays a simplified functional diagram of the input track-and-hold (T/H) circuit in both track and hold mode. In track mode, switches S1, S2a, S2b, S4a, S4b, S5a, and S5b are closed. The fully differential circuit samples the input signal onto the two capacitors (C2a and C2b). Switches S2a and S2b set the common mode for the amplifier input. The resulting differential

voltage is held on C2a and C2b. Switches S4a, S4b, S5a, S5b, S1, S2a, and S2b are then opened before S3a, S3b, and S4c are closed, connecting capacitors C1a and C1b to the amplifier output. This charges C1a and C1b to the same values originally held on C2a and C2b. This value is then presented to the first-stage quantizer and isolates the pipeline from the fast-changing input. The wide-input-bandwidth T/H amplifier allows the MAX1444 to track and sample/hold analog inputs of high frequencies beyond Nyquist. The analog inputs (IN+ and IN-) can be driven either differentially or single-ended. It is recommended to match the impedance of IN+ and IN- and set the common-mode voltage to midsupply ($V_{DD}/2$) for optimum performance.

Analog Input and Reference Configuration

The MAX1444 full-scale range is determined by the internally generated voltage difference between REFP ($V_{DD}/2 + V_{REFIN}/4$) and REFN ($V_{DD}/2 - V_{REFIN}/4$). The ADC's full-scale range is user-adjustable through the REFIN pin, which provides a high input impedance for this purpose. REFOUT, REFP, COM ($V_{DD}/2$), and REFN are internally buffered, low-impedance outputs.

Figure 1. Pipelined Architecture—Stage Blocks

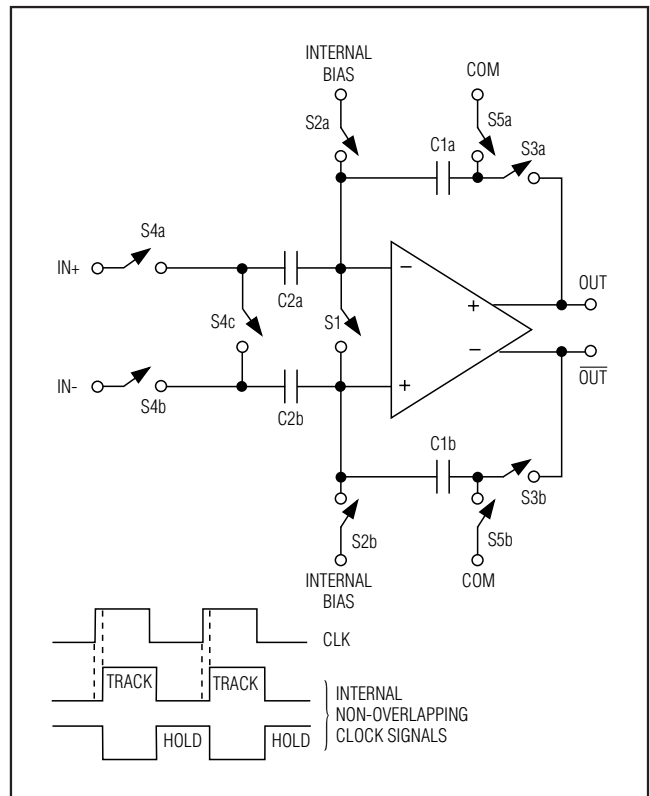

Figure 2. Internal T/H Circuit

10-Bit, 40Msps, 3.0V, Low-Power ADC with Internal Reference

The MAX1444 provides three modes of reference operation:

- Internal reference mode
- Buffered external reference mode
- Unbuffered external reference mode

In internal reference mode, the internal reference output (REFOUT) can be connected to the REFIN pin through a resistor (e.g., 10k Ω) or resistor-divider if an application requires a reduced full-scale range. For stability purposes, it is recommended to bypass REFIN with a >10nF capacitor to GND.

In buffered external reference mode, the reference voltage levels can be adjusted externally by applying a stable and accurate voltage at REFIN. In this mode, REFOUT may be left open or connected to REFIN through a >10k Ω resistor.

In unbuffered external reference mode, REFIN is connected to GND, thereby deactivating the on-chip buffers of REFP, COM, and REFN. With their buffers shut down, these pins become high impedance inputs and can be driven by external reference sources.

Clock Input (CLK)

The MAX1444 CLK input accepts CMOS-compatible clock signals. Since the interstage conversion of the device depends on the repeatability of the rising and falling edges of the external clock, use a clock with low jitter and fast rise and fall times (<2ns). In particular, sampling occurs on the falling edge of the clock signal, mandating this edge to provide lowest possible jitter. Any significant aperture jitter would limit the SNR performance of the ADC as follows:

$$\text{SNR} = 20\log(1 / 2\pi f_{IN} t_{AJ})$$

where f_{IN} represents the analog input frequency, and t_{AJ} is the time of the aperture jitter.

Clock jitter is especially critical for undersampling applications. The clock input should always be considered as an analog input and routed away from any analog input or other digital signal lines.

The MAX1444 clock input operates with a voltage threshold set to $V_{DD}/2$. Clock inputs with a duty cycle other than 50% must meet the specifications for high and low periods as stated in the *Electrical Characteristics*. See Figures 3a, 3b, 4a, and 4b for the relationship between spurious-free dynamic range (SFDR), signal-to-noise ratio (SNR), total harmonic distortion (THD), or signal-to-noise plus distortion (SINAD) versus clock duty cycle.

Output Enable (\overline{OE}), Power Down (PD), and Output Data (D0–D9)

All data outputs, D0 (LSB) through D9 (MSB), are TTL/CMOS-logic compatible. There is a 5.5 clock-cycle latency between any particular sample and its valid output data. The output coding is straight offset binary (Table 1). With \overline{OE} and PD (power down) high, the digital output enters a high-impedance state. If \overline{OE} is held low with PD high, the outputs are latched at the last value prior to the power down.

The capacitive load on the digital outputs D0–D9 should be kept as low as possible (<15pF) to avoid large digital currents that could feed back into the analog portion of the MAX1444, thus degrading its dynamic performance. The use of buffers on the ADC's digital outputs can further isolate the digital outputs from heavy capacitive loads.

Figure 5 displays the timing relationship between output enable and data output valid as well as power-down/wake-up and data output valid.

Table 1. MAX1444 Output Code for Differential Inputs

DIFFERENTIAL INPUT VOLTAGE*	DIFFERENTIAL INPUT	STRAIGHT OFFSET BINARY
$V_{REF} \times 511/512$	+Full Scale -1LSB	11 1111 1111

Figure 5. Output Enable Timing

10-Bit, 40MSPS, 3.0V, Low-Power ADC with Internal Reference

System Timing Requirements

Figure 6 shows the relationship between the clock input, analog input, and data output. The MAX1444 samples at the falling edge of the input clock. Output data is valid on the rising edge of the input clock. The output data has an internal latency of 5.5 clock cycles. Figure 5 shows the relationship between the input clock parameters and the valid output data.

Applications Information

Figure 7 shows a typical application circuit containing a single-ended to differential converter. The internal reference provides a $V_{DD}/2$ output voltage for level shifting purposes. The input is buffered and then split to a voltage follower and inverter. A lowpass filter follows the op amps to suppress some of the wideband noise associated with high-speed op amps. The user may select the R_{ISO} and C_{IN} values to optimize the filter performance to suit a particular application. For the application in Figure 7, an R_{ISO} of 50Ω is placed before the capacitive load to prevent ringing and oscillation. The 22pF C_{IN} capacitor acts as a small bypassing capacitor.

Using Transformer Coupling

An RF transformer (Figure 8) provides an excellent solution for converting a single-ended source signal to a fully differential signal, required by the MAX1444 for optimum performance. Connecting the transformer's center tap to COM provides a $V_{DD}/2$ DC level shift to the input. Although a 1:1 transformer is shown, a step-up transformer may be selected to reduce the drive requirements. A reduced signal swing from the input driver, such as an op amp, may also improve the overall distortion.

In general, the MAX1444 provides better SFDR and THD with fully differential input signals than single-ended drive, especially for very high input frequencies. In differential input mode, even-order harmonics are lower since both inputs (IN+, IN-) are balanced, and each of the inputs only requires half the signal swing compared to single-ended mode.

Single-Ended AC-Coupled Input Signal

Figure 9 shows an AC-coupled, single-ended application. The MAX4108 op amp provides high speed, high bandwidth, low noise, and low distortion to maintain the integrity of the input signal.

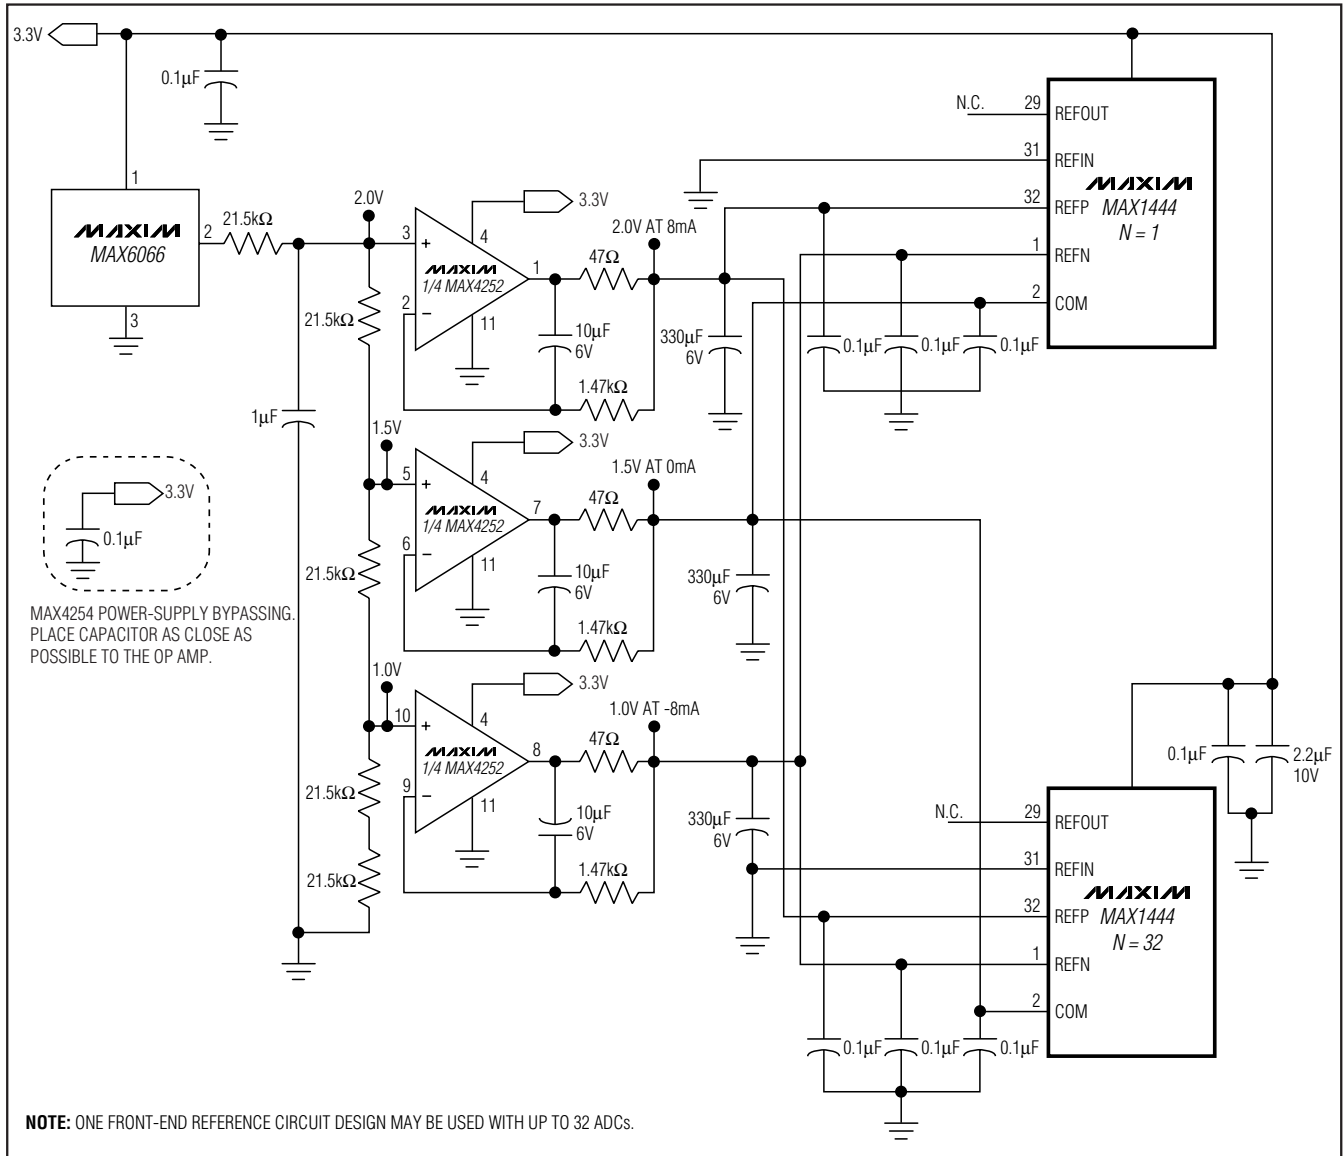

Figure 11. Unbuffered External Reference Drives Up to 32 ADCs

Unbuffered External Reference Drives Multiple ADCs

Connecting each REFIN to analog ground disables the internal reference of each device, allowing the internal reference ladders to be driven directly by a set of external reference sources. Followed by a 10Hz lowpass filter and precision voltage-divider (Figure 11), the MAX6066 generates a DC level of 2.500V. The buffered outputs of this divider are set to 2.0V, 1.5V, and 1.0V, with an accuracy that depends on the tolerance of the

divider resistors. The three voltages are buffered by the MAX4252, which provides low noise and low DC offset. The individual voltage followers are connected to 10Hz lowpass filters, which filter both the reference voltage and amplifier noise to a level of $3nV/\sqrt{Hz}$. The 2.0V and 1.0V reference voltages set the differential full-scale range of the associated ADCs at 2V_{p-p}. The 2.0V and 1.0V buffers drive the ADC's internal ladder resistances between them. Note that the common power supply for all active components removes any concern regarding

10-Bit, 40Msps, 3.0V, Low-Power ADC with Internal Reference

power-supply sequencing when powering up or down. With the outputs of the MAX4252 matching better than 0.1%, the buffers and subsequent lowpass filters can be replicated to support as many as 32 ADCs. For applications that require more than 32 matched ADCs, a voltage reference and divider string common to all converters is highly recommended.

Grounding, Bypassing, and Board Layout

The MAX1444 requires high-speed board layout design techniques. Locate all bypass capacitors as close to the device as possible, preferably on the same side as the ADC, using surface-mount devices for minimum inductance. Bypass V_{DD} , REFP, REFN, and COM with two parallel 0.1 μ F ceramic capacitors and a 2.2 μ F bipolar capacitor to GND. Follow the same rules to bypass the digital supply (OV $_{DD}$) to OGND. Multilayer boards with separated ground and power planes produce the highest level of signal integrity. Consider using a split ground plane arranged to match the physical location of the analog ground (GND) and the digital output driver ground (OGND) on the ADC's package.

The two ground planes should be joined at a single point so that the noisy digital ground currents do not interfere with the analog ground plane. The ideal location of this connection can be determined experimentally at a point along the gap between the two ground planes that produces optimum results. Make this connection with a low-value, surface-mount resistor (1 Ω to 5 Ω), a ferrite bead, or a direct short. Alternatively, all ground pins could share the same ground plane if the ground plane is sufficiently isolated from any noisy, digital systems ground plane (e.g., downstream output buffer or DSP ground plane). Route high-speed digital signal traces away from sensitive analog traces. Keep all signal lines short and free of 90° turns.

Static Parameter Definitions

Integral Nonlinearity

Integral nonlinearity (INL) is the deviation of the values on an actual transfer function from a straight line. This straight line can be either a best straight-line fit or a line drawn between the endpoints of the transfer function once offset and gain errors have been nullified. The MAX1444's static linearity parameters are measured using the best straight-line fit method.

Differential Nonlinearity

Differential nonlinearity (DNL) is the difference between an actual step width and the ideal value of 1LSB. A DNL error specification of less than 1LSB guarantees no missing codes and a monotonic transfer function.

Dynamic Parameter Definitions

Aperture Jitter

Figure 12 depicts the aperture jitter (t_{AJ}), which is the sample-to-sample variation in the aperture delay.

Aperture Delay

Aperture delay (t_{AD}) is the time defined between the falling edge of the sampling clock and the instant when an actual sample is taken (Figure 12).

Signal-to-Noise Ratio (SNR)

For a waveform perfectly reconstructed from digital samples, the theoretical maximum SNR is the ratio of the full-scale analog input (RMS value) to the RMS quantization error (residual error). The ideal, theoretical minimum A/D noise is caused by quantization error only and results directly from the ADC's resolution (N bits):

$$\text{SNR}_{(\text{MAX})} = (6.02 \times N + 1.76)\text{dB}$$

In reality, there are other noise sources besides quantization noise: thermal noise, reference noise, clock jitter, etc. SNR is computed by taking the ratio of the RMS signal to the RMS noise, which includes all spectral components minus the fundamental, the first five harmonics, and the DC offset.

Figure 12. T/H Aperture Timing

10-Bit, 40MSPS, 3.0V, Low-Power ADC with Internal Reference

Signal-to-Noise Plus Distortion (SINAD)

SINAD is computed by taking the ratio of the RMS signal to all spectral components minus the fundamental and the DC offset.

Effective Number of Bits (ENOB)

ENOB specifies the dynamic performance of an ADC at a specific input frequency and sampling rate. An ideal ADC's error consists of quantization noise only. ENOB is computed from:

$$ENOB = \frac{(SINAD - 1.76)}{6.02}$$

Total Harmonic Distortion (THD)

THD is typically the ratio of the RMS sum of the input signal's first four harmonics to the fundamental itself. This is expressed as:

$$THD = 20 \times \log \left(\frac{\sqrt{V_2^2 + V_3^2 + V_4^2 + V_5^2}}{V_1} \right)$$

where V_1 is the fundamental amplitude, and V_2 through V_5 are the amplitudes of the 2nd- through 5th-order harmonics.

Spurious-Free Dynamic Range (SFDR)

SFDR is the ratio expressed in decibels of the RMS amplitude of the fundamental (maximum signal component) to the RMS value of the next largest spurious component, excluding DC offset.

Intermodulation Distortion (IMD)

The two-tone IMD is the ratio expressed in decibels of either input tone to the worst 3rd-order (or higher) intermodulation products. The individual input tone levels are at -6.5dB full scale.
