

# THE DATASHEET OF MPC564CZP66

# MPC561/MPC563 Reference Manual

**Additional Devices Supported:**

**MPC562**

**MPC564**

MPC561RM

REV 1.2

08/2005

## **How to Reach Us:**

### **Home Page:**

[www.freescale.com](http://www.freescale.com)

### **E-mail:**

[support@freescale.com](mailto:support@freescale.com)

### **USA/Europe or Locations Not Listed:**

Freescale Semiconductor  
Technical Information Center, CH370  
1300 N. Alma School Road  
Chandler, Arizona 85224  
+1-800-521-6274 or +1-480-768-2130  
[support@freescale.com](mailto:support@freescale.com)

### **Europe, Middle East, and Africa:**

Freescale Halbleiter Deutschland GmbH  
Technical Information Center  
Schatzbogen 7  
81829 Muenchen, Germany  
+44 1296 380 456 (English)  
+46 8 52200080 (English)  
+49 89 92103 559 (German)  
+33 1 69 35 48 48 (French)  
[support@freescale.com](mailto:support@freescale.com)

### **Japan:**

Freescale Semiconductor Japan Ltd.  
Headquarters  
ARCO Tower 15F  
1-8-1, Shimo-Meguro, Meguro-ku,  
Tokyo 153-0064, Japan  
0120 191014 or +81 3 5437 9125  
[support.japan@freescale.com](mailto:support.japan@freescale.com)

### **Asia/Pacific:**

Freescale Semiconductor Hong Kong Ltd.  
Technical Information Center  
2 Dai King Street  
Tai Po Industrial Estate  
Tai Po, N.T., Hong Kong  
+800 26668334  
[support.asia@freescale.com](mailto:support.asia@freescale.com)

### **For Literature Requests Only:**

Freescale Semiconductor Literature Distribution Center  
P.O. Box 5405  
Denver, Colorado 80217  
1-800-441-2447 or 303-675-2140  
Fax: 303-675-2150  
[LDCForFreescaleSemiconductor@hibbertgroup.com](mailto:LDCForFreescaleSemiconductor@hibbertgroup.com)

Information in this document is provided solely to enable system and software implementers to use Freescale Semiconductor products. There are no express or implied copyright licenses granted hereunder to design or fabricate any integrated circuits or integrated circuits based on the information in this document.

Freescale Semiconductor reserves the right to make changes without further notice to any products herein. Freescale Semiconductor makes no warranty, representation or guarantee regarding the suitability of its products for any particular purpose, nor does Freescale Semiconductor assume any liability arising out of the application or use of any product or circuit, and specifically disclaims any and all liability, including without limitation consequential or incidental damages. "Typical" parameters that may be provided in Freescale Semiconductor data sheets and/or specifications can and do vary in different applications and actual performance may vary over time. All operating parameters, including "Typicals", must be validated for each customer application by customer's technical experts. Freescale Semiconductor does not convey any license under its patent rights nor the rights of others. Freescale Semiconductor products are not designed, intended, or authorized for use as components in systems intended for surgical implant into the body, or other applications intended to support or sustain life, or for any other application in which the failure of the Freescale Semiconductor product could create a situation where personal injury or death may occur. Should Buyer purchase or use Freescale Semiconductor products for any such unintended or unauthorized application, Buyer shall indemnify and hold Freescale Semiconductor and its officers, employees, subsidiaries, affiliates, and distributors harmless against all claims, costs, damages, and expenses, and reasonable attorney fees arising out of, directly or indirectly, any claim of personal injury or death associated with such unintended or unauthorized use, even if such claim alleges that Freescale Semiconductor was negligent regarding the design or manufacture of the part.

Freescale™ and the Freescale logo are trademarks of Freescale Semiconductor, Inc. All other product or service names are the property of their respective owners. The described product is a PowerPC microprocessor. The PowerPC name is a trademark of IBM Corp. and used under license

| 1.3.1                         | High-Performance CPU System .....                                         | 1-3         |
| 1.3.1.1                       | RISC MCU Central Processing Unit (RCPU) .....                             | 1-4         |
| 1.3.1.2                       | Unified System Interface Unit (USIU) .....                                | 1-4         |
| 1.3.1.3                       | Burst Buffer Controller (BBC) Module .....                                | 1-4         |
| 1.3.1.4                       | Flexible Memory Protection Unit .....                                     | 1-5         |
| 1.3.1.5                       | Memory Controller .....                                                   | 1-5         |
| 1.3.1.6                       | 512-Kbytes of CDR3 Flash EEPROM Memory (UC3F) –<br>MPC563/MPC564 Only 1-5 |             |
| 1.3.1.7                       | 32-Kbyte Static RAM (CALRAM) .....                                        | 1-6         |
| 1.3.1.8                       | General Purpose I/O Support (GPIO) .....                                  | 1-6         |
| 1.3.2                         | Nexus Debug Port (Class 3) .....                                          | 1-6         |
| 1.3.3                         | Integrated I/O System .....                                               | 1-6         |
| 1.3.3.1                       | Two Time Processor Units (TPU3) .....                                     | 1-6         |
| 1.3.3.2                       | 22-Channel Modular I/O System (MIOS14) .....                              | 1-6         |
| 1.3.3.3                       | Two Enhanced Queued Analog-to-Digital Converter Modules (QADC64E) .....   | 1-7         |
| 1.3.3.4                       | Three CAN 2.0B Controller (TouCAN) Modules .....                          | 1-7         |
| 1.3.3.5                       | Queued Serial Multi-Channel Module (QSMCM) .....                          | 1-8         |
| 1.3.3.6                       | Peripheral Pin Multiplexing (PPM) .....                                   | 1-8         |
| 1.4                           | MPC561/MPC563 Optional Features .....                                     | 1-9         |
| 1.5                           | Comparison of MPC561/MPC563 and MPC555 .....                              | 1-9         |
| 1.6                           | Additional MPC561/MPC563 Differences .....                                | 1-10        |
| 1.7                           | SRAM Keep-Alive Power Behavior .....                                      | 1-11        |
| 1.8                           | MPC561/MPC563 Address Map .....                                           | 1-11        |

| 1.9              | Supporting Documentation List ..... | 1-14        |

## Chapter 2 Signal Descriptions

|         |                                                                             |      |
|---------|-----------------------------------------------------------------------------|------|
| 2.1     | Signal Groupings .....                                                      | 2-1  |
| 2.2     | Signal Summary .....                                                        | 2-3  |
| 2.2.1   | MPC561/MPC563 Signal Multiplexing .....                                     | 2-20 |
| 2.2.2   | READI Port Signal Sharing .....                                             | 2-21 |
| 2.3     | Pad Module Configuration Register (PDMCR) .....                             | 2-22 |
| 2.4     | Pad Module Configuration Register (PDMCR2) .....                            | 2-23 |
| 2.5     | MPC561/MPC563 Development Support Signal Sharing .....                      | 2-28 |
| 2.5.1   | JTAG Mode Selection .....                                                   | 2-29 |
| 2.5.2   | BDM Mode Selection .....                                                    | 2-30 |
| 2.5.3   | Nexus Mode Selection .....                                                  | 2-30 |
| 2.6     | Reset State .....                                                           | 2-31 |
| 2.6.1   | Signal Functionality Configuration Out of Reset .....                       | 2-31 |
| 2.6.2   | Signal State During Reset .....                                             | 2-31 |
| 2.6.3   | Power-On Reset and Hard Reset .....                                         | 2-32 |
| 2.6.4   | Pull-Up/Pull-Down .....                                                     | 2-32 |
| 2.6.4.1 | Pull-Up/Pull-Down Enable and Disable for 5-V Only and 2.6-V Only Signals .. | 2-32 |
| 2.6.4.2 | Pull-Down Enable and Disable for 5-V/2.6-V Multiplexed Signals .....        | 2-32 |
| 2.6.4.3 | Special Pull Resistor Disable Control Functionality (SPRDS) .....           | 2-32 |
| 2.6.4.4 | Pull Device Select (PULL_SEL) .....                                         | 2-33 |
| 2.6.5   | Signal Reset States .....                                                   | 2-33 |

## Chapter 3 Central Processing Unit

|       |                                              |     |
|-------|----------------------------------------------|-----|
| 3.1   | RCPU Block Diagram .....                     | 3-1 |
| 3.2   | RCPU Key Features .....                      | 3-3 |
| 3.3   | Instruction Sequencer .....                  | 3-3 |
| 3.4   | Independent Execution Units .....            | 3-4 |
| 3.4.1 | Branch Processing Unit (BPU) .....           | 3-5 |
| 3.4.2 | Integer Unit (IU) .....                      | 3-5 |
| 3.4.3 | Load/Store Unit (LSU) .....                  | 3-6 |
| 3.4.4 | Floating-Point Unit (FPU) .....              | 3-6 |
| 3.5   | Levels of the PowerPC ISA Architecture ..... | 3-6 |
| 3.6   | RCPU Programming Model .....                 | 3-7 |

# Contents

|-------|--------------------------------------|-----|
| 5.1   | Memory Map and Registers .....       | 5-2 |
| 5.1.1 | USIU Special-Purpose Registers ..... | 5-6 |

## Chapter 6 System Configuration and Protection

|           |                                                                              |      |
|-----------|------------------------------------------------------------------------------|------|
| 6.1       | System Configuration and Protection Features .....                           | 6-3  |
| 6.1.1     | System Configuration .....                                                   | 6-3  |
| 6.1.1.1   | USIU Pin Multiplexing .....                                                  | 6-4  |
| 6.1.1.2   | Arbitration Support .....                                                    | 6-4  |
| 6.1.2     | External Master Modes .....                                                  | 6-4  |
| 6.1.2.1   | Operation in External Master Modes .....                                     | 6-5  |
| 6.1.2.2   | Address Decoding for External Accesses .....                                 | 6-6  |
| 6.1.3     | USIU General-Purpose I/O .....                                               | 6-6  |
| 6.1.4     | Enhanced Interrupt Controller .....                                          | 6-8  |
| 6.1.4.1   | Key Features .....                                                           | 6-8  |
| 6.1.4.2   | Interrupt Configuration .....                                                | 6-8  |
| 6.1.4.3   | Regular Interrupt Controller Operation (MPC555/MPC556-Compatible Mode) ..... | 6-10 |
| 6.1.4.4   | Enhanced Interrupt Controller Operation .....                                | 6-11 |
| 6.1.4.4.1 | Lower Priority Request Masking .....                                         | 6-14 |
| 6.1.4.4.2 | Backward Compatibility with MPC555/MPC556 .....                              | 6-14 |

|------------------|----------------------------------------------------------------------------|-------------|
| 6.1.4.5          | Interrupt Overhead Estimation for Enhanced Interrupt Controller Mode ..... | 6-16        |
| 6.1.5            | Hardware Bus Monitor .....                                                 | 6-17        |
| 6.1.6            | Decrementer (DEC) .....                                                    | 6-18        |
| 6.1.7            | Time Base (TB) .....                                                       | 6-19        |
| 6.1.8            | Real-Time Clock (RTC) .....                                                | 6-19        |
| 6.1.9            | Periodic Interrupt Timer (PIT) .....                                       | 6-20        |
| 6.1.10           | Software Watchdog Timer (SWT) .....                                        | 6-21        |
| 6.1.11           | Freeze Operation .....                                                     | 6-23        |
| 6.1.12           | Low Power Stop Operation .....                                             | 6-23        |
| 6.2              | Memory Map and Register Definitions .....                                  | 6-23        |
| 6.2.1            | Memory Map .....                                                           | 6-23        |
| 6.2.2            | System Configuration and Protection Registers .....                        | 6-24        |
| 6.2.2.1          | System Configuration Registers .....                                       | 6-24        |
| 6.2.2.1.1        | SIU Module Configuration Register (SIUMCR) .....                           | 6-25        |
| 6.2.2.1.2        | Internal Memory Map Register (IMMR) .....                                  | 6-28        |
| 6.2.2.1.3        | External Master Control Register (EMCR) .....                              | 6-29        |
| 6.2.2.2          | SIU Interrupt Controller Registers .....                                   | 6-31        |
| 6.2.2.2.1        | SIU Interrupt Pending Register (SIPEND) .....                              | 6-32        |
| 6.2.2.2.2        | SIU Interrupt Pending Register 2 (SIPEND2) .....                           | 6-32        |
| 6.2.2.2.3        | SIU Interrupt Pending Register 3 (SIPEND3) .....                           | 6-33        |
| 6.2.2.2.4        | SIU Interrupt Mask Register (SIMASK) .....                                 | 6-33        |
| 6.2.2.2.5        | SIU Interrupt Mask Register 2 (SIMASK2) .....                              | 6-34        |
| 6.2.2.2.6        | SIU Interrupt Mask Register 3 (SIMASK3) .....                              | 6-35        |
| 6.2.2.2.7        | SIU Interrupt Edge Level Register (SIEL) .....                             | 6-35        |
| 6.2.2.2.8        | SIU Interrupt Vector Register (SIVVEC) .....                               | 6-35        |
| 6.2.2.2.9        | Interrupt In-Service Registers (SISR2 and SISR3) .....                     | 6-37        |
| 6.2.2.3          | System Protection Registers .....                                          | 6-37        |
| 6.2.2.3.1        | System Protection Control Register (SYPCR) .....                           | 6-37        |
| 6.2.2.3.2        | Software Service Register (SWSR) .....                                     | 6-38        |
| 6.2.2.3.3        | Transfer Error Status Register (TESR) .....                                | 6-39        |
| 6.2.2.4          | System Timer Registers .....                                               | 6-40        |
| 6.2.2.4.1        | Decrementer Register (DEC) .....                                           | 6-40        |
| 6.2.2.4.2        | Time Base SPRs (TB) .....                                                  | 6-40        |
| 6.2.2.4.3        | Time Base Reference Registers (TBREF0 and TBREF1) .....                    | 6-41        |
| 6.2.2.4.4        | Time Base Control and Status Register (TBSCR) .....                        | 6-42        |
| 6.2.2.4.5        | Real-Time Clock Status and Control Register (RTCSC) .....                  | 6-42        |
| 6.2.2.4.6        | Real-Time Clock Register (RTC) .....                                       | 6-43        |
| 6.2.2.4.7        | Real-Time Clock Alarm Register (RTCAL) .....                               | 6-44        |
| 6.2.2.4.8        | Periodic Interrupt Status and Control Register (PISCR) .....               | 6-44        |
| 6.2.2.4.9        | Periodic Interrupt Timer Count Register (PITC) .....                       | 6-45        |
| 6.2.2.4.10       | Periodic Interrupt Timer Register (PITR) .....                             | 6-45        |

| 6.2.2.5          | General-Purpose I/O Registers .....    | 6-46        |
| 6.2.2.5.1        | SGPIO Data Register 1 (SGPIODT1) ..... | 6-46        |
| 6.2.2.5.2        | SGPIO Data Register 2 (SGPIODT2) ..... | 6-47        |
| 6.2.2.5.3        | SGPIO Control Register (SGPIOCR) ..... | 6-48        |

## Chapter 7 Reset

|        |                                           |      |
|--------|-------------------------------------------|------|
| 7.1    | Reset Operation .....                     | 7-1  |
| 7.1.1  | Power-On Reset .....                      | 7-1  |
| 7.1.2  | Hard Reset .....                          | 7-2  |
| 7.1.3  | Soft Reset .....                          | 7-2  |
| 7.1.4  | Loss of PLL Lock .....                    | 7-2  |
| 7.1.5  | On-Chip Clock Switch .....                | 7-3  |
| 7.1.6  | Software Watchdog Reset .....             | 7-3  |
| 7.1.7  | Checkstop Reset .....                     | 7-3  |
| 7.1.8  | Debug Port Hard Reset .....               | 7-3  |
| 7.1.9  | Debug Port Soft Reset .....               | 7-3  |
| 7.1.10 | JTAG Reset .....                          | 7-3  |
| 7.1.11 | ILBC Illegal Bit Change .....             | 7-3  |
| 7.2    | Reset Actions Summary .....               | 7-3  |
| 7.3    | Data Coherency During Reset .....         | 7-4  |
| 7.4    | Reset Status Register (RSR) .....         | 7-5  |
| 7.5    | Reset Configuration .....                 | 7-7  |
| 7.5.1  | Hard Reset Configuration .....            | 7-7  |
| 7.5.2  | Hard Reset Configuration Word (RCW) ..... | 7-11 |
| 7.5.3  | Soft Reset Configuration .....            | 7-13 |

## Chapter 8 Clocks and Power Control

|       |                                            |     |
|-------|--------------------------------------------|-----|
| 8.1   | System Clock Sources .....                 | 8-3 |
| 8.2   | System PLL .....                           | 8-3 |
| 8.2.1 | Frequency Multiplication .....             | 8-4 |
| 8.2.2 | Skew Elimination .....                     | 8-4 |
| 8.2.3 | Pre-Divider .....                          | 8-4 |
| 8.2.4 | PLL Block Diagram .....                    | 8-4 |
| 8.2.5 | PLL Pins .....                             | 8-5 |
| 8.3   | System Clock During PLL Loss of Lock ..... | 8-6 |
| 8.4   | Low-Power Divider .....                    | 8-6 |

# Contents

| Paragraph Number | Title                                                     | Page Number |
|------------------|-----------------------------------------------------------|-------------|
| 8.5              | Internal Clock Signals .....                              | 8-7         |
| 8.5.1            | General System Clocks .....                               | 8-10        |
| 8.5.2            | Clock Out (CLKOUT) .....                                  | 8-13        |
| 8.5.3            | Engineering Clock (ENGCLK) .....                          | 8-14        |
| 8.6              | Clock Source Switching .....                              | 8-14        |
| 8.7              | Low-Power Modes .....                                     | 8-16        |
| 8.7.1            | Entering a Low-Power Mode .....                           | 8-16        |
| 8.7.2            | Power Mode Descriptions .....                             | 8-17        |
| 8.7.3            | Exiting from Low-Power Modes .....                        | 8-17        |
| 8.7.3.1          | Exiting from Normal-Low Mode .....                        | 8-18        |
| 8.7.3.2          | Exiting from Doze Mode .....                              | 8-19        |
| 8.7.3.3          | Exiting from Deep-Sleep Mode .....                        | 8-19        |
| 8.7.3.4          | Exiting from Power-Down Mode .....                        | 8-19        |
| 8.7.3.5          | Low-Power Modes Flow .....                                | 8-19        |
| 8.8              | Basic Power Structure .....                               | 8-21        |

| 9.5.14           | Show Cycle Transactions .....                | 9-55        |

## Chapter 10 Memory Controller

|          |                                                       |       |
|----------|-------------------------------------------------------|-------|
| 10.1     | Overview .....                                        | 10-1  |
| 10.2     | Memory Controller Architecture .....                  | 10-3  |
| 10.2.1   | Associated Registers .....                            | 10-4  |
| 10.2.2   | Port Size Configuration .....                         | 10-4  |
| 10.2.3   | Write-Protect Configuration .....                     | 10-5  |
| 10.2.4   | Address and Address Space Checking .....              | 10-5  |
| 10.2.5   | Burst Support .....                                   | 10-5  |
| 10.2.6   | Reduced Data Setup Time .....                         | 10-6  |
| 10.2.6.1 | Case 1: Normal Setup Time .....                       | 10-6  |
| 10.2.6.2 | Case 2: Short Setup Time .....                        | 10-7  |
| 10.2.6.3 | Summary of Short Setup Time .....                     | 10-8  |
| 10.3     | Chip-Select Timing .....                              | 10-10 |
| 10.3.1   | Memory Devices Interface Example .....                | 10-12 |
| 10.3.2   | Peripheral Devices Interface Example .....            | 10-13 |
| 10.3.3   | Relaxed Timing Examples .....                         | 10-14 |
| 10.3.4   | Extended Hold Time on Read Accesses .....             | 10-18 |
| 10.3.5   | Summary of GPCM Timing Options .....                  | 10-22 |
| 10.4     | Write and Byte Enable Signals .....                   | 10-24 |
| 10.5     | Dual Mapping of the Internal Flash EEPROM Array ..... | 10-24 |
| 10.6     | Dual Mapping of an External Flash Region .....        | 10-26 |
| 10.7     | Global (Boot) Chip-Select Operation .....             | 10-27 |
| 10.8     | Memory Controller External Master Support .....       | 10-28 |
| 10.9     | Programming Model .....                               | 10-31 |
| 10.9.1   | General Memory Controller Programming Notes .....     | 10-31 |
| 10.9.2   | Memory Controller Status Registers (MSTAT) .....      | 10-32 |
| 10.9.3   | Memory Controller Base Registers (BR0–BR3) .....      | 10-32 |
| 10.9.4   | Memory Controller Option Registers (OR0–OR3) .....    | 10-34 |
| 10.9.5   | Dual-Mapping Base Register (DMBR) .....               | 10-36 |
| 10.9.6   | Dual-Mapping Option Register (DMOR) .....             | 10-37 |

| 12.4.1           | Interrupt Sources and Levels on IMB3 .....        | 12-3        |
| 12.4.2           | IMB3 Interrupt Multiplexing .....                 | 12-4        |
| 12.4.3           | ILBS Sequencing .....                             | 12-4        |
| 12.4.4           | Interrupt Synchronizer .....                      | 12-5        |
| 12.5             | Programming Model .....                           | 12-6        |
| 12.5.1           | UIMB Module Configuration Register (UMCR) .....   | 12-7        |
| 12.5.2           | Test Control Register (UTSTCREG) .....            | 12-8        |
| 12.5.3           | Pending Interrupt Request Register (UIPEND) ..... | 12-8        |

## Chapter 13 QADC64E Legacy Mode Operation

|          |                                                                |       |
|----------|----------------------------------------------------------------|-------|
| 13.1     | QADC64E Block Diagram .....                                    | 13-1  |
| 13.2     | Key Features and Quick Reference Diagrams .....                | 13-2  |
| 13.2.1   | Features of the QADC64E Legacy Mode Operation .....            | 13-2  |
| 13.2.2   | Memory Map .....                                               | 13-3  |
| 13.2.3   | Legacy and Enhanced Modes of Operation .....                   | 13-4  |
| 13.2.4   | Using the Queue and Result Word Table .....                    | 13-5  |
| 13.2.5   | External Multiplexing .....                                    | 13-5  |
| 13.3     | Programming the QADC64E Registers .....                        | 13-7  |
| 13.3.1   | QADC64E Module Configuration Register (QADMCR) .....           | 13-8  |
| 13.3.1.1 | Low Power Stop Mode .....                                      | 13-9  |
| 13.3.1.2 | Freeze Mode .....                                              | 13-9  |
| 13.3.1.3 | Switching Between Legacy and Enhanced Modes of Operation ..... | 13-10 |
| 13.3.1.4 | Supervisor/Unrestricted Address Space .....                    | 13-10 |
| 13.3.2   | QADC64E Interrupt Register (QADCINT) .....                     | 13-12 |
| 13.3.3   | Port Data Register (PORTQA and PORTQB) .....                   | 13-13 |
| 13.3.4   | Port Data Direction Register (DDRQA) .....                     | 13-14 |
| 13.3.5   | Control Register 0 (QACR0) .....                               | 13-14 |
| 13.3.6   | Control Register 1 (QACR1) .....                               | 13-15 |
| 13.3.7   | Control Register 2 (QACR2) .....                               | 13-17 |
| 13.3.8   | Status Registers (QASR0 and QASR1) .....                       | 13-20 |
| 13.3.9   | Conversion Command Word Table .....                            | 13-27 |
| 13.3.10  | Result Word Table .....                                        | 13-32 |
| 13.4     | Analog Subsystem .....                                         | 13-34 |
| 13.4.1   | Analog-to-Digital Converter Operation .....                    | 13-34 |
| 13.4.1.1 | Conversion Cycle Times .....                                   | 13-35 |
| 13.4.1.2 | Amplifier Bypass Mode Conversion Timing .....                  | 13-35 |
| 13.4.2   | Channel Decode and Multiplexer .....                           | 13-36 |
| 13.4.3   | Sample Buffer Amplifier .....                                  | 13-36 |
| 13.4.4   | Digital-to-Analog Converter (DAC) Array .....                  | 13-36 |

|------------------|----------------------------------------------------------|-------------|
| 13.4.5           | Comparator .....                                         | 13-37       |
| 13.4.6           | Bias .....                                               | 13-37       |
| 13.4.7           | Successive Approximation Register .....                  | 13-37       |
| 13.4.8           | State Machine .....                                      | 13-37       |
| 13.5             | Digital Subsystem .....                                  | 13-37       |
| 13.5.1           | Queue Priority .....                                     | 13-38       |
| 13.5.2           | Paused Sub-Queues .....                                  | 13-38       |
| 13.5.3           | Boundary Conditions .....                                | 13-40       |
| 13.5.4           | Scan Modes .....                                         | 13-41       |
| 13.5.4.1         | Disabled Mode .....                                      | 13-41       |
| 13.5.4.2         | Reserved Mode .....                                      | 13-41       |
| 13.5.4.3         | Single-Scan Modes .....                                  | 13-42       |
| 13.5.4.3.1       | Software Initiated Single-Scan Mode .....                | 13-42       |
| 13.5.4.3.2       | External Trigger Single-Scan Mode .....                  | 13-43       |
| 13.5.4.3.3       | External Gated Single-Scan Mode .....                    | 13-43       |
| 13.5.4.3.4       | Periodic/Interval Timer Single-Scan Mode .....           | 13-44       |
| 13.5.4.4         | Continuous-Scan Modes .....                              | 13-44       |
| 13.5.4.4.1       | Software Initiated Continuous-Scan Mode .....            | 13-45       |
| 13.5.4.4.2       | External Trigger Continuous-Scan Mode .....              | 13-46       |
| 13.5.4.4.3       | External Gated Continuous-Scan Mode .....                | 13-46       |
| 13.5.4.4.4       | Periodic/Interval Timer Continuous-Scan Mode .....       | 13-47       |
| 13.5.5           | QADC64E Clock (QCLK) Generation .....                    | 13-47       |
| 13.5.6           | Periodic / Interval Timer .....                          | 13-51       |
| 13.5.7           | Configuration and Control Using the IMB3 Interface ..... | 13-51       |
| 13.5.7.1         | QADC64E Bus Interface Unit .....                         | 13-51       |
| 13.5.7.2         | QADC64E Bus Accessing .....                              | 13-52       |
| 13.6             | Trigger and Queue Interaction Examples .....             | 13-54       |
| 13.6.1           | Queue Priority Schemes .....                             | 13-54       |
| 13.6.2           | Conversion Timing Schemes .....                          | 13-63       |
| 13.7             | QADC64E Integration Requirements .....                   | 13-66       |
| 13.7.1           | Port Digital Input/Output Signals .....                  | 13-66       |
| 13.7.2           | External Trigger Input Signals .....                     | 13-67       |
| 13.7.3           | Analog Power Signals .....                               | 13-67       |
| 13.7.3.1         | Analog Supply Filtering and Grounding .....              | 13-69       |
| 13.7.4           | Analog Reference Signals .....                           | 13-71       |
| 13.7.5           | Analog Input Signals .....                               | 13-71       |
| 13.7.5.1         | Analog Input Considerations .....                        | 13-73       |
| 13.7.5.2         | Settling Time for the External Circuit .....             | 13-75       |
| 13.7.5.3         | Error Resulting from Leakage .....                       | 13-75       |
| 13.7.5.4         | Accommodating Positive/Negative Stress Conditions .....  | 13-76       |

| 15.4.3           | Access Protection .....                                   | 15-6        |
| 15.4.4           | QSMCM Interrupts .....                                    | 15-7        |
| 15.4.5           | QSPI Interrupt Generation .....                           | 15-8        |
| 15.4.6           | QSMCM Configuration Register (QSMCMMCR) .....             | 15-8        |
| 15.4.7           | QSMCM Test Register (QTEST) .....                         | 15-9        |
| 15.4.8           | QSMCM Interrupt Level Registers (QDSCI_IL, QSPI_IL) ..... | 15-9        |
| 15.5             | QSMCM Pin Control Registers .....                         | 15-10       |
| 15.5.1           | Port QS Data Register (PORTQS) .....                      | 15-11       |
| 15.5.2           | PORTQS Pin Assignment Register (PQSPAR) .....             | 15-12       |
| 15.5.3           | PORTQS Data Direction Register (DDRQS) .....              | 15-13       |
| 15.6             | Queued Serial Peripheral Interface .....                  | 15-14       |
| 15.6.1           | QSPI Registers .....                                      | 15-16       |
| 15.6.1.1         | QSPI Control Register 0 (SPCR0) .....                     | 15-17       |
| 15.6.1.2         | QSPI Control Register 1 (SPCR1) .....                     | 15-19       |
| 15.6.1.3         | QSPI Control Register 2 (SPCR2) .....                     | 15-20       |
| 15.6.1.4         | QSPI Control Register 3 (SPCR3) .....                     | 15-20       |
| 15.6.1.5         | QSPI Status Register (SPSR) .....                         | 15-21       |
| 15.6.2           | QSPI RAM .....                                            | 15-22       |
| 15.6.2.1         | Receive RAM .....                                         | 15-23       |
| 15.6.2.2         | Transmit RAM .....                                        | 15-23       |
| 15.6.2.3         | Command RAM .....                                         | 15-23       |
| 15.6.3           | QSPI Pins .....                                           | 15-24       |
| 15.6.4           | QSPI Operation .....                                      | 15-25       |
| 15.6.4.1         | Enabling, Disabling, and Halting the SPI .....            | 15-26       |
| 15.6.4.2         | QSPI Interrupts .....                                     | 15-26       |
| 15.6.4.3         | QSPI Flow .....                                           | 15-27       |
| 15.6.5           | Master Mode Operation .....                               | 15-34       |
| 15.6.5.1         | Clock Phase and Polarity .....                            | 15-35       |
| 15.6.5.2         | Baud Rate Selection .....                                 | 15-35       |
| 15.6.5.3         | Delay Before Transfer .....                               | 15-36       |
| 15.6.5.4         | Delay After Transfer .....                                | 15-36       |
| 15.6.5.5         | Transfer Length .....                                     | 15-37       |
| 15.6.5.6         | Peripheral Chip Selects .....                             | 15-37       |
| 15.6.5.7         | Optional Enhanced Peripheral Chip Selects .....           | 15-37       |
| 15.6.5.8         | Master Wraparound Mode .....                              | 15-38       |
| 15.6.6           | Slave Mode .....                                          | 15-39       |
| 15.6.6.1         | Description of Slave Operation .....                      | 15-40       |
| 15.6.7           | Slave Wraparound Mode .....                               | 15-41       |
| 15.6.8           | Mode Fault .....                                          | 15-42       |
| 15.7             | Serial Communication Interface .....                      | 15-42       |
| 15.7.1           | SCI Registers .....                                       | 15-45       |

| Paragraph Number | Title                                                         | Page Number |
|------------------|---------------------------------------------------------------|-------------|
| 16.3.1.1         | Common Fields for Extended and Standard Format Frames .....   | 16-4        |
| 16.3.1.2         | Fields for Extended Format Frames .....                       | 16-6        |
| 16.3.1.3         | Fields for Standard Format Frames .....                       | 16-6        |
| 16.3.1.4         | Serial Message Buffers .....                                  | 16-6        |
| 16.3.1.5         | Message Buffer Activation/Deactivation Mechanism .....        | 16-7        |
| 16.3.1.6         | Message Buffer Lock/Release/Busy Mechanism .....              | 16-7        |
| 16.3.2           | Receive Mask Registers .....                                  | 16-7        |
| 16.3.3           | Bit Timing .....                                              | 16-8        |
| 16.3.3.1         | Configuring the TouCAN Bit Timing .....                       | 16-10       |
| 16.3.4           | Error Counters .....                                          | 16-10       |
| 16.3.5           | Time Stamp .....                                              | 16-12       |
| 16.4             | TouCAN Operation .....                                        | 16-12       |
| 16.4.1           | TouCAN Reset .....                                            | 16-12       |
| 16.4.2           | TouCAN Initialization .....                                   | 16-13       |
| 16.4.3           | Transmit Process .....                                        | 16-13       |
| 16.4.3.1         | Transmit Message Buffer Deactivation .....                    | 16-14       |
| 16.4.3.2         | Reception of Transmitted Frames .....                         | 16-14       |
| 16.4.4           | Receive Process .....                                         | 16-14       |
| 16.4.4.1         | Receive Message Buffer Deactivation .....                     | 16-16       |
| 16.4.4.2         | Locking and Releasing Message Buffers .....                   | 16-16       |
| 16.4.5           | Remote Frames .....                                           | 16-17       |
| 16.4.6           | Overload Frames .....                                         | 16-17       |
| 16.5             | Special Operating Modes .....                                 | 16-17       |
| 16.5.1           | Debug Mode .....                                              | 16-17       |
| 16.5.2           | Low-Power Stop Mode .....                                     | 16-18       |
| 16.5.3           | Auto Power Save Mode .....                                    | 16-19       |
| 16.6             | Interrupts .....                                              | 16-20       |
| 16.7             | Programming Model .....                                       | 16-21       |
| 16.7.1           | TouCAN Module Configuration Register (CANMCR) .....           | 16-25       |
| 16.7.2           | TouCAN Test Configuration Register .....                      | 16-27       |
| 16.7.3           | TouCAN Interrupt Configuration Register (CANICR) .....        | 16-27       |
| 16.7.4           | Control Register 0 (CANCTRL0) .....                           | 16-27       |
| 16.7.5           | Control Register 1 (CANCTRL1) .....                           | 16-28       |
| 16.7.6           | Prescaler Divide Register (PRESDIV) .....                     | 16-29       |
| 16.7.7           | Control Register 2 (CANCTRL2) .....                           | 16-30       |
| 16.7.8           | Free Running Timer (TIMER) .....                              | 16-31       |
| 16.7.9           | Receive Global Mask Registers (RXGMSKHI, RXGMSKLO) .....      | 16-31       |
| 16.7.10          | Receive Buffer 14 Mask Registers (RX14MSKHI, RX14MSKLO) ..... | 16-32       |
| 16.7.11          | Receive Buffer 15 Mask Registers (RX15MSKHI, RX15MSKLO) ..... | 16-33       |
| 16.7.12          | Error and Status Register (ESTAT) .....                       | 16-33       |
| 16.7.13          | Interrupt Mask Register (IMASK) .....                         | 16-35       |

|------------------|---------------------------------------|-------------|
| 16.7.14          | Interrupt Flag Register (IFLAG) ..... | 16-36       |
| 16.7.15          | Error Counters (RXECTR, TXECTR) ..... | 16-36       |

## Chapter 17 Modular Input/Output Subsystem (MIOS14)

|          |                                                             |       |
|----------|-------------------------------------------------------------|-------|
| 17.1     | Block Diagram .....                                         | 17-1  |
| 17.2     | MIOS14 Key Features .....                                   | 17-3  |
| 17.2.1   | Submodule Numbering, Naming, and Addressing .....           | 17-4  |
| 17.2.2   | Signal Naming Convention .....                              | 17-5  |
| 17.3     | MIOS14 Configuration .....                                  | 17-6  |
| 17.3.1   | MIOS14 Signals .....                                        | 17-9  |
| 17.3.2   | MIOS14 Bus System .....                                     | 17-9  |
| 17.3.3   | Read/Write and Control Bus .....                            | 17-10 |
| 17.3.4   | Request Bus .....                                           | 17-10 |
| 17.3.5   | Counter Bus Set .....                                       | 17-10 |
| 17.4     | MIOS14 Programming Model .....                              | 17-10 |
| 17.4.1   | Bus Error Support .....                                     | 17-10 |
| 17.4.2   | Wait States .....                                           | 17-11 |
| 17.5     | MIOS14 I/O Ports .....                                      | 17-13 |
| 17.6     | MIOS14 Bus Interface Submodule (MBISM) .....                | 17-13 |
| 17.6.1   | MIOS14 Bus Interface (MBISM) Registers .....                | 17-13 |
| 17.6.1.1 | MIOS14 Test and Signal Control Register (MIOS14TPCR) .....  | 17-13 |
| 17.6.1.2 | MIOS14 Vector Register (MIOS14VECT) .....                   | 17-14 |
| 17.6.1.3 | MIOS14 Module and Version Number Register (MIOS14VNR) ..... | 17-14 |
| 17.6.1.4 | MIOS14 Module Configuration Register (MIOS14MCR) .....      | 17-15 |
| 17.7     | MIOS14 Counter Prescaler Submodule (MCPSM) .....            | 17-16 |
| 17.7.1   | MCPSM Features .....                                        | 17-16 |
| 17.7.1.1 | MCPSM Signal Functions .....                                | 17-17 |
| 17.7.1.2 | Modular I/O Bus (MIOB) Interface .....                      | 17-17 |
| 17.7.2   | Effect of RESET on MCPSM .....                              | 17-17 |
| 17.7.3   | MCPSM Registers .....                                       | 17-17 |
| 17.7.3.1 | MCPSM Registers Organization .....                          | 17-17 |
| 17.7.3.2 | MCPSM Status/Control Register (MCPSMSCR) .....              | 17-18 |
| 17.8     | MIOS14 Modulus Counter Submodule (MMCSM) .....              | 17-19 |
| 17.8.1   | MMCSM Features .....                                        | 17-20 |
| 17.8.1.1 | MMCSM Signal Functions .....                                | 17-21 |
| 17.8.2   | MMCSM Prescaler .....                                       | 17-21 |
| 17.8.3   | Modular I/O Bus (MIOB) Interface .....                      | 17-21 |
| 17.8.4   | Effect of RESET on MMCSM .....                              | 17-22 |
| 17.8.5   | MMCSM Registers .....                                       | 17-22 |

|------------------|-----------------------------------------------------------------|-------------|
| 17.8.5.1         | MMCSM Register Organization .....                               | 17-22       |
| 17.8.5.2         | MMCSM Up-Counter Register (MMCSMCNT) .....                      | 17-23       |
| 17.8.5.3         | MMCSM Modulus Latch Register (MMCSMML) .....                    | 17-24       |
| 17.8.5.4         | MMCSM Status/Control Register (MMCSMSCRD)<br>(Duplicated) ..... | 17-24       |
| 17.8.5.5         | MMCSM Status/Control Register (MMCSMSCR) .....                  | 17-24       |
| 17.9             | MIOS14 Double Action Submodule (MDASM) .....                    | 17-26       |
| 17.9.1           | MDASM Features .....                                            | 17-27       |
| 17.9.1.1         | MDASM Signal Functions .....                                    | 17-28       |
| 17.9.2           | MDASM Description .....                                         | 17-28       |
| 17.9.3           | MDASM Modes of Operation .....                                  | 17-29       |
| 17.9.3.1         | Disable (DIS) Mode .....                                        | 17-29       |
| 17.9.3.2         | Input Pulse Width Measurement (IPWM) Mode .....                 | 17-30       |
| 17.9.3.3         | Input Period Measurement (IPM) Mode .....                       | 17-31       |
| 17.9.3.4         | Input Capture (IC) Mode .....                                   | 17-32       |
| 17.9.3.5         | Output Compare (OCB and OCAB) Modes .....                       | 17-33       |
| 17.9.3.5.1       | Single Shot Output Pulse Operation .....                        | 17-34       |
| 17.9.3.5.2       | Single Output Compare Operation .....                           | 17-35       |
| 17.9.3.5.3       | Output Port Bit Operation .....                                 | 17-36       |
| 17.9.3.6         | Output Pulse Width Modulation (OPWM) Mode .....                 | 17-36       |
| 17.9.4           | Modular I/O Bus (MIOB) Interface .....                          | 17-39       |
| 17.9.5           | Effect of RESET on MDASM .....                                  | 17-39       |
| 17.9.6           | MDASM Registers .....                                           | 17-39       |
| 17.9.6.1         | MDASM Registers Organization .....                              | 17-39       |
| 17.9.6.2         | MDASM Data A (MDASMAR) Register .....                           | 17-41       |
| 17.9.6.3         | MDASM Data B (MDASMBR) Register .....                           | 17-42       |
| 17.9.6.4         | MDASM Status/Control Register (MDASMSCRD) (Duplicated) .....    | 17-43       |
| 17.9.6.5         | MDASM Status/Control Register (MDASMSCR) .....                  | 17-43       |
| 17.10            | MIOS14 Pulse Width Modulation Submodule (MPWMSM) .....          | 17-46       |
| 17.10.1          | MPWMSM Terminology .....                                        | 17-47       |
| 17.10.2          | MPWMSM Features .....                                           | 17-47       |
| 17.10.3          | MPWMSM Description .....                                        | 17-48       |
| 17.10.3.1        | Clock Selection .....                                           | 17-49       |
| 17.10.3.2        | Counter .....                                                   | 17-49       |
| 17.10.3.3        | Period Register .....                                           | 17-49       |
| 17.10.3.4        | Pulse Width Registers .....                                     | 17-50       |
| 17.10.3.5        | Duty Cycles (0% and 100%) .....                                 | 17-51       |
| 17.10.3.6        | Pulse/Frequency Range Table .....                               | 17-52       |
| 17.10.3.7        | MPWMSM Status and Control Register (SCR) .....                  | 17-53       |
| 17.10.3.8        | MPWMSM Interrupt .....                                          | 17-53       |
| 17.10.3.9        | MPWMSM Port Functions .....                                     | 17-54       |

| 17.10.3.10       | MPWMSM Data Coherency .....                              | 17-54       |
| 17.10.4          | Modular Input/Output Bus (MIOS14) Interface .....        | 17-54       |
| 17.10.5          | Effect of RESET on MPWMSM .....                          | 17-54       |
| 17.10.6          | MPWMSM Registers .....                                   | 17-55       |
| 17.10.6.1        | MPWMSM Registers Organization .....                      | 17-55       |
| 17.10.6.2        | MPWMSM Period Register (MPWMPERR) .....                  | 17-57       |
| 17.10.6.3        | MPWMSM Pulse Width Register (MPWMPULR) .....             | 17-57       |
| 17.10.6.4        | MPWMSM Counter Register (MPWMCNTR) .....                 | 17-58       |
| 17.10.6.5        | MPWMSM Status/Control Register (MPWMSCR) .....           | 17-58       |
| 17.11            | MIOS14 16-bit Parallel Port I/O Submodule (MPIOSM) ..... | 17-60       |
| 17.11.1          | MPIOSM Features .....                                    | 17-61       |
| 17.11.2          | MPIOSM Signal Functions .....                            | 17-61       |
| 17.11.3          | MPIOSM Description .....                                 | 17-61       |
| 17.11.3.1        | MPIOSM Port Function .....                               | 17-61       |
| 17.11.3.2        | Non-Bonded MPIOSM Pads .....                             | 17-61       |
| 17.11.4          | Modular I/O Bus (MIOB) Interface .....                   | 17-62       |
| 17.11.5          | Effect of RESET on MPIOSM .....                          | 17-62       |
| 17.11.6          | MPIOSM Testing .....                                     | 17-62       |
| 17.11.7          | MPIOSM Registers .....                                   | 17-62       |
| 17.11.8          | MPIOSM Register Organization .....                       | 17-62       |
| 17.11.8.1        | MPIOSM Data Register (MPIOSMDR) .....                    | 17-62       |
| 17.11.8.2        | MPIOSM Data Direction Register (MPIOSMDDR) .....         | 17-63       |
| 17.12            | MIOS14 Interrupts .....                                  | 17-63       |
| 17.12.1          | MIOS14 Interrupt Structure .....                         | 17-63       |
| 17.12.2          | MIOS14 Interrupt Request Submodule (MIRSM) .....         | 17-64       |
| 17.12.3          | MIRSM0 Interrupt Registers .....                         | 17-65       |
| 17.12.3.1        | Interrupt Status Register (MIOS14SR0) .....              | 17-65       |
| 17.12.3.2        | Interrupt Enable Register (MIOS14ER0) .....              | 17-66       |
| 17.12.3.3        | Interrupt Request Pending Register (MIOS14RPR0) .....    | 17-66       |
| 17.12.4          | MIRSM1 Interrupt Registers .....                         | 17-67       |
| 17.12.4.1        | Interrupt Status Register (MIOS14SR1) .....              | 17-67       |
| 17.12.4.2        | Interrupt Enable Register (MIOS14ER1) .....              | 17-68       |
| 17.12.4.3        | Interrupt Request Pending Register (MIOS14RPR1) .....    | 17-68       |
| 17.12.5          | Interrupt Control Section (ICS) .....                    | 17-69       |
| 17.12.6          | MBISM Interrupt Registers .....                          | 17-69       |
| 17.12.6.1        | MIOS14 Interrupt Level Register 0 (MIOS14LVL0) .....     | 17-69       |
| 17.12.6.2        | MIOS14 Interrupt Level Register 1 (MIOS14LVL1) .....     | 17-70       |
| 17.13            | MIOS14 Function Examples .....                           | 17-70       |
| 17.13.1          | MIOS14 Input Double Edge Pulse Width Measurement .....   | 17-70       |
| 17.13.2          | MIOS14 Input Double Edge Period Measurement .....        | 17-71       |
| 17.13.3          | MIOS14 Double Edge Single Output Pulse Generation .....  | 17-72       |

# Contents

|------------------|-------------------------------------------------------|-------------|
| 17.13.4          | MIOS14 Output Pulse Width Modulation with MDASM ..... | 17-73       |
| 17.13.5          | MIOS14 Input Pulse Accumulation .....                 | 17-74       |

## Chapter 18 Peripheral Pin Multiplexing (PPM) Module

|          |                                                                      |       |
|----------|----------------------------------------------------------------------|-------|
| 18.1     | Key Features .....                                                   | 18-1  |
| 18.2     | Programming Model .....                                              | 18-2  |
| 18.3     | Functional Description .....                                         | 18-3  |
| 18.3.1   | PPM Parallel-to-Serial Communication Protocol .....                  | 18-3  |
| 18.3.1.1 | Internal Multiplexing .....                                          | 18-4  |
| 18.3.1.2 | PPM Clocks .....                                                     | 18-5  |
| 18.3.1.3 | PPM Control Settings .....                                           | 18-7  |
| 18.3.2   | PPM Signal Short Functionality .....                                 | 18-9  |
| 18.3.2.1 | TouCAN Shorting .....                                                | 18-9  |
| 18.3.2.2 | TPU Shorting .....                                                   | 18-9  |
| 18.3.2.3 | ETRIG1 and ETRIG2 .....                                              | 18-9  |
| 18.3.2.4 | T2CLK .....                                                          | 18-10 |
| 18.3.3   | PPM Module Pad Configuration .....                                   | 18-10 |
| 18.4     | PPM Registers .....                                                  | 18-10 |
| 18.4.1   | Module Configuration Register (PPMMCR) .....                         | 18-10 |
| 18.4.1.1 | Entering Stop Mode .....                                             | 18-11 |
| 18.4.2   | PPM Control Register (PPMPCR) .....                                  | 18-12 |
| 18.4.3   | Transmit Configuration Registers (TX_CONFIG_1 and TX_CONFIG_2) ..... | 18-15 |
| 18.4.4   | Receive Configuration Registers (RX_CONFIG_1 and RX_CONFIG_2) .....  | 18-16 |
| 18.4.5   | Receive Data Register (RX_DATA) .....                                | 18-17 |
| 18.4.6   | Receive Shift Register (RX_SHIFTER) .....                            | 18-18 |
| 18.4.7   | Transmit Data Register (TX_DATA) .....                               | 18-18 |
| 18.4.8   | General-Purpose Data Out (GPDO) .....                                | 18-18 |
| 18.4.9   | General-Purpose Data In (GPDI) .....                                 | 18-19 |
| 18.4.10  | Short Register (SHORT_REG) .....                                     | 18-19 |
| 18.4.11  | Short Channels Register (SHORT_CH_REG) .....                         | 18-22 |
| 18.4.12  | Scale Transmit Clock Register (SCALE_TCLK_REG) .....                 | 18-24 |

## Chapter 19 Time Processor Unit 3

|        |                       |      |
|--------|-----------------------|------|
| 19.1   | Overview .....        | 19-2 |
| 19.2   | TPU3 Components ..... | 19-2 |
| 19.2.1 | Time Bases .....      | 19-2 |

# Contents

| Paragraph Number | Title                                                | Page Number |
|------------------|------------------------------------------------------|-------------|
| 19.2.2           | Timer Channels .....                                 | 19-2        |
| 19.2.3           | Scheduler .....                                      | 19-2        |
| 19.2.4           | Microengine .....                                    | 19-3        |
| 19.2.5           | Host Interface .....                                 | 19-3        |
| 19.2.6           | Parameter RAM .....                                  | 19-3        |
| 19.3             | TPU Operation .....                                  | 19-3        |
| 19.3.1           | Event Timing .....                                   | 19-3        |
| 19.3.2           | Channel Orthogonality .....                          | 19-4        |
| 19.3.3           | Interchannel Communication .....                     | 19-4        |
| 19.3.4           | Programmable Channel Service Priority .....          | 19-4        |
| 19.3.5           | Coherency .....                                      | 19-4        |
| 19.3.6           | Emulation Support .....                              | 19-4        |
| 19.3.7           | TPU3 Interrupts .....                                | 19-5        |
| 19.3.8           | Prescaler Control for TCR1 .....                     | 19-5        |
| 19.3.9           | Prescaler Control for TCR2 .....                     | 19-7        |
| 19.4             | Programming Model .....                              | 19-8        |
| 19.4.1           | TPU Module Configuration Register (TPUMCR) .....     | 19-11       |
| 19.4.2           | Development Support Control Register (DSCR) .....    | 19-12       |
| 19.4.3           | Development Support Status Register (DSSR) .....     | 19-13       |
| 19.4.4           | TPU3 Interrupt Configuration Register (TICR) .....   | 19-14       |
| 19.4.5           | Channel Interrupt Enable Register (CIER) .....       | 19-15       |
| 19.4.6           | Channel Function Select Registers (CFSRn) .....      | 19-15       |
| 19.4.7           | Host Sequence Registers (HSQRn) .....                | 19-16       |
| 19.4.8           | Host Service Request Registers (HSRRn) .....         | 19-17       |
| 19.4.9           | Channel Priority Registers (CPRx) .....              | 19-18       |
| 19.4.10          | Channel Interrupt Status Register (CISR) .....       | 19-19       |
| 19.4.11          | TPU3 Module Configuration Register 2 (TPUMCR2) ..... | 19-19       |
| 19.4.12          | TPU Module Configuration Register 3 (TPUMCR3) .....  | 19-21       |
| 19.4.13          | SIU Test Register (SIUTST) .....                     | 19-22       |
| 19.4.14          | Factory Test Registers .....                         | 19-22       |
| 19.4.15          | TPU3 Parameter RAM .....                             | 19-23       |
| 19.5             | Time Functions .....                                 | 19-23       |

## Chapter 20 Dual-Port TPU3 RAM (DPTRAM)

|        |                                                     |      |
|--------|-----------------------------------------------------|------|
| 20.1   | Features .....                                      | 20-1 |
| 20.2   | DPTRAM Configuration Block Diagram .....            | 20-2 |
| 20.3   | Programming Model .....                             | 20-2 |
| 20.3.1 | DPTRAM Module Configuration Register (DPTMCR) ..... | 20-3 |
| 20.3.2 | DPTRAM Test Register (DPTTCR) .....                 | 20-4 |

# Contents

| Paragraph Number | Title                                                  | Page Number |
|------------------|--------------------------------------------------------|-------------|
| 20.3.3           | RAM Base Address Register (RAMBAR) .....               | 20-4        |
| 20.3.4           | MISR High (MISRH) and MISR Low Registers (MISRL) ..... | 20-5        |
| 20.3.5           | MISC Counter (MISCNT) .....                            | 20-6        |
| 20.4             | DPTRAM Operation .....                                 | 20-6        |
| 20.4.1           | Normal Operation .....                                 | 20-6        |
| 20.4.2           | Standby Operation .....                                | 20-6        |
| 20.4.3           | Reset Operation .....                                  | 20-7        |
| 20.4.4           | Stop Operation .....                                   | 20-7        |
| 20.4.5           | Freeze Operation .....                                 | 20-7        |
| 20.4.6           | TPU3 Emulation Mode Operation .....                    | 20-7        |
| 20.5             | Multiple Input Signature Calculator (MISC) .....       | 20-8        |

## Chapter 21 CDR3 Flash (UC3F) EEPROM

|          |                                                              |       |
|----------|--------------------------------------------------------------|-------|
| 21.0.1   | Features of the CDR3 Flash EEPROM (UC3F) .....               | 21-3  |
| 21.1     | UC3F Interface .....                                         | 21-4  |

| 23.5.1           | Freeze Indication .....                                             | 23-38       |
| 23.6             | Development Support Registers .....                                 | 23-39       |
| 23.6.1           | Register Protection .....                                           | 23-40       |
| 23.6.2           | Comparator A–D Value Registers (CMPA–CMPD) .....                    | 23-41       |
| 23.6.3           | Exception Cause Register (ECR) .....                                | 23-41       |
| 23.6.4           | Debug Enable Register (DER) .....                                   | 23-43       |
| 23.6.5           | Breakpoint Counter A Value and Control Register .....               | 23-45       |
| 23.6.6           | Breakpoint Counter B Value and Control Register .....               | 23-46       |
| 23.6.7           | Comparator E–F Value Registers (CMPE–CMPF) .....                    | 23-46       |
| 23.6.8           | Comparator G–H Value Registers (CMPG–CMPH) .....                    | 23-47       |
| 23.6.9           | L-Bus Support Control Register 1 .....                              | 23-47       |
| 23.6.10          | L-Bus Support Control Register 2 .....                              | 23-48       |
| 23.6.11          | I-Bus Support Control Register (ICTRL) .....                        | 23-51       |
| 23.6.12          | Breakpoint Address Register (BAR) .....                             | 23-53       |
| 23.6.13          | Development Port Data Register (DPDR) .....                         | 23-53       |

## Chapter 24 READI Module

|        |                                |      |
|--------|--------------------------------|------|
| 24.1   | Features Summary .....         | 24-1 |
| 24.1.1 | Functional Block Diagram ..... | 24-2 |
| 24.2   | Modes of Operation .....       | 24-3 |
| 24.2.1 | Reset Configuration .....      | 24-3 |

|------------------|--------------------------------------------------------------------|-------------|
| 24.2.2           | Security .....                                                     | 24-4        |
| 24.2.3           | Normal .....                                                       | 24-4        |
| 24.2.4           | Disabled .....                                                     | 24-4        |
| 24.3             | Parametrics .....                                                  | 24-4        |
| 24.4             | Messages .....                                                     | 24-4        |
| 24.5             | Terms and Definitions .....                                        | 24-6        |
| 24.6             | Programming Model .....                                            | 24-8        |
| 24.6.1           | Register Map .....                                                 | 24-8        |
| 24.6.1.1         | User-Mapped Register (OTR) .....                                   | 24-8        |
| 24.6.1.2         | Tool-Mapped Registers .....                                        | 24-9        |
| 24.6.1.3         | Device ID Register (DID) .....                                     | 24-9        |
| 24.6.1.4         | Development Control Register (DC) .....                            | 24-10       |
| 24.6.1.5         | Mode Control Register (MC) .....                                   | 24-11       |
| 24.6.1.6         | User Base Address Register (UBA) .....                             | 24-12       |
| 24.6.1.7         | Read/Write Access Register (RWA) .....                             | 24-13       |
| 24.6.1.8         | Upload/Download Information Register (UDI) .....                   | 24-15       |
| 24.6.1.9         | Data Trace Attributes 1 and 2 Registers (DTA1 and DTA2) .....      | 24-17       |
| 24.6.2           | Accessing Memory-Mapped Locations Via<br>the Auxiliary Port .....  | 24-18       |
| 24.6.3           | Accessing READI Tool Mapped Registers Via the Auxiliary Port ..... | 24-19       |
| 24.6.4           | Partial Register Updates .....                                     | 24-19       |
| 24.6.5           | Programming Considerations .....                                   | 24-20       |
| 24.6.5.1         | Program Trace Guidelines .....                                     | 24-20       |
| 24.6.5.2         | Compressed Code Mode Guidelines .....                              | 24-20       |
| 24.7             | Signal Interface .....                                             | 24-20       |
| 24.7.1           | Functional Description .....                                       | 24-21       |
| 24.7.1.1         | Signals Implemented .....                                          | 24-21       |
| 24.7.2           | Functional Block Diagram .....                                     | 24-22       |
| 24.7.3           | Message Priority .....                                             | 24-22       |
| 24.7.4           | Signal Protocol .....                                              | 24-23       |
| 24.7.5           | Messages .....                                                     | 24-24       |
| 24.7.5.1         | Message Formats .....                                              | 24-28       |
| 24.7.5.2         | Rules of Messages .....                                            | 24-31       |
| 24.7.5.3         | Branch Trace Message Examples .....                                | 24-32       |
| 24.7.5.3.1       | Example of Indirect Branch Message .....                           | 24-32       |
| 24.7.5.3.2       | Example of Direct Branch Message .....                             | 24-33       |
| 24.7.5.4         | Non-Temporal Ordering of Transmitted Messages .....                | 24-33       |
| 24.7.6           | READI Reset Configuration .....                                    | 24-34       |
| 24.7.7           | READI Signals .....                                                | 24-36       |
| 24.7.7.1         | Reset Configuration for Debug Mode .....                           | 24-36       |
| 24.7.7.2         | Reset Configuration for Non-Debug Mode .....                       | 24-37       |

|------------------|--------------------------------------------------------------------|-------------|
| 24.7.7.3         | Secure Mode .....                                                  | 24-37       |
| 24.7.7.4         | Disabled Mode .....                                                | 24-37       |
| 24.7.7.5         | Guidelines for Transmitting Input Messages .....                   | 24-37       |
| 24.8             | Program Trace .....                                                | 24-38       |
| 24.8.1           | Branch Trace Messaging .....                                       | 24-38       |
| 24.8.1.1         | RCPU Instructions that Cause BTM Messages .....                    | 24-38       |
| 24.8.2           | BTM Message Formats .....                                          | 24-38       |
| 24.8.2.1         | Direct Branch Messages .....                                       | 24-38       |
| 24.8.2.2         | Indirect Branch Messages .....                                     | 24-39       |
| 24.8.2.3         | Correction Messages .....                                          | 24-40       |
| 24.8.2.4         | Synchronization Messages .....                                     | 24-42       |
| 24.8.2.4.1       | Direct Branch Synchronization Message .....                        | 24-44       |
| 24.8.2.4.2       | Indirect Branch Synchronization Message .....                      | 24-44       |
| 24.8.2.4.3       | Direct Branch Synchronization Message With Compressed Code .....   | 24-44       |
| 24.8.2.4.4       | Indirect Branch Synchronization Message with Compressed Code ..... | 24-45       |
| 24.8.2.4.5       | Resource Full Message .....                                        | 24-45       |
| 24.8.2.5         | Error Messages .....                                               | 24-46       |
| 24.8.2.6         | Relative Addressing .....                                          | 24-46       |
| 24.8.3           | Queue Overflow Program Trace Error Message .....                   | 24-47       |
| 24.8.4           | Branch Trace Message Operation .....                               | 24-47       |
| 24.8.4.1         | BTM Capture and Encoding Algorithm .....                           | 24-47       |
| 24.8.4.2         | Instruction Fetch Snooping .....                                   | 24-48       |
| 24.8.4.3         | Instruction Execution Tracking .....                               | 24-48       |
| 24.8.4.4         | Instruction Flush Cases .....                                      | 24-48       |
| 24.8.5           | Branch Trace Message Queueing .....                                | 24-48       |
| 24.8.6           | BTM Timing Diagrams .....                                          | 24-49       |
| 24.8.7           | Program Trace Guidelines .....                                     | 24-51       |
| 24.9             | Data Trace .....                                                   | 24-52       |
| 24.9.1           | Data Trace for the Load/Store Bus (L-Bus) .....                    | 24-52       |
| 24.9.2           | Data Trace Message Formats .....                                   | 24-52       |
| 24.9.2.1         | Data Write Message .....                                           | 24-52       |
| 24.9.2.2         | Data Read Message .....                                            | 24-53       |
| 24.9.2.3         | Data Trace Synchronization Messages .....                          | 24-53       |
| 24.9.2.4         | Data Write Synchronization Message .....                           | 24-54       |
| 24.9.2.5         | Data Read Synchronization Messaging .....                          | 24-54       |
| 24.9.2.6         | Relative Addressing .....                                          | 24-54       |
| 24.9.3           | Queue Overflow Data Trace Error Message .....                      | 24-54       |
| 24.9.4           | Data Trace Operation .....                                         | 24-54       |
| 24.9.5           | Data Trace Windowing .....                                         | 24-56       |
| 24.9.6           | Special L-Bus Cases .....                                          | 24-56       |
| 24.9.7           | Data Trace Queuing .....                                           | 24-56       |

| C.3.3                             | IRAMSTBY Regulator Circuit.....                                        | C-7         |

## **Appendix D** **TPU3 ROM Functions**

|        |                                                         |      |
|--------|---------------------------------------------------------|------|
| D.1    | Overview.....                                           | D-1  |
| D.2    | Programmable Time Accumulator (PTA).....                | D-3  |
| D.3    | Queued Output Match TPU3 Function (QOM).....            | D-5  |
| D.4    | Table Stepper Motor (TSM).....                          | D-7  |
| D.5    | Frequency Measurement (FQM) .....                       | D-10 |
| D.6    | Universal Asynchronous Receiver/Transmitter (UART)..... | D-12 |
| D.7    | New Input Capture/Transition Counter (NITC).....        | D-15 |
| D.8    | Multiphase Motor Commutation (COMM) .....               | D-17 |
| D.9    | Hall Effect Decode (HALLD) .....                        | D-20 |
| D.10   | Multichannel Pulse-Width Modulation (MCPWM) .....       | D-22 |
| D.11   | Multi TPU (MULTI).....                                  | D-30 |
| D.12   | Fast Quadrature Decode TPU3 Function (FQD) .....        | D-35 |
| D.13   | Period/Pulse-Width Accumulator (PPWA).....              | D-38 |
| D.14   | ID TPU3 Function (ID).....                              | D-40 |
| D.15   | Output Compare (OC) .....                               | D-42 |
| D.16   | Pulse-Width Modulation (PWM).....                       | D-44 |
| D.17   | Discrete Input/Output (DIO).....                        | D-46 |
| D.18   | Synchronized Pulse-Width Modulation (SPWM).....         | D-48 |
| D.19   | Read/Write Timers and Pin TPU3 Function (RWTPIN) .....  | D-51 |
| D.20   | Serial Input/Output Port (SIOP) .....                   | D-53 |
| D.20.1 | Parameters.....                                         | D-53 |

# Contents

# About This Book

This manual describes the capabilities, operation, and function of the Freescale MPC561/MPC563 microcontrollers. The documentation follows the modular construction of the devices in the MPC500 family product line. Each microcontroller in the MPC500 family has a comprehensive reference manual that provides sufficient information for normal operation of the device. The reference manual is supplemented by module-specific reference manuals that provide detailed information about module operation and applications. Where information in this manual varies from information in other references, this manual takes precedence. Refer to [Suggested Reading](#) for further information.

Unless otherwise noted, references to the MPC561 and MPC563 also apply to their code compressed counterparts, the MPC562 and MPC564, respectively. Any functional differences between the MPC561/MPC563 and MPC562/MPC564 are noted. MPC562/MPC564-specific information is located in [Appendix A, “MPC562/MPC564 Compression Features.”](#)

## Audience

This manual is intended for system software and hardware developers and applications programmers who want to develop products for the MPC561/MPC563. It is assumed that the reader understands operating systems and microprocessor and microcontroller system design.

## Organization

Following is a summary and brief description of the major sections of this manual:

- [Chapter 1, “Overview,”](#) provides an overview of the MPC561/MPC563 microcontroller, including a block diagram showing the major modular components, a features list, and a summary of differences between the MPC561/MPC563 and the MPC555.
- [Chapter 2, “Signal Descriptions,”](#) describes the MPC561/MPC563 microcontroller’s external signals.
- [Chapter 3, “Central Processing Unit,”](#) describes the RISC processor (RCPU) used in the MPC500 family of microcontrollers.
- [Chapter 4, “Burst Buffer Controller 2 Module,”](#) describes the three main functional parts: the bus interface unit (BIU), the instruction memory protection unit (IMPU), and the instruction code decompressor unit (ICDU).
- [Chapter 5, “Unified System Interface Unit \(USIU\) Overview.”](#) The unified system interface unit (USIU) of the MPC561/MPC563 consists of several functional modules that control system start-up, system initialization and operation, system protection, and the external system bus.
- [Chapter 6, “System Configuration and Protection.”](#) The MPC561/MPC563 incorporates many system functions that normally must be provided in external circuits. In addition, it is designed to

provide maximum system safeguards against hardware and software faults. This chapter provides a detailed explanation of this functionality.

- [Chapter 7, “Reset.”](#) This section describes the MPC561/MPC563 reset sources, operation, control, and status.
- [Chapter 8, “Clocks and Power Control,”](#) describes the main timing and power control reference for the MPC561/MPC563.
- [Chapter 9, “External Bus Interface,”](#) describes the functionality of the MPC561/MPC563 external bus.
- [Chapter 10, “Memory Controller,”](#) generates interface signals to support a glueless interface to external memory and peripheral devices.
- [Chapter 11, “L-Bus to U-Bus Interface \(L2U\),”](#) describes the interface between the load/store bus (L-bus) and the unified bus (U-bus). The L2U module includes the Data Memory Protection Unit (DMPU), which provides protection for data memory accesses.
- [Chapter 12, “U-Bus to IMB3 Bus Interface \(UIMB\).”](#) The U-bus to IMB3 bus interface (UIMB) structure is used to connect the CPU internal unified bus (U-bus) to the intermodule bus 3 (IMB3). It controls bus communication between the U-bus and the IMB3.
- [Chapter 13, “QADC64E Legacy Mode Operation.”](#) The two queued analog-to-digital converter (QADC) modules on MPC561/MPC563 devices are 10-bit, unipolar, successive approximation converters. The modules can be configured to operate in one of two modes, legacy mode (MPC555 compatible) and enhanced mode. This chapter describes how the modules operate in legacy mode, which is the default mode of operation.
- [Chapter 14, “QADC64E Enhanced Mode Operation.”](#) The two queued analog-to-digital converter (QADC) modules on the MPC561/MPC563 devices are 10-bit, unipolar, successive approximation converters. The modules can be configured to operate in one of two modes, legacy mode (for MPC555 compatibility) and enhanced mode. This chapter describes how the module operates in enhanced mode.
- [Chapter 15, “Queued Serial Multi-Channel Module.”](#) The MPC561/MPC563 contains one queued serial multi-channel module (QSMCM) which provides three serial communication interfaces: the queued serial peripheral interface (QSPI) and two serial communications interfaces (SCI/UART). This chapter describes the functionality of each.
- [Chapter 16, “CAN 2.0B Controller Module,”](#) describes the three CAN 2.0B controller modules (TouCAN) implemented on the MPC561/MPC563. Each TouCAN is a communication controller that implements the Controller Area Network (CAN) protocol, an asynchronous communications protocol used in automotive and industrial control systems. It is a high speed (one Mbit/sec), short distance, priority based protocol that can run over a variety of mediums.
- [Chapter 17, “Modular Input/Output Subsystem \(MIOS14\).”](#) The modular I/O system (MIOS) consists of a library of flexible I/O and timer functions including I/O port, counters, input capture, output compare, pulse and period measurement, and PWM. Because the MIOS14 is composed of submodules, it is easily configurable for different kinds of applications.
- [Chapter 18, “Peripheral Pin Multiplexing \(PPM\) Module.”](#) The PPM functions as a parallel-to-serial communications module that reduces the number of signals required to connect

the MPC561/MPC563 to an external device; and shorts internal signals to increase access to multiple functions multiplexed on the same external signal.

- [Chapter 19, “Time Processor Unit 3,”](#) describes an enhanced version of the original TPU, an intelligent, semi-autonomous microcontroller designed for timing control.
- [Chapter 20, “Dual-Port TPU3 RAM \(DPTRAM\).”](#) The dual-port RAM (DPTRAM) module consists of a control register block and an 8-Kbyte array of static RAM that can be used either as microcode storage for the TPU3 or as general-purpose memory. The MPC561/MPC563 has one DPTRAM module that serves two TPU3 modules.
- [Chapter 21, “CDR3 Flash \(UC3F\) EEPROM.”](#) The MPC563 U-bus CDR3 (UC3F) EEPROM module is designed for use in embedded microcontroller applications targeted for high-speed read performance and high-density byte count requirements.
- [Chapter 22, “CALRAM Operation.”](#) This module provides the MPC561/MPC563 with a general purpose memory that may be read from or written to as either bytes, half-words, or words. In addition to this, a portion of the CALRAM, called the overlay region, can be used for calibration (i.e., overlaying portions of the U-bus Flash with a portion of the CALRAM array).
- [Chapter 23, “Development Support,”](#) covers program flow tracking support, breakpoint/watchpoint support, development system interface support (debug mode) and software monitor debugger support. These features allow efficiency in debugging systems based on the MPC561/MPC563.
- [Chapter 24, “READI Module.”](#) The READI module provides development support capabilities for MCUs in single chip mode, without requiring address and data signals for internal visibility.
- [Chapter 25, “IEEE 1149.1-Compliant Interface \(JTAG\),”](#) describes MPC561/MPC563 compatibility with the IEEE 1149.1 Standard Test Access Port and Boundary Scan Architecture as well as any potential incompatibility issues.
- [Appendix A, “MPC562/MPC564 Compression Features,”](#) includes information about code compression features of the MPC562/MPC564.
- [Appendix B, “Internal Memory Map,”](#) provides memory maps for the MPC561/MPC563 modules.
- [Appendix C, “Clock and Board Guidelines.”](#) The MPC561/MPC563 built-in PLL, oscillator, and other analog and sensitive circuits require that the board design follow special layout guidelines to ensure proper operation of the chip clocks. This appendix describes how the clock supplies and external components should be connected in a system.
- [Appendix D, “TPU3 ROM Functions,”](#) provides a brief description of the pre-programmed functions in the TPU3.
- [Appendix E, “Memory Access Timing,”](#) lists memory access timings for internal and external memory combinations.
- [Appendix F, “Electrical Characteristics,”](#) contains detailed information on power considerations, DC/AC electrical characteristics, and AC timing characteristics of the MPC561/MPC563 at the default 40 MHz and optional 56 MHz operating frequencies.
- [Appendix G, “66-MHz Electrical Characteristics,”](#) contains detailed information on power considerations, DC/AC electrical characteristics, and AC timing characteristics of the MPC561/MPC563 at the optional operating frequency of 66 MHz.

This document also includes a register index and comprehensive index.

## Suggested Reading

This section lists additional reading that provides background for the information in this manual as well as general information about the PowerPC™ architecture. Also listed are documents that further complement this manual by providing in-depth functional descriptions of certain modules:

- *QSM (Queued Serial Module) Reference Manual* (QSMRM/AD)
- TPU (Time Processor Unit) documentation (TPULITPAK/D, including the TPURM/AD)
- *RCPU (RISC Central Processor Unit) Reference Manual* (RCPURM/AD)
- Nexus Standard Specification Rev 1.0 (IEEE-ISTO 5001-1999) available at:  
<http://www.nexus5001.org/>
- JTAG IEEE 1149.1 Specification

The following general documentation, available through Morgan-Kaufmann Publishers, 340 Pine Street, Sixth Floor, San Francisco, CA, provides useful information about the PowerPC architecture:

- *The PowerPC Architecture: A Specification for a New Family of RISC Processors*, Second Edition, by International Business Machines, Inc.

Freescall documentation is available from the sources listed on the back cover of this manual. A brief summary of available documentation is listed below:

- *Programming Environments Manual for 32-Bit Implementations of the PowerPC Architecture* (MPCFPE32B/AD)—Describes resources defined by the PowerPC architecture.
- Reference manuals—These books provide details about individual implementations and are intended for use with the *Programming Environments Manual*.
- Addenda/errata to reference manuals—Because some processors have follow-on parts, an addendum is provided that describes the additional features and functionality changes and are intended for use with the corresponding reference manuals.
- Product Briefs—Each device has a product brief that provides an overview of its features. This document is roughly the equivalent to the overview chapter (Chapter 1) of an implementation's reference manual.
- *The Programmer's Reference Guide for the PowerPC Architecture* (MPCPRG/D)—This concise reference includes the register summary, exception vectors, and the PowerPC ISA instruction set.
- Application notes—These short documents address specific design issues useful to programmers and engineers working with Freescale processors.

Additional literature is published as new processors become available. For a current list of documentation, refer to <http://www.motorola.com/semiconductors>.

## Conventions and Nomenclature

This document uses the following notational conventions:

|             |                                                                                                                |
|-------------|----------------------------------------------------------------------------------------------------------------|
| cleared/set | When a bit takes the value zero, it is said to be cleared; when it takes a value of one, it is said to be set. |
|-------------|----------------------------------------------------------------------------------------------------------------|

|                                 |                                                                                                                                                                                                                                                                                                                                                                                                      |
|---------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ACTIVE_HIGH                     | Names for signals that are active high are shown in uppercase text. Signals that are active high are referred to as asserted when they are high and negated when they are low.                                                                                                                                                                                                                       |
| $\overline{\text{ACTIVE\_LOW}}$ | Names for signals that are active low are shown in uppercase text with an overbar. Active-low signals are referred to as asserted (active) when they are low and negated when they are high.                                                                                                                                                                                                         |
| 0x0                             | Prefix to denote hexadecimal number                                                                                                                                                                                                                                                                                                                                                                  |
| 0b0                             | Prefix to denote binary number                                                                                                                                                                                                                                                                                                                                                                       |
| <i>italics</i>                  | Italics indicate variable command parameters.<br>Book titles in text are also set in italics.                                                                                                                                                                                                                                                                                                        |
| REG[FIELD]                      | Abbreviations for registers are shown in uppercase. Specific bits, fields, or ranges appear in brackets. For example, CRAMMCR[DIS] identifies the array disable bit (DIS) within the CALRAM module configuration register.<br>A range of bits or signals is referred to by mnemonic and the numbers that define the range. For example, DATA[24:31] form the least significant byte of the data bus. |
| x                               | In some contexts, such as signal encodings, x indicates a don't care.                                                                                                                                                                                                                                                                                                                                |
| n                               | Used to express an undefined numerical value                                                                                                                                                                                                                                                                                                                                                         |
| ¬                               | NOT logical operator                                                                                                                                                                                                                                                                                                                                                                                 |
| &                               | AND logical operator                                                                                                                                                                                                                                                                                                                                                                                 |
|                                 | OR logical operator                                                                                                                                                                                                                                                                                                                                                                                  |
| Logic level one                 | is the voltage that corresponds to Boolean true (1) state.                                                                                                                                                                                                                                                                                                                                           |
| Logic level zero                | is the voltage that corresponds to Boolean false (0) state.                                                                                                                                                                                                                                                                                                                                          |
| To set a bit or bits            | means to establish logic level one on the bit or bits.                                                                                                                                                                                                                                                                                                                                               |
| To clear a bit or bits          | means to establish logic level zero on the bit or bits.                                                                                                                                                                                                                                                                                                                                              |
| LSB                             | means least significant bit or bits.                                                                                                                                                                                                                                                                                                                                                                 |
| MSB                             | means most significant bit or bits.                                                                                                                                                                                                                                                                                                                                                                  |
| Asserted                        | means that a signal is in active logic state. An active low signal changes from logic level one to logic level zero when asserted, and an active high signal changes from logic level zero to logic level one.                                                                                                                                                                                       |
| Negated                         | means that an asserted signal changes logic state. An active low signal changes from logic level zero to logic level one when negated, and an active high signal changes from logic level one to logic level zero.                                                                                                                                                                                   |

## Notational Conventions

Table i contains notational conventions that are used in this document.

**Table i. Notational Conventions**

| Symbol | Function                                   |
|--------|--------------------------------------------|
| +      | Addition                                   |
| −      | Subtraction (two's complement) or negation |
| *      | Multiplication                             |
| /      | Division                                   |
| >      | Greater                                    |
| <      | Less                                       |
| =      | Equal                                      |
| ≥      | Equal or greater                           |
| ≤      | Equal or less                              |
| ≠      | Not equal                                  |
| •      | AND                                        |
|        | Inclusive OR (OR)                          |
| ⊕      | Exclusive OR (EOR)                         |
| NOT    | Complementation                            |
| :      | Concatenation                              |
| ?      | Transferred                                |
| ↔      | Exchanges                                  |
| ±      | Sign bit; also used to show tolerance      |
| «      | Sign extension                             |

## Acronyms and Abbreviations

Table ii contains acronyms and abbreviations that are used in this document.

**Table ii. Acronyms and Abbreviated Terms**

| Term  | Meaning                                    |
|-------|--------------------------------------------|
| ALU   | Arithmetic logic unit                      |
| BIST  | Built-in self test                         |
| BIU   | Bus interface unit                         |
| BPU   | Branch processing unit                     |
| BSDL  | Boundary-scan description language         |
| CMOS  | Complementary metal-oxide semiconductor    |
| EA    | Effective address                          |
| EAR   | External access register                   |
| FIFO  | First-in-first-out                         |
| FPR   | Floating-point register                    |
| FPSCR | Floating-point status and control register |

**Table ii. Acronyms and Abbreviated Terms (continued)**

| Term  | Meaning                                                                                      |
|-------|----------------------------------------------------------------------------------------------|
| FPU   | Floating-point unit                                                                          |
| GPR   | General-purpose register                                                                     |
| IABR  | Instruction address breakpoint register                                                      |
| IEEE  | Institute for Electrical and Electronics Engineers                                           |
| IU    | Integer unit                                                                                 |
| JTAG  | Joint Test Action Group                                                                      |
| LIFO  | Last-in-first-out                                                                            |
| LR    | Link register                                                                                |
| LSB   | Least-significant bit                                                                        |
| LSU   | Load/store unit                                                                              |
| MSB   | Most-significant bit                                                                         |
| MSR   | Machine state register                                                                       |
| NaN   | Not a number                                                                                 |
| No-op | No operation                                                                                 |
| OEA   | Operating environment architecture                                                           |
| PLL   | Phase-locked loop                                                                            |
| POR   | Power-on reset                                                                               |
| PVR   | Processor version register                                                                   |
| RISC  | Reduced instruction set computing                                                            |
| SPR   | Special-purpose register                                                                     |
| SRR0  | Machine status save/restore register 0                                                       |
| SRR1  | Machine status save/restore register 1                                                       |
| TB    | Time base facility                                                                           |
| TBL   | Time base lower register                                                                     |
| TBU   | Time base upper register                                                                     |
| TLB   | Translation lookaside buffer                                                                 |
| TTL   | Transistor-to-transistor logic                                                               |
| UIMM  | Unsigned immediate value                                                                     |
| UISA  | User instruction set architecture                                                            |
| VEA   | Virtual environment architecture                                                             |
| XER   | Register used for indicating conditions such as carries and overflows for integer operations |

# Chapter 1

## Overview

This chapter provides an overview of the MPC561/MPC563 microcontrollers, including a block diagram showing the major modular components and sections that list the major features, and differences between the MPC561/MPC563 and the MPC555. The MPC561, MPC562, MPC563, and MPC564 devices are members of the Freescale MPC500 RISC Microcontroller family. The parts herein will be referred to only as MPC561/MPC563 unless specific parts need to be referenced.

**Table 1-1. MPC56x Family Features**

| Device | Flash            | Code Compression |
|--------|------------------|------------------|
| MPC561 | None             | Not Supported    |
| MPC562 | None             | Supported        |
| MPC563 | 512-Kbytes Flash | Not Supported    |
| MPC564 | 512-Kbytes Flash | Supported        |

### 1.1 Introduction

The MPC561/MPC563 devices offer the following features:

- PowerPC ISA-compliant 32-bit single issue RISC processor (RCPU)
- 64-bit floating-point unit (FPU)
- Unified system integration unit (USIU) with a flexible memory controller and enhanced interrupt controller (EIC)
- 512-Kbytes of Flash EEPROM memory (available on the MPC563 only)
  - Typical endurance of 100,000 write/erase cycles @ 25°C
  - Typical data retention of 100 years @ 25°C
- 32-Kbytes of static RAM in one CALRAM module, configured as
  - 28-Kbyte normal access only array
  - 4-Kbyte normal access or overlay access array (eight 512-byte regions)
- Two time processing units (TPU3) with one 8-Kbyte dual port TPU RAM (DPTRAM)
- One 22-timer channel modular I/O system (MIOS14)
- Three TouCAN modules (TouCAN)
- Two enhanced queued analog systems (QADC64E)
- One queued serial multi-channel module (QSMCM), which contains one queued serial peripheral interface (QSPI) and two serial controller interfaces (SCI/UART)
- One peripheral pin multiplexing module (PPM) with a parallel to serial driver

- Debug features:
  - Nexus debug port (Class 3)
  - Background debug mode (BDM)
  - IEEE 1194.1-compliant interface (JTAG) for boundary scan
- Plastic ball grid array (PBGA) packaging
  - 388 ball PBGA
  - 27 mm x 27 mm body size
  - 1.0 mm ball pitch
- Default 40-, and optional 56-, and 66-MHz operation
- -40°C–125°C
- Independent power supplies
  - 5-V I/O ( $5.0 \pm 0.25$  V)
  - $2.6 \pm 0.1$ -V external bus with a 5-V tolerant I/O system
  - $2.6 \pm 0.1$ -V internal logic
  - <150μA on-chip voltage shunt regulator for RAM standby operation

## 1.2 Block Diagram

Figure 1-1 is a block diagram of the MPC561/MPC563.

Figure 1-1. MPC561/MPC563 Block Diagram

## 1.3 Key Features

The MPC561/MPC563 key features are explained in the following sections.

### 1.3.1 High-Performance CPU System

- Fully static design
- Four major power saving modes
  - On, doze, sleep, deep-sleep, and power-down

### 1.3.1.1 RISC MCU Central Processing Unit (RCPU)

- PowerPC™-compliant 32-bit single issue core
- Precise exception model
- 64-bit floating point unit (FPU)
- Code compression supported on MPC562/MPC564
- Reduces usage of internal/external Flash memory (up to 50% for code) on the MPC564
- Reduces code size up to 50%
- Extensive system development support
- On-chip watchpoints and breakpoints
- Program flow tracking capability

### 1.3.1.2 Unified System Interface Unit (USIU)

- System configuration and protection features:
  - Periodic-interrupt timer
  - Bus monitor
  - Software watchdog timer
  - Real-time clock (RTC)
  - PPC decrementer
  - Time base
- Clock synthesizer
- Power management
- Reset controller
- External bus interface that tolerates 5-V inputs, provides 2.6-V outputs, and supports multi-master designs
- Enhanced interrupt controller that supports up to eight external and 40 internal interrupts, simplifies the interrupt structure, and decreases interrupt processing time
- USIU supports dual mapping to map part of one internal/external memory to another external memory
- External bus, supporting non-wraparound burst for instruction fetches, with up to 8 instructions per memory cycle

### 1.3.1.3 Burst Buffer Controller (BBC) Module

- Support for enhanced interrupt controller (EIC)
- Support for enhanced exception table relocation feature
- Branch target buffer
- Contains 2 Kbytes of decompression RAM (DECRAM) for code compression. This RAM may also be used as general-purpose RAM when the code compression feature is not used.

#### 1.3.1.4 Flexible Memory Protection Unit

- Flexible memory protection units (MPU) in BBC and L2U
- Default attributes available in one global entry
- Attribute support for speculative accesses
- Up to eight memory regions are supported, four for data and four for instructions

#### 1.3.1.5 Memory Controller

- Four flexible chip selects via memory controller
- 32-bit address and data buses
- 4-Kbyte to one 16-Mbyte (data) or 4-Gbyte (instruction) region size support
- Supports enhanced external burst
  - Up to eight-beat transfer bursts, two-clock minimum bus transactions
- Use with SRAM, EPROM, Flash and other peripherals
- Byte selects or write enables
- 32-bit address fully decodes internal address space (4 Gbytes) with bit masks
- Four regions

#### 1.3.1.6 512-Kbytes of CDR3 Flash EEPROM Memory (UC3F) – MPC563/MPC564 Only

- One 512-Kbyte module
- Page read mode (2/1/1/1 clock read access time)
- Byte, half-word or word programmable.
- Block (64 Kbytes) erasable
- External 4.75- to 5.25-V VFLASH power supply for program, erase, and read operations
- Security modes for software protection
- Typical endurance of 100,000 write/erase cycles @ 25°C
- Typical data retention of 100 years @ 25°C

### 1.3.1.7 32-Kbyte Static RAM (CALRAM)

- Composed of one 32-Kbyte CALRAM module
  - 28-Kbyte static RAM
  - 4-Kbyte calibration (overlay) RAM feature that allows calibration of Flash-based constants
- Eight 512-byte overlay regions
- One clock fast accesses
- Two clock cycle access option for power saving
- Standby power supply (IRAMSTBY) for data retention

### 1.3.1.8 General Purpose I/O Support (GPIO)

- 24 address signals and 32 data signals can be used for general-purpose I/O in single-chip mode
- 16 GPIO in MIOS14
- Many peripheral signals can be used as GPIO when not used as primary functions
- 5-V outputs with slew rate control

## 1.3.2 Nexus Debug Port (Class 3)

- Compliant with Class 3 of the IEEE-ISTO 5001-1999
- Program trace via branch trace messaging (BTM)
- Data trace via data write messaging (DWM) and data read messaging (DRM)
- Ownership trace via ownership trace messaging (OTM)
- Run-time access to on-chip memory map and special-purpose registers (SPRs) via the READI read/write access protocol
- Watchpoint messaging via the auxiliary port
- 9 or 16 full-duplex auxiliary pin interface for medium and high visibility throughput
- All features configurable and controllable via the auxiliary port
- Supports the RCPU debug mode via the auxiliary port

## 1.3.3 Integrated I/O System

### 1.3.3.1 Two Time Processor Units (TPU3)

- True 5 V I/O
- Two time processing units (TPU3) with 16 channels each
- Each TPU3 is a micro-coded timer subsystem
- 8 Kbytes of dual port TPU RAM (DPTRAM) shared by two TPU3 modules for TPU micro-code

### 1.3.3.2 22-Channel Modular I/O System (MIOS14)

- Six modulus counter sub-modules (MCSM)
- 10 double-action sub-modules (DASM)

- 12 dedicated PWM sub-modules (PWMSM)
- One MIOS14 16-bit parallel port I/O sub-modules (MPIOSM)

### 1.3.3.3 Two Enhanced Queued Analog-to-Digital Converter Modules (QADC64E)

- Two queued analog-to-digital converter modules (QADC64E\_A, QADC64E\_B) providing a total of 32 analog channels
- 16 analog input channels on each QADC64E module using internal multiplexing
- Directly supports up to four external multiplexers
- Up to 41 total input channels on the two QADC64E modules with external multiplexing
- Software configurable to operate in enhanced or legacy (MPC555 compatible) mode
- Unused analog channels can be used as digital input/output signals
  - GPIO on all channels in enhanced mode
- 10-bit A/D converter with internal sample/hold
- Minimum conversion time of 7  $\mu$ s (with typical QCLK frequency, 2 MHz) and +/- 2 bits accuracy
- Two conversion command queues of variable length
- Automated queue modes initiated by:
  - External edge trigger
  - Software command
  - Periodic/interval timer within the QADC64E module, that can be assigned to both queue 1 and 2
  - External gated trigger (queue 1 only)
- 64 result registers
  - Output data is right- or left-justified, signed or unsigned.
- Alternate reference input (ALTREF), with control in the conversion command word (CCW)

### 1.3.3.4 Three CAN 2.0B Controller (TouCAN) Modules

- Three TouCAN modules (TouCAN\_A, TouCAN\_B, TouCAN\_C)
- Each TouCAN provides the following features:
  - 16 message buffers, programmable I/O modes
  - Maskable interrupts
  - Independent of the transmission medium (external transceiver is assumed)
  - Open network architecture, multi-master concept
  - High immunity to EMI
  - Short latency time for high-priority messages
  - Low-power sleep mode, with programmable wake-up on bus activity
  - TouCAN\_C pins are shared with MIOS14 GPIO or QSMCM

### 1.3.3.5 Queued Serial Multi-Channel Module (QSMCM)

- One queued serial module with one queued SPI and two SCIs (QSMCM)
- QSMCM matches full MPC555 QSMCM functionality
- Queued SPI
  - Provides full-duplex communication port for peripheral expansion or inter-processor communication
  - Up to 32 preprogrammed transfers, reducing overhead
  - Synchronous serial interface with baud rate of up to system clock / 4
  - Four programmable peripheral-selects signals:
  - Supports up to 16 devices with external decoding
  - Supports up to eight devices with internal decoding
  - Special wrap-around mode allows continuous sampling of a serial peripheral for efficient interfacing to serial analog-to-digital (A/D) converters
- SCI
  - UART mode provides NRZ format and half- or full-duplex interface
  - 16 register receive buffers and 16 register transmit buffers on one SCI
  - Advanced error detection and optional parity generation and detection
  - Word-length programmable as eight or nine bits
  - Separate transmitter and receiver enable bits, and double buffering of data
  - Wake-up functions allow the CPU to run uninterrupted until either a true idle line is detected, or a new address byte is received

### 1.3.3.6 Peripheral Pin Multiplexing (PPM)

- Synchronous serial interface between the microprocessor and an external device
- Four internal parallel data sources can be multiplexed through the PPM
  - TPU3\_A: 16 channels
  - TPU3\_B: 16 channels
  - MIOS14: 12 PWM channels, four MDA channels
  - Internal GPIO: 16 general-purpose inputs, 16 general-purpose outputs
- Software configurable stream size
- Software configurable clock (TCLK) based on system clock
- Software selectable clock modes (SPI mode and TDM mode)
- Software selectable operation modes
  - Continuous mode
  - Start-transmit-receive (STR) mode
- Software configurable internal modules interconnect (shorting)

## 1.4 MPC561/MPC563 Optional Features

The following features of the MPC561/MPC563 are optional features and may not appear in certain configurations:

- 56- or 66-MHz operation (40 MHz is default)
- Code compression (available on MPC562 and MPC564 only)
- 512 Kbytes Flash (available on MPC563 and MPC564 only)

## 1.5 Comparison of MPC561/MPC563 and MPC555

In [Table 1-2](#), the MPC555 is used as a baseline to compare the high level differences from an early device offering in the MPC500 family to the MPC561/MPC563.

**Table 1-2. Differences Between MPC555 and MPC561/MPC563**

| Module   | MPC555                                                | MPC561/MPC563                                                                                                           |
|----------|-------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------|
| CPU Core | Identical                                             |                                                                                                                         |
| BBC      | Basic                                                 | Enhanced Code Compression (classes scheme with 2 Kbytes DECRAM)<br>Code Compression is available only on MPC562/MPC564. |
| L2U      | Identical                                             |                                                                                                                         |
| SRAM     | 26 Kbytes                                             | 32 Kbytes calibration SRAM with overlay features                                                                        |
| Flash    | 448-Kbyte CMF<br>(2 modules, 256-Kbyte and 192-Kbyte) | 512-Kbyte UC3F (1 module) on MPC563 only.<br>No Flash on MPC561                                                         |
| USIU     | Basic                                                 | Enhanced Interrupt Controller                                                                                           |
| JTAG     | Selectable by RCW                                     | Selectable at $\overline{\text{PORESET}}$                                                                               |
| READI    | None                                                  | New Module (Class 3 Nexus IEEE-ISTO 5001-1999)                                                                          |
| UIMB     | Identical                                             |                                                                                                                         |

**Table 1-2. Differences Between MPC555 and MPC561/MPC563 (continued)**

| Module | MPC555                          | MPC561/MPC563 |
|--------|---------------------------------|---------------|
| TouCAN | (2) Identical (3)               |               |
| TPU3   | (2) Identical (2)               |               |
| DPTRAM | (6 Kbytes) Identical (8 Kbytes) |               |
| PPM    | —                               | New Module    |

## 1.6 Additional MPC561/MPC563 Differences

- The MPC561/MPC563 devices are very similar to the MPC555 with the following differences:
  - Up to 66 MHz operating frequency (Refer to the applicable electrical characteristics document for more information.)
  - CDR3 technology
  - Two power supplies: 5.0-V I/O, 2.6-V external bus signals, 2.6-V internal logic
  - New modules: READI, CALRAM, PPM
  - Extra TouCAN module, additional 6 Kbytes of SRAM on L-bus (32 Kbytes total) with CALRAM overlay features, extra 2 Kbytes of DPTRAM (8 Kbytes total)
- QADC64E
  - GPO on all channel signals in addition to GPI functions
- TouCAN, TPU3, QSMCM, UIMB, Core, L2U
  - No changes
- BBC2
  - Enhanced interrupt controller support
  - Enhanced exception relocation table
  - Branch target buffer
  - 2 Kbytes of decompression RAM for code compression. This may also be used as general-purpose RAM while not used for code compression.
- CALRAM (with overlay features)
  - New module
  - Overlay features allow calibration of Flash-based constants
- UC3F (U-bus CDR3 Flash module) on MPC563/MPC564 only
  - 512 Kbytes of non-volatile memory (NVM)
  - Designed for use in embedded microcontroller (MCU) applications targeted for high speed read performance and high density byte count requirements
- READI
  - New module
- USIU
  - Enhanced interrupt controller
  - ENGCLK default frequency

- READI support
- Reduced data setup time
- Enhanced external burst support
- MIOS14
  - Four additional PWM channels
  - Four additional MCSM timers
- DPTRAM (8 Kbytes)
  - No functional changes
- PPM (peripheral pin multiplexing)
  - New module
  - Four-to-one multiplexing
  - Parallel-to-serial driver (SPI and TDM)

## 1.7 SRAM Keep-Alive Power Behavior

The IRAMSTBY pin provides keep-alive power to RAM when the main power supply is shut down. The IRAMSTBY pin can be powered directly from a battery using an internal shunt regulator or via a small battery for standby use. See [Figure 1-2](#).

**Figure 1-2. Recommended Connection Diagram for IRAMSTBY**

While power is off, the IRAMSTBY supply powers the following:

- 32-Kbyte CALRAM
- 8-Kbyte DPTRAM module
- 2-Kbyte BBC DECRAM module

### NOTE

IRAMSTBY must always be supplied with at least 50μA for correct operation.

## 1.8 MPC561/MPC563 Address Map

The internal memory map is organized as a single 4-Mbyte block. The user can assign this block to one of eight locations by programming a register in the USIU (IMMR[ISB]). The eight possible locations are the

first eight 4-Mbyte memory blocks starting with address 0x0000 0000 (refer to [Figure 1-3](#)). The programmability of the internal memory map location allows the user to implement a multiple-chip system.

**Figure 1-3. MPC561/MPC563 Memory Map**

The internal memory space is divided into the following sections. Refer to [Figure 1-4](#).

- Flash memory (512-Kbytes)
- CALRAM static RAM memory (32-Kbytes)
- Control registers and IMB3 modules (64 Kbytes)
  - BBC control registers (16-Kbytes)
  - USIU and Flash control registers (16-Kbytes)
  - UIMB interface and IMB3 modules (32-Kbytes)
  - CALRAM/READI control registers (256-bytes)

**Figure 1-4. MPC561/MPC563 Internal Memory Map**

## 1.9 Supporting Documentation List

This list contains references to currently available and planned documentation.

- *MPC555 User's Manual* (MPC555UM/AD)
- *RCPU Reference Manual* (RCPURM/AD)
- Nexus Standard Specification (non-Freescale document) available at: <http://www.nexus5001.org/>
- IEEE 1149.1 Specification (non-Freescale document)

## Chapter 2

# Signal Descriptions

This chapter describes the MPC561/MPC563 microcontroller's external signals. It contains a description of individual signals, shows their behavior, shows whether the signal is an input or an output, and indicates signal multiplexing.

### NOTE

A bar over a signal name indicates that the signal is active-low—for example,  $\overline{TA}$  (transfer acknowledge). Active-low signals are referred to as asserted (active) when they are low and negated when they are high. Signals that are not active-low, such as ADDR[8:31] (address bus signals) and DATA[0:31] (data bus signals) are referred to as asserted when they are high and negated when they are low.

Refer to [Appendix F, “Electrical Characteristics,”](#) and [Appendix G, “66-MHz Electrical Characteristics,”](#) for detailed electrical information for each signal.

## 2.1 Signal Groupings

[Figure 2-1](#) illustrates the external signals of the MPC561/MPC563 grouped by functional module.

**Figure 2-1. MPC561/MPC563 Signal Groupings**

## 2.2 Signal Summary

Table 2-1 describes individual MPC561/MPC563 signals, grouped by functional module.

**Table 2-1. MPC561/MPC563 Signal Descriptions**

| Signal Name                | No. of Signals | Type | Function after Reset <sup>1</sup>      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|----------------------------|----------------|------|----------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Bus Interface</b>       |                |      |                                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| ADDR[8:31] / SGPIOA[8:31]  | 24             | I/O  | Controlled by RCW[SC]. See Table 6-10. | Address Bus [8:31]. Specifies the physical address of the bus transaction. The address is driven onto the bus and kept valid until a transfer acknowledge is received from the slave. ADDR8 is the MSB for this bus.                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|                            |                | I/O  |                                        | Port SGPIOA[8:31]. Allows the signals to be used as general-purpose inputs/outputs.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| DATA[0:31] / SGPIOD[0:31]  | 32             | I/O  | Controlled by RCW[SC]. See Table 6-10. | Data Bus [0:31]. Provides the general-purpose data path between the MPC561/MPC563 and all other devices. Although the data path is a maximum of 32 bits wide, it can be sized to support 8-, 16-, or 32-bit transfers. DATA0 is the MSB of the data bus.                                                                                                                                                                                                                                                                                                                                                                                                           |
|                            |                | I/O  |                                        | Port SGPIOD[0:31]. Allows the signals to be used as general-purpose inputs/outputs.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| TSIZ[0:1]                  | 2              | I/O  | TSIZ[0:1]                              | Transfer Size [0:1]. Indicates the size of the requested data transfer in the current bus cycle.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| RD/ $\overline{\text{WR}}$ | 1              | I/O  | RD/ $\overline{\text{WR}}$             | Read/Write. Indicates the direction of the data transfer for a transaction. A logic one indicates a read from a slave device; a logic zero indicates a write to a slave device.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| $\overline{\text{BURST}}$  | 1              | I/O  | $\overline{\text{BURST}}$              | Burst Indicator. Driven by the bus master to indicate that the currently initiated transaction is a burst.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| $\overline{\text{BDIP}}$   | 1              | I/O  | $\overline{\text{BDIP}}$               | Burst Data In Progress. Indicates to the slave that there is a data beat following the current data beat.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| $\overline{\text{TS}}$     | 1              | I/O  | $\overline{\text{TS}}$                 | Transfer Start. Indicates the start of a bus cycle that transfers data to/from a slave device. This signal is driven by the master only when it has gained ownership of the bus. Every master should negate this signal before relinquishing the bus. This is an active-low signal and needs an external pull-up resistor to ensure proper operation and meet signal timing specifications.                                                                                                                                                                                                                                                                        |
| $\overline{\text{TA}}$     | 1              | I/O  | $\overline{\text{TA}}$                 | Transfer Acknowledge. This line indicates that the slave device addressed in the current transaction has accepted the data transferred by the master (write) or has driven the data bus with valid data (read). The slave device negates the $\overline{\text{TA}}$ signal after the end of the transaction. The slave device will then immediately three-state the $\overline{\text{TA}}$ signal to prevent contention on the line in case a new transfer that addresses another slave device(s) is initiated. This signal is an active-low signal and needs an external pull-up resistor to ensure proper operation and conform to signal timing specifications. |

Table 2-1. MPC561/MPC563 Signal Descriptions (continued)

| Signal Name                                    | No. of Signals | Type | Function after Reset <sup>1</sup>                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|------------------------------------------------|----------------|------|--------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $\overline{\text{TEA}}$                        | 1              | I/O  | $\overline{\text{TEA}}$                          | Transfer Error Acknowledge. This signal indicates that a bus error occurred in the current transaction. The MPC561/MPC563 asserts this signal when the bus monitor does not detect a bus cycle termination within 2040 clock cycles. The assertion of $\overline{\text{TEA}}$ causes the termination of the current bus cycle, regardless of the state of $\overline{\text{TA}}$ . An external pull-up device is required to negate $\overline{\text{TEA}}$ quickly, before a second error is detected. That is, the signal must be pulled up within one clock cycle of the time it was three-stated by the MPC561/MPC563. |
| $\overline{\text{OE}}$                         | 1              | O    | $\overline{\text{OE}}$                           | Output Enable. This output line is asserted when a read access is initiated by the MPC561/MPC563 to an external slave controlled by the memory controller's GPCM.                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| $\overline{\text{RSTCONF}} / \text{TEXP}$      | 1              | I    | $\overline{\text{RSTCONF}}$ until reset negates. | Reset Configuration. This input line is sampled by the MPC561/MPC563 during the assertion of the $\overline{\text{HRESET}}$ signal in order to sample the reset configuration. If the line is asserted, the configuration mode is sampled from the external data bus. When this line is negated, the configuration mode adopted by the MPC561/MPC563 is either the internal default or read from the internal Flash (MPC563 only).                                                                                                                                                                                         |
|                                                |                | O    |                                                  | Timer Expired. This output line reflects the status of PLPRCR[TEXPS] in the USIU. This bit indicates an expired timer value.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| $\overline{\text{BI}} / \overline{\text{STS}}$ | 1              | I/O  | Controlled by RCW[DBGC]. See Table 6-8.          | Burst Inhibit. This bidirectional, active-low, three-state signal indicates that the slave device addressed in the current burst transaction is not able to support burst transfers. When the MPC561/MPC563 drives out the signal for a specific transaction, it asserts or negates $\overline{\text{BI}}$ according to the value specified in the appropriate control registers. The signal is negated after the end of the transaction and then is immediately three-stated. This is an active-low signal and needs an external pull-up resistor to ensure proper operation and signal timing specifications.            |
|                                                |                | O    |                                                  | Special Transfer Start. This output signal is driven by the MPC561/MPC563 to indicate the start of a transaction on the external bus or signals the beginning of an internal transaction in show cycle mode.                                                                                                                                                                                                                                                                                                                                                                                                               |

Table 2-1. MPC561/MPC563 Signal Descriptions (continued)

| Signal Name                                                                             | No. of Signals | Type | Function after Reset <sup>1</sup>                                                                                | Description                                                                                                                                                                                                                                    |
|-----------------------------------------------------------------------------------------|----------------|------|------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Interrupt Controller</b>                                                             |                |      |                                                                                                                  |                                                                                                                                                                                                                                                |
| $\overline{\text{IRQ0}}$ / SGPIOC0 / MDO4                                               | 1              | I    | MDO4 if the Nexus (READI) port is enabled, $\overline{\text{IRQ0}}$ otherwise. See <a href="#">Section 2.5</a> . | Interrupt Request 0. One of the eight external signals that can request, by means of the internal interrupt controller, a service routine from the RCPU. $\overline{\text{IRQ0}}$ is a non-maskable interrupt (NMI).                           |
|                                                                                         |                | I/O  |                                                                                                                  | Port SGPIOC0. Allows the signal to be used as a general-purpose input/output.                                                                                                                                                                  |
|                                                                                         |                | O    |                                                                                                                  | READI Message Data Out. Message data out (MDO4) are output signals used for uploading OTM, BTM, DTM, and read/write accesses. External latching of MDO occurs on rising edge of MCKO. Eight signals are implemented.                           |
| $\overline{\text{IRQ1}}$ / $\overline{\text{RSV}}$ / SGPIOC1                            | 1              | I    | $\overline{\text{IRQ1}}$                                                                                         | Interrupt Request 1. One of the eight external signals that can request, by means of the internal interrupt controller, a service routine from the RCPU.                                                                                       |
|                                                                                         |                | O    |                                                                                                                  | Reservation. This signal is used, together with the address bus, to indicate that the internal core initiated a transfer as a result of a STWCX or a LWARX instruction.                                                                        |
|                                                                                         |                | I/O  |                                                                                                                  | Port SGPIOC1. Allows the signal to be used as a general-purpose input/output.                                                                                                                                                                  |
| $\overline{\text{IRQ2}}$ / $\overline{\text{CR}}$ / SGPIOC2 / MTS <sup>2</sup>          | 1              | I    | $\overline{\text{IRQ2}}$                                                                                         | Interrupt Request 2. One of the eight external signals that can request, by means of the internal interrupt controller, a service routine from the RCPU.                                                                                       |
|                                                                                         |                | I    |                                                                                                                  | Cancel Reservation. Instructs the MPC561/MPC563 to clear its reservation because some other master has touched its reserved space. An external bus snooper asserts this signal.                                                                |
|                                                                                         |                | I/O  |                                                                                                                  | Port SGPIOC2. Allows the signal to be used as a general-purpose input/output.                                                                                                                                                                  |
|                                                                                         |                | O    |                                                                                                                  | Memory Transfer Start. This is the transfer start signal from the MPC561's memory controller that allows external memory access by an external bus master.                                                                                     |
| $\overline{\text{IRQ3}}$ / $\overline{\text{KR}}$ / $\overline{\text{RETRY}}$ / SGPIOC3 | 1              | I    | $\overline{\text{IRQ3}}$                                                                                         | Interrupt Request 3. One of the eight external signals that can request, by means of the internal interrupt controller, a service routine from the RCPU.                                                                                       |
|                                                                                         |                | I/O  |                                                                                                                  | Kill Reservation. In case of a bus cycle initiated by a STWCX instruction issued by the RCPU core to a non-local bus on which the storage reservation has been lost, this signal is used by the non-local bus interface to back-off the cycle. |
|                                                                                         |                | I/O  |                                                                                                                  | Retry. Indicates to a master that the cycle is terminated but should be repeated. As an input, it is driven by the external slave to retry a cycle.                                                                                            |
|                                                                                         |                | I/O  |                                                                                                                  | Port SGPIOC3. Allows the signal to be used as a general-purpose input/output.                                                                                                                                                                  |

Table 2-1. MPC561/MPC563 Signal Descriptions (continued)

| Signal Name                                                         | No. of Signals | Type | Function after Reset <sup>1</sup>                                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

|                                                      |                | O    |                                                      | Program Trace. Indicates an instruction fetch is taking place (for program flow tracking).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| SGPIOC7 / $\overline{\text{IRQOUT}}$ / LWP0          | 1              | I/O  | LWP0                                                 | Port SGPIOC7. Allows the signal to be used as general-purpose inputs/outputs.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|                                                      |                | O    |                                                      | Interrupt Out. Indicates that an interrupt has been requested to all external devices.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|                                                      |                | O    |                                                      | Load/Store Watchpoint 0. This output signal reports the detection of a data watchpoint in the program flow executed by the RCPU. See <a href="#">Chapter 23, “Development Support,”</a> for more details.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

Table 2-1. MPC561/MPC563 Signal Descriptions (continued)

| Signal Name                  | No. of Signals | Type | Function after Reset <sup>1</sup>       | Description                                                                                                                                                                                                                                                                                                                       |
|------------------------------|----------------|------|-----------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $\overline{BG}$ / VF0 / LWP1 | 1              | I/O  | Controlled by RCW[DBGC]. See Table 6-8. | Bus Grant. Indicates external bus status. $\overline{BG}$ is asserted low when the external bus arbiter grants ownership of the external bus to a specific master. This is an active-low signal and needs an external pull-up resistor to ensure proper operation and meet signal timing specifications.                          |
|                              |                | O    |                                         | Visible Instruction Queue Flush Status 0. This output signal together with VF1 and VF2 is output by the MPC561/MPC563 when program instruction flow tracking is required. VFs report the number of instructions flushed from the instruction queue in the internal core. See Chapter 23, "Development Support," for more details. |
|                              |                | O    |                                         | Load/Store Watchpoint 1. This output signal reports the detection of a data watchpoint in the program flow executed by the RCPU.                                                                                                                                                                                                  |
| $\overline{BR}$ / VF1 / IWP2 | 1              | I/O  | Controlled by RCW[DBGC]. See Table 6-8. | Bus Request. Indicates that the external bus has been requested for external cycle. This is an active-low signal and needs an external pull-up resistor to ensure proper operation and meet signal timing specifications.                                                                                                         |
|                              |                | O    |                                         | Visible Instruction Queue Flush Status 1. This output signal together with VF0 and VF2 is output by the MPC561/MPC563 when program instruction flow tracking is required. VFs report the number of instructions flushed from the instruction queue in the internal core. See Chapter 23, "Development Support," for more details. |
|                              |                | O    |                                         | Instruction Watchpoint 2. This output signal reports the detection of an instruction watchpoint in the program flow executed by the RCPU.                                                                                                                                                                                         |
| $\overline{BB}$ / VF2 / IWP3 | 1              | I/O  | Controlled by RCW[DBGC]. See Table 6-8  | Bus Busy. Indicates that the master is using the external bus. $\overline{BB}$ is an active-low signal and needs an external pull-up resistor to ensure proper operation and signal timing specifications.                                                                                                                        |
|                              |                | O    |                                         | Visible Instruction Queue Flush Status 2. This output signal together with VF0 and VF1 is output by the MPC561/MPC563 when a program instructions flow tracking is required. VFs report the number of instructions flushed from the instruction queue in the internal core.                                                       |
|                              |                | O    |                                         | Instruction Watchpoint 3. This output signal reports the detection of an instruction watchpoint in the program flow executed by the internal core.                                                                                                                                                                                |
| IWP[0:1] / VFLS[0:1]         | 2              | O    | Controlled by RCW[DBGC]. See Table 6-8. | Instruction Watchpoint [0:1]. These output signals report the detection of an instruction watchpoint in the program flow executed by the RCPU.                                                                                                                                                                                    |
|                              |                | O    |                                         | Visible History Buffer Flush Status [0:1]. These signals are output by the MPC561/MPC563 to enable program instruction flow tracking. They report the number of instructions flushed from the history buffer in the RCPU. See Chapter 23, "Development Support," for details.                                                     |

Table 2-1. MPC561/MPC563 Signal Descriptions (continued)

| Signal Name                      | No. of Signals | Type | Function after Reset <sup>1</sup>                                                                               | Description                                                                                                                                                                                                              |
|----------------------------------|----------------|------|-----------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>JTAG/BDM/READI</b>            |                |      |                                                                                                                 |                                                                                                                                                                                                                          |
| TMS / $\overline{\text{EVTI}}$   | 1              | I    | TMS unless the Nexus (READI) port is enabled, then $\overline{\text{EVTI}}$ . See <a href="#">Section 2.5</a> . | Test Mode Select. This input controls test mode operations for on-board test logic (JTAG).                                                                                                                               |
|                                  |                | I    |                                                                                                                 | $\overline{\text{EVTI}}$ . Event in ( $\overline{\text{EVTI}}$ ) is level sensitive when configured for breakpoint generation, otherwise it is edge sensitive.                                                           |
| TDI / DSDI / MDIO                | 1              | I    | DSDI unless the Nexus (READI) port (MDIO) or JTAG mode (TDI) is enabled. See <a href="#">Section 2.5</a> .      | Test Data In. This input is used for serial test instructions and test data for on-board test logic (JTAG).                                                                                                              |
|                                  |                | I    |                                                                                                                 | Development Serial Data Input. This input signal is the data in for the debug port interface. See <a href="#">Chapter 23</a> , “ <a href="#">Development Support</a> ,” for details.                                     |
|                                  |                | I    |                                                                                                                 | Message Data In. MDIO is a Nexus input signal used for downloading configuration information, writes to user resources, and so forth. Internal latching of MDI occurs on the rising edge of MCKI.                        |
| TCK / DSCK / MCKI                | 1              | I    | DSCK unless the Nexus (READI) port (MCKI) or JTAG mode (TCK) is enabled. See <a href="#">Section 2.5</a> .      | Test Clock. This input provides a clock for on-board test logic (JTAG).                                                                                                                                                  |
|                                  |                | I    |                                                                                                                 | Development Serial Clock. This input signal is the clock for the debug port interface. See <a href="#">Chapter 23</a> , “ <a href="#">Development Support</a> ,” for details.                                            |
|                                  |                | I    |                                                                                                                 | Message Clock In. This input line is the input clock to the READI module for the Nexus message clock input.                                                                                                              |
| TDO / DSDO / MDO0                | 1              | O    | DSDO unless the Nexus (READI) port (MDO0) or JTAG mode (TDO) is enabled. See <a href="#">Section 2.5</a> .      | Test Data Out. This output is used for serial test instructions and test data for on-board test logic (JTAG).                                                                                                            |
|                                  |                | O    |                                                                                                                 | Development Serial Data Output. This output signal is the data-out line of the debug port interface. See <a href="#">Chapter 23</a> , “ <a href="#">Development Support</a> ,” for details.                              |
|                                  |                | O    |                                                                                                                 | READI Message Data Out. Message data out: MDO0 is an output signal used for uploading OTM, BTM, DTM, and read/write accesses. External latching of MDO occurs on rising edge of MCKO. Eight MDO signals are implemented. |
| JCOMP / $\overline{\text{RSTI}}$ | 1              | I    | See <a href="#">Section 2.5</a> .                                                                               | JTAG Compliancy. This signal enables the IEEE1149.1 JTAG compliant circuitry in the MPC561/MPC563.<br>0 JTAG disabled<br>1 JTAG enabled                                                                                  |
|                                  |                | I    |                                                                                                                 | $\overline{\text{RSTI}}$ . Reset input for the Nexus port.                                                                                                                                                               |

Table 2-1. MPC561/MPC563 Signal Descriptions (continued)

| Signal Name           | No. of Signals | Type | Function after Reset <sup>1</sup> | Description                                                                                                                                                                                                                                                                                                                                                |
|-----------------------|----------------|------|-----------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Clocks and PLL</b> |                |      |                                   |                                                                                                                                                                                                                                                                                                                                                            |
| XTAL                  | 1              | O    | XTAL                              | XTAL. This output signal is one of the connections to an external crystal for the internal oscillator circuitry.                                                                                                                                                                                                                                           |
| EXTAL                 | 1              | I    | EXTAL                             | EXTAL. This signal is one of the connections to an external crystal for the internal oscillator circuitry. If EXTAL is unused, it must be grounded.                                                                                                                                                                                                        |
| XFC                   | 1              | I    | XFC                               | External Filter Capacitance. This input signal is the connection for an external capacitor filter for the PLL circuitry.                                                                                                                                                                                                                                   |
| CLKOUT                | 1              | O    | CLKOUT                            | Clock Out. This output signal is the clock system frequency. The CLKOUT drive strength can be configured to full strength, half strength, quarter strength, or disabled. The drive strength is configured using the COM[0:1] bits and CQDS bits in the SCCR register in the USIU.                                                                          |
| EXTCLK                | 1              | I    | EXTCLK                            | EXTCLK. This is the external frequency source for the MPC561/MPC563. If EXTCLK is unused, it must be grounded.                                                                                                                                                                                                                                             |
| ENGCLK / BUCLK        | 1              | O    | ENGCLK (2.6 V)                    | ENGCLK. This is the engineering clock output. Drive voltage can be configured to 2.6 V, 5 V (with slew-rate control), or disabled. The drive voltage is configured using the EECLK[0:1] bits in the SCCR register in the SIU.                                                                                                                              |
|                       |                | O    |                                   | BUCLK. When the MPC561/MPC563 is in limp mode, it is operating from a less precise on-chip ring oscillator to allow the system to continue minimum functionality until the system clock is fixed. This backup clock can be seen externally if selected by the values of the EECLK[0:1] bits in the SCCR register in the USIU.                              |
| VDDSYN                | 1              | I    | VDDSYN                            | VDDSYN. This is the power supply of the PLL circuitry.                                                                                                                                                                                                                                                                                                     |
| VSSSYN                | 1              | I    | VSSSYN                            | VSSSYN. This is the ground reference of the PLL circuitry.                                                                                                                                                                                                                                                                                                 |
| <b>Configuration</b>  |                |      |                                   |                                                                                                                                                                                                                                                                                                                                                            |
| PULL_SEL <sup>3</sup> | 1              | I    | PULL_SEL                          | Pull Select. PULL_SEL determines whether the pull devices on the MIOS and TPU signals are pull-ups or pull-downs. When pull-ups are selected, the pull-ups are to 5.0 V except the following MIOS signals will be pulled to 2.6V: VF[0:2]/MPIO32B[0:2], VFSL[0:1]/MPIO32B[3:4], and MDO[7:4]/MPIO32B[7:10]. When this pin is low, pull-downs are selected. |
| <b>TouCAN</b>         |                |      |                                   |                                                                                                                                                                                                                                                                                                                                                            |
| A_CNTX0               | 1              | O    | A_CNTX0                           | TouCAN_A Transmit Data. This signal is the serial data output.                                                                                                                                                                                                                                                                                             |
| A_CNRX0               | 1              | I    | A_CNRX0                           | TouCAN_A Receive Data. This signal is the serial data input.                                                                                                                                                                                                                                                                                               |
| B_CNTX0               | 1              | O    | B_CNTX0                           | TouCAN_B Transmit Data. This signal is the serial data output.                                                                                                                                                                                                                                                                                             |

Table 2-1. MPC561/MPC563 Signal Descriptions (continued)

| Signal Name                    | No. of Signals | Type             | Function after Reset <sup>1</sup> | Description                                                                                                                                                                                                                                                                                 |
|--------------------------------|----------------|------------------|-----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| B_CNRX0                        | 1              | I                | B_CNRX0                           | TouCAN_B Receive Data. This signal is the serial data input.                                                                                                                                                                                                                                |
| <b>UC3F Flash<sup>4</sup></b>  |                |                  |                                   |                                                                                                                                                                                                                                                                                             |
| EPEE <sup>4</sup>              | 1              | I                | EPEE                              | EPEE. This external program/erase enable control signal externally controls the program or erase operations. When held low, program or erase operations on the entire internal Flash module are disabled. Available in the MPC563 only. This signal is not connected on the MPC561.         |
| B0EPEE <sup>4</sup>            | 1              | I                | B0EPEE                            | B0EPEE. This control signal externally controls the program or erase operations on block 0 of the internal Flash. When held low, program or erase operations on block 0 only are disabled. Available in the MPC563 only. This signal is not connected on the MPC561.                        |
| VFLASH <sup>4</sup>            | 1              | I                | VFLASH                            | VFLASH. Flash supply voltage (5-V supply) used during all operations of the UC3F. Available in the MPC563 only. This signal is not connected on the MPC561.                                                                                                                                 |
| VDDF <sup>4</sup>              | 1              | I                | VDDF                              | VDDF. Flash core voltage input (2.6-V supply). Available in the MPC563 only. This signal should be connected to VDD, preferably directly to a 2.6V plane on the circuit board. This signal is not connected on the MPC561.                                                                  |
| VSSF <sup>4</sup>              | 1              | I                | VSSF                              | VSSF. Flash core ground reference. Available in the MPC563 only. This signal is not connected on the MPC561.                                                                                                                                                                                |
| <b>QADC64E_A and QADC64E_B</b> |                |                  |                                   |                                                                                                                                                                                                                                                                                             |
| ETRIG[1:2] / PCS[6:7]          | 2              | I                | ETRIG[1:2]                        | ETRIG[1:2]. These are the external trigger inputs to the QADC64E_A and QADC64E_B modules. ETRIG1 can be configured to be used by both QADC64E_A and QADC64E_B. Likewise, ETRIG2 can be used by both QADC64E_B and QADC64E_A. The trigger input signals are associated with the scan queues. |
|                                |                | O                |                                   | PCS[6:7]. This signals provide QSPI peripheral chip select when the enhanced PCS mode is selected.                                                                                                                                                                                          |
| A_AN0 / A_ANw / A_PQB0         | 1              | I                | A_AN0                             | Analog Channel 0. Internally multiplexed input-only analog channel. Passed on as a separate signal to the QADC64E.                                                                                                                                                                          |
|                                |                | I                |                                   | Multiplexed Analog Input (A_ANw). Externally multiplexed analog input.                                                                                                                                                                                                                      |
|                                |                | I/O <sup>5</sup> |                                   | Port A_PQB0. This is a bidirectional general-purpose I/O if the QADC64E is configured in enhanced mode, otherwise it is an input only.                                                                                                                                                      |
| A_AN1 / A_ANx/ A_PQB1          | 1              | I                | A_AN1                             | Analog Channel 1. Internally multiplexed input-only analog channel. Passed on as a separate signal to the QADC64E.                                                                                                                                                                          |
|                                |                | I                |                                   | Multiplexed Analog Input (A_ANx). Externally multiplexed analog input.                                                                                                                                                                                                                      |
|                                |                | I/O <sup>5</sup> |                                   | Port A_PQB1. This is a bidirectional general-purpose I/O if the QADC64E is configured in enhanced mode, otherwise it is an input only.                                                                                                                                                      |

Table 2-1. MPC561/MPC563 Signal Descriptions (continued)

| Signal Name                          | No. of Signals | Type             | Function after Reset <sup>1</sup> | Description                                                                                                                                                                     |
|--------------------------------------|----------------|------------------|-----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| A_AN2 / A_ANy / A_PQB2               | 1              | I                | A_AN2                             | Analog Channel 2. Internally multiplexed input-only analog channel. The input is passed on as a separate signal to the QADC64E.                                                 |
|                                      |                | I                |                                   | Multiplexed Analog Input (A_ANy). Externally multiplexed analog input.                                                                                                          |
|                                      |                | I/O <sup>5</sup> |                                   | Port A_PQB2. This is a bidirectional general-purpose I/O if the QADC64E is configured in enhanced mode, otherwise it is an input only.                                          |
| A_AN3 / A_ANz / A_PQB3               | 1              | I                | A_AN3                             | Analog Input 3. Internally multiplexed input-only analog channel. The input is passed on as a separate signal to the QADC64E.                                                   |
|                                      |                | I                |                                   | Multiplexed Analog Input (A_ANz). Externally multiplexed analog input.                                                                                                          |
|                                      |                | I/O <sup>5</sup> |                                   | Port A_PQB 3. This is a bidirectional general-purpose I/O if the QADC64E is configured in enhanced mode, otherwise it is an input only.                                         |
| A_AN[48:51] / A_PQB[4:7]             | 4              | I                | AN[48:51]                         | Analog Input [48:51]. Analog input channel. The input is passed on as a separate signal to the QADC64E.                                                                         |
|                                      |                | I/O <sup>5</sup> |                                   | Port A_PQB[4:7]. This is a bidirectional general-purpose I/O if the QADC64E is configured in enhanced mode, otherwise it is an input only.                                      |
| A_AN[52:54] / A_MA[0:2] / A_PQA[0:2] | 3              | I                | A_AN[52:54]                       | Analog Input [52:54]. Input-only. These inputs are passed on as separate signals to the QADC64E.                                                                                |
|                                      |                | I                |                                   | Multiplexed Address [0:2] for QADC64E Module A. Provides a three-bit multiplexed address output to the external multiplexer chip to allow selection of one of the eight inputs. |
|                                      |                | I/O              |                                   | Port A_PQA[0:2]. This is a bidirectional general-purpose I/O.                                                                                                                   |
| A_AN[55:59] / A_PQA[3:7]             | 5              | I                | A_AN[55:59]                       | Analog Input [55:59]. Input-only. These inputs are passed on as separate signals to the QADC64E.                                                                                |
|                                      |                | I/O              |                                   | Port A_PQA[3:7]. This is a bidirectional general-purpose I/O.                                                                                                                   |
| B_AN0 / B_ANw / B_PQB0               | 1              | I                | B_AN0                             | Analog Channel 0. Internally multiplexed input-only analog channel. Passed on as a separate signal to the QADC64E.                                                              |
|                                      |                | I                |                                   | Multiplexed Analog Input (B_ANw). Externally multiplexed analog input.                                                                                                          |
|                                      |                | I/O              |                                   | Port B_PQB0. This is a bidirectional general-purpose I/O if the QADC64E is configured in enhanced mode, otherwise it is an input only.                                          |

Table 2-1. MPC561/MPC563 Signal Descriptions (continued)

| Signal Name                          | No. of Signals | Type | Function after Reset <sup>1</sup> | Description                                                                                                                                                                     |
|--------------------------------------|----------------|------|-----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| B_AN1 / B_ANx/ B_PQB1                | 1              | I    | B_AN1                             | Analog Channel 1. Internally multiplexed input-only analog channel. Passed on as a separate signal to the QADC64E.                                                              |
|                                      |                | I    |                                   | Multiplexed Analog Input (B_ANx). Externally multiplexed analog input.                                                                                                          |
|                                      |                | I/O  |                                   | Port B_PQB1. This is a bidirectional general-purpose I/O if the QADC64E is configured in enhanced mode, otherwise it is an input only.                                          |
| B_AN2 / B_ANy/ B_PQB2                | 1              | I    | B_AN2                             | Analog Channel 2. Internally multiplexed input-only analog channel. The input is passed on as a separate signal to the QADC64E.                                                 |
|                                      |                | I    |                                   | Multiplexed Analog Input (B_ANy). Externally multiplexed analog input.                                                                                                          |
|                                      |                | I/O  |                                   | Port B_PQB2. This is a bidirectional general-purpose I/O if the QADC64E is configured in enhanced mode, otherwise it is an input only.                                          |
| B_AN3 / B_ANz / B_PQB3               | 1              | I    | B_AN3                             | Analog Input 3. Internally multiplexed input-only analog channel. The input is passed on as a separate signal to the QADC64E.                                                   |
|                                      |                | I    |                                   | Multiplexed Analog Input (B_ANz). Externally multiplexed analog input.                                                                                                          |
|                                      |                | I/O  |                                   | Port B_PQB3. This is a bidirectional general-purpose I/O if the QADC64E is configured in enhanced mode, otherwise it is an input only.                                          |
| B_AN[48:51] / B_PQB[4:7]             | 4              | I    | B_AN[48:51]                       | Analog Input [48:51]. Analog input channel. The input is passed on as a separate signal to the QADC64E.                                                                         |
|                                      |                | I/O  |                                   | Port B_PQB[4:7]. This is a bidirectional general-purpose I/O if the QADC64E is configured in enhanced mode, otherwise it is an input only.                                      |
| B_AN[52:54] / B_MA[0:2] / B_PQA[0:2] | 3              | I    | B_AN[52:54]                       | Analog Input [52:54]. These inputs are passed on as separate signals to the QADC64E.                                                                                            |
|                                      |                | I    |                                   | Multiplexed Address [0:2] for QADC64E Module A. Provides a three-bit multiplexed address output to the external multiplexer chip to allow selection of one of the eight inputs. |
|                                      |                | I/O  |                                   | Port B_PQA[0:2]. This is a bidirectional general-purpose I/O.                                                                                                                   |
| B_AN[55:59] / B_PQA[3:7]             | 5              | I    | B_AN[55:59]                       | Analog Input [55:59]. These inputs are passed on as separate signals to the QADC64E.                                                                                            |
|                                      |                | I/O  |                                   | Port B_PQA[3:7]. This is a bidirectional general-purpose I/O.                                                                                                                   |
| VRH                                  | 1              | I    | VRH                               | VRH. Input signal for high reference voltage for the QADC64E_A and QADC64E_B modules.                                                                                           |
| VRL                                  | 1              | I    | VRL                               | VRL. Input signal for low reference voltage for the QADC64E_A and QADC64E_B modules.                                                                                            |

Table 2-1. MPC561/MPC563 Signal Descriptions (continued)

| Signal Name                     | No. of Signals | Type | Function after Reset <sup>1</sup> | Description                                                                                                                                                                                                                                                     |
|---------------------------------|----------------|------|-----------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ALTREF                          | 1              | I    | ALTREF                            | ALTREF. Input signal for alternate reference voltage for the QADC64E_A and QADC64E_B modules.                                                                                                                                                                   |
| VDDA                            | 1              | I    | VDDA                              | VDDA. Power supply input to analog subsystems of the QADC64E_A and QADC64E_B modules.                                                                                                                                                                           |
| VSSA                            | 1              | I    | VSSA                              | VSSA. Ground level for analog subsystems of the QADC64E_A and QADC64E_B modules.                                                                                                                                                                                |
| <b>QSMCM</b>                    |                |      |                                   |                                                                                                                                                                                                                                                                 |
| PCS0 / $\overline{SS}$ / QGPIO0 | 1              | I/O  | QGPIO0                            | PCS0. This signal provides QSPI peripheral chip select 0 for the QSMCM module.                                                                                                                                                                                  |
|                                 |                | I/O  |                                   | $\overline{SS}$ . Assertion of this bidirectional signal places the QSPI in slave mode.                                                                                                                                                                         |
|                                 |                | I/O  |                                   | Port QGPIO0. When this signal is not needed for a QSPI application it can be configured as a general-purpose input/output.                                                                                                                                      |
| PCS[1:3] / QGPIO[1:3]           | 3              | I/O  | QGPIO[1:3]                        | PCS[1:3]. These signals provide QSPI peripheral chip selects for the QSMCM module.                                                                                                                                                                              |
|                                 |                | I/O  |                                   | Port QGPIO[1:3]. When these signals are not needed for QSPI applications they can be configured as general-purpose input/outputs.                                                                                                                               |
| MISO / QGPIO4                   | 1              | I/O  | QGPIO4                            | Master-In Slave-Out (MISO). This bidirectional signal is the serial data input to the QSPI in master mode, and serial data output from the QSPI in slave mode.                                                                                                  |
|                                 |                | I/O  |                                   | Port QGPIO4. When this signal is not needed for a QSPI application it can be configured as a general-purpose input/output.                                                                                                                                      |
| MOSI / QGPIO5                   | 1              | I/O  | QGPIO5                            | Master-Out Slave-In (MOSI). This bidirectional signal is the serial data output from the QSPI in master mode and serial data input to the QSPI in slave mode.                                                                                                   |
|                                 |                | I/O  |                                   | Port QGPIO5. When this signal is not needed for a QSPI application it can be configured as a general-purpose input/output.                                                                                                                                      |
| SCK / QGPIO6                    | 1              | I/O  | QGPIO6                            | SCK. This bidirectional signal is the clock from the QSPI in master mode or is the clock to the QSPI in slave mode.                                                                                                                                             |
|                                 |                | I/O  |                                   | Port QGPIO6 for the QSMCM module. When this signal is not needed for a QSPI application it can be configured as a general-purpose input/output. When the QSPI is enabled for serial transmitting, the signal cannot function as a GPIO.                         |
| TXD1 / QGPO1                    | 1              | O    | QGPO1                             | Transmit Data 1. This is the serial data output from the SCI1.                                                                                                                                                                                                  |
|                                 |                | O    |                                   | Port QGPO 1. When these signals are not needed for SCI applications, they can be configured as general-purpose outputs. When the transmit enable bit in the SCI control register is set to a logic 1, these signals cannot function as general-purpose outputs. |

Table 2-1. MPC561/MPC563 Signal Descriptions (continued)

| Signal Name                         | No. of Signals | Type | Function after Reset <sup>1</sup>                                                            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| TXD2 / QGPO2 / C_CNTX0 <sup>6</sup> | 1              | O    | QGPO2                                                                                        | Transmit Data 2. This is the serial data output from the SCI2                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|                                     |                | O    |                                                                                              | Port QGPO 2. When this signal is not needed for SCI applications it can be configured as general-purpose output. When the transmit enable bit in the SCI control register is set to a logic 1, this signal cannot function as a general-purpose output.                                                                                                                                                                                                                                                                                                                                                                                             |
|                                     |                | O    |                                                                                              | TouCAN Transmit Data. This signal is the serial data output for the TouCAN_C module.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| RXD1 / QGPI1                        | 1              | I    | QGPI1                                                                                        | Receive Data 1. This input signal is the serial data input to the SCI.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|                                     |                | I    |                                                                                              | Port QGPI 1. When this signal is not needed for SCI applications, it can be configured as a general-purpose input. When the receive enable bit in the SCI control register is set to a logic 1, this signal cannot function as a general-purpose input.                                                                                                                                                                                                                                                                                                                                                                                             |
| RXD2 / QGPI2 / C_CNRX0 <sup>6</sup> | 1              | I    | QGPI2                                                                                        | Receive Data 2. This input signal provides serial data input to the SCI2.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|                                     |                | I    |                                                                                              | Port QGPI 2. When this signal is not needed for SCI applications it can be configured as a general-purpose input. When the receive enable bit in the SCI control register is set to a logic 1, this signal cannot function as a general-purpose input.                                                                                                                                                                                                                                                                                                                                                                                              |
|                                     |                | I    |                                                                                              | TouCAN Receive Data. This is the serial data input signal for the TouCAN_C module.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| MPIO32B0 / VF0 / MDO1              | 1              | I/O  | MPIO32B0 unless the Nexus (READI) port is enabled, then MDO1. See <a href="#">Section 2.5</a> .               | MIOS14 GPIO 0. Allows the signals to be used as general-purpose inputs/outputs.                                                                                                                                                                                                                                                                                                                                |
|                                    |                | O    |                                                                                                               | Visible Instruction Queue Flush Status 0. These signals output by the MPC561/MPC563 when program instruction flow tracking is required. VF reports the number of instructions flushed from the instruction queue in the internal core. VF signals are also multiplexed with the development and debug signals VF0 / LWP1 / $\overline{BG}$ , VF1 / IWP2 / $\overline{BR}$ , and VF2 / IWP3 / $\overline{BB}$ . |
|                                    |                | O    |                                                                                                               | READI Message Data Out. Message data out (MDO1) is an output signal used for uploading OTM, BTM, DTM, and read/write accesses. External latching of MDO occurs on rising edge of MCKO. Eight MDO signals are implemented.                                                                                                                                                                                      |
| MPIO32B1 / VF1 / MCKO              | 1              | I/O  | MPIO32B1 unless the Nexus (READI) port is enabled, then MCKO. See <a href="#">Section 2.5</a> .               | MIOS14 GPIO 1. Allows the signals to be used as general-purpose inputs/outputs.                                                                                                                                                                                                                                                                                                                                |
|                                    |                | O    |                                                                                                               | Visible Instruction Queue Flush Status 1. These signals output by the MPC561/MPC563 when program instruction flow tracking is required. VF reports the number of instructions flushed from the instruction queue in the internal core. VF signals are also multiplexed with the development and debug signals VF0 / LWP1 / $\overline{BG}$ , VF1 / IWP2 / $\overline{BR}$ , and VF2 / IWP3 / $\overline{BB}$ . |
|                                    |                | O    |                                                                                                               | MCKO. Message clock-out (MCKO) is a free-running output clock to development tools for timing of MDO and MSEO signal functions. MCKO is the same as the MPC561/MPC563 system clock.                                                                                                                                                                                                                            |
| MPIO32B2 / VF2 / $\overline{MSEI}$ | 1              | I/O  | MPIO32B2 unless the Nexus (READI) port is enabled, then $\overline{MSEI}$ . See <a href="#">Section 2.5</a> . | MIOS14 GPIO 2. Allows the signals to be used as general-purpose inputs/outputs.                                                                                                                                                                                                                                                                                                                                |
|                                    |                | O    |                                                                                                               | Visible Instruction Queue Flush Status 2. These signals output by the MPC561/MPC563 when program instruction flow tracking is required. VF reports the number of instructions flushed from the instruction queue in the internal core. VF signals are also multiplexed with the development and debug signals VF0 / LWP1 / $\overline{BG}$ , VF1 / IWP2 / $\overline{BR}$ , and VF2 / IWP3 / $\overline{BB}$ . |
|                                    |                | I    |                                                                                                               | $\overline{MSEI}$ . Message Start/End Input. The $\overline{MSEI}$ input is a Nexus input signal that indicates when a message on the MDI signals has started, when a variable length packet has ended, and when the message has ended. Internal latching of $\overline{MSEI}$ occurs on rising edge of MCKI.                                                                                                  |

Table 2-1. MPC561/MPC563 Signal Descriptions (continued)

| Signal Name                                 | No. of Signals | Type | Function after Reset <sup>1</sup>                                              | Description                                                                                                                                                                                                                                                                                                            |
|---------------------------------------------|----------------|------|--------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| MPIO32B3 / VFLS0 / $\overline{\text{MSEO}}$ | 2              | I/O  | MPIO32B3 unless the Nexus (READI) port is enabled. See Section 2.5.            | MIOS14 GPIO 3. Allows the signal to be used as a general-purpose input/output.                                                                                                                                                                                                                                         |
|                                             |                | O    |                                                                                | Visible History Buffer Flush Status 0. This signal is output by the MPC561/MPC563 to allow program instruction flow tracking. It reports the number of instructions flushed from the history buffer in the RCP. See Chapter 23, "Development Support," for details.                                                    |
|                                             |                | O    |                                                                                | $\overline{\text{MSEO}}$ . Message start/end out ( $\overline{\text{MSEO}}$ ) is an output signal which indicates when a message on the MDO signals has started, when a variable length packet has ended, and when the message has ended. External latching of $\overline{\text{MSEO}}$ occurs on rising edge of MCKO. |
| MPIO32B4 / VFLS1                            | 1              | I/O  | MPIO32B4                                                                       | MIOS14 GPIO 4. Allows the signal to be used as a general-purpose input/output.                                                                                                                                                                                                                                         |
|                                             |                | O    |                                                                                | Visible History Buffer Flush Status 1. This signal is output by the MPC561/MPC563 to allow program instruction flow tracking. It reports the number of instructions flushed from the history buffer in the RCP. See Chapter 23, "Development Support," for details.                                                    |
| MPIO32B5 / MDO5                             | 1              | I/O  | MPIO32B5 unless the Nexus (READI) port is enabled, then MDO5. See Section 2.5. | MIOS14 GPIO 5. Allows the signal to be used as a general-purpose input/output.                                                                                                                                                                                                                                         |
|                                             |                | O    |                                                                                | READI Message Data Out. Message data out (MDO5) is an output signal used for uploading OTM, BTM, DTM, and read/write accesses. External latching of MDO occurs on rising edge of MCKO. Eight MDO signals are implemented.                                                                                              |
| MPIO32B6 / MPWM4 / MDO6                     | 1              | I/O  | MPIO32B6 unless the Nexus (READI) port is enabled, then MDO6. See Section 2.5. | MIOS14 GPIO 6. Allows the signal to be used as general-purpose input/output.                                                                                                                                                                                                                                           |
|                                             |                | I/O  |                                                                                | Pulse Width Modulation 4. These signals provide variable pulse width outputs at a wide range of frequencies.                                                                                                                                                                                                           |
|                                             |                | O    |                                                                                | READI Message Data Out. Message data out (MDO6) is an output signal used for uploading OTM, BTM, DTM, and read/write accesses. External latching of MDO occurs on rising edge of MCKO. Eight MDO signals are implemented.                                                                                              |
| MPIO32B[7:9] / MPWM[5, 20:21]               | 3              | I/O  | MPIO32B[7:9]                                                                   | MIOS14 GPIO[7:9]. Allows these signals to be used as general-purpose input/outputs.                                                                                                                                                                                                                                    |
|                                             |                | I/O  |                                                                                | Pulse Width Modulation [5, 20:21]. These signals provide variable pulse width outputs at a wide range of frequencies.                                                                                                                                                                                                  |
| MPIO32B10 / PPM_TSYNC                       | 1              | I/O  | MPIO32B10                                                                      | MIOS14 GPIO 10. This function allows the signals to be used as general-purpose inputs/outputs.                                                                                                                                                                                                                         |
|                                             |                | O    |                                                                                | PPM_TSYNC. Synchronizes the data between the PPM and peripheral devices.                                                                                                                                                                                                                                               |
| MPIO32B11 / C_CNRX0 <sup>6</sup>            | 1              | I/O  | MPIO32B11                                                                      | MIOS14 GPIO 11. This function allows the signals to be used as general-purpose inputs/outputs.                                                                                                                                                                                                                         |
|                                             |                | I    |                                                                                | TouCAN_C Receive Data. This is the serial data input signal for the TouCAN_C module.                                                                                                                                                                                                                                   |

Table 2-1. MPC561/MPC563 Signal Descriptions (continued)

| Signal Name                      | No. of Signals | Type | Function after Reset <sup>1</sup> | Description                                                                                                                                                                                                                                                            |
|----------------------------------|----------------|------|-----------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| MPIO32B12 / C_CNTX0 <sup>6</sup> | 1              | I/O  | MPIO32B12                         | MIOS14 GPIO 12. This function allows the signals to be used as general-purpose inputs/outputs.                                                                                                                                                                         |
|                                  |                | O    |                                   | TouCAN_C Transmit Data. This is the serial data output signal for the TouCAN_C module.                                                                                                                                                                                 |
| MPIO32B13 / PPM_TCLK             | 1              | I/O  | MPIO32B13                         | MIOS14 GPIO 13. This function allows the signals to be used as general-purpose inputs/outputs.                                                                                                                                                                         |
|                                  |                | O    |                                   | PPM_TCLK. PPM bus clock                                                                                                                                                                                                                                                |
| MPIO32B14 / PPM_RX0              | 1              | I/O  | MPIO32B14                         | MIOS14 GPIO 14. This function allows the signals to be used as general-purpose inputs/outputs.                                                                                                                                                                         |
|                                  |                | I    |                                   | PPM_RX0. Receive data to the PPM channel number 0.                                                                                                                                                                                                                     |
| MPIO32B15 / PPM_TX0              | 1              | I/O  | MPIO32B15                         | MIOS14 GPIO 15. This function allows the signals to be used as general-purpose inputs/outputs.                                                                                                                                                                         |
|                                  |                | O    |                                   | PPM_TX0. Transmit data from PPM channel number 0.                                                                                                                                                                                                                      |
| TPU                              |                |      |                                   |                                                                                                                                                                                                                                                                        |
| A_TPUCH[0:15]                    | 16             | I/O  | A_TPUCH[0:15]                     | Provides TPU module A with 16 input/output programmable timed events.                                                                                                                                                                                                  |
| A_T2CLK / PCS5                   | 1              | I/O  | A_T2CLK                           | This signal is used to clock or gate the timer count register 2 (TCR2) within the TPU module A. This signal is an output-only in special test mode.                                                                                                                    |
|                                  |                | O    |                                   | PCS5. This signal provides QSPI peripheral chip select when the enhanced PCS mode is selected.                                                                                                                                                                         |
| B_TPUCH[0:15]                    | 16             | I/O  | B_TPUCH[0:15]                     | Provides TPU module B with 16 input/output programmable timed events.                                                                                                                                                                                                  |
| B_T2CLK / PCS4                   | 1              | I/O  | B_T2CLK                           | This signal is used to clock or gate the timer count register 2 (TCR2) within the TPU module B. This signal is an output-only in special test mode.                                                                                                                    |
|                                  |                | O    |                                   | PCS4. This signal provides QSPI peripheral chip select when the enhanced PCS mode is selected.                                                                                                                                                                         |
| Global Power                     |                |      |                                   |                                                                                                                                                                                                                                                                        |
| NVDDL                            | 1              | I    | NVDDL                             | NVDDL. Noisy 2.6-V voltage supply input. This signal supplies the final output stage of the 2.6-V pad output drivers. The NVDDL and QVDDL supplies should be connected to the same power supply in a user's system.                                                    |
| QVDDL                            | 1              | I    | QVDDL                             | QVDDL. Quiet 2.6-V voltage supply input. This signal supplies all pad logic and pre-driver circuitry, except for the final output stage of the 2.6-V pad output drivers. The NVDDL and QVDDL supplies should be connected to the same power supply in a user's system. |
| VDDH                             | 1              | I    | VDDH                              | VDDH. 5-V voltage supply input.                                                                                                                                                                                                                                        |
| VDD                              | 1              | I    | VDD                               | VDD. 2.6-V voltage supply input for internal logic.                                                                                                                                                                                                                    |
| KAPWR                            | 1              | I    | KAPWR                             | Keep-Alive Power. 2.6-V voltage supply input for the oscillator and keep-alive registers.                                                                                                                                                                              |

**Table 2-1. MPC561/MPC563 Signal Descriptions (continued)**

| Signal Name | No. of Signals | Type | Function after Reset <sup>1</sup> | Description                                                                                                                                                                                                                                                                                                                   |
|-------------|----------------|------|-----------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| VSS         | 1              | I    | VSS                               | VSS. Zero supply/ground level for internal logic/external bus.                                                                                                                                                                                                                                                                |
| IRAMSTBY    | 1              | I    | IRAMSTBY                          | SRAM Keep-Alive Power. This is an input current source for an internal regulator that supplies voltage to all SRAM modules in standby mode. This pad connects through a voltage regulator and a voltage switch to the following modules: CALRAM (32-Kbyte SRAM), DPTRAM (8-Kbyte SRAM), BBC DECRAM (2-Kbyte vocabulary SRAM). |

<sup>1</sup> This is the function after  $\overline{\text{PORESET}}/\text{TRST}$  and  $\overline{\text{HRESET}}$ .

<sup>2</sup> This signal also included the MDO5 function on the K27S mask set of the MPC561.

<sup>3</sup> This signal was ECK on K27S mask set of MPC561.

<sup>4</sup> Only the MCP563/MPC564 have Flash memory.

<sup>5</sup> The input only applies in legacy mode.

<sup>6</sup> C\_CNTX0 and C\_CNRX0 can be shared either with the MIOS14 GPIO pins (MPIO32B12, MPIO32B11) or with the QSMCM SC12 pins (TXD2 / QGPO2, RXD2 / QGPI2). The selection is made by the TCNC bits in the PDMCR2 register. Refer to [Section 2.4, "Pad Module Configuration Register \(PDMCR2\)."](#)

## 2.2.1 MPC561/MPC563 Signal Multiplexing

[Table 2-2](#) describes the signal multiplexing that occurs between different modules of the MPC561/MPC563. Most of the signal functions are controlled by the PDMCR2 register.

**Table 2-2. MPC561/MPC563 Signal Sharing**

| Signal Name                                                                           | Module Sharing                                 |
|---------------------------------------------------------------------------------------|------------------------------------------------|
| C_CNTX0/MPIO32B12,<br>C_CNRX0/MPIO32B11                                               | TouCAN shared with MIOS14 GPIO                 |
| TXD2/QGPO2/C_CNTX0<br>RXD2/QGPI2/C_CNRX0                                              | TouCAN shared with QSMCM SC12                  |
| MPIO32B5/MDO5                                                                         | READI submodule shared with MIOS14 GPIO        |
| MPIO32B6/MPWM4,<br>MPIO32B7/MPWM5,<br>MPIO32B8/MPWM20,<br>MPIO32B9/MPWM21             | MIOS14 PWM submodule shared with MIOS14 GPIO   |
| VF0/MPIO32B0/MDO1,<br>VF1/MPIO32B1/MCKO,<br>VF2/MPIO32B2/MSET,<br>VFLS0/MPIO32B3/MSEO | Debug pins shared with MIOS14 GPIO and READI   |
| MPIO32B13/PPM_TCLK<br>MPIO32B14/PPM_RX0<br>MPIO32B15/PPM_TX0                          | PPM submodule shared with MIOS14 GPIO          |
| MPWM2/PPM_TX1<br>MPWM3/PPM_RX1                                                        | PPM submodule shared with MIOS14 PWM submodule |

**Table 2-2. MPC561/MPC563 Signal Sharing (continued)**

| Signal Name                                                        | Module Sharing                                   |
|--------------------------------------------------------------------|--------------------------------------------------|
| MPWM0/MDI1,<br>MPWM1/MDO2,<br>MPWM17/MDO3,<br>MPWM[18:19]/MDO[6:7] | READI submodule shared with MIOS14 PWM submodule |
| B_T2CLK/PCS4<br>A_T2CLK/PCS5                                       | TPU3 modules shared with QSMCM module.           |
| ETRIG1/PCS6<br>ETRIG2/PCS7                                         | QADC64E modules shared with QSMCM module.        |

## 2.2.2 READI Port Signal Sharing

Table 2-3 and Table 2-4 show the signal functionality of the READI signals when the Nexus port is in reduced port mode and full port mode.

**Table 2-3. Reduced and Full Port Mode Pads**

| Pad Name                                 | Functionality in Reduced Port Mode | Functionality When Not in Reduced Port Mode |
|------------------------------------------|------------------------------------|---------------------------------------------|
| TDI/DSDI/MDI0 <sup>1</sup>               | MDI0                               | TDI/DSDI                                    |
| TDO/DSDO/MDO0                            | MDO0                               | TDO/DSDO <sup>2</sup>                       |
| VF0/MPIO32B0/MDO1                        | MDO1                               | VF0/MPIO32B0 <sup>3</sup>                   |
| VF1/MPIO32B1/MCKO                        | MCKO                               | VF1/MPIO32B1 <sup>3</sup>                   |
| VF2/MPIO32B2/ $\overline{\text{MSEI}}$   | $\overline{\text{MSEI}}$           | VF2/MPIO32B2 <sup>3</sup>                   |
| VFLS0/MPIO32B3/ $\overline{\text{MSEO}}$ | $\overline{\text{MSEO}}$           | VFLS0/MPIO32B3 <sup>4</sup>                 |

<sup>1</sup> TDI in JTAG mode, DSDI in BDM mode.

<sup>2</sup> TDO in JTAG mode, DSDO in BDM mode.

<sup>3</sup> Selected by the VF bit in the MIOS14TPCR.

<sup>4</sup> Selected by the VFLS bit in the MIOS14TPCR.

**Table 2-4. Full Port Only Mode Pads**

| Pad Name                                            | Functionality in Full Port Mode | Functionality when not in Full Port Mode |
|-----------------------------------------------------|---------------------------------|------------------------------------------|
| MPWM0/MDI1                                          | MDI1                            | MPWM0                                    |
| MPWM1/MDO2                                          | MDO2                            | MPWM1                                    |
| MPWM17/MDO3                                         | MDO3                            | MPWM17                                   |
| $\overline{\text{IRQ0}}/\text{SGPIOC0}/\text{MDO4}$ | MDO4                            | $\overline{\text{IRQ0}}/\text{SGPIOC0}$  |
| MPIO32B5/MDO5                                       | MDO5                            | MPIO32B5                                 |
| MPIO32B6 / MPWM4 / MDO6                             | MDO6 <sup>1</sup>               | MPIO32B6/MPWM4                           |
| MPWM18/MDO6                                         | MDO6 <sup>1</sup>               | MPWM18                                   |
| MPWM19/MDO7                                         | MDO7                            | MPWM19                                   |

<sup>1</sup> The MDO6 bit in the PDMCR2 register determines where the MDO6 signal is available.

Bits in the PDMCR (which resides in the SIU memory map) control the slew rate and weak pull-up/pull-down characteristics of some signals; refer to [Appendix F, “Electrical Characteristics.”](#) The PORESET/TRST signal resets all the PDMCR bits asynchronously.

### Figure 2-2. Pads Module Configuration Register (PDMCR)

Table 2-5 contains bit descriptions for the PDMCR.

### Table 2-5. PDMCR Field Descriptions

| Bits | Name      | Description                                                                                                                                                                                                                                                  |
|------|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0:5  | SLRC[0:5] | SLRC0 controls the slew rate of signals on the following modules: TPU3, QADC64E, SGPIOA, SGPIOD, SGPIOC. For the slew rate refer to <a href="#">Appendix F, “Electrical Characteristics.”</a><br>0 Slew rate controlled<br>1 Not slew rate controlled        |
|      |           | SLRC1 controls the slew rate of signals on the following modules: QSPI, TouCAN_A, TouCAN_B. For the slew rate refer to <a href="#">Appendix F, “Electrical Characteristics.”</a><br>0 Slew rate controlled<br>1 Not slew rate controlled                     |
|      |           | SLRC2 controls the slew rate of signals on the QSCI in QSMCM . For the slew rate refer to <a href="#">Appendix F, “Electrical Characteristics.”</a><br>0 Slew rate controlled<br>1 Not slew rate controlled                                                  |
|      |           | SLRC3 controls the slew rate of signals on the following modules: MIOS14 except MPWM2/PPM_TX1 and MPWM3 signal. For the slew rate refer to <a href="#">Appendix F, “Electrical Characteristics.”</a><br>0 Slew rate controlled<br>1 Not slew rate controlled |
|      |           | SLRC4 controls the slew rate of the MIOS14 MPWM2 signal. For the slew rate refer to <a href="#">Appendix F, “Electrical Characteristics.”</a><br>0 Slew rate controlled<br>1 Not slew rate controlled                                                        |
|      |           | SLRC5 controls the slew rate of the MIOS14 MPWM3 signal. For the slew rate refer to <a href="#">Appendix F, “Electrical Characteristics.”</a><br>0 Slew rate controlled<br>1 Not slew rate controlled                                                        |
|      |           |                                                                                                                                                                                                                                                              |

**Table 2-5. PDMCR Field Descriptions (continued)**

| Bits  | Name     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

<sup>1</sup> This bit was RESERVED on the K27S mask set of MPC561.

## 2.4 Pad Module Configuration Register (PDMCR2)

The PDMCR2 controls alternate functionality of signals shared between different modules, as well as the pre-discharge circuitry to allow 5V friendliness on the data bus.

| 1111        |                          |                          |

### NOTE

PCS\_IN[3:0] are driven from the QSMCM module. PCS\_OUT[7:0] values are driven by the corresponding PCS[7:0] pads. If all of the PCS enable bits PCS4EN, PCS5EN, PCS6EN and PCS7EN bits are zero, PCS[3:0] will be driven directly by the QSMCM module. If one or more of these enable bits is set, the enhanced PCS function is selected, and the enabled pads drive PCS\_OUT[7:0] value, as shown in [Table 2-9](#).

[Table 2-10](#) details the functionality of the A\_T2CLK/PCS5 and B\_T2CLK/PCS4 pads dependent on the values of PDMCR2[PCS5EN], PDMCR2[PCS4EN] and SHORT\_REG [SH\_T2CLK]. Also shown in this table is the internal connection of the TPU signals when the enhanced chip select function is used.

**Table 2-10. Enhanced PCS 4 & 5 Pad Function**

| PDMCR2 [PCS5EN] | PDMCR2 [PCS4EN] | SHORT_REG [SH_T2CLK] | A_T2CLK/PCS5 PAD Function | B_T2CLK/PCS4 PAD Function | A_T2CLK internal TPU_A Connection | B_T2CLK internal TPU_B Connection   |

| 0               | 1               | 1                    | A_T2CLK                   | PCS4                      | A_T2CLK/PCS5 Pad                    | A_T2CLK/PCS5 Pad                                             |
| 1               | 0               | 0                    | PCS5                      | B_T2CLK                   | A_T2CLK Signal driven HI internally | B_T2CLK/PCS4 Pad                                             |
| 1               | 0               | 1                    | PCS5                      | B_T2CLK                   | A_T2CLK Signal driven HI internally | B_T2CLK Signal driven HI internally by connection to A_T2CLK |
| 1               | 1               | 0                    | PCS5                      | PCS4                      | A_T2CLK Signal driven HI internally | B_T2CLK Signal driven HI internally                          |
| 1               | 1               | 1                    | PCS5                      | PCS4                      | A_T2CLK Signal driven HI internally | B_T2CLK Signal driven HI internally by connection to A_T2CLK |

1. If PCS4/5EN = 1 then A/B\_T2CLK into the module is pulled up internally (enabling Div/8 clock, in gate mode).
2. If only PCS4EN=1, then A\_T2CLK can be driven into B\_T2CLK if PPM\_SHORT[SH\_T2CLK] is set.
3. If only PCS5EN=1 then A\_T2CLK will be pulled up, if PPM\_SHORT[SH\_T2CLK] is set, then, B\_T2CLK will be high regardless of pin state.

All of this is regardless of the Pull up/down state.

**Note:** The PPM shorting function has higher priority logic. If shorting is selected, then A\_T2CLK → B\_T2CLK. If A\_T2CLK is selected as PCS then both A\_T2CLK and B\_T2CLK will be high regardless of B\_T2CLK/PCS4 Pad state.

Table 2-11 details the functionality of the ETRIG1/PCS6 and ETRIG2/PCS7 pads dependent on the values of PDMCR2[PCS6EN], PDMCR2[PCS7EN], SHORT\_REG [SH\_ET1] and SHORT\_REG [SH\_ET2]. Also shown in this table is the internal connection of the ETRIG signals when the enhanced chip select function is used.

| 1                  | 1                  | 0             | 1                         | 1                         | PCS6                        | PCS7                        | Enabled        | A_TPUCH15                         | B_TPUCH15                        |
| 1                  | 1                  | 1             | 0                         | 0                         | PCS6                        | PCS7                        | Disabled       | PCS6                              | PCS7                             |
| 1                  | 1                  | 1             | 1                         | 1                         | PCS6                        | PCS7                        | Disabled       | A_TPUCH15                         | B_TPUCH15                        |

On the MPC561/MPC563, the JTAG, BDM, and READI (Nexus interface) signals are all shared. Only one set of signals can be active at a time. [Table 2-12](#) shows the shared functions in the different modes.

Table 2-12. MPC561/MPC563 Development Support Shared Signals

| Signal <sup>1</sup>             | Direction | JTAG  | BDM  | READI                    |
|---------------------------------|-----------|-------|------|--------------------------|
| JCOMP/ $\overline{\text{RSTI}}$ | Input     | JCOMP | 0    | $\overline{\text{RSTI}}$ |
| TCK/DSCK/MCKI                   | Input     | TCK   | DSCK | MCKI                     |
| TDI/DSDI/MDIO                   | Input     | TDI   | DSDI | MDIO                     |
| TDO/DSDO/MDO0                   | Output    | TDO   | DSDO | MDO0                     |
| TMS/ $\overline{\text{EVTI}}$   | Input     | TMS   | —    | $\overline{\text{EVTI}}$ |

<sup>1</sup>Only one set of signals are enabled at a time.

Table 2-13. MPC561/MPC563 Mode Selection Options

| Signal                     | State | When Sampled                              | Affect                |
|----------------------------|-------|-------------------------------------------|-----------------------|
| <b>BDM Mode</b>            |       |                                           |                       |
| DSCK                       | High  | $\overline{\text{SRESET}}$ negation       | BDM mode enabled      |

|                            | Low   | $\overline{\text{RSTI}}$ negation         | READI module Enabled  |
| MDI0                       | High  | $\overline{\text{EVTI}}$ negation         | Full Port mode        |
|                            | Low   | $\overline{\text{EVTI}}$ negation         | Reduced port mode     |
| <b>JTAG Selection</b>      |       |                                           |                       |
| JCOMP                      | Low   | $\overline{\text{PORESET}}$               | Nexus or BDM allowed  |
|                            | High  | $\overline{\text{PORESET}}$               | JTAG Mode Selected    |

## 2.5.1 JTAG Mode Selection

The MPC561/MPC563 has five JTAG signals. The test data input (TDI) and test data output (TDO) scan ports are used to scan instructions as well as data into the various scan registers for JTAG operations. The scan operation is controlled by the test access port (TAP) controller, which in turn is controlled by the test mode select (TMS) input sequence. The scan data is latched at the rising edge of the test clock (TCK).

On the MPC561/MPC563, JTAG is used for boundary scan only. There is no access to internal MPC561/MPC563 circuitry. When JTAG mode is enabled, the READI module will be held inactive. See [Figure 2-4](#) for JTAG mode selection.

JTAG is entered by the following sequence of events:

- Assert  $\overline{\text{PORESET}}/\overline{\text{TRST}}$  to reset the JTAG TAP controller
- Hold JCOMP/ $\overline{\text{RSTI}}$  high prior to  $\overline{\text{PORESET}}/\overline{\text{TRST}}$  negation and keep high as long as JTAG mode is required

(The READI module will be held inactive since only one of the multiplexed functions JCOMP and  $\overline{\text{RSTI}}$  can be asserted at the negation of  $\overline{\text{PORESET}}/\overline{\text{TRST}}$ ).

JTAG mode is exited by:

- Drive JCOMP/ $\overline{\text{RSTI}}$  low.

### NOTE

$\overline{\text{PORESET}}/\overline{\text{TRST}}$  and analog signals ANx, EXTAL, XTAL, and TDI/TDO/TMS/TCK are not in the JTAG scan path.

Figure 2-4. Debug Mode Selection (JTAG)

## 2.5.2 BDM Mode Selection

The MPC561/MPC563 has a 10 pin BDM port. See [Figure 2-5](#) for BDM mode selection.

The BDM mode is entered by the following sequence of events:

- Hold DSCK high at reset negation ( $\overline{\text{SRESET}}$ )
- Configure DSDI to select BDM clock mode, within 8 clocks of reset negation

BDM mode is exited by:

- Reset the device by asserting  $\overline{\text{PORESET/TRST}}$  or  $\overline{\text{HRESET}}$

Figure 2-5. Debug Mode Selection (BDM)

## 2.5.3 Nexus Mode Selection

The READI module signals support the Nexus (IEEE-ISTO 5001-1999) auxiliary port interface for debug. There are two modes available: full port mode and reduced port mode. Reduced port mode allows for a 1 bit input stream and a 2 bit output stream. Full port mode allows for a 2-bit input stream and an 8-bit output stream. If MDI0 is held high when Nexus mode is enabled, full port mode will be used during Nexus debug. If MDI0 is held low when Nexus mode is enabled, reduced port mode will be used. See [Figure 2-6](#) for Nexus mode selection.

The Nexus interface is entered by the following sequence of events:

- Hold JCOMP/ $\overline{\text{RSTI}}$  low while negating  $\overline{\text{PORESET/TRST}}$
- Hold TMS/ $\overline{\text{EVTI}}$  low to enable Nexus mode and configure TDI/DSDI/MDI0 for full or reduced port mode. Both of these should be done at least 4 clocks before driving JCOMP/ $\overline{\text{RSTI}}$  high

- Drive JCOMP/ $\overline{\text{RSTI}}$  high

Nexus mode is exited by:

- Hold JCOMP/ $\overline{\text{RSTI}}$  low to reset Nexus port
- Hold TMS/ $\overline{\text{EVTI}}$  high to disable Nexus mode at least 4 clocks before driving JCOMP/ $\overline{\text{RSTI}}$  high
- Drive JCOMP/ $\overline{\text{RSTI}}$  high

Figure 2-6. Debug Mode Selection (Nexus)

## 2.6 Reset State

During reset, a 130- $\mu\text{A}$  (maximum) resistor “weakly pulls” all input signals, with the exception of the power-supply and clock-related signals, to a value based on conditions described in [Appendix F, “Electrical Characteristics.”](#) In reset state, all I/O signals become inputs, and all outputs (except for CLKOUT,  $\overline{\text{HRESET}}$ , and  $\overline{\text{SRESET}}$ ) are pulled only by the pull-up/pull-down.

### 2.6.1 Signal Functionality Configuration Out of Reset

The reset configuration word (RCW) defines the post-reset functionality of some multiplexed signals. For details on these signals and how they are configured, refer to Section 7.5.2, “Hard Reset Configuration Word.”

The 2.6-V bus related signals have selectable output buffer drive strengths that are controlled by the COM0 bit in the USIU’s system clock and reset control register (SCCR). The control is as follows:

- 0 = 2.6-V bus signals full drive (50-pF load)
- 1 = 2.6-V bus signals reduced drive (25-pF load)

### 2.6.2 Signal State During Reset

While  $\overline{\text{HRESET}}$  is asserted, the reset-configuration value is latched from the data bus into various bits on the part. The function of many signals depends upon the value latched. If the value on the data bus changes, then the function of various signals may also change. This is especially true if the reset configuration word (RCW) comes from the Flash, because the Flash does not drive the RCW until 256 clocks after the start of

$\overline{\text{HRESET}}$ . However, the signals must not cause any spurious conditions or consume an excessive amount of power during reset. To prevent these conditions, the signals need to have a defined reset state.

Table 2-14 describes the reset state of the signals based on signal functionality.

All signals are initialized to a “reset state” during reset. This state remains active until reset is negated or until software disables the pull-up or pull-down device based on the signal functionality. Upon assertion of the corresponding bits in the signal control registers and negation of reset, the signal acquires the functionality that was programmed.

### 2.6.3 Power-On Reset and Hard Reset

Power-on reset and hard reset affect the functionality of the signals out of reset. (During soft reset, the functionality of the signals is unaltered.)

Upon assertion of the power-on reset signal ( $\overline{\text{PORESET}}/\overline{\text{TRST}}$ ) the functionality of the signal is not yet known to the RCP. The weak pull-up or weak pull-down resistors are enabled. The reset configuration word configures the system, and towards the end of reset the signal functionality is known. Based upon the signal functionality, the pull-up or pull-down devices are either disabled immediately at the negation of reset or remain enabled, as shown in Table 2-14.

Because hard reset can occur when a bus cycle is pending, the PDMCR bits that enable and disable the pull-up or pull-down resistors are set or reset synchronously to eliminate contention on the signals. ( $\overline{\text{PORESET}}/\overline{\text{TRST}}$  affects these bits asynchronously.)

### 2.6.4 Pull-Up/Pull-Down

#### 2.6.4.1 Pull-Up/Pull-Down Enable and Disable for 5-V Only and 2.6-V Only Signals

The pull resistors are enabled and disabled by the corresponding bits in the PDMCR register in the USIU (see Table 2-14). When those bits are negated (logic 0), the pull resistors are enabled. When asserted (logic 1), the devices are disabled.

#### 2.6.4.2 Pull-Down Enable and Disable for 5-V/2.6-V Multiplexed Signals

The 5-V/2.6-V multiplexed pad does not have a pull-up device. The pull-down will be controlled by the corresponding bits in the PDMCR register. When this bit is negated, the pull-down is enabled, when asserted the pull-down will be disabled.

#### NOTE

All pull-up/pull-down devices are disabled when all the signals are forced to three state in JTAG mode.

#### 2.6.4.3 Special Pull Resistor Disable Control Functionality (SPRDS)

For the signals that support debug, opcode tracking, and bus control functionality, the pull resistors will be controlled by the SPRDS bit in the PDMCR register. During reset this signal will be synchronously used

to enable the pull resistors in the pads. On negation of reset, based on which functionality is selected for the signals, this signal is set to disable the pull resistors, or is continued to be held in its reset state to indicate that the pulls are disabled only when the output driver is enabled.

#### 2.6.4.4 Pull Device Select (PULL\_SEL)

The MIOS14 and the TPU signals have selectable pull-up or pull-down devices. The devices are controlled by the PULL\_SEL signal. A high on the PULL\_SEL signal enables pull-up devices on the MIOS14 and TPU signals. A low enables pull-down devices. Note that the pull devices can be disabled by the PULL\_DIS0 (MIOS14) and PRDS (TPU) bits in the PDMCR register. See [Section 2.3, “Pad Module Configuration Register \(PDMCR\)”](#).

#### 2.6.5 Signal Reset States

[Table 2-14](#) summarizes the reset states of all signals on the MPC561/MPC563. Note that PD refers to a weak pull-down, PU2.6 refers to a weak pull-up to 2.6 V, and PU5 refers to a weak pull-up to 5 V. All control of the weak-pull devices is in the pad module configuration register, described in [Table 2-5](#).

##### NOTE

2.6-V inputs are 5-V tolerant, but 2.6-V outputs are not. Do not connect 2.6-V outputs to a driver or pull-up greater than 3.1 V.

##### NOTE

Depending on the application, pins may require a pull-down resistor to avoid getting any command due to noise.

Table 2-14. MPC561/MPC563 Signal Reset State

| VDDA                     | 5 V          | —                            | —                            | —           | —                   | VDDA                                                                         |
| VSSA                     | 0 V          | —                            | —                            | —           | —                   | VSSA                                                                         |

<sup>1</sup> This column contains only the list of signals and should not be confused with the actual pin name. For actual pin names, see [Appendix F, “Electrical Characteristics.”](#)

<sup>2</sup> For 5-V outputs, the left hand value represents slew rate control off, and the right hand value represents slew rate control on. For 2.6-V outputs, the left hand value represents loads that are full drive, and the right hand value represents loads that are half drive.

<sup>3</sup> Care should be taken that neither a pull-up to greater than 3.1 V or an external output that can drive greater than 3.1 V is connected to this pin while the 2.6-V driver is enabled.

<sup>4</sup> Pull-up/pull-down is active when pin is defined as an input and/or during reset, therefore, output enable is negated. This also means that external pull-up/pull-down is NOT required unless specified.

<sup>5</sup> For this 5-V output, a drive load of 200 pF is possible but with a rise/fall time of 300 ns.

<sup>6</sup> During reset, the output enable to the pad driver is negated and the PD is active. After reset is negated, the PD is disabled.

<sup>7</sup> 2.6-V outputs cannot be connected to a pull-up or driver greater than 3.1 V.

<sup>8</sup> This pin requires a pull-up to 2.6 V if interrupts are ever enabled for this IRQ input.

<sup>9</sup> This signal also includes the MDO5 function on the K27S mask set of the MPC561.

<sup>10</sup> The MODCK[1:3] are shared functions with  $\overline{\text{IRQ}}[5:7]$ . If  $\overline{\text{IRQ}}[5:7]$  are used as interrupts, the interrupt source should be removed during  $\overline{\text{PORESET/TRST}}$  to insure the MODCK pins are in the correct state on the rising edge of  $\overline{\text{PORESET/TRST}}$ .

<sup>11</sup> These pins are powered by KAPWR (keep-alive power supply). Any pull-ups on these pins should pull-up to KAPWR.

- <sup>12</sup> An external pull-up is required in order to negate the signal in the appropriate time.
- <sup>13</sup> This pin is 5-V tolerant.
- <sup>14</sup> This signal was PD only until SPRDS is set on mask set K27S of the MPC561.
- <sup>15</sup> These values represent full drive, half drive and quarter drive.
- <sup>16</sup> Whether the Pull device is a pull-up or a pull-down is determined by the state of the PULL\_SEL signal.
- <sup>17</sup> For this 5-V output, a drive load of 200 pf is possible, but will have a rise/fall time of 100ns.
- <sup>18</sup> MPC563 only, no connection on MPC561.
- <sup>19</sup> IRAMSTBY is the input to an approximately 1.7V voltage regulator. It should be connected through a resistor to a standby power supply.

## Chapter 3

# Central Processing Unit

The RISC processor (RCPU) used in the MPC500 family of microcontrollers integrates five independent execution units: an integer unit (IU), a load/store unit (LSU), a branch processing unit (BPU), a floating-point unit (FPU) and an integer multiplier divider (IMD). The RISC's use of simple instructions with rapid execution times yields high efficiency and throughput for PowerPC ISA-based systems.

Most integer instructions execute in one clock cycle. Instructions can complete out of order for increased performance; however, the processor makes execution appear sequential.

This section provides an overview of the RCPU. For a detailed description of this processor, refer to the *RCPU Reference Manual*. The following sections describe each block and sub-block.

### 3.1 RCPU Block Diagram

Figure 3-1 provides a block diagram of the RCPU.

Figure 3-1. RCPU Block Diagram

## 3.2 RCPU Key Features

Major features of the RCPU include:

- High-performance microprocessor
  - Single clock-cycle execution for many instructions
- Five independent execution units and two register files
  - Independent LSU for load and store operations
  - BPU featuring static branch prediction
  - A 32-bit integer unit (IU)
  - Fully IEEE 754-compliant FPU for both single- and double-precision operations except as noted in [Section 3.4.4, “Floating-Point Unit \(FPU\)”](#), or refer to the *RCPU Reference Manual*.
  - 32 general-purpose registers (GPRs) for integer operands
  - 32 floating-point registers (FPRs) for single- or double-precision operands
- Facilities for enhanced system performance
  - Atomic memory references
- In-system testability and debugging features
- High instruction and data throughput
  - Condition register (CR) look-ahead operations performed by BPU
  - Branch-folding capability during execution (zero-cycle branch execution time)
  - Programmable static branch prediction on unresolved conditional branches
  - A pre-fetch queue that can hold up to four instructions, providing look-ahead capability
  - Interlocked pipelines with feed-forwarding that control data dependencies in hardware
- Class code compression model support
  - Efficient use of internal Flash (MPC564) and external Flash (MPC562/MPC564) by increasing code density up to 100%

## 3.3 Instruction Sequencer

The instruction sequencer provides centralized control over data flow between execution units and register files. It implements the basic instruction pipeline, fetches instructions from the memory system, issues them to available execution units, and maintains a state history that is used to back up the machine in the event of an exception.

The instruction sequencer fetches instructions from the burst buffer controller into the instruction pre-fetch queue. The BPU extracts branch instructions from the pre-fetch queue and, using branch prediction on unresolved conditional branches, allows the instruction sequencer to fetch instructions from a predicted target stream while a conditional branch is evaluated. The BPU folds out branch instructions for unconditional or conditional branches unaffected by instructions in the execution stage.

Instructions issued beyond a predicted branch do not complete execution until the branch is resolved, preserving the programming model of sequential execution. If branch prediction is incorrect, the instruction unit flushes all predicted path instructions, and instructions are issued from the correct path.

Figure 3-2. Sequencer Data Path

### 3.4 Independent Execution Units

The PowerPC ISA architecture provides independent floating-point, integer, load/store, and branch processing execution units, making it possible to implement advanced features such as look-ahead operations. For example, since branch instructions do not depend on GPRs, branches can often be resolved early, eliminating stalls caused by taken branches.

Table 3-1 summarizes the RCPU execution units.

Table 3-1. RCPU Execution Units

| Unit                         | Description                                                                                                                                   |
|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| Branch processing unit (BPU) | Includes the implementation of all branch instructions.                                                                                       |
| Load/store unit (LSU)        | Includes implementation of all load and store instructions, whether defined as part of the integer processor or the floating-point processor. |

**Table 3-1. RCPU Execution Units (continued)**

| Unit                      | Description                                                                                                                                                                                                                                                                                                                                                                                                           |
|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Integer unit (IU)         | Includes implementation of all integer instructions except load/store instructions. This module includes the GPRs (including GPR history and scoreboard) and the following subunits: the IMUL-IDIV, which includes the implementation of the integer multiply and divide instructions and the ALU-BFU, which includes implementation of all integer logic, add and subtract instructions, and bit field instructions. |
| Floating-point unit (FPU) | Includes the FPRs (including FPR history and scoreboard) and the implementation of all floating-point instructions except load/store floating-point instructions.                                                                                                                                                                                                                                                     |

The following sections describe these execution units in greater detail.

### 3.4.1 Branch Processing Unit (BPU)

The BPU, located within the instruction sequencer, performs condition register look-ahead operations on conditional branches. The BPU looks through the instruction queue for a conditional branch instruction and attempts to resolve it early, achieving the effect of a zero-cycle branch in many cases.

The BPU uses a bit in the instruction encoding to predict the direction of the conditional branch. Therefore, when it encounters an unresolved conditional branch instruction, the processor pre-fetches instructions from the predicted target stream until the conditional branch is resolved.

The BPU uses a calculation feature to compute branch target addresses with three special-purpose, user-accessible registers: the link register (LR), the count register (CTR), and the condition register (CR). The BPU calculates the return pointer for a subroutine, then calls and saves it into the LR. The LR also contains the branch target address for the branch conditional to link register (bclrx) instruction. The CTR contains the branch target address for the branch conditional to count register (bcctrx) instruction. The contents of the LR and CTR can be copied to or from any GPR. Because the BPU uses dedicated registers rather than general-purpose or floating-point registers, execution of branch instructions is independent from execution of integer instructions. The CR bits indicate conditions that may result from the execution of relevant instructions.

### 3.4.2 Integer Unit (IU)

The IU executes all integer processor instructions (except the integer storage access instructions) implemented by the load/store unit. The IU contains the following subunits:

- The IMUL-IDIV unit, which implements the integer multiply and divide instructions
- The Arithmetic Logic Unit (ALU)-BFU unit, which implements all integer logic, add, subtract, and bit-field instructions

The IU also includes the integer exception register (XER) and the general-purpose register file.

IMUL-IDIV and ALU-BFU are implemented as separate execution units. The ALU-BFU unit can execute one instruction per clock cycle. IMUL-IDIV instructions require multiple clock cycles to execute. IMUL-IDIV is pipelined for multiply instructions, so that consecutive multiply instructions can be issued

on consecutive clock cycles. Divide instructions are not pipelined; an integer divide instruction preceded or followed by an integer divide or multiply instruction results in a processor-pipeline stall. However, since IMUL–IDIV and ALU–BFU are implemented as separate execution units, an integer divide instruction preceded or followed by an ALU–BFU instruction does not cause a delay in the pipeline.

### 3.4.3 Load/Store Unit (LSU)

The load/store unit handles all data transfer between the general-purpose register file and the internal load/store bus (L-bus). The load/store unit is implemented as an independent execution unit so that stalls in the memory pipeline do not stall the master instruction pipeline (unless there is a data dependency). The unit is fully pipelined so that memory instructions of any size may be issued on back-to-back cycles.

There is a 32-bit wide data path between the load/store unit and the general-purpose register file. Single-word accesses can be achieved with an internal on-chip data RAM, resulting in a two-clock latency. Double-word accesses require two clocks, resulting in a three-clock latency. Since the L-bus is 32 bits wide, double-word transfers require two bus accesses. The load/store unit performs zero-fill for byte and half-word transfers and sign extension for half-word transfers.

Addresses are formed by adding the source-one register operand specified by the instruction (or zero) to either a source-two register operand or to a 16-bit, immediate value embedded in the instruction.

### 3.4.4 Floating-Point Unit (FPU)

The FPU contains a double-precision multiply array, the floating-point status and control register (FPSCR), and the FPRs. The multiply-add array allows the RCPU to efficiently implement floating-point operations such as multiply, multiply-add, and divide.

The RCPU depends on a software envelope to fully implement the IEEE floating-point specification. Overflows, underflows, NaNs (not a number), and denormalized numbers cause floating-point assist exceptions that invoke a software routine to deliver (with hardware assistance) the correct IEEE result.

To accelerate time-critical operations and make them more deterministic, the RCPU provides a mode of operation that avoids invoking a software envelope and attempts to deliver results in hardware that are adequate for most applications, if not in strict compliance with IEEE standards. In this mode, denormalized numbers, NaNs, and IEEE invalid operations are legitimate, returning default results rather than causing floating-point assist exceptions.

## 3.5 Levels of the PowerPC ISA Architecture

The PowerPC ISA architecture consists of three levels:

- User instruction set architecture (UISA) — defines the base user-level instruction set, user-level registers, data types, floating-point exception model, memory models for a uniprocessor environment, and programming model for a uniprocessor environment.
- Virtual environment architecture (VEA) — describes the memory model for a multiprocessor environment, and describes other aspects of virtual environments. Implementations that conform to the VEA also adhere to the UISA, but may not necessarily adhere to the OEA.

- Operating environment architecture (OEA) — defines the memory-management model, supervisor-level registers, synchronization requirements, and the exception model. Implementations that conform to the OEA also adhere to the UISA and the VEA.

Adherence to the PowerPC ISA architecture can be measured in terms of which of the levels are implemented.

## 3.6 RCPU Programming Model

The PowerPC ISA architecture defines register-to-register operations for most computational instructions. Source operands for these instructions are accessed from the registers or are embedded in the instruction opcode. The three-register instruction format allows specification of a target register distinct from the two source operands. Load and store instructions transfer data between memory and on-chip registers.

PowerPC ISA-compliant processors have two levels of privilege: supervisor mode (typically used by the operating environment) and user mode (used by the application software). The programming model incorporates 32 GPRs, special-purpose registers (SPRs), and several miscellaneous registers.

Supervisor-level access is provided through the processor's exception mechanism. That is, when an exception is taken (whether automatically, because of an error or problem that needs to be serviced, or deliberately, as in the case of a trap instruction), the processor begins operating in supervisor mode. The access level is indicated by the privilege-level (PR) bit in the machine state register (MSR).

Figure 3-3 illustrates the user-level and supervisor-level RCPU programming models and the three levels of the PowerPC ISA architecture. Note that registers such as the general-purpose registers (GPRs) are accessed through operands that are part of the instructions. Registers can be accessed explicitly through specific instructions such as move to special-purpose register (mtspr) or move from special-purpose register (mfspr), or implicitly as part of an instruction's execution. Some registers are accessed both explicitly and implicitly.

Figure 3-3. RCPU Programming Model

Table 3-2 lists the MPC561/MPC563 supervisor-level registers; refer also to [Chapter 6, “System Configuration and Protection,”](#) [Chapter 11, “L-Bus to U-Bus Interface \(L2U\),”](#) and [Chapter 4, “Burst Buffer Controller 2 Module,”](#) for more information.

**Table 3-2. Supervisor-Level SPRs**

| SPR Number<br>(Decimal) | Special-Purpose Register                                                                                                                                       |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 18                      | DAE/Source Instruction Service Register (DSISR)<br>See <a href="#">Section 3.9.2, “DAE/Source Instruction Service Register (DSISR),”</a> for bit descriptions. |
| 19                      | Data Address Register (DAR)<br>See <a href="#">Section 3.9.3, “Data Address Register (DAR),”</a> for bit descriptions.                                         |
| 22                      | Decrementer Register (DEC)<br>See <a href="#">Section 6.1.6, “Decrementer (DEC).”</a> for bit descriptions.                                                    |

<sup>1</sup> All development-support SPRs are implementation-specific.

Unless otherwise noted, reserved fields should be written with a zero when written and return zero when read. An exception to this rule is XER[16:23]; see [Section 3.7.5, “Integer Exception Register \(XER\)”](#). These bits are set to the value written to them and return that value when read.

## 3.7 User Instruction Set Architecture (UISA) Register Set

The UISA registers can be accessed by either user- or supervisor-level instructions. The general-purpose registers are accessed through instruction operands.

### 3.7.1 General-Purpose Registers (GPRs)

Integer data is manipulated in the integer unit’s thirty-two 32-bit GPRs, shown below. These registers are accessed as source and destination registers through operands in the instruction syntax.

**Figure 3-4. General-Purpose Registers (GPRs)**

### 3.7.2 Floating-Point Registers (FPRs)

The PowerPC ISA architecture provides 32 64-bit FPRs. These registers are accessed as source and destination registers through operands in floating-point instructions. Each FPR supports the double-precision, floating-point format. Every instruction that interprets the contents of an FPR as a

floating-point value does so using the double-precision floating-point format. Therefore, all floating-point numbers are stored in double-precision format.

All floating-point arithmetic instructions operate on data located in FPRs and, with the exception of the compare instructions (which update the CR), place the result into an FPR. Information about the status of floating-point operations is placed into the floating-point status and control register (FPSCR) and in some cases, after the completion of the operation's writeback stage, into the CR. For information on how the CR is affected by floating-point operations, see [Section 3.7.4, "Condition Register \(CR\)."](#)

**Figure 3-5. Floating-Point Registers (FPRs)**

### 3.7.3 Floating-Point Status and Control Register (FPSCR)

The FPSCR controls the handling of floating-point exceptions and records status resulting from the floating-point operations. FPSCR[0:23] are status bits. FPSCR[24:31] are control bits.

FPSCR[0:12] and FPSCR[21:23] are floating-point exception condition bits. These bits are sticky, except for the floating-point enabled exception summary (FEX) and floating-point invalid operation exception summary (VX). Once set, sticky bits remain set until they are cleared by an mcrfs, mtfsfi, mtfsf, or mtfsb0 instruction.

[Table 3-4](#) summarizes which bits in the FPSCR are sticky status bits, which are normal status bits, and which are control bits.

**Table 3-4. FPSCR Bit Categories**

| Bits                 | Type               |
|----------------------|--------------------|
| [0], [3:12], [21:23] | Status, sticky     |
| [1:2], [13:20]       | Status, not sticky |
| [24:31]              | Control            |

FEX and VX are the logical ORs of other FPSCR bits. Therefore these two bits are not listed among the FPSCR bits directly affected by the various instructions.

**Figure 3-6. Floating-Point Status and Control Register (FPSCR)**

A listing of FPSCR bit settings is shown in [Table 3-5](#).

**Table 3-5. FPSCR Bit Descriptions**

| Bits | Name   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                  |            |
|------|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------|
| 0    | FX     | Floating-point exception summary. Every floating-point instruction implicitly sets FPSCR[FX] if that instruction causes any of the floating-point exception bits in the FPSCR to change from 0 to 1. The mcrfs instruction implicitly clears FPSCR[FX] if the FPSCR field containing FPSCR[FX] has been copied. The mtfsf, mtfsfi, mtfsb0, and mtfsb1 instructions can set or clear FPSCR[FX] explicitly.                                    | Sticky bit |
| 1    | FEX    | Floating-point enabled exception summary. This bit signals the occurrence of any of the enabled exception conditions. It is the logical OR of all the floating-point exception bits masked with their respective enable bits. The mcrfs instruction implicitly clears FPSCR[FEX] if the result of the logical OR described above becomes zero. The mtfsf, mtfsfi, mtfsb0, and mtfsb1 instructions cannot set or clear FPSCR[FEX] explicitly. | Not sticky |
| 2    | VX     | Floating-point invalid operation exception summary. This bit signals the occurrence of any invalid operation exception. It is the logical OR of all of the invalid operation exceptions. The mcrfs instruction implicitly clears FPSCR[VX] if the result of the logical OR described above becomes zero. The mtfsf, mtfsfi, mtfsb0, and mtfsb1 instructions cannot set or clear FPSCR[VX] explicitly.                                        | Not sticky |
| 3    | OX     | Floating-point overflow exception.                                                                                                                                                                                                                                                                                                                                                                                                           | Sticky bit |
| 4    | UX     | Floating-point underflow exception.                                                                                                                                                                                                                                                                                                                                                                                                          | Sticky bit |
| 5    | ZX     | Floating-point zero divide exception.                                                                                                                                                                                                                                                                                                                                                                                                        | Sticky bit |
| 6    | XX     | Floating-point inexact exception.                                                                                                                                                                                                                                                                                                                                                                                                            | Sticky bit |
| 7    | VXSNAN | Floating-point invalid operation exception for SNaN.                                                                                                                                                                                                                                                                                                                                                                                         | Sticky bit |
| 8    | VXISI  | Floating-point invalid operation exception for $\infty - \infty$ .                                                                                                                                                                                                                                                                                                                                                                           | Sticky bit |
| 9    | VXIDI  | Floating-point invalid operation exception for $\infty/\infty$ .                                                                                                                                                                                                                                                                                                                                                                             | Sticky bit |
| 10   | VXZDZ  | Floating-point invalid operation exception for 0/0.                                                                                                                                                                                                                                                                                                                                                                                          | Sticky bit |
| 11   | VXIMZ  | Floating-point invalid operation exception for $\infty \times 0$ .                                                                                                                                                                                                                                                                                                                                                                           | Sticky bit |

**Table 3-5. FPSCR Bit Descriptions (continued)**

| Bits    | Name   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |            |

| 12      | VXVC   | Floating-point invalid operation exception for invalid compare.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | Sticky bit |
| 13      | FR     | Floating-point fraction rounded. The last floating-point instruction that potentially rounded the intermediate result incremented the fraction.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | Not sticky |
| 14      | FI     | Floating-point fraction inexact. The last floating-point instruction that potentially rounded the intermediate result produced an inexact fraction or a disabled exponent overflow.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | Not sticky |
| [15:19] | FPRF   | <p>Floating-point result flags. This field is based on the value placed into the target register even if that value is undefined. Refer to <a href="#">Table 3-6</a> for specific bit settings.</p> <p>15 Floating-point result class descriptor (C). Floating-point instructions other than the compare instructions may set this bit with the FPCC bits, to indicate the class of the result.</p> <p>16-19 Floating-point condition code (FPCC). Floating-point compare instructions always set one of the FPCC bits to one and the other three FPCC bits to zero. Other floating-point instructions may set the FPCC bits with the C bit, to indicate the class of the result. Note that in this case the high-order three bits of the FPCC retain their relational significance indicating that the value is less than, greater than, or equal to zero.</p> <p>16 Floating-point less than or negative (FL or &lt;)</p> <p>17 Floating-point greater than or positive (FG or &gt;)</p> <p>18 Floating-point equal or zero (FE or =)</p> <p>19 Floating-point unordered or NaN (FU or ?)</p> | Not sticky |

| 21      | VXSOFT | Floating-point invalid operation exception for software request. This bit can be altered only by the mcrfs, mtfshi, mtfsh, mtfshb0, or mtfshb1 instructions. The purpose of VXSOFT is to allow software to cause an invalid operation condition for a condition that is not necessarily associated with the execution of a floating-point instruction. For example, it might be set by a program that computes a square root if the source operand is negative.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | Sticky bit |
| 22      | VXSQRT | Floating-point invalid operation exception for invalid square root. This guarantees that software can simulate fsqrt and frsqre, and can provide a consistent interface to handle exceptions caused by square root operations.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | Sticky bit |

Table 3-6 illustrates the floating-point result flags that correspond to FPSCR[15:19].

**Table 3-6. Floating-Point Result Flags in FPSCR**

| Result Flags<br>(Bits 15:19)<br>C<=>=? | Result Value Class    |
|----------------------------------------|-----------------------|
| 10001                                  | Quiet NaN             |
| 01001                                  | – Infinity            |
| 01000                                  | – Normalized number   |
| 11000                                  | – Denormalized number |
| 10010                                  | – Zero                |
| 00010                                  | + Zero                |
| 10100                                  | + Denormalized number |
| 00100                                  | + Normalized number   |
| 00101                                  | + Infinity            |

### 3.7.4 Condition Register (CR)

The condition register (CR) is a 32-bit register that reflects the result of certain operations and provides a mechanism for testing and branching. The bits in the CR are grouped into eight 4-bit fields: CR0 to CR7.

**Figure 3-7. Condition Register (CR)**

The CR fields can be set in the following ways:

- Specified fields of the CR can be set by an instruction (mterf) to move to the CR from a GPR.
- Specified fields of the CR can be moved from one CRx field to another with the mcrf instruction.
- A specified field of the CR can be set by an instruction (mcrxr) to move to the CR from the XER.
- Condition register logical instructions can be used to perform logical operations on specified bits in the condition register.
- CR0 can be the implicit result of an integer operation.

- A specified CR field can be the explicit result of an integer compare instruction.

Instructions are provided to test individual CR bits.

### 3.7.4.1 Condition Register CR0 Field Definition

In most integer instructions, when the CR is set to reflect the result of the operation (that is, when  $R_c = 1$ ), and for addic., andi., and andis., the first three bits of CR0 are set by an algebraic comparison of the result to zero; the fourth bit of CR0 is copied from XER[SO]. For integer instructions, CR0[0:3] are set to reflect the result as a signed quantity. The EQ bit reflects the result as an unsigned quantity or bit string.

The CR0 bits are interpreted as shown in [Table 3-7](#). If any portion of the result (the 32-bit value placed into the destination register) is undefined, the value placed in the first three bits of CR0 is undefined.

**Table 3-7. Bit Settings for CR0 Field of CR**

| CR0 Bit | Description                                                                                               |
|---------|-----------------------------------------------------------------------------------------------------------|
| 0       | Negative (LT). This bit is set when the result is negative.                                               |
| 1       | Positive (GT). This bit is set when the result is positive (and not zero).                                |
| 2       | Zero (EQ). This bit is set when the result is zero.                                                       |
| 3       | Summary overflow (SO). This is a copy of the final state of XER[SO] at the completion of the instruction. |

### 3.7.4.2 Condition Register CR1 Field Definition

In all floating-point instructions when the CR is set to reflect the result of the operation (that is, when  $R_c = 1$ ), the CR1 field (bits 4 to 7 of the CR) is copied from FPSCR[0:3] to indicate the floating-point exception status. For more information about the FPSCR, see [Section 3.7.3, “Floating-Point Status and Control Register \(FPSCR\).”](#) The bit settings for the CR1 field are shown in [Table 3-8](#).

**Table 3-8. Bit Settings for CR1 Field of CR**

| CR1 Bit | Description                                                                                                                   |
|---------|-------------------------------------------------------------------------------------------------------------------------------|
| 0       | Floating-point exception (FX). This is a copy of the final state of FPSCR[FX] at the completion of the instruction.           |
| 1       | Floating-point enabled exception (FEX). This is a copy of the final state of FPSCR[FEX] at the completion of the instruction. |
| 2       | Floating-point invalid exception (VX). This is a copy of the final state of FPSCR[VX] at the completion of the instruction.   |
| 3       | Floating-point overflow exception (OX). This is a copy of the final state of FPSCR[OX] at the completion of the instruction.  |

### 3.7.4.3 Condition Register CR<sub>n</sub> Field — Compare Instruction

When a specified CR field is set by a compare instruction, the bits of the specified field are interpreted as shown in [Table 3-9](#). A condition register field can also be accessed by the mfc<sub>r</sub>, mcr<sub>f</sub>, and mtrcf instructions.

**Table 3-9. CRn Field Bit Settings for Compare Instructions**

| CRn Bit <sup>1</sup> | Description                                                                                                                                                                                                                                                                 |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0                    | Less than, floating-point less than (LT, FL).<br>For integer compare instructions, (rA) < SIMM, UIMM, or (rB) (algebraic comparison) or (rA) SIMM, UIMM, or (rB) (logical comparison). For floating-point compare instructions, (frA) < (frB).                              |
| 1                    | Greater than, floating-point greater than (GT, FG).<br>For integer compare instructions, (rA) > SIMM, UIMM, or (rB) (algebraic comparison) or (rA) SIMM, UIMM, or (rB) (logical comparison). For floating-point compare instructions, (frA) > (frB).                        |
| 2                    | Equal, floating-point equal (EQ, FE).<br>For integer compare instructions, (rA) = SIMM, UIMM, or (rB).<br>For floating-point compare instructions, (frA) = (frB).                                                                                                           |
| 3                    | Summary overflow, floating-point unordered (SO, FU).<br>For integer compare instructions, this is a copy of the final state of XER[SO] at the completion of the instruction. For floating-point compare instructions, one or both of (frA) and (frB) is not a number (NaN). |

<sup>1</sup> Here, the bit indicates the bit number in any one of the four-bit subfields, CR0–CR7

### 3.7.5 Integer Exception Register (XER)

The integer exception register (XER), SPR 1, is a user-level, 32-bit register.

|       |           |    |    |   |   |   |                          |   |   |   |    |    |    |    |    |    |    |    |    |    |    |    |    |    |           |    |    |    |    |    |     |    |
|-------|-----------|----|----|---|---|---|--------------------------|---|---|---|----|----|----|----|----|----|----|----|----|----|----|----|----|----|-----------|----|----|----|----|----|-----|----|
|       | MSB       |    |    |   |   |   |                          |   |   |   |    |    |    |    |    |    |    |    |    |    |    |    |    |    |           |    |    |    |    |    | LSB |    |
|       | 0         | 1  | 2  | 3 | 4 | 5 | 6                        | 7 | 8 | 9 | 10 | 11 | 12 | 13 | 14 | 15 | 16 | 17 | 18 | 19 | 20 | 21 | 22 | 23 | 24        | 25 | 26 | 27 | 28 | 29 | 30  | 31 |
| Field | SO        | OV | CA | — |   |   |                          |   |   |   |    |    |    |    |    |    |    |    |    |    |    |    |    |    | BYTES     |    |    |    |    |    |     |    |
| Reset | Unchanged |    |    |   |   |   | 00_0000_0000_0000_0000_0 |   |   |   |    |    |    |    |    |    |    |    |    |    |    |    |    |    | Unchanged |    |    |    |    |    |     |    |
| Addr  | SPR 1     |    |    |   |   |   |                          |   |   |   |    |    |    |    |    |    |    |    |    |    |    |    |    |    |           |    |    |    |    |    |     |    |

**Figure 3-8. Integer Exception Register (XER)**

The bit descriptions for XER, shown in [Table 3-10](#), are based on the operation of an instruction considered as a whole, not on intermediate results. For example, the result of the subtract from carrying (subfcx) instruction is specified as the sum of three values. This instruction sets bits in the XER based on the entire operation, not on an intermediate sum.

In most cases, reserved fields in registers are ignored when written to and return zero when read. However, XER[16:23] are set to the value written to them and return that value when read.

**Table 3-10. Integer Exception Register Bit Descriptions**

| Bits | Name | Description                                                                                                                                                                                                                                                                                                                                                       |
|------|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0    | SO   | Summary Overflow (SO). The summary overflow bit is set whenever an instruction sets the overflow bit (OV) to indicate overflow and remains set until software clears it. It is not altered by compare instructions or other instructions that cannot overflow.                                                                                                    |
| 1    | OV   | Overflow (OV). The overflow bit is set to indicate that an overflow has occurred during execution of an instruction. Integer and subtract instructions having OE=1 set OV if the carry out of bit 0 is not equal to the carry out of bit 1, and clear it otherwise. The OV bit is not altered by compare instructions or other instructions that cannot overflow. |

**Table 3-10. Integer Exception Register Bit Descriptions**

| Bits  | Name  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-------|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2     | CA    | Carry (CA). In general, the carry bit is set to indicate that a carry out of bit 0 occurred during execution of an instruction. Add carrying, subtract from carrying, add extended, and subtract from extended instructions set CA if there is a carry out of bit 0, and clear it otherwise. The CA bit is not altered by compare instructions or other instructions that cannot carry, except that shift right algebraic instructions set the CA bit to indicate whether any '1' bits have been shifted out of a negative quantity. |
| 3:24  | —     | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| 25:31 | BYTES | This field specifies the number of bytes to be transferred by a Load String Word Indexed (lswx) or Store String Word Indexed (stswx) instruction.                                                                                                                                                                                                                                                                                                                                                                                    |

### 3.7.6 Link Register (LR)

The link register (LR), SPR 8, supplies the branch target address for the branch conditional to link register (bclrx) instruction, and can be used to hold the logical address of the instruction that follows a branch and link instruction.

Note that although the two least-significant bits can accept any values written to them, they are ignored when the LR is used as an address.

Both conditional and unconditional branch instructions include the option of placing the effective address of the instruction after the branch instruction in the LR. This is done regardless of whether the branch is taken.

**Figure 3-9. Link Register (LR)**

### 3.7.7 Count Register (CTR)

The count register (CTR), SPR 9, is used to hold a loop count that can be decremented during execution of branch instructions with an appropriately coded BO field. If the value in CTR is 0 before being decremented, it is –1 afterward. The count register provides the branch target address for the branch conditional to count register (bcctrx) instruction.

**Figure 3-10. Count Register (CTR)**

### 3.8 VEA Register Set — Time Base (TB)

The virtual environment architecture (VEA) defines registers in addition to the UISA register set. The VEA register set can be accessed by all software with either user- or supervisor-level privileges. Refer to [Section 6.1.7, “Time Base \(TB\)”](#) for more information.

### 3.9 OEA Register Set

The operating environment architecture (OEA) includes a number of SPRs and other registers that are accessible only by supervisor-level instructions. Some SPRs are RCPU-specific; some RCPU SPRs may not be implemented in other PowerPC ISA processors, or may not be implemented in the same way.

#### 3.9.1 Machine State Register (MSR)

The machine state register is a 32-bit register that defines the state of the processor. When an exception occurs, the contents of the MSR are loaded into SRR1, and the MSR is updated to reflect the exception-processing machine state. The MSR can also be modified by the mtmsr, sc, and rfi instructions. It can be read by the mfmsr instruction.

**Figure 3-11. Machine State Register (MSR)**

- <sup>1</sup> This bit is available only on code compression-enabled options of the MPC561/MPC563.
- <sup>2</sup> The reset value is a reset configuration word value extracted from the internal bus line. Refer to [Section 7.5.2, “Hard Reset Configuration Word \(RCW\)”](#).
- <sup>3</sup> The reset value is defined by the equation "BBCMCR[EN\_COMP] AND BBCMCR[EXC\_COMP]". At HRESET the BBCMCR[EN\_COMP] and BBCMCR[EXC\_COMP] bits receive their values from RCW bits 21 and 22. The BBCMCR does not change at SRESET. Thus the DCMPE1 reset value may be different on SRESET and HRESET, if software changes these BBCMCR bits from their reset values.

[Table 3-11](#) shows the bit definitions for the MSR.

**Table 3-11. Machine State Register Bit Descriptions**

| Bits | Name | Description                                                                                                                        |
|------|------|------------------------------------------------------------------------------------------------------------------------------------|
| 0:12 | —    | Reserved                                                                                                                           |

| Bits | Name | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|------|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 14   | —    | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| 15   | ILE  | Exception little-endian mode. When an exception occurs, this bit is copied into MSR[LE] to select the endian mode for the context established by the exception. Little-endian mode is not supported on the MPC561/MPC563. This bit should be cleared to 0 at all times.<br>0 The processor runs in big-endian mode during exception processing.<br>1 The processor runs in little-endian mode during exception processing.                                                                                                                                                                       |
| 16   | EE   | External interrupt enable. Interrupts should only be negated while the EE bit is disabled (0). Software should disable interrupts (EE = 0) in the RCPU before clearing or masking any interrupt source from the USIU or external pins. For external interrupts, it is recommended that the edge-triggered interrupt scheme be used. See <a href="#">Section 6.1.4, “Enhanced Interrupt Controller.”</a><br>0 The processor delays recognition of external interrupts and decremter exception conditions.<br>1 The processor is enabled to take an external interrupt or the decremter exception. |
| 17   | PR   | Privilege level.<br>0 The processor can execute both user- and supervisor-level instructions.<br>1 The processor can only execute user-level instructions.                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| 18   | FP   | Floating-point available.<br>0 The processor prevents dispatch of floating-point instructions, including floating-point loads, stores and moves. Floating-point enabled program exceptions can still occur and the FPRs can still be accessed.<br>1 The processor can execute floating-point instructions, and can take floating-point enabled exception type program exceptions.                                                                                                                                                                                                                |
| 19   | ME   | Machine check enable.<br>0 Machine check exceptions are disabled.<br>1 Machine check exceptions are enabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 20   | FE0  | Floating-point exception mode 0 (See <a href="#">Table 3-12.</a> )                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| 21   | SE   | Single-step trace enable.<br>0 The processor executes instructions normally.<br>1 The processor generates a single-step trace exception when the next instruction executes successfully. When this bit is set, the processor dispatches instructions in strict program order. Successful execution means the instruction caused no other exception.                                                                                                                                                                                                                                              |
| 22   | BE   | Branch trace enable.<br>0 No trace exception occurs when a branch instruction is completed.<br>1 Trace exception occurs when a branch instruction is completed.                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| 23   | FE1  | Floating-point exception mode 1 (See <a href="#">Table 3-12.</a> )                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| 24   | —    | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| 25   | IP   | Exception prefix. The setting of this bit specifies the location of the exception vector table.<br>0 Exception vector table starts at the physical address 0x0000 0000.<br>1 Exception vector table starts at the physical address 0xFFFF0 0000.                                                                                                                                                                                                                                                                                                                                                 |
| 26   | IR   | Instruction relocation.<br>0 Instruction address translation is off; the BBC IMPU does not check for address permission attributes.<br>1 Instruction address translation is on; the BBC IMPU checks for address permission attributes.                                                                                                                                                                                                                                                                                                                                                           |

**Table 3-11. Machine State Register Bit Descriptions (continued)**

| Bits | Name   | Description                                                                                                                                                                                                                                                                                                                                                                                                                            |
|------|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 27   | DR     | Data relocation.<br>0 Data address translation is off; the L2U DMPU does not check for address permission attributes.<br>1 Data address translation is on; the L2U DMPU checks for address permission attributes.                                                                                                                                                                                                                      |
| 28   | —      | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                               |
| 29   | DCMPEN | Decompression On/Off. The reset value of this bit is (BBCMCR[EN_COMP] AND BBCMCR[EXC_COMP]).<br><b>Note:</b> This bit should not be set for the MPC561/MPC563.<br>0 The RCPU runs in normal operation mode.<br>1 The RCPU runs in compressed mode.<br><b>Note:</b> MSR[DCMPEN] should not be changed by software by a direct MSR register write (MTMSR instruction). It can be changed only by the RFI instruction or by an exception. |
| 30   | RI     | Recoverable exception (for machine check and non-maskable breakpoint exceptions).<br>0 Machine state is not recoverable.<br>1 Machine state is recoverable.                                                                                                                                                                                                                                                                            |
| 31   | LE     | Little-endian mode. This mode is not supported on MPC561/MPC563. This bit should be cleared to 0 at all times.<br>0 The processor operates in big-endian mode during normal processing.<br>1 The processor operates in little-endian mode during normal processing.                                                                                                                                                                    |

The floating-point exception mode bits are interpreted as shown in [Table 3-12](#).

**Table 3-12. Floating-Point Exception Mode Bits**

| FE[0:1]    | Mode                                                                                                                                                   |
|------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| 00         | Ignore exceptions mode. Floating-point exceptions do not cause the floating-point assist error handler to be invoked.                                  |
| 01, 10, 11 | Floating-point precise mode. The system floating-point assist error handler is invoked precisely at the instruction that caused the enabled exception. |

### 3.9.2 DAE/Source Instruction Service Register (DSISR)

The DSISR, SPR 18, identifies the cause of data access and alignment exceptions.

|       |           |   |   |   |   |   |   |   |   |   |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |     |
|-------|-----------|---|---|---|---|---|---|---|---|---|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|-----|
|       | MSB       |   |   |   |   |   |   |   |   |   |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    | LSB |
|       | 0         | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 | 13 | 14 | 15 | 16 | 17 | 18 | 19 | 20 | 21 | 22 | 23 | 24 | 25 | 26 | 27 | 28 | 29 | 30 | 31  |
| Field | DSISR     |   |   |   |   |   |   |   |   |   |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |     |
| Reset | Unchanged |   |   |   |   |   |   |   |   |   |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |     |
| Addr  | SPR 18    |   |   |   |   |   |   |   |   |   |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |     |

**Figure 3-12. DAE/Source Instruction Service Register (DSISR)**

For more information about bit settings, see [Section 3.15.4.2, “Machine Check Exception \(0x0200\),”](#) [Section 3.15.4.6, “Alignment Exception \(0x00600\),”](#) and [Section 3.15.4.15, “Implementation-Specific Data Protection Error Exception \(0x1400\).”](#)

### 3.9.3 Data Address Register (DAR)

After an alignment exception, the DAR, SPR 19, is set to the effective address of a load or store element.

|       |              |   |   |   |   |   |   |   |   |   |   |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |     |
|-------|--------------|---|---|---|---|---|---|---|---|---|---|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|-----|
|       | MSB          | 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 | 13 | 14 | 15 | 16 | 17 | 18 | 19 | 20 | 21 | 22 | 23 | 24 | 25 | 26 | 27 | 28 | 29 | 30 | 31 | LSB |
| Field | Data Address |   |   |   |   |   |   |   |   |   |   |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |     |
| Reset | Unchanged    |   |   |   |   |   |   |   |   |   |   |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |     |
| Addr  | SPR 19       |   |   |   |   |   |   |   |   |   |   |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |     |

Figure 3-13. Data Address Register (DAR)

### 3.9.4 Time Base Facility (TB) — OEA

Refer to [Section 6.1.7, “Time Base \(TB\),”](#) for information.

### 3.9.5 Decrementer Register (DEC)

Refer to [Section 6.1.6, “Decrementer \(DEC\),”](#) for information.

### 3.9.6 Machine Status Save/Restore Register 0 (SRR0)

The machine status save/restore register 0 (SRR0), SPR 26, identifies where instruction execution should resume when an rfi instruction is executed following an exception. It also holds the effective address of the instruction that follows the system call (sc) instruction.

|       |           |   |   |   |   |   |   |   |   |   |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |     |
|-------|-----------|---|---|---|---|---|---|---|---|---|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|-----|
|       | MSB       |   |   |   |   |   |   |   |   |   |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    | LSB |
|       | 0         | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 | 13 | 14 | 15 | 16 | 17 | 18 | 19 | 20 | 21 | 22 | 23 | 24 | 25 | 26 | 27 | 28 | 29 | 30 | 31  |
| Field | SRR0      |   |   |   |   |   |   |   |   |   |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |     |
| Reset | Undefined |   |   |   |   |   |   |   |   |   |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |     |
| Addr  | SPR 26    |   |   |   |   |   |   |   |   |   |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |     |

Figure 3-14. Machine Status Save/Restore Register 0 (SRR0)

When an exception occurs, SRR0 is set to point to an instruction such that all prior instructions have completed execution and no subsequent instruction has begun execution. The instruction addressed by SRR0 may not have completed execution, depending on the exception type. SRR0 addresses either the instruction causing the exception or the instruction immediately following. The instruction addressed can be determined from the exception type and status bits.

### 3.9.7 Machine Status Save/Restore Register 1 (SRR1)

The machine status save/restore register 1 (SRR1), SPR 27, saves the machine status on exceptions and restores the machine status when an rfi instruction is executed.

**Figure 3-15. Machine Status Save/Restore Register 1 (SRR1)**

In general, when an exception occurs, SRR1[0:15] are loaded with exception-specific information, and MSR[16:31] are placed into SRR1[16:31].

### 3.9.8 General SPRs (SPRG0–SPRG3)

SPRG0–SPRG3, SPRs 272–275, are provided for general operating system use, such as fast-state saves and multiprocessor-implementation support. SPRG0–SPRG3 are shown below.

**Figure 3-16. SPRG0–SPRG3 — General Special-Purpose Registers 0–3**

Uses for SPRG0–SPRG3 are shown in [Table 3-13](#).

**Table 3-13. Uses of SPRG0–SPRG3**

| Register | Description                                                                                                                                                                                             |
|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SPRG0    | Software may load a unique physical address in this register to identify an area of memory reserved for use by the exception handler. This area must be unique for each processor in the system.        |
| SPRG1    | This register may be used as a scratch register by the exception handler to save the content of a GPR. That GPR then can be loaded from SPRG0 and used as a base register to save other GPRs to memory. |
| SPRG2    | This register may be used by the operating system as needed.                                                                                                                                            |
| SPRG3    | This register may be used by the operating system as needed.                                                                                                                                            |

### 3.9.9 Processor Version Register (PVR)

The PVR is a 32-bit, read-only register that identifies the version and revision level of the processor. The contents of the PVR can be copied to a GPR by the mfspr instruction. Read access to the PVR is available in supervisor mode only; write access is not provided.

|       |                     |   |   |   |   |   |   |   |   |   |    |    |    |    |    |    |                     |    |    |    |    |    |    |    |    |    |    |    |    |    |    |     |  |
|-------|---------------------|---|---|---|---|---|---|---|---|---|----|----|----|----|----|----|---------------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|-----|--|
|       | MSB                 |   |   |   |   |   |   |   |   |   |    |    |    |    |    |    |                     |    |    |    |    |    |    |    |    |    |    |    |    |    |    | LSB |  |
|       | 0                   | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 | 13 | 14 | 15 | 16                  | 17 | 18 | 19 | 20 | 21 | 22 | 23 | 24 | 25 | 26 | 27 | 28 | 29 | 30 | 31  |  |
| Field | VERSION             |   |   |   |   |   |   |   |   |   |    |    |    |    |    |    | REVISION            |    |    |    |    |    |    |    |    |    |    |    |    |    |    |     |  |
| Reset | 0000_0000_0000_0010 |   |   |   |   |   |   |   |   |   |    |    |    |    |    |    | 0000_0000_0010_0000 |    |    |    |    |    |    |    |    |    |    |    |    |    |    |     |  |
| Addr  | SPR 287             |   |   |   |   |   |   |   |   |   |    |    |    |    |    |    |                     |    |    |    |    |    |    |    |    |    |    |    |    |    |    |     |  |

Figure 3-17. Processor Version Register (PVR)

Table 3-14. Processor Version Register Bit Descriptions

| Bits  | Name     | Description                                                                                                    |
|-------|----------|----------------------------------------------------------------------------------------------------------------|
| 0:15  | VERSION  | A 16-bit number that identifies the version of the PowerPC ISA processor. The RCPU value is 0x0002.            |
| 16:31 | REVISION | A 16-bit number that distinguishes between various releases of a particular version. The RCPU value is 0x0020. |

### 3.9.10 Implementation-Specific SPRs

The MPC561/MPC563 includes several implementation-specific SPRs that are not defined by the PowerPC ISA architecture. These registers, listed in [Table 3-2](#) and [Table 3-3](#), can be accessed by supervisor-level instructions only.

#### 3.9.10.1 EIE, EID, and NRI Special-Purpose Registers

The RCPU includes three implementation-specific SPRs that facilitate the software manipulation of the MSR[RI] and MSR[EE] bits: External Interrupt Enable (EIE), External Interrupt Disable (EID), and Non-recoverable Interrupt (NRI). Issuing the mtspr instruction with one of these registers as an operand causes the RI and EE bits to be set or cleared as shown in [Table 3-15](#).

Table 3-15. EIE, EID, AND NRI Registers

| SPR Number (Decimal) | Mnemonic | MSR[EE] | MSR[RI] |
|----------------------|----------|---------|---------|
| 80                   | EIE      | 1       | 1       |
| 81                   | EID      | 0       | 1       |
| 82                   | NRI      | 0       | 0       |

A read (mfspr) of any of these locations is treated as an unimplemented instruction, resulting in a software emulation exception.

### 3.9.10.2 Floating-Point Exception Cause Register (FPECR)

The FPECR, SPR 1022, is a supervisor-level internal status and control register used by the user's floating-point assist software envelope. It contains four status bits that indicate whether the result of the operation is tiny and whether any of three source operands are denormalized. In addition, it contains one control bit to enable or disable SIE mode. This register must not be accessed by user code.

**Figure 3-18. Floating-Point Exception Cause Register (FPECR)**

A listing of FPECR bit settings is shown in [Table 3-16](#).

**Table 3-16. FPECR Bit Descriptions**

| Bits | Name | Description                                                                                                               |
|------|------|---------------------------------------------------------------------------------------------------------------------------|
| 0    | SIE  | Synchronized ignore exception mode control bit.<br>0 Disable SIE mode<br>1 Enable SIE mode                                |
| 1:27 | —    | Reserved                                                                                                                  |
| 28   | DNC  | Source operand C denormalized status bit.<br>0 Source operand C is not denormalized<br>1 Source operand C is denormalized |
| 29   | DNB  | Source operand B denormalized status bit.<br>0 Source operand B is not denormalized<br>1 Source operand B is denormalized |
| 30   | DNA  | Source operand A denormalized status bit.<br>0 Source operand A is not denormalized<br>1 Source operand A is denormalized |
| 31   | TR   | Floating-point tiny result.<br>0 Floating-point result is not tiny<br>1 Floating-point result is tiny                     |

#### NOTE

Software must insert a sync instruction before reading the FPECR.

### 3.9.10.3 Additional Implementation-Specific Registers

Refer to the following sections for details on additional implementation-specific registers in the MPC561/MPC563:

- [Section 4.6, “BBC Programming Model”](#)
- [Section 6.2.2.1.2, “Internal Memory Map Register \(IMMR\)”](#)
- [Section 11.8, “L2U Programming Model”](#)
- [Chapter 23, “Development Support”](#)

## 3.10 Instruction Set

All PowerPC ISA instructions are encoded as single words (32 bits) and are consistent among all instruction types. The fixed instruction length and consistent format simplify instruction pipelining and permit efficient decoding to occur in parallel with operand accesses.

The PowerPC ISA instructions are divided into the following categories:

- Integer instructions, which include computational and logical instructions
  - Integer arithmetic instructions
  - Integer compare instructions
  - Integer logical instructions
  - Integer rotate and shift instructions
- Floating-point instructions, which include floating-point computational instructions, as well as instructions that affect the floating-point status and control register (FPSCR)
  - Floating-point arithmetic instructions
  - Floating-point multiply/add instructions
  - Floating-point rounding and conversion instructions
  - Floating-point compare instructions
  - Floating-point status and control instructions
- Load/store instructions, which include integer and floating-point load and store instructions
  - Integer load and store instructions
  - Integer load and store multiple instructions
  - Floating-point load and store
  - Primitives used to construct atomic memory operations (lwarx and stwex. instructions)
- Flow control instructions, which include branching instructions, condition register logical instructions, trap instructions, and other instructions that affect the instruction flow
  - Branch and trap instructions
  - Condition register logical instructions
- Processor control instructions, which are used for synchronizing memory accesses.
  - Move to/from SPR instructions
  - Move to/from MSR

- Synchronize
- Instruction synchronize

### NOTE

This grouping of the instructions does not indicate which execution unit executes a particular instruction or group of instructions.

Integer instructions operate on byte, half-word, and word operands. Floating-point instructions operate on single-precision (one word) and double-precision (one double word) floating-point operands. The PowerPC ISA architecture uses instructions that are four bytes long and word-aligned. It provides for byte, half-word, and word operand loads and stores between memory and a set of 32 GPRs.

Computational instructions do not modify memory. To use a memory operand in a computation and then modify the same or another memory location, the memory contents must be loaded into a register, modified, and then written back to the target location with distinct instructions.

PowerPC ISA-compliant processors follow the program flow when they are in the normal execution state. However, the flow of instructions can be interrupted directly by the execution of an instruction or by an asynchronous event. Either kind of exception may cause one of several components of the system software to be invoked.

## 3.10.1 Instruction Set Summary

Table 3-17 provides a summary of RCPU instructions. Refer to the *RCPU Reference Manual* for a detailed description of the instruction set.

**Table 3-17. Instruction Set Summary**

| Mnemonic                      | Operand Syntax | Name                              |
|-------------------------------|----------------|-----------------------------------|
| add (add. addo addo.)         | rD,rA,rB       | Add                               |
| addc (addc. addco addco.)     | rD,rA,rB       | Add Carrying                      |
| adde (adde. addeo addeo.)     | rD,rA,rB       | Add Extended                      |
| addi                          | rD,rA,SIMM     | Add Immediate                     |
| addic                         | rD,rA,SIMM     | Add Immediate Carrying            |
| addic.                        | rD,rA,SIMM     | Add Immediate Carrying and Record |
| addis                         | rD,rA,SIMM     | Add Immediate Shifted             |
| addme (addme. addmeo addmeo.) | rD,rA          | Add to Minus One Extended         |
| addze (addze. addzeo addzeo.) | rD,rA          | Add to Zero Extended              |
| and (and.)                    | rA,rS,rB       | AND                               |
| andc (andc.)                  | rA,rS,rB       | AND with Complement               |
| andi.                         | rA,rS,UIMM     | AND Immediate                     |

Table 3-17. Instruction Set Summary (continued)

| Mnemonic                    | Operand Syntax    | Name                                                    |
|-----------------------------|-------------------|---------------------------------------------------------|
| bc (bca bcl bcla)           | BO,BI,target_addr | Branch Conditional                                      |
| bcctr (bcctrl)              | BO,BI             | Branch Conditional to Count Register                    |
| bclr (bclrl)                | BO,BI             | Branch Conditional to Link Register                     |
| cmp                         | crfD,L,rA,rB      | Compare                                                 |
| cmpi                        | crfD,L,rA,SIMM    | Compare Immediate                                       |
| cmpl                        | crfD,L,rA,rB      | Compare Logical                                         |
| cmpi                        | crfD,L,rA,UIMM    | Compare Logical Immediate                               |
| cntlzw (cntlzw.)            | rA,rS             | Count Leading Zeros Word                                |
| crand                       | crbD,crbA,crbB    | Condition Register AND                                  |
| crandc                      | crbD,crbA, crbB   | Condition Register AND with Complement                  |
| creqv                       | crbD,crbA, crbB   | Condition Register Equivalent                           |
| crnand                      | crbD,crbA,crbB    | Condition Register NAND                                 |
| crnor                       | crbD,crbA,crbB    | Condition Register NOR                                  |
| cror                        | crbD,crbA,crbB    | Condition Register OR                                   |
| crorc                       | crbD,crbA, crbB   | Condition Register OR with Complement                   |
| crxor                       | crbD,crbA,crbB    | Condition Register XOR                                  |
| divw (divw. divwo divwo.)   | rD,rA,rB          | Divide Word                                             |
| divwu divwu. divwuo divwuo. | rD,rA,rB          | Divide Word Unsigned                                    |
| eieio                       | —                 | Enforce In-Order Execution of I/O                       |
| eqv (eqv.)                  | rA,rS,rB          | Equivalent                                              |
| extsb (extsb.)              | rA,rS             | Extend Sign Byte                                        |
| extsh (extsh.)              | rA,rS             | Extend Sign Half Word                                   |
| fabs (fabs.)                | frD,frB           | Floating Absolute Value                                 |
| fadd (fadd.)                | frD,frA,frB       | Floating Add (Double-Precision)                         |
| fadds (fadds.)              | frD,frA,frB       | Floating Add Single                                     |
| fcmpo                       | crfD,frA,frB      | Floating Compare Ordered                                |
| fcmpu                       | crfD,frA,frB      | Floating Compare Unordered                              |
| fctiw (fctiw.)              | frD,frB           | Floating Convert to Integer Word                        |
| fctiwz (fctiwz.)            | frD,frB           | Floating Convert to Integer Word with Round Toward Zero |
| fdiv (fdiv.)                | frD,frA,frB       | Floating Divide (Double-Precision)                      |
| fdivs (fdivs.)              | frD,frA,frB       | Floating Divide Single                                  |
| fmadd (fmadd.)              | frD,frA,frC,frB   | Floating Multiply-Add (Double-Precision)                |

Table 3-17. Instruction Set Summary (continued)

| Mnemonic           | Operand Syntax  | Name                                                   |
|--------------------|-----------------|--------------------------------------------------------|
| fmadds (fmadds.)   | frD,frA,frC,frB | Floating Multiply-Add Single                           |
| fmr (fmr.)         | frD,frB         | Floating Move Register                                 |
| fmsub (fmsub.)     | frD,frA,frC,frB | Floating Multiply-Subtract (Double-Precision)          |
| fmsubs (fmsubs.)   | frD,frA,frC,frB | Floating Multiply-Subtract Single                      |
| fmul (fmul.)       | frD,frA,frC     | Floating Multiply (Double-Precision)                   |
| fmuls (fmuls.)     | frD,frA,frC     | Floating Multiply Single                               |
| fnabs (fnabs.)     | frD,frB         | Floating Negative Absolute Value                       |
| fneg (fneg.)       | frD,frB         | Floating Negate                                        |
| fnmadd (fnmadd.)   | frD,frA,frC,frB | Floating Negative Multiply-Add (Double-Precision)      |
| fnmadds (fnmadds.) | frD,frA,frC,frB | Floating Negative Multiply-Add Single                  |
| fnmsub (fnmsub.)   | frD,frA,frC,frB | Floating Negative Multiply-Subtract (Double-Precision) |
| fnmsubs (fnmsubs.) | frD,frA,frC,frB | Floating Negative Multiply-Subtract Single             |
| frsp (frsp.)       | frD,frB         | Floating Round to Single                               |
| fsub (fsub.)       | frD,frA,frB     | Floating Subtract (Double-Precision)                   |
| fsubs (fsubs.)     | frD,frA,frB     | Floating Subtract Single                               |
| isync              | —               | Instruction Synchronize                                |
| lbz                | rD,d(rA)        | Load Byte and Zero                                     |
| lbzu               | rD,d(rA)        | Load Byte and Zero with Update                         |
| lbzux              | rD,rA,rB        | Load Byte and Zero with Update Indexed                 |
| lbzx               | rD,rA,rB        | Load Byte and Zero Indexed                             |
| lfd                | frD,d(rA)       | Load Floating-Point Double                             |
| lfdv               | frD,d(rA)       | Load Floating-Point Double with Update                 |
| lfdvux             | frD,rA,rB       | Load Floating-Point Double with Update Indexed         |
| lfdx               | frD,rA,rB       | Load Floating-Point Double Indexed                     |
| lfs                | frD,d(rA)       | Load Floating-Point Single                             |
| lfsu               | frD,d(rA)       | Load Floating-Point Single with Update                 |
| lfsux              | frD,rA,rB       | Load Floating-Point Single with Update Indexed         |
| lfsx               | frD,rA,rB       | Load Floating-Point Single Indexed                     |
| lha                | rD,d(rA)        | Load Half-Word Algebraic                               |
| lhau               | rD,d(rA)        | Load Half-Word Algebraic with Update                   |
| lhaux              | rD,rA,rB        | Load Half-Word Algebraic with Update Indexed           |

Table 3-17. Instruction Set Summary (continued)

| Mnemonic         | Operand Syntax | Name                                       |
|------------------|----------------|--------------------------------------------|
| lhax             | rD,rA,rB       | Load Half-Word Algebraic Indexed           |
| lhbrx            | rD,rA,rB       | Load Half-Word Byte-Reverse Indexed        |
| lhz              | rD,d(rA)       | Load Half-Word and Zero                    |
| lhzu             | rD,d(rA)       | Load Half-Word and Zero with Update        |
| lhzux            | rD,rA,rB       | Load Hal-Word and Zero with Update Indexed |
| lhzx             | rD,rA,rB       | Load Half-Word and Zero Indexed            |
| lmw              | rD,d(rA)       | Load Multiple Word                         |
| lswi             | rD,rA,NB       | Load String Word Immediate                 |
| lswx             | rD,rA,rB       | Load String Word Indexed                   |
| lwarx            | rD,rA,rB       | Load Word and Reserve Indexed              |
| lwbrx            | rD,rA,rB       | Load Word Byte-Reverse Indexed             |
| lwz              | rD,d(rA)       | Load Word and Zero                         |
| lwzu             | rD,d(rA)       | Load Word and Zero with Update             |
| lwzux            | rD,rA,rB       | Load Word and Zero with Update Indexed     |
| lwzx             | rD,rA,rB       | Load Word and Zero Indexed                 |
| mcrf             | crfD,crfS      | Move Condition Register Field              |
| mcrfs            | crfD,crfS      | Move to Condition Register from FPSCR      |
| mcrxr            | crfD           | Move to Condition Register from XER        |
| mfcrr            | rD             | Move from Condition Register               |
| mffs (mffs.)     | frD            | Move from FPSCR                            |
| mfmsr            | rD             | Move from Machine State Register           |
| mfspr            | rD,SPR         | Move from Special Purpose Register         |
| mttb             | rD, TBR        | Move from Time Base                        |
| mtcrf            | CRM,rS         | Move to Condition Register Fields          |
| mtfsb0 (mtfsb0.) | crbD           | Move to FPSCR Bit 0                        |
| mtfsb1 (mtfsb1.) | crbD           | Move to FPSCR Bit 1                        |
| mtfsf (mtfsf.)   | FM,frB         | Move to FPSCR Fields                       |
| mtfsfi (mtfsfi.) | crfD,IMM       | Move to FPSCR Field Immediate              |
| mtmsr            | rS             | Move to Machine State Register             |
| mtspr            | SPR,rS         | Move to Special Purpose Register           |
| mulhw (mulhw.)   | rD,rA,rB       | Multiply High Word                         |
| mulhwu (mulhwu.) | rD,rA,rB       | Multiply High Word Unsigned                |
| mulli            | rD,rA,SIMM     | Multiply Low Immediate                     |

Table 3-17. Instruction Set Summary (continued)

| Mnemonic                      | Operand Syntax | Name                                            |
|-------------------------------|----------------|-------------------------------------------------|
| mullw (mullw. mullwo mullwo.) | rD,rA,rB       | Multiply Low                                    |
| nand (nand.)                  | rA,rS,rB       | NAND                                            |
| neg (neg. nego nego.)         | rD,rA          | Negate                                          |
| nor (nor.)                    | rA,rS,rB       | NOR                                             |
| or (or.)                      | rA,rS,rB       | OR                                              |
| orc (orc.)                    | rA,rS,rB       | OR with Complement                              |
| ori                           | rA,rS,UIMM     | OR Immediate                                    |
| oris                          | rA,rS,UIMM     | OR Immediate Shifted                            |
| rfi                           | —              | Return from Interrupt                           |
| rlwimi (rlwimi.)              | rA,rS,SH,MB,ME | Rotate Left Word Immediate then Mask Insert     |
| rlwinm (rlwinm.)              | rA,rS,SH,MB,ME | Rotate Left Word Immediate then AND with Mask   |
| rlwnm (rlwnm.)                | rA,rS,rB,MB,ME | Rotate Left Word then AND with Mask             |
| sc                            | —              | System Call                                     |
| slw (slw.)                    | rA,rS,rB       | Shift Left Word                                 |
| sraw (sraw.)                  | rA,rS,rB       | Shift Right Algebraic Word                      |
| srawi (srawi.)                | rA,rS,SH       | Shift Right Algebraic Word Immediate            |
| srw (srw.)                    | rA,rS,rB       | Shift Right Word                                |
| stb                           | rS,d(rA)       | Store Byte                                      |
| stbu                          | rS,d(rA)       | Store Byte with Update                          |
| stbux                         | rS,rA,rB       | Store Byte with Update Indexed                  |
| stbx                          | rS,rA,rB       | Store Byte Indexed                              |
| stfd                          | frS,d(rA)      | Store Floating-Point Double                     |

| xoris                             | rA,rS,UIMM     | XOR Immediate Shifted                |

**Note:** The dot (.) suffix on a mnemonic indicates that the CR register update is enabled. The **o** suffix on a mnemonic indicates that the overflow bit update in the XER is enabled.

### 3.10.2 Recommended Simplified Mnemonics

To simplify assembly language coding, a set of alternative mnemonics is provided for some frequently used operations (such as no-op, load immediate, load address, move register, and complement register).

For a complete list of simplified mnemonics, see the *RCPU Reference Manual*. Programs written to be portable across the various assemblers for the PowerPC ISA architecture should not assume the existence of mnemonics not described in that manual.

### 3.10.3 Calculating Effective Addresses

The effective address (EA) is the 32-bit address computed by the processor when executing a memory access or branch instruction or when fetching the next sequential instruction.

The PowerPC ISA architecture supports two simple memory addressing modes:

- $EA = (rA[0] + 16\text{-bit offset (including offset = 0)})$  (register indirect with immediate index)
- $EA = (rA[0] + rB)$  (register indirect with index)

These simple addressing modes allow efficient address generation for memory accesses. Calculation of the effective address for aligned transfers occurs in a single clock cycle.

For a memory access instruction, if the sum of the effective address and the operand length exceeds the maximum effective address, the storage operand is considered to wrap around from the maximum effective address to effective address 0.

Effective address computations for both data and instruction accesses use 32-bit unsigned binary arithmetic. A carry from bit 0 is ignored in 32-bit implementations.

## 3.11 Exception Model

The PowerPC ISA exception mechanism allows the processor to change to supervisor state as a result of external signals, errors, or unusual conditions that arise in the execution of instructions. When exceptions occur, information about the state of the processor is saved to certain registers, and the processor begins execution at an address (exception vector) predetermined for each exception. Processing of exceptions occurs in supervisor mode.

Although multiple exception conditions can map to a single exception vector, a more specific condition may be determined by examining a register associated with the exception — for example, the DAE/source instruction service register (DSISR). Additionally, some exception conditions can be explicitly enabled or disabled by software.

The PowerPC ISA architecture requires that exceptions be taken in program order; therefore, although a particular implementation may recognize exception conditions out of order, they are handled strictly in order with respect to the instruction stream. When an instruction-caused exception is recognized, any unexecuted instructions that appear earlier in the instruction stream, including any that have not yet entered the execute state, are required to complete before the exception is taken. For example, if a single instruction encounters multiple exception conditions, those exceptions are taken and handled sequentially. Likewise, exceptions that are asynchronous and precise are recognized when they occur, but are not handled until all instructions currently in the execute stage successfully complete execution and report their results.

Note that exceptions can occur while an exception handler routine is executing, and multiple exceptions can become nested. It is up to the exception handler to save the appropriate machine state if it is desired that control be returned to the excepting program.

In many cases, after the exception handler handles an exception, there is an attempt to execute the instruction that caused the exception. Instruction execution continues until the next exception condition is encountered. This method of recognizing and handling exception conditions sequentially guarantees that the machine state is recoverable and processing can resume without losing instruction results.

To prevent the loss of state information, exception handlers must save the information stored in SRR0 and SRR1 soon after the exception is taken to prevent this information from being lost due to another exception being taken.

### 3.11.1 Exception Classes

The RCPU exception classes are shown in [Table 3-18](#).

**Table 3-18. RCPU Exception Classes**

| Class                          | Exception Type                    |
|--------------------------------|-----------------------------------|
| Asynchronous, unordered        | Machine check<br>System reset     |
| Asynchronous, ordered          | External interrupt<br>Decrementer |
| Synchronous (ordered, precise) | Instruction-caused exceptions     |

### 3.11.2 Ordered Exceptions

In the RCPU, all exceptions except for reset, debug port non-maskable interrupts, and machine check exceptions are ordered. Ordered exceptions satisfy the following criteria:

- Only one exception is reported at a time. If, for example, a single instruction encounters multiple exception conditions, those conditions are encountered sequentially. After the exception handler handles an exception, instruction execution continues until the next exception condition is encountered.
- When the exception is taken, no program state is lost.

### 3.11.3 Unordered Exceptions

Unordered exceptions may be reported at any time and are not guaranteed to preserve program state information. The processor can never recover from a reset exception. It can recover from other unordered exceptions in most cases. However, if a debug port non-maskable interrupt or machine check exception occurs during the servicing of a previous exception, the machine state information in SRR0 and SRR1 (and, in some cases, the DAR and DSISR) may not be recoverable; the processor may be in the process of saving or restoring these registers.

To determine whether the machine state is recoverable, the RI (recoverable exception) bit in SRR1 can be read. During exception processing, the RI bit in the MSR is copied to SRR1 and then cleared. The

operating system should set the RI bit in the MSR at the end of each exception handler's prologue (after saving the program state) and clear the bit at the start of each exception handler's epilogue (before restoring the program state). Then, if an unordered exception occurs during the servicing of an exception handler, the RI bit in SRR1 will contain the correct value.

### 3.11.4 Precise Exceptions

In the RCPU, all synchronous (instruction-caused) exceptions are precise. When a precise exception occurs, the processor backs the machine up to the instruction causing the exception. This ensures that the machine is in its correct architecturally-defined state. The following conditions exist at the point a precise exception occurs:

1. Architecturally, no instruction following the faulting instruction in the code stream has begun execution.
2. All instructions preceding the faulting instruction appear to have completed with respect to the executing processor.
3. SRR0 addresses either the instruction causing the exception or the immediately following instruction. Which instruction is addressed can be determined from the exception type and the status bits.
4. Depending on the type of exception, the instruction causing the exception may not have begun execution, may have partially completed, or may have completed execution.

### 3.11.5 Exception Vector Table

The setting of the exception prefix (IP) bit in the MSR determines how exceptions are vectored. If the bit is cleared, the exception vector table begins at the physical address 0x0000 0000; if IP is set, the exception vector table begins at the physical address 0xFFFF0 0000. [Table 3-19](#) shows the exception vector offset of the first instruction of the exception handler routine for each exception type.

#### NOTE

In the MPC561/MPC563, the exception table can additionally be relocated by the BBC module to internal memory and reduce the total size required by the exception table (see [Section 4.3](#), "Exception Table Relocation (ETR)."

**Table 3-19. Exception Vector Offset Table**

| Vector Offset (hex) | Exception Type              | Section                                                                     |
|---------------------|-----------------------------|-----------------------------------------------------------------------------|

<sup>1</sup> This exception will not be generated by hardware.

## 3.12 Instruction Timing

The RCPU processor is pipelined. Because the processing of an instruction is broken into a series of stages, an instruction does not require the processor’s full resources.

The instruction pipeline in the MPC561/MPC563 has four stages:

1. The dispatch stage is implemented using a distributed mechanism. The central dispatch unit broadcasts the instruction to all units. In addition, scoreboard information (regarding data dependencies) is broadcast to each execution unit. Each execution unit decodes the instruction. If the instruction is not implemented, a program exception is taken. If the instruction is legal and no data dependency is found, the instruction is accepted by the appropriate execution unit, and the data found in the destination register is copied to the history buffer. If a data dependency exists, the machine is stalled until the dependency is resolved.
2. In the execute stage, each execution unit that has an executable instruction executes the instruction. (For some instructions, this occurs over multiple cycles.)
3. In the writeback stage, the execution unit writes the result to the destination register and reports to the history buffer that the instruction is completed.
4. In the retirement stage, the history buffer retires instructions in architectural order. An instruction retires from the machine if it completes execution with no exceptions and if all instructions preceding it in the instruction stream have finished execution with no exceptions. As many as six instructions can be retired in one clock.

The history buffer maintains the correct architectural machine state. An exception is taken only when the instruction is ready to be retired from the machine (i.e., after all previously-issued instructions have already been retired from the machine). When an exception is taken, all instructions following the excepting instruction are canceled, (i.e., the values of the affected destination registers are restored using the values saved in the history buffer during the dispatch stage).

Figure 3-19 shows basic instruction pipeline timing.

Figure 3-19. Basic Instruction Pipeline

Table 3-20 indicates the latency and blockage for each type of instruction. Latency refers to the interval from the time an instruction begins execution until it produces a result that is available for use by a

subsequent instruction. Blockage refers to the interval from the time an instruction begins execution until its execution unit is available for a subsequent instruction.

## NOTE

When the blockage equals the latency, it is not possible to issue another instruction to the same unit in the same cycle in which the first instruction is being written back.

**Table 3-20. Instruction Latency and Blockage**

| Instruction Type               | Precision | Latency               | Blockage              |
|--------------------------------|-----------|-----------------------|-----------------------|
| Floating-point multiply-add    | Double    | 7                     | 7                     |

<sup>1</sup> Refer to Section 7, “Instruction Timing,” in the *RCPU Reference Manual* (RCPURM/AD) for details.

## 3.13 User Instruction Set Architecture (UISA)

### 3.13.1 Computation Modes

The RCPURM is a 32-bit implementation of the PowerPC ISA architecture. Any reference in the PowerPC ISA architecture books (UISA, VEA, OEA) regarding 64-bit implementations are not supported by the core. All registers except the floating-point registers are 32 bits wide.

### 3.13.2 Reserved Fields

Reserved fields in instructions are described under the specific instruction definition sections. Unless otherwise noted, reserved fields should be written with a zero when written and return a zero when read. Thus, this type of invalid form instructions yield results of the defined instructions with the appropriate field zero.

In most cases, the reserved fields in registers are ignored on write and return zeros for them on read on any control register implemented by the MPC561/MPC563. Exception to this rule are bits [16:23] of the fixed-point exception cause register (XER) and the reserved bits of the machine state register (MSR), which are set by the source value on write and return the value last set for it on read.

### 3.13.3 Classes of Instructions

Non-optional instructions are implemented by the hardware. Optional instructions are executed by implementation-dependent code and any attempt to execute one of these commands causes the RCPU to take the implementation-dependent software emulation interrupt (offset 0x01000 of the vector table).

Illegal and reserved instruction class instructions are supported by implementation-dependent code and, thus, the RCPU hardware generates the implementation-dependent software emulation interrupt. Invalid and preferred instruction forms treatment by the RCPU is described under the specific processor compliance sections.

### 3.13.4 Exceptions

Invocation of the system software for any instruction-caused exception in the RCPU is precise, regardless of the type and setting.

### 3.13.5 Branch Processor

The RCPU implements all the instructions defined for the branch processor in the UISA in the hardware.

### 3.13.6 Instruction Fetching

The core fetches a number of instructions into its internal buffer (the instruction pre-fetch queue) prior to execution. If a program modifies the instructions it intends to execute, it should call a system library program to ensure that the modifications have been made visible to the instruction fetching mechanism prior to execution of the modified instructions.

### 3.13.7 Branch Instructions

The core implements all the instructions defined for the branch processor by the UISA in the hardware. For performance of various instructions, refer to [Table 3-20](#) of this manual.

#### 3.13.7.1 Invalid Branch Instruction Forms

Bits marked with z in the BO encoding definition are discarded by the MPC561/MPC563 decoding. Thus, these types of invalid form instructions yield results of the defined instructions with the z-bit zero. If the decrement and test CTR option is specified for the bcctr or bcctrl instructions, the target address of the branch is the new value of the CTR. Condition is evaluated correctly, including the value of the counter after decrement.

#### 3.13.7.2 Branch Prediction

The core uses the y bit to predict path for pre-fetch. Prediction is only done for not-ready branch conditions. No prediction is done for branches to the link or count register if the target address is not ready. Refer to the *RCPU Reference Manual* (conditional branch control) for more information.

### 3.13.8 Fixed-Point Processor

#### 3.13.8.1 Fixed-Point Instructions

The core implements the following instructions:

- Fixed-point arithmetic instructions
- Fixed-point compare instructions
- Fixed-point trap instructions
- Fixed-point logical instructions
- Fixed-point rotate and shift instructions
- Move to/from system register instructions

All instructions are defined for the fixed-point processor in the UISA in the hardware. For performance of the various instructions, refer to [Table 3-20](#).

- Move To/From System Register Instructions. Move to/from invalid special registers in which  $SPR0 = 1$  yields invocation of the privilege instruction error interrupt handler if the processor is in problem state. For a list of all implemented special registers, refer to [Table 3-2](#), and [Table 3-3](#).
- Fixed-Point Arithmetic Instructions. If an attempt is made to perform any of the divisions in the `divw[o][.]` instruction ( $0x80000000 \div -1$ ,  $\langle \text{anything} \rangle \div 0$ ), then the contents of rD are  $0x80000000$ ; if  $Rc = 1$ , the contents of bits in CR field 0 are  $LT = 1$ ,  $GT = 0$ ,  $EQ = 0$ , and  $SO$  is set to the correct value. If an attempt is made to perform any of the divisions in the `divw[o][.]` instruction,  $\langle \text{anything} \rangle \div 0$ . In `cmpi`, `cmp`, `cmpli`, and `cmpl` instructions, the L-bit is applicable for 64-bit implementations. In 32-bit implementations, if  $L = 1$  the instruction form is invalid. The core ignores this bit and therefore, the behavior when  $L = 1$  is identical to the valid form instruction with  $L = 0$ .

### 3.13.9 Floating-Point Processor

#### 3.13.9.1 General

The RCPU implements all floating-point features as defined in the UISA, including the non-IEEE working mode. Some features require software assistance. For more information refer to the *RCPU Reference Manual* (Floating-point Load Instructions).

#### 3.13.9.2 Optional Instructions

The only optional instruction implemented by RCPU hardware is store floating-point as integer word indexed (`stfiwx`). An attempt to execute any other optional instruction causes an implementation dependent software emulation exception.

### 3.13.10 Load/Store Processor

The load/store processor supports all of the 32-bit implementation fixed-point PowerPC ISA load/store instructions in the hardware.

#### 3.13.10.1 Fixed-Point Load with Update and Store with Update Instructions

For load with update and store with update instructions, when  $rA = 0$ , the EA is written into R0. For load with update instructions, when  $rA = rD$ ,  $rA$  is boundedly undefined.

#### 3.13.10.2 Fixed-Point Load and Store Multiple Instructions

For these types of instructions, EA must be a multiple of four. If it is not, the system alignment error handler is invoked. For a *lmw* instruction (if  $rA$  is in the range of registers to be loaded), the instruction completes normally.  $rA$  is then loaded from the memory location as follows:

$$rA \leftarrow \text{MEM}(\text{EA} + (rA - rD) * 4, 4)$$

#### 3.13.10.3 Fixed-Point Load String Instructions

Load string instructions behave the same as load multiple instructions, with respect to invalid format in which  $rA$  is in the range of registers to be loaded. When  $rA$  is in range, it is updated from memory.

#### 3.13.10.4 Storage Synchronization Instructions

For these type of instructions, EA must be a multiple of four. If it is not, the system alignment error handler is invoked.

#### 3.13.10.5 Floating-Point Load and Store With Update Instructions

For Load and Store with update instructions, if  $rD = 0$  then the EA is written into R0.

#### 3.13.10.6 Floating-Point Load Single Instructions

When the operand falls in the range of a single denormalized number, the floating-point assist interrupt handler is invoked.

Refer to the *RCPU Reference Manual* (Floating-point Assist For Denormalized Operands) for complete description of handling denormalized floating-point numbers.

#### 3.13.10.7 Floating-Point Store Single Instructions

When the operand falls in the range of a single denormalized number, the floating-point assist interrupt handler is invoked.

When the operand is ZERO it is converted to the correct signed ZERO in single-precision format.

When the operand is between the range of single denormalized and double denormalized it is considered a programming error. The hardware will handle this case as if the operand was single denormalized.

When the operand falls in the range of double denormalized numbers it is considered a programming error. The hardware will handle this case as if the operand was ZERO.

The following check is done on the stored operand in order to determine whether it is a denormalized single-precision operand and invoke the floating-point assist interrupt handler:

$$(\text{frS}[1:11] \neq 0) \text{ AND } (\text{frS}[1:11] \leq 896) \quad \text{Eqn. 3-1}$$

Refer to the *RCPU Reference Manual* (Floating-Point Assist for Denormalized Operands) for complete description of handling denormalized floating-point numbers.

### 3.13.10.8 Optional Instructions

No optional instructions are supported.

## 3.14 Virtual Environment Architecture (VEA)

### 3.14.1 Atomic Update Primitives

Both the lwarx and stwex instructions are implemented according to the PowerPC ISA architecture requirements. The MPC561/MPC563 does not provide support for snooping an external bus activity outside the chip. The provision is made to cancel the reservation inside the MPC561/MPC563 by using the  $\overline{\text{CR}}$  and  $\overline{\text{KR}}$  input signals. Internal buses are snooped for RCPU accesses, and the reservation mechanism can be used for multitask single master applications.

### 3.14.2 Effect of Operand Placement on Performance

The load/store unit hardware supports all of the PowerPC ISA load/store instructions. An optimal performance is obtained for naturally aligned operands. These accesses result in optimal performance (one bus cycle) for up to four bytes in size and good performance (two bus cycles) for double precision floating-point operands. Unaligned operands are supported in hardware and are broken into a series of aligned transfers. The effect of operand placement on performance is as stated in the VEA, except for the case of 8-byte operands. In that case, since the RCPU uses a 32-bit wide data bus, the performance is good rather than optimal.

### 3.14.3 Storage Control Instructions

The RCPU does not implement the following cache control instructions: icbi, dcbl, dcbl, dcbl, dcbl, dcbl, and dcbl.

### 3.14.4 Instruction Synchronize (isync) Instruction

The isync instruction causes a reflect which waits for all prior instructions to complete and then executes the next sequential instruction. Any instruction after an isync will see all effects of prior instructions.

### 3.14.5 Enforce In-Order Execution of I/O (eieio) Instruction

When executing an eieio instruction, the load/store unit will wait until all previous accesses have terminated before issuing cycles associated with load/store instructions following the eieio instruction.

### 3.14.6 Time Base

A description of the time base register may be found in [Chapter 6, “System Configuration and Protection,”](#) and in [Chapter 8, “Clocks and Power Control.”](#)

## 3.15 Operating Environment Architecture (OEA)

The MPC561/MPC563 has an internal memory space that includes memory-mapped control registers and internal memory used by various modules on the chip. This memory is part of the main memory as seen by the RCPU and can be accessed by an external system master.

### 3.15.1 Branch Processor Registers

#### 3.15.1.1 Machine State Register (MSR)

The floating-point exception mode encoding in the RCPU is as shown in [Table 3-21](#).

**Table 3-21. Floating-Point Exception Mode Encoding**

| Mode              | FE0 | FE1 |
|-------------------|-----|-----|
| Ignore exceptions | 0   | 0   |
| Precise           | 0   | 1   |
| Precise           | 1   | 0   |
| Precise           | 1   | 1   |

The SF bit is reserved set to zero. The IP bit initial state after reset is set as programmed by the reset configuration as specified by the USIU characteristics.

#### 3.15.1.2 Branch Processors Instructions

The RCPU implements all the instructions defined for the branch processor in the UISA in the hardware.

### 3.15.2 Fixed-Point Processor

#### 3.15.2.1 Special Purpose Registers

- **Unsupported Registers** — The following registers are not supported by the MPC561/MPC563: SDR, EAR, IBAT0U, IBAT0L, IBAT1U, IBAT1L, IBAT2U, IBAT2L, IBAT3U, IBAT3L, DBAT0U, DBAT0L, DBAT1U, DBAT1L, DBAT2L, DBAT3U, DBAT3L.
- **Added Registers** — For a list of added special purpose registers, refer to [Table 3-2](#), and [Table 3-3](#).

### 3.15.3 Storage Control Instructions

Storage control instructions mtsr, mtsrin, mfsr, mfsrin, dcbi, tlbie, tlbias, and tlbisync are not implemented by the MPC561/MPC563.

### 3.15.4 Exceptions

The following paragraphs define the types of OEA exceptions. The exception table vector defines the offset value by exception type. Refer to [Table 3-19](#).

#### 3.15.4.1 System Reset Exception and NMI (0x0100)

A system reset exception occurs when:

- Any reset signal is asserted:  $\overline{\text{PORESET}}$ ,  $\overline{\text{HRESET}}$ , or  $\overline{\text{SRESET}}$
- An internal reset is requested, such as from the software watchdog timer

Settings caused by reset as shown in [Table 3-22](#).

**Table 3-22. Settings Caused by Reset**

| Register      | Setting                                                                                                                                                           |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| MSR           | IP depends on internal data bus configuration word; ME is unchanged. DCMPE is set according to (BBCMCR[EN_COMP] AND BBCMCR[EXC_COMP]). All other bits are cleared |
| SRR0          | Undefined                                                                                                                                                         |
| SRR1          | Undefined                                                                                                                                                         |
| FPECR         | 0x0000 0000                                                                                                                                                       |
| ICTRL         | 0x0000 0000                                                                                                                                                       |
| LCTRL1        | 0x0000 0000                                                                                                                                                       |
| LCTRL2        | 0x0000 0000                                                                                                                                                       |
| COUNTA[16:31] | 0x0000 0000                                                                                                                                                       |
| COUNTB[16:31] | 0x0000 0000                                                                                                                                                       |

A non-maskable interrupt (NMI) occurs when the  $\overline{\text{IRQ0}}$  is asserted and the following registers are set.

**Table 3-23. Register Settings following an NMI**

| Register Name                               | Bits  | Description                                                                                                                                      |
|---------------------------------------------|-------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| Save/Restore Register 0 (SRR0) <sup>1</sup> | All   | Set to the effective address of the next instruction the processor executes if no interrupt conditions are present                               |
| Save/Restore Register 1 (SRR1)              | 1:4   | Cleared to 0                                                                                                                                     |
|                                             | 10:15 | Cleared to 0                                                                                                                                     |
|                                             | Other | Loaded from bits [16:31] of MSR. In the current implementation, bit 30 of the SRR1 is never cleared, except by loading a zero value from MSR[RI] |

**Table 3-23. Register Settings following an NMI (continued)**

| Register Name                | Bits   | Description                                                         |
|------------------------------|--------|---------------------------------------------------------------------|
| Machine State Register (MSR) | IP     | No change                                                           |
|                              | ME     | No change                                                           |
|                              | LE     | Bit is copied from ILE                                              |
|                              | DCMPEN | This bit is set according to (BBCMCR[EN_COMP] AND BBCMCR[EXC_COMP]) |
|                              | Other  | Cleared to 0                                                        |

<sup>1</sup> If the RCPU is in decompression on mode, SRR0 will contain a compressed address.

Execution begins at physical address 0x0100 if the hard reset configuration word IP bit is cleared to 0.  
Execution begins at physical address 0xFFF0 0100 if the hard reset configuration word IP bit is set to 1.

### 3.15.4.2 Machine Check Exception (0x0200)

A machine-check exception is assumed to be caused by one of the following conditions:

- The accessed address does not exist.
- A data error was detected.
- A storage protection violation was detected by chip-select logic.

When a machine-check exception occurs, the processor does one of the following:

- Takes a machine check exception;
- Enters the checkstop state; or
- Enters debug mode.

Which action is taken depends on the value of the MSR[ME] bit, whether or not debug mode was enabled at reset, and (if debug mode is enabled) the values of the CHSTPE (checkstop enable) and MCIE (machine check enable) bits in the debug enable register (DER). [Table 3-24](#) summarizes the possibilities. When the processor is in the checkstop state, instruction processing is suspended and cannot be restarted without resetting the core.

**Table 3-24. Machine Check Exception Processor Actions**

| MSR[ME] | Debug Mode Enable | CHSTPE | MCIE | Action Performed when Exception Detected  |
|---------|-------------------|--------|------|-------------------------------------------|
| 0       | 0                 | X      | X    | Enter checkstop state                     |
| 1       | 0                 | X      | X    | Branch to machine-check exception handler |
| 0       | 1                 | 0      | X    | Enter checkstop state                     |
| 0       | 1                 | 1      | X    | Enter debug mode                          |
| 1       | 1                 | X      | 0    | Branch to machine-check exception handler |
| 1       | 1                 | X      | 1    | Enter debug mode                          |

An indication is sent to the USIU which may generate an automatic reset in this condition. Refer to [Chapter 7, “Reset,”](#) for more details.

The register settings for machine check exceptions are shown in [Table 3-25](#).

**Table 3-25. Register Settings following a Machine Check Exception**

| Register Name                               | Bits               | Description                                                                                                                                      |
|---------------------------------------------|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| Save/Restore Register 0 (SRR0) <sup>1</sup> | All                | Set to the effective address of the instruction that caused the interrupt                                                                        |
| Save/Restore Register 1 (SRR1)              | 0 <sup>2</sup>     | MSR0                                                                                                                                             |
|                                             | 1                  | Set to 1 for instruction fetch-related errors and 0 for load/store-related errors                                                                |
|                                             | 2:4                | Cleared to 0                                                                                                                                     |
|                                             | 5:9 <sup>2</sup>   | MSR[5:9]                                                                                                                                         |
|                                             | 10:15              | Cleared to 0                                                                                                                                     |
|                                             | 16:31 <sup>2</sup> | Loaded from bits [16:31] of MSR. In the current implementation, bit 30 of the SRR1 is never cleared, except by loading a zero value from MSR[RI] |

**Table 3-25. Register Settings following a Machine Check Exception (continued)**

| Register Name                                               | Bits   | Description                                                                  |
|-------------------------------------------------------------|--------|------------------------------------------------------------------------------|
| Machine State Register (MSR)                                | IP     | No change                                                                    |
|                                                             | ME     | No change                                                                    |
|                                                             | LE     | Bit is copied from ILE                                                       |
|                                                             | DCMPEN | This bit is set according to (BBCMCR[EN_COMP] AND BBCMCR[EXC_COMP])          |
|                                                             | Other  | Cleared to 0                                                                 |
| Data/Storage Interrupt Status Register (DSISR) <sup>3</sup> | 0:14   | Cleared to 0                                                                 |
|                                                             | 15:16  | Set to bits [29:30] of the instruction if X-form and to 0b00 if D-form       |
|                                                             | 17     | Set to bit 25 of the instruction if X-form and to Bit 5 if D-form            |
|                                                             | 18:21  | Set to bits [21:24] of the instruction if X-form and to bits [1:4] if D-form |
|                                                             | 22:31  | Set to bits [6:15] of the instruction                                        |
| Data Address Register (DAR) <sup>3</sup>                    | All    | Set to the effective address of the data access that caused the interrupt    |

<sup>1</sup> If the exception occurs due to a data error caused by a Load/Store instruction and the processor in Decompression On mode, the SRR0 register will contain the address of the Load/Store instruction in compressed format. If the exception occurs due to an instruction fetch in Decompression On mode, the SRR0 register will contain an indeterminate value.

<sup>2</sup> This bit is loaded from the corresponding bit in the MSR when an interrupt is taken. The appropriate bit in MSR is loaded from this bit when an RFI is executed.

<sup>3</sup> DSISR and DAR registers are only updated when the machine check exception is caused by a data access violation.

when a machine check exception is taken, instruction execution resumes at offset 0x0200 from the base address indicated by MSR[IP].

### 3.15.4.3 Data Storage Exception (0x0300)

A data storage exception is never generated by the RCPU. The software may branch to this location as a result of implementation-specific data storage protection error exception.

### 3.15.4.4 Instruction Storage Exception (0x0400)

An instruction storage interrupt is never generated by them RCPU. The software may branch to this location as a result of an implementation-specific instruction storage protection error exception.

### 3.15.4.5 External Interrupt (0x0500)

The external interrupt exception is taken on assertion of the internal  $\overline{\text{IRQ}}$  line to the RCPU, that is driven by on-chip interrupt controller. The interrupt may be caused by the assertion of an external  $\overline{\text{IRQ}}$  signal, by a USIU timer, or by an internal chip peripheral. Refer to [Section 6.1.4, “Enhanced Interrupt Controller,”](#) for more information on the interrupt controller.

The interrupt may be delayed by other higher priority exceptions or if the MSR[EE] bit is cleared when the exception occurs. MSR[EE] is automatically cleared by hardware to disable external interrupts when any exception is taken.

Upon detecting an external interrupt, the processor assigns it to the instruction at the head of the history buffer (after retiring all instructions that are ready to retire).

The enhanced interrupt controller mode is available for interrupt-driven applications on MPC561/MPC563. It allows the single external interrupt exception vector 0x500 to be split into up to 48 different vectors corresponding to 48 interrupt sources to speed up interrupt processing. It also supports a low priority source masking feature in hardware to handle nested interrupts more easily. See [Section 6.1.4, “Enhanced Interrupt Controller,”](#) and [Chapter 4, “Burst Buffer Controller 2 Module.”](#)

The register settings for the external interrupt exception are shown in [Table 3-26](#).

**Table 3-26. Register Settings following External Interrupt**

| Register                                    | Bits    | Setting Description                                                                                                                              |
|---------------------------------------------|---------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| Save/Restore Register 0 (SRR0) <sup>1</sup> | All     | Set to the effective address of the instruction that the processor would have attempted to execute next if no interrupt conditions were present. |
| Save/Restore Register 1 (SRR1)              | [0:15]  | Cleared to 0                                                                                                                                     |
|                                             | [16:31] | Loaded from bits [16:31] of MSR. In the current implementation, bit 30 of the SRR1 is never cleared, except by loading a zero value from MSR[RI] |
| Machine State Register (MSR)                | IP      | No change                                                                                                                                        |
|                                             | ME      | No change                                                                                                                                        |
|                                             | LE      | Set to value of ILE bit prior to the exception                                                                                                   |
|                                             | DCMPEN  | This bit is set according to (BBCMCR[EN_COMP] AND BBCMCR[EXC_COMP])                                                                              |
|                                             | Other   | Cleared to 0                                                                                                                                     |

<sup>1</sup> If the exception occurs during an instruction fetch in Decompression On mode, the SRR0 register will contain an address in compressed format.

When an external interrupt is taken, instruction execution resumes at offset 0x00500 from the physical base address indicated by MSR[IP].

### 3.15.4.6 Alignment Exception (0x00600)

The following conditions cause an alignment exception:

- The operand of a floating-point load or store instruction is not word-aligned.
- The operand of a load or store multiple instruction is not word-aligned.
- The operand of lwarx or stwex. is not word-aligned.

Alignment exceptions use the SRR0 and SRR1 to save the machine state and the DSISR to determine the source of the exception.

The register settings for alignment exceptions are shown in [Table 3-27](#).

**Table 3-27. Register Settings for Alignment Exception**

| Register                                       | Bits    | Setting Description                                                                                                                                                                                                                               |
|------------------------------------------------|---------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Save/Restore Register 0 (SRR0) <sup>1</sup>    |         | Set to the effective address of the instruction that caused the exception.                                                                                                                                                                        |
| Save/Restore Register 1 (SRR1)                 | [0:15]  | Cleared to 0                                                                                                                                                                                                                                      |
|                                                | [16:31] | Loaded from bits [16:31] of MSR. In the current implementation, bit 30 of the SRR1 is never cleared, except by loading a zero value from MSR[RI]                                                                                                  |
| Machine State Register (MSR)                   | IP      | No change                                                                                                                                                                                                                                         |
|                                                | ME      | No change                                                                                                                                                                                                                                         |
|                                                | LE      | Set to value of ILE bit prior to the exception                                                                                                                                                                                                    |
|                                                | DCMPEN  | This bit is set according to (BBCMCR[EN_COMP] AND BBCMCR[EXC_COMP])                                                                                                                                                                               |
|                                                | Other   | Cleared to 0                                                                                                                                                                                                                                      |
| Data/Storage Interrupt Status Register (DSISR) | [0:11]  | Cleared to 0                                                                                                                                                                                                                                      |
|                                                | [12:13] | Cleared to 0                                                                                                                                                                                                                                      |
|                                                | 14      | Cleared to 0                                                                                                                                                                                                                                      |
|                                                | [15:16] | For instructions that use register indirect with index addressing, set to bits [29:30] of the instruction.<br>For instructions that use register indirect with immediate index addressing, cleared.                                               |
|                                                | 17      | For instructions that use register indirect with index addressing, set to bit 25 of the instruction.<br>For instructions that use register indirect with immediate index addressing, set to bit 5 of the instruction.                             |
|                                                | [18:21] | For instructions that use register indirect with index addressing, set to bits [21:24] of the instruction.<br>For instructions that use register indirect with immediate index addressing, set to bits [1:4] of the instruction.                  |
|                                                | [22:26] | Set to bits [6:10] (source or destination) of the instruction.                                                                                                                                                                                    |
|                                                | [27:31] | Set to bits [11:15] of the instruction (rA). Set to either bits [11:15] of the instruction or to any register number not in the range of registers loaded by a valid form instruction, for lmw, lswi, and lswx instructions. Otherwise undefined. |

<sup>1</sup> If the exception occurs during an instruction fetch in Decompression On mode, the SRR0 register will contain a compressed address.

## NOTE

For load or store instructions that use register indirect with index addressing, the DSISR can be set to the same value that would have resulted if the corresponding instruction uses register indirect with immediate index addressing had caused the exception. Similarly, for load or store instructions that use register indirect with immediate index addressing, DSISR can hold a value that would have resulted from an instruction that uses register indirect with index addressing. (If there is no corresponding instruction, no alternative value can be specified.)

When an alignment exception is taken, instruction execution resumes at offset 0x00600 from the physical base address indicated by MSR[IP].

### 3.15.4.7 Program Exception (0x0700)

A program exception occurs when no higher priority exception exists and one or more of the following exception conditions, which correspond to bit settings in SRR1, occur during execution of an instruction:

- System floating-point enabled exception — A system floating-point enabled exception is generated when the following condition is met as a result of a move to FPSCR instruction, move to MSR (mtmsr) instruction, or return from interrupt (rfi) instruction:
- (MSR[FE0] | MSR[FE1]) and- FPSCR[FEX] = 1.
- Notice that in the RCPU implementation of the PowerPC ISA architecture, a program interrupt is not generated by a floating-point arithmetic instruction that results in the condition shown above; a floating-point assist exception is generated instead.
- Privileged instruction — A privileged instruction type program exception is generated by any of the following conditions:
  - The execution of a privileged instruction (mfmsr, mtmsr, or rfi) is attempted and the processor is operating at the user privilege level (MSR[PR] = 1).
  - The execution of mtspr or mfspr where SPR0 = 1 in the instruction encoding (indicating a supervisor-access register) and MSR[PR] = 1 (indicating the processor is operating at the user privilege level), provided the SPR instruction field encoding represents either:
    - a valid internal-to-the-processor special-purpose register; or
    - an external-to-the-processor special-purpose register (either valid or invalid).
- Trap — A trap type program exception is generated when any of the conditions specified in a trap instruction is met.

The register settings for program exceptions are shown in [Table 3-28](#).

**Table 3-28. Register Settings following Program Exception**

| Register                                    | Bits    | Setting Description                                                                                                                                   |
|---------------------------------------------|---------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| Save/Restore Register 0 (SRR0) <sup>1</sup> | All     | Contains the effective address of the excepting instruction                                                                                           |
| Save/Restore Register 1 (SRR1) <sup>2</sup> | [0:10]  | Cleared to 0                                                                                                                                          |
|                                             | 11      | Set for a floating-point enabled program exception; otherwise cleared.                                                                                |
|                                             | 12      | Cleared to 0.                                                                                                                                         |
|                                             | 13      | Set for a privileged instruction program exception; otherwise cleared.                                                                                |
|                                             | 14      | Set for a trap program exception; otherwise cleared.                                                                                                  |
|                                             | 15      | Cleared to 0 if SRR0 contains the address of the instruction causing the exception, and set if SRR0 contains the address of a subsequent instruction. |
|                                             | [16:31] | Loaded from bits [16:31] of MSR. In the current implementation, bit 30 of the SRR1 is never cleared, except by loading a zero value from MSR[RI].     |
| Machine State Register (MSR)                | IP      | No change                                                                                                                                             |
|                                             | ME      | No change                                                                                                                                             |
|                                             | LE      | Set to value of ILE bit prior to the exception                                                                                                        |
|                                             | DCMPEN  | This bit is set according to (BBCMCR[EN_COMP] AND BBCMCR[EXC_COMP])                                                                                   |
|                                             | Other   | Cleared to 0                                                                                                                                          |

<sup>1</sup> If the exception occurs during an instruction fetch in Decompression On mode, the SRR0 register will contain a compressed address.

<sup>2</sup> Only one of bits 11, 13, and 14 can be set.

When a program exception is taken, instruction execution resumes at offset 0x0700 from the physical base address indicated by MSR[IP].

### 3.15.4.8 Floating-Point Unavailable Exception (0x0800)

A floating-point unavailable exception occurs when no higher priority exception exists, an attempt is made to execute a floating-point instruction (including floating-point load, store, and move instructions), and the floating-point available bit in the MSR is disabled, (MSR[FP] = 0).

**Table 3-29. Register Settings following a Floating-Point Unavailable Exception**

| Register                                    | Bits    | Setting Description                                                        |
|---------------------------------------------|---------|----------------------------------------------------------------------------|
| Save/Restore Register 0 (SRR0) <sup>1</sup> | All     | Set to the effective address of the instruction that caused the exception. |
| Save/Restore Register 1 (SRR1)              | [0:15]  | Cleared to 0                                                               |
|                                             | [16:31] | Loaded from MSR[16:31]                                                     |

**Table 3-29. Register Settings following a Floating-Point Unavailable Exception (continued)**

| Register                     | Bits   | Setting Description                                                 |
|------------------------------|--------|---------------------------------------------------------------------|
| Machine State Register (MSR) | IP     | No change                                                           |
|                              | ME     | No change                                                           |
|                              | LE     | Set to value of ILE bit prior to the exception                      |
|                              | DCMPEN | This bit is set according to (BBCMCR[EN_COMP] AND BBCMCR[EXC_COMP]) |
|                              | Other  | Cleared to 0                                                        |

<sup>1</sup> If the exception occurs during an instruction fetch in Decompression On mode, the SRR0 register will contain a compressed address.

### 3.15.4.9 Decrementer Exception (0x0900)

A decrementer exception occurs when no higher priority exception exists, the decrementer register has completed decrementing, and MSR[EE] = 1. The decrementer exception request is canceled when the exception is handled. The decrementer register counts down, causing an exception (unless masked) when passing through zero. The decrementer implementation meets the following requirements:

- Loading a GPR from the decrementer does not affect the decrementer.
- Storing a GPR value to the decrementer replaces the value in the decrementer with the value in the GPR.
- Whenever bit 0 of the decrementer changes from zero to one, an exception request is signaled. If multiple decrementer exception requests are received before the first can be reported, only one exception is reported. The occurrence of a decrementer exception cancels the request.
- If the decrementer is altered by software and if bit 0 is changed from zero to one, an interrupt request is signaled.

The register settings for the decrementer exception are shown in [Table 3-30](#).

**Table 3-30. Register Settings Following a Decrementer Exception**

| Register                                    | Bits    | Setting Description                                                                                                                              |
|---------------------------------------------|---------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| Save/Restore Register 0 (SRR0) <sup>1</sup> | All     | Set to the effective address of the instruction that the processor would have attempted to execute next if no exception conditions were present. |
| Save/Restore Register 1 (SRR1)              | [0:15]  | Cleared to 0                                                                                                                                     |
|                                             | [16:31] | Loaded from MSR[16:31]                                                                                                                           |
| Machine State Register (MSR)                | IP      | No change                                                                                                                                        |
|                                             | ME      | No change                                                                                                                                        |
|                                             | LE      | Set to value of ILE bit prior to the exception                                                                                                   |
|                                             | DCMPEN  | This bit is set according to (BBCMCR[EN_COMP] AND BBCMCR[EXC_COMP])                                                                              |
|                                             | Other   | Cleared to 0                                                                                                                                     |

- <sup>1</sup> If the exception occurs during an instruction fetch in Decompression On mode, the SRR0 register will contain a compressed address.

When a decremter exception is taken, instruction execution resumes at offset 0x0900 from the physical base address indicated by MSR[IP].

### 3.15.4.10 System Call Exception (0x0C00)

A system call exception occurs when a system call instruction is executed. The effective address of the instruction following the sc instruction is placed into SRR0. MSR[16:31] are placed into SRR1[16:31], and SRR1[0:15] are set to undefined values. Then a system call exception is generated.

The system call instruction is context synchronizing. That is, when a system call exception occurs, instruction dispatch is halted and the following synchronization is performed:

1. The exception mechanism waits for all instructions in execution to complete to a point where they report all exceptions they will cause.
2. The processor ensures that all instructions in execution complete in the context in which they began execution.
3. Instructions dispatched after the exception is processed are fetched and executed in the context established by the exception mechanism.

Register settings are shown in [Table 3-31](#).

**Table 3-31. Register Settings following a System Call Exception**

| Register                                    |         | Setting Description                                                                   |
|---------------------------------------------|---------|---------------------------------------------------------------------------------------|
| Save/Restore Register 0 (SRR0) <sup>1</sup> | All     | Set to the effective address of the instruction following the System Call instruction |
| Save/Restore Register 1 (SRR1)              | [0:15]  | Undefined                                                                             |
|                                             | [16:31] | Loaded from MSR[16:31]                                                                |
| Machine State Register (MSR)                | IP      | No change                                                                             |
|                                             | ME      | No change                                                                             |
|                                             | LE      | Set to value of ILE bit prior to the exception                                        |
|                                             | DCMPEN  | This bit is set according to (BBCMCR[EN_COMP] AND BBCMCR[EXC_COMP])                   |
|                                             | Other   | Cleared to 0                                                                          |

- <sup>1</sup> If the exception occurs during a data access in Decompression On mode, the SRR0 register will contain the address of the Load/Store instruction in compressed format. If the exception occurs during an instruction fetch in decompression on mode, the SRR0 register will contain an indeterminate value.

When a system call exception is taken, instruction execution resumes at offset 0x00C00 from the physical base address indicated by MSR[IP].

### 3.15.4.11 Trace Exception (0x0D00)

A trace interrupt occurs if MSR[SE] = 1 and any instruction except rfi is successfully completed or MSR[BE] = 1 and a branch is completed. Notice that the trace interrupt does not occur after an instruction that caused an interrupt (for instance, sc). Monitor/debugger software must change the vectors of other

possible interrupt addresses to single-step such instructions. If this is unacceptable, other debug features can be used. Refer to [Chapter 23, “Development Support,”](#) for more information. See [Table 3-32](#) for Trace Exception register settings.

**Table 3-32. Register Settings following a Trace Exception**

| Register Name                               | Bits   | Description                                                                                                                                      |
|---------------------------------------------|--------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| Save/Restore Register 0 (SRR0) <sup>1</sup> | All    | Set to the effective address of the instruction following the executed instruction                                                               |
| Save/Restore Register 1 (SRR1)              | 1:4    | Cleared to 0                                                                                                                                     |
|                                             | 10:15  | Cleared to 0                                                                                                                                     |
|                                             | Other  | Loaded from bits [16:31] of MSR. In the current implementation, bit 30 of the SRR1 is never cleared, except by loading a zero value from MSR[RI] |
| Machine State Register (MSR)                | IP     | No change                                                                                                                                        |
|                                             | ME     | No change                                                                                                                                        |
|                                             | LE     | Bit is copied from ILE                                                                                                                           |
|                                             | DCMPEN | This bit is set according to (BBCMCR[EN_COMP] AND BBCMCR[EXC_COMP])                                                                              |
|                                             | Other  | Cleared to 0                                                                                                                                     |

<sup>1</sup> If the exception occurs during an instruction fetch in Decompression On mode, the SRR0 register will contain a compressed address.

Execution resumes at offset 0x0D00 from the base address indicated by MSR[IP].

### 3.15.4.12 Floating-Point Assist Exception (0x0E00)

A floating point assist exception occurs when the following conditions are true:

- A floating-point enabled exception condition is detected;
- The corresponding floating-point enable bit in the FPSCR (floating point status and control register) is set (exception enabled); and
- $\text{MSR}[\text{FE0}] \mid \text{MSR}[\text{FE1}] = 1$

These conditions are summarized in the following equation:

$$(\text{MSR}[\text{FE0}] \mid \text{MSR}[\text{FE1}]) \text{ AND } \text{FPSCR}[\text{FEX}] = 1$$

Note that when  $((\text{MSR}[\text{FE0}] \mid \text{MSR}[\text{FE1}]) \text{ AND } \text{FPSCR}[\text{FEX}])$  is set as a result of move to FPSCR, move to MSR or rfi, a program exception is generated, rather than a floating-point assist exception.

A floating point assist exception also occurs when a tiny result is detected and the floating point underflow exception is disabled ( $\text{FPSCR}[\text{UE}] = 0$ ).

The register settings for floating-point assist exceptions are shown in [Table 3-33](#).

**Table 3-33. Register Settings following Floating-Point Assist Exceptions**

| Register Name                               | Bits | Description                                                               |
|---------------------------------------------|------|---------------------------------------------------------------------------|
| Save/Restore Register 0 (SRR0) <sup>1</sup> | All  | Set to the effective address of the instruction that caused the interrupt |

**Table 3-33. Register Settings following Floating-Point Assist Exceptions**

| Register Name                  | Bits   | Description                                                                                                                                      |
|--------------------------------|--------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| Save/Restore Register 1 (SRR1) | 1:4    | Cleared to 0                                                                                                                                     |
|                                | 10:15  | Cleared to 0                                                                                                                                     |
|                                | Other  | Loaded from bits [16:31] of MSR. In the current implementation, bit 30 of the SRR1 is never cleared, except by loading a zero value from MSR[RI] |
| Machine State Register (MSR)   | IP     | No change                                                                                                                                        |
|                                | ME     | No change                                                                                                                                        |
|                                | LE     | Bit is copied from ILE                                                                                                                           |
|                                | DCMPEN | This bit is set according to (BBCMCR[EN_COMP] AND BBCMCR[EXC_COMP])                                                                              |
|                                | Other  | Cleared to 0                                                                                                                                     |

<sup>1</sup> If the exception occurs during an instruction fetch in Decompression On mode, the SRR0 register will contain a compressed address.

When a floating-point exception is taken, instruction execution resumes at offset 0x0E00 from the base address indicated by MSR[IP].

### 3.15.4.13 Implementation-Dependent Software Emulation Exception (0x1000)

An implementation-dependent software emulation exception occurs in the following instances:

- When executing any non-implemented instruction. This includes all illegal and unimplemented optional instructions and all floating-point instructions.
- When executing a mtspr or mfspr instruction that specifies an un-implemented internal-to-the-processor SPR, regardless of the value of bit 0 of the SPR.
- When executing a mtspr or mfspr that specifies an un-implemented external-to-the-processor register and SPR0 = 0 or MSR[PR] = 0 (no program interrupt condition).

Table 3-34 shows the register settings set when a software emulation exception occurs.

**Table 3-34. Register Settings following a Software Emulation Exception**

| Register Name                               | Bits  | Description                                                                                                                                       |
|---------------------------------------------|-------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| Save/Restore Register 0 (SRR0) <sup>1</sup> | All   | Set to the effective address of the instruction that caused the interrupt                                                                         |
| Save/Restore Register 1 (SRR1)              | 1:4   | Cleared to 0                                                                                                                                      |
|                                             | 10:15 | Cleared to 0                                                                                                                                      |
|                                             | Other | Loaded from bits [16:31] of MSR. In the current implementation, bit 30 of the SRR1 is never cleared, except by loading a zero value from MSR[RI]. |

**Table 3-34. Register Settings following a Software Emulation Exception**

| Register Name                | Bits   | Description                                                         |
|------------------------------|--------|---------------------------------------------------------------------|
| Machine State Register (MSR) | IP     | No change                                                           |
|                              | ME     | No change                                                           |
|                              | LE     | Bit is copied from ILE                                              |
|                              | DCMPEN | This bit is set according to (BBCMCR[EN_COMP] AND BBCMCR[EXC_COMP]) |
|                              | Other  | Cleared to 0                                                        |

<sup>1</sup> If the exception occurs during an instruction fetch in Decompression On mode, the SRR0 register will contain a compressed address.

Execution resumes at offset 0x01000 from the base address indicated by MSR[IP].

### 3.15.4.14 Implementation-Dependent Instruction Protection Exception (0x1300)

The implementation-specific instruction storage protection error interrupt occurs in the following cases:

- The fetch access violates storage protection and MSR[IR] = 1.
- The fetch access is to guarded storage and MSR[IR] = 1.

The register settings for instruction protection exceptions are shown in [Table 3-35](#).

**Table 3-35. Register Settings following an Instruction Protection Exception**

| Register Name                               | Bits   | Description                                                                                                                                      |
|---------------------------------------------|--------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| Save/Restore Register 0 (SRR0) <sup>1</sup> | All    | Set to the effective address of the instruction that caused the exception                                                                        |
| Save/Restore Register 1 (SRR1)              | 0:2    | Cleared to 0                                                                                                                                     |
|                                             | 3      | Set to 1 if the fetch access was to a guarded storage when MSR[IR] = 1, otherwise clear to 0                                                     |
|                                             | 4      | Set to 1 if the storage access is not permitted by the protection mechanism (IMPU in BBC) and MSR[IR] = 1; otherwise clear to 0                  |
|                                             | 5:15   | Cleared to 0                                                                                                                                     |
|                                             | 16:31  | Loaded from bits [16:31] of MSR. In the current implementation, bit 30 of the SRR1 is never cleared, except by loading a zero value from MSR[IR] |
| Machine State Register (MSR)                | IP     | No change                                                                                                                                        |
|                                             | ME     | No change                                                                                                                                        |
|                                             | LE     | Bit is copied from ILE                                                                                                                           |
|                                             | DCMPEN | This bit is set according to (BBCMCR[EN_COMP] AND BBCMCR[EXC_COMP])                                                                              |
|                                             | Other  | Cleared to 0                                                                                                                                     |

- <sup>1</sup> If the exception occurs during an instruction fetch in Decompression On mode, the SRR0 register will contain an indeterminate value.

Execution resumes at offset 0x1300 from the base address indicated by MSR[IP].

#### 3.15.4.15 Implementation-Specific Data Protection Error Exception (0x1400)

The implementation-specific data protection error exception occurs in the following case:

- The data access violates the storage protection and MSR[DR]=1. See [Chapter 11, “L-Bus to U-Bus Interface \(L2U\).”](#)

See [Table 3-36](#) for data-protection-error exception register settings.

**Table 3-36. Register Settings Following a Data Protection Error Exception**

| Register Name                                  | Bits   | Description                                                                                                                                      |
|------------------------------------------------|--------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| Save/Restore Register 0 (SRR0) <sup>1</sup>    | All    | Set to the effective address of the instruction that caused the exception                                                                        |
| Save/Restore Register 1 (SRR1)                 | 0:15   | Cleared to 0                                                                                                                                     |
|                                                | Other  | Loaded from bits [16:31] of MSR. In the current implementation, bit 30 of the SRR1 is never cleared, except by loading a zero value from MSR[RI] |
| Machine State Register (MSR)                   | IP     | No change                                                                                                                                        |
|                                                | ME     | No change                                                                                                                                        |
|                                                | LE     | Bit is copied from ILE                                                                                                                           |
|                                                | DCMPEN | This bit is set according to (BBCMCR[EN_COMP] AND BBCMCR[EXC_COMP])                                                                              |
|                                                | Other  | Cleared to 0                                                                                                                                     |
| Data/Storage Interrupt Status Register (DSISR) | 0:3    | Cleared to 0                                                                                                                                     |
|                                                | 4      | Set to 1 if the storage access is not permitted by the protection mechanism. Otherwise cleared to 0                                              |
|                                                | 5      | Cleared to 0                                                                                                                                     |
|                                                | 6      | Set to 1 for a store operation and cleared to 0 for a load operation                                                                             |
|                                                | 7:31   | Cleared to 0                                                                                                                                     |
| Data Address Register (DAR)                    | All    | Set to the effective address of the data access that caused the exception                                                                        |

<sup>1</sup> If the exception occurs during a data access in Decompression On mode, the SRR0 register will contain the address of the Load/Store instruction in compressed format.

When a data protection error exception is taken, instruction execution resumes at offset 0x1400 from the base address indicated by MSR[IP].

### 3.15.4.16 Implementation-Dependent Debug Exceptions

Implementation-dependent debug exceptions occur in the following cases:

- When there is an internal breakpoint match (for more details, refer to [Chapter 23, “Development Support.”](#))
- When a peripheral breakpoint request is asserted to the RCPU.
- When the development port request is asserted to the RCPU. Refer to [Chapter 23, “Development Support,”](#) for details on how to generate the development port-interrupt request.

See [Table 3-37](#) for debug-exception register settings.

**Table 3-37. Register Settings Following a Debug Exception**

| Register Name                               | Bits   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|---------------------------------------------|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Save/Restore Register 0 (SRR0) <sup>1</sup> | All    | For I-breakpoints, set to the effective address of the instruction that caused the interrupt. For L-breakpoint, set to the effective address of the instruction following the instruction that caused the interrupt. For development port maskable request or a peripheral breakpoint, set to the effective address of the instruction that the processor would have executed next if no interrupt conditions were present. If the development port request is asserted at reset, the value of SRR0 is undefined. |
| Save/Restore Register 1 (SRR1)              | 1:4    | Cleared to 0                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|                                             | 10:15  | Cleared to 0                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|                                             | Other  | Loaded from bits [16:31] of MSR. In the current implementation, bit 30 of the SRR1 is never cleared, except by loading a zero value from MSR[RI].<br>If the development port request is asserted at reset, the value of SRR1 is undefined.                                                                                                                                                                                                                                                                        |
| Machine State Register (MSR)                | IP     | No change                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|                                             | ME     | No change                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

|                                             | DCMPEN | This bit is set according to (BBCMCR[EN_COMP] AND BBCMCR[EXC_COMP])                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|                                             | Other  | Cleared to 0                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

<sup>1</sup> If the exception occurs during an instruction fetch in Decompression On mode, the SRR0 register will contain the instruction address in compressed format.

For data breakpoint exceptions, the register shown in [Table 3-38](#) is set.

**Table 3-38. Register Settings for Data Breakpoint Match**

| Register Name | Bits | Description                                                                                              |
|---------------|------|----------------------------------------------------------------------------------------------------------|
| BAR           |      | Set to the effective address of the data access as computed by the instruction that caused the interrupt |

Execution resumes at offset from the base address indicated by MSR[IP] as follows:

- 0x01C00 – For data breakpoint match
- 0x01D00 – For instruction breakpoint match
- 0x01E00 – For development port maskable request or a peripheral breakpoint
- 0x01F00 – For development port non-maskable request

### 3.15.5 Partially Executed Instructions

In general, the architecture permits instructions to be partially executed when an alignment or data storage interrupt occurs. In the core, instructions are not executed at all if an alignment interrupt condition is

detected and data storage interrupt is never generated by the hardware. In the RCPU, the instruction can be partially executed only in the case of the load/store instructions that cause multiple accesses to the memory subsystem. These instructions are:

- Multiple/string instructions
- Unaligned load/store instructions

In the last case, the store instruction can be partially completed if one of the accesses (except the first one) causes the data storage protection error. The implementation-specific data storage protection interrupt is taken in this case. For the update forms, the update register (rA) is not altered.

### 3.15.6 Timer Facilities

Descriptions of the timebase and decremter registers can be found in [Chapter 6, “System Configuration and Protection,”](#) and in [Chapter 8, “Clocks and Power Control.”](#)

### 3.15.7 Optional Facilities and Instructions

Any other OEA optional facilities and instructions (except those that are discussed here) are not implemented by the RCPU hardware. Attempting to execute any of these instructions causes an implementation dependent software emulation interrupt to be taken.

## Chapter 4

# Burst Buffer Controller 2 Module

The burst buffer controller module (BBC) consists of four main functional parts: the bus interface unit (BIU), the instruction memory protection unit (IMPU), branch target buffer (BTB) and the instruction code decompressor unit (ICDU). See [Figure 4-1](#). Information about decompression features of the BBC is found in [Appendix A, “MPC562/MPC564 Compression Features.”](#)

The BBC master BIU interfaces between the RCPU instruction port and the internal U-bus and can support burstable and non-burstable U-bus accesses.

The IMPU allows the instruction memory to be divided into four regions with different protection attributes. The IMPU compares the attributes of the RCPU memory access request with the attributes of the appropriate region. If the access is allowed, the proper signals are sent to the BIU. If access to the memory region is disallowed because the region is protected, an interrupt is sent to the RCPU and the master BIU cancels U-bus access.

The IMPU is able to relocate the RCPU exception vectors. The IMPU always maps the exception vectors into the internal memory space of the MPC561/MPC563. This feature is important for a multi-MPC561/MPC563 system, where, although the internal memories of some controllers are not shifted to the lower 4 Mbytes, they can still have their own internal exception vector tables with the same exception addresses issued by their RCPU cores.

The IMPU also supports an MPC561/MPC563-enhanced interrupt controller by extending an exception vector's relocation mechanism to translate the RCPU external interrupt exception vector separately and splitting it into 48 different vectors, corresponding to the code generated by the interrupt controller. See also [Section 6.1.4.4, “Enhanced Interrupt Controller Operation.”](#)

The branch target buffer (BTB) improves the performance of the MPC561/MPC563 by holding and supplying previously accessed or decompressed instructions to the RCPU core. The BTB can be enabled in either decompression on or off mode.

The ICDU provides decompressed instructions to RCPU in the decompression ON mode and contains a 2 Kbyte RAM (DECRAM) to hold decompression vocabularies. The DECRAM can serve as a general purpose RAM memory on the U-bus if code compression is not used.

Figure 4-1. BBC Module Block Diagram

## 4.1 Key Features

### 4.1.1 BIU Key Features

- Supports pipelined and burstable and single accesses to internal and external memories
- Supports the decoupled interface with the RCPu instruction unit

- Implements a parked master on the U-bus, resulting in zero clock delays for RCPU fetch accesses to the U-bus
- Fully utilizes the U-bus pipeline for fetch accesses
- Avoids undesirable delays through a tight interface with the L2U module (fully utilizing U-bus bandwidth and back-to-back accesses)
- Supports program trace and show cycles
- Supports a special attribute for debug port fetch accesses.

### 4.1.2 IMPU Key Features

- There are four regions in which the base address and size can be programmed.
- Available region sizes include 2 Kbytes, 8 Kbytes, 16 Kbytes, 32 Kbytes, 64 Kbytes, 128 Kbytes, 256 Kbytes, 512 Kbytes, 1 Mbyte, 2 Mbytes, 4 Mbytes, 8 Mbytes, 16 Mbytes....4 Gbytes.
- Overlap between regions is allowed.
- Each of the four regions supports the following attributes:
  - User/supervisor
  - Guard attribute (causes an interrupt in case of speculative fetch attempt)
  - Compressed/non-compressed (MPC562/MPC564 only)
  - Regions are enabled or disabled in software.
- Global region entry declares the default access attributes for all memory areas not covered by the four regions:
- The RCPU gets the instruction storage protection exception generated upon
  - An access violation of protection attributes
  - A fetch from a guarded region.
- The RCPU MSR[IR] bit controls IMPU protection.
- Programming is performed by using the RCPU mtspr/mfspr instructions to/from implementation specific special-purpose registers.
- The IMPU supplies relocation addresses of all the exceptions within the internal memory space.
- The IMPU implements external interrupt vector splitting to reduce the external interrupt latency.
- There is a special reset exception vector for decompression on mode (MPC562/MPC564 only).

### 4.1.3 ICDU Key Features

The following are instruction code decompression unit key features of the MPC562/MPC564. See [Appendix A, “MPC562/MPC564 Compression Features”](#) for more information.

- Instruction code on-line decompression based on “instruction classes” algorithm.
- No need for address translation between compressed and non-compressed address spaces — ICDU provides “next instruction address” to the RCPU
- In most cases, instruction decompression takes one clock
- Code decompression is pipelined:

- No performance penalty during sequential program flow execution
- Minimal performance penalty due to change of program flow execution
- Two operation modes are available: decompression on and decompression off. Switch between compressed and non-compressed user application software parts is possible.
- Adaptive vocabularies scheme is supported; each user application can have its own optimum vocabularies.

#### 4.1.4 DECRAM Key Features

- 2 Kbytes RAM for decompression vocabulary tables
- 2 clock read/write accesses when used as a U-bus general-purpose RAM
- 4 clock load/store accesses from the L-bus
- Byte, half-word (16-bit) or word (32-bit) read/write accesses and fetches
- Special access protection functions
- Low-power standby operation for data retention

#### 4.1.5 Branch Target Buffer Key Features

- Consists of eight “branch target entries” (BTE). Each entry contains:
  - A 32-bit register that stores the target of historical change of flow (COF) address
  - Four RAM entries, 38 bits each, which hold up to four valid instruction OPCODES (32 bits). The six extra bits are used by ICDU in decompression on mode.
  - A 32-bit register that stores the values used to calculate the address following the last valid instruction.
- FIFO removal policy management is implemented for the eight BTEs
- Software-controlled BTB enable/disable and invalidate
- User transparent (that is, no user management is required)

### 4.2 Operation Modes

#### 4.2.1 Instruction Fetch

The BBC provides two instruction fetch modes: decompression off and decompression on. The operational modes are defined by RCPUR MSR[DCMPEN] bit. If the bit is set, the mode is decompression on. Otherwise, it is in decompression off.

##### 4.2.1.1 Decompression Off Mode

In this mode, the BBC bus interface unit (BIU) module transfers fetch accesses from the RCPUR to the U-bus. When a new access is issued by the RCPUR, it is transferred in parallel to both the IMPUR and the BIU. The IMPUR compares the address of the access to its region programming. The BIU checks if the access can be immediately transferred to the U-bus, otherwise it requests the U-bus for the next clock.

The BIU may be programmed for burstable or non-burstable access. If the BIU is programmed for burstable access, the U-bus address phase transaction is accompanied by the burst request attribute. If burstable access is allowed by the U-bus slave, the BIU continues current access as burstable, otherwise current access is executed as a single access. If any protection violation is detected by the IMPU, the current U-bus access is aborted by the BIU and an exception is signaled to the RCPU.

Show cycle, program trace and debug port access attributes accompanying the RCPU access are forwarded by the BIU along with the U-bus access.

#### 4.2.1.2 Decompression On Mode

See [Appendix A, “MPC562/MPC564 Compression Features”](#) for explanation of the decompression on mode.

### 4.2.2 Burst Operation of the BBC

The BBC may initiate and handle burst accesses on the U-bus. The BBCMCR[BE] bit determines whether the BBC operates burst cycles or not. Burst requests are enabled when the BE bit is set. The BBC handles non-wrap-around bursts with up to 4 data beats on the internal U-bus.

#### NOTE

The burst operation in the MPC561/MPC563 is useful if a user system implements burstable memory devices on the external bus. Otherwise the mode will cause performance degradation when running code from external memory.

When the RCPU runs in serialized mode it is recommended that bursts be disabled by the BBC to speed up MPC561/MPC563 operation.

Burst operation for decompression on and in debug mode is disabled regardless of BBCMCR[BE] bit setting.

The BBC burst should be turned off if the USIU burst feature is enabled.

### 4.2.3 Access Violation Detection

Instruction memory protection is assigned on a regional basis. Default operation of IMPU is done on a global region. The IMPU has control registers which contain the following information: region protection on/off, region base address, size and access permissions.

Protection logic is activated only if the RCPU MSR[IR] bit is set.

During each fetch request from the RCPU core to instruction memory, the address is compared to a value in the region base address of enabled regions. Any address matching the specific region within its appropriate size as defined in the region attribute register sets a match indication.

When more than one match indication occurs, the effective region is the region with the highest priority. Priority is determined by region number. The lowest region number has the highest priority and the global region has lowest priority.

When no match happens, the effective region is the global region.

The region attribute registers contain the region protection fields: PP, G, and CMPR. The protection fields are compared to address attributes issued by the RCPU. If the access is permitted, the address is passed to the BIU and further to the U-bus.

Whenever the IMPU detects access violation, the following actions are taken:

1. The request forwarded to the BIU is canceled
2. The RCPU is informed that the requested address caused an access violation by exception request.

However, if the required address contains a show cycle attribute, the BIU delivers the access onto the U-bus to obtain program tracking.

The exception vector (address) that the RCPU issues for this exception has a 0x1300 offset in the RCPU exception vector table. The access violation status is provided in the RCPU SRR1 special purpose register.

The encoding of the status bits is as follows:

- SRR1 [1] = 0
- SRR1 [3] = Guarded storage
- SRR1 [4] = Protected storage or compression violation
- SRR1 [10] = 0

Only one bit is set at a time.

#### 4.2.4 Slave Operation

The BBC is operating as a U-bus slave when the IMPU registers, decompressor RAM (DECRAM) or ICDU registers are accessed from the U-bus. The IMPU register programming is done using PowerPC ISA mtspr/mfspr instructions. The ICDU configuration registers (DCCRs) and DECRAM are mapped into the chip memory space and accessed by load/store instructions. DCCR and DECRAM accesses may be disabled by BBCMCR[DCAE]. Refer to [Section 4.6.2.1, “BBC Module Configuration Register \(BBCMCR\).”](#)

#### 4.2.5 Reset Behavior

Upon soft reset, the BBC switches to an idle state and all pending U-bus accesses are ignored, the ICDU internal queue is flushed and the IMPU switches to a disabled state where all memory space is accessible for both user and supervisor.

Hard reset sets some of the fields and bits in the BBC configuration registers to their default reset state. Some bits in the BBCMCR register get their values from the reset configuration word.

All the registers are reset using  $\overline{\text{HRESET}}$ ;  $\overline{\text{SRESET}}$  alone has no effect on them.

## NOTE

Because  $\overline{\text{HRESET}}$  resets the EN\_COMP bit and the EXC\_COMP bit but  $\overline{\text{SRESET}}$  does not, there may be different behavior between  $\overline{\text{HRESET}}$  and  $\overline{\text{SRESET}}$  when both EN\_COMP and EXC\_COMP are set. Special care must be taken to ensure operation in a known mode whenever reset occurs. The reset states of these bits are determined by reset configuration words. The location of the reset vector is dependent on the value of the MSR[IP] bit in the RCPU. If MSR[IP] is set, the exception table relocation feature can be used. See [Section 4.3.1, “ETR Operation.”](#)

## 4.2.6 Debug Operation Mode

When the MPC561/MPC563 RCPU core is in debug mode, the BBC initiates non-burstable access to the debug port and ICDU is bypassed (i.e., instructions transmitted to the debug port must be non-compressed regardless of RCPU MSR[DCMPEN] bit state).

## 4.3 Exception Table Relocation (ETR)

The BBC is able to relocate the exception addresses of the RCPU. The relocation feature always maps the exception addresses into the internal memory space of the MPC561/MPC563. See [Figure 4-2](#). This feature is important in multi-MPC561/MPC563 systems, where, although the memory map in some was shifted to not be on the lower 4 Mbytes, their RCPU cores can still access their own exception handlers in their internal Flash in spite of several RCPUs issuing the same exception addresses.

The relocation also saves wasted space between the exception table entries in the case where each exception entry contained only a branch instruction to the exception routine, which is located elsewhere.

The exception vector table may be programmed to be located in four places in the MPC561/MPC563 internal memory space.

The exception table relocation is supported in both decompression on and decompression off operation modes.

The RESET routine vector is relocated differently in decompression on and in decompression off modes. This feature may be used by a software code compression tool to guarantee that a vocabulary table initialization routine is always executed before application code is running.

Figure 4-2. Exception Table Entries Mapping

### 4.3.1 ETR Operation

The exception vectors generated by the RCPU are 0x100 bytes apart from each other, starting at address 0x0000 0100 or 0xFFFF 0100, depending on the value of MSR[IP] bit in the RCPU.

If the exception table relocation is disabled by the ETRE bit in the BBCMCR register, the BBC transfers the exception fetch address to the U-bus of the MPC561/MPC563 with no interference. In this case, normal PowerPC ISA exception addressing is implemented.

If the exception table relocation is enabled, the BBC translates the exception vector into the exception relocation address as shown in Table 4-1. At that location, a branch instruction with absolute addressing (ba) must be placed. Each ba instruction branches to the required exception routine. These branch instructions should be successive in that region of memory. That way, a table of branch instructions is implemented. Executing the branch instruction causes the core to branch twice until it gets to the exception routine.

Each exception relocation table entry occupies two words to support decompression on mode, where a branch instruction can be more than 32 bits long. The branch table can be located in four locations in the internal memory, the location is defined by BBCMCR[OERC] as shown in Table 4-2.

## NOTE

The 8 Kbytes allocated for the original PowerPC ISA exception table can be almost fully utilized. This is possible if the MPC561/MPC563 system memory is *not* mapped to the exception address space, (i.e., the addresses 0xFFFF0 0000 to 0xFFFF0 1FFF are not used).

In such case, these 8 Kbytes can be fully utilized by the compiler, except for the lower 64 words (256 bytes) which are dedicated for the branch instructions.

If the RCPU, while executing an exception, issues any address between two successive exception entries (e.g., 0xFFFF0 0104), then the operation of the MPC561/MPC563 is not guaranteed if the ETR is enabled.

In order to activate the exception table relocation feature, the following steps are required:

1. Set the RCPU MSR[IP] bit
2. Set the BBCMCR[ETRE] bit. See [Section 4.6.2.1, “BBC Module Configuration Register \(BBCMCR\),”](#) for programming details.

The ETR feature can be activated from reset, by setting corresponding bits in the reset configuration word.

**Table 4-1. Exception Addresses Mapping**

| Name of Exception                           | Original Address Issues by Core | Mapped Address by Exception Table Relocation Logic |                                 |
|---------------------------------------------|---------------------------------|----------------------------------------------------|---------------------------------|
| Reserved                                    | 0xFFFF0 0000                    | Page_Offset+0x000                                  |                                 |
| System Reset                                | 0xFFFF0 0100                    | Compression disabled                               | Compression enabled             |
|                                             |                                 | Page_Offset <sup>1</sup> +0x08                     | Page_Offset <sup>1</sup> +0x0B8 |
| Machine Check                               | 0xFFFF0 0200                    | Page_Offset+0x010                                  |                                 |
| Reserved                                    | 0xFFFF0 0300                    | Page_Offset+0x018                                  |                                 |
| Reserved                                    | 0xFFFF0 0400                    | Page_Offset+0x020                                  |                                 |
| External Interrupt <sup>2</sup>             | 0xFFFF0 0500                    | Page_Offset+0x028                                  |                                 |
| Alignment                                   | 0xFFFF0 0600                    | Page_Offset+0x030                                  |                                 |
| Program                                     | 0xFFFF0 0700                    | Page_Offset+0x038                                  |                                 |
| Floating Point unavailable                  | 0xFFFF0 0800                    | Page_Offset+0x040                                  |                                 |
| Decrementer                                 | 0xFFFF0 0900                    | Page_Offset+0x048                                  |                                 |
| Reserved                                    | 0xFFFF0 0A00                    | Page_Offset+0x050                                  |                                 |
| Reserved                                    | 0xFFFF0 0B00                    | Page_Offset+0x058                                  |                                 |
| System Call                                 | 0xFFFF0 0C00                    | Page_Offset+0x060                                  |                                 |
| Trace                                       | 0xFFFF0 0D00                    | Page_Offset+0x068                                  |                                 |
| Floating Point Assist                       | 0xFFFF0 0E00                    | Page_Offset+0x070                                  |                                 |
| Implementation Dependent Software Emulation | 0xFFFF0 1000                    | Page_Offset+0x080                                  |                                 |

Table 4-1. Exception Addresses Mapping (continued)

| Name of Exception                                             | Original Address Issues by Core | Mapped Address by Exception Table Relocation Logic |
|---------------------------------------------------------------|---------------------------------|----------------------------------------------------|
| Implementation Dependent Instruction Storage Protection Error | 0xFFFF0 1300                    | Page_Offset+0x098                                  |
| Implementation Dependent Data Storage Protection Error        | 0xFFFF0 1400                    | Page_Offset+0x0A0                                  |
| Implementation Dependent Data Breakpoint                      | 0xFFFF0 1C00                    | Page_Offset+0x0E0                                  |
| Implementation Dependent Instruction Breakpoint               | 0x0FFF 1D00                     | Page_Offset+0x0E8                                  |
| Implementation Dependent Maskable External Breakpoint         | 0xFFFF0 1E00                    | Page_Offset+0x0F0                                  |
| Non-Maskable External Breakpoint                              | 0xFFFF0 1F00                    | Page_Offset+0x0F8                                  |

<sup>1</sup> Refer to [Table 4-2](#).

<sup>2</sup> 0x500 is remapped if the EEIR feature is enabled. See [Section 4.3.2, “Enhanced External Interrupt Relocation \(EEIR\)”](#).

Table 4-2. Exception Relocation Page Offset

| BBCMCR(OERC[0:1]) |   | Page Offset                   | Comments               |
|-------------------|---|-------------------------------|------------------------|
| 0                 | 0 | 0x0 + ISB offset <sup>1</sup> | 0                      |
| 0                 | 1 | 0x1 0000 + ISB offset         | 64 Kbytes <sup>2</sup> |
| 1                 | 0 | 0x8 0000 + ISB offset         | 512 Kbytes             |
| 1                 | 1 | 0x3F E000 + ISB offset        | L-bus (CALRAM) Address |

<sup>1</sup> ISB offset is equal  $4M * ISB$  ( $0x400000 * ISB$ ), where ISB is value of bit field in USIU IMMR register.

<sup>2</sup> This offset is different from the MPC555.

### 4.3.2 Enhanced External Interrupt Relocation (EEIR)

The BBC also supports the enhanced external interrupt model of the MPC561/MPC563 which allows the removal of the interrupt requesting a source detection stage from the interrupt routine. The interrupt controller provides the interrupt vector to the BBC together with an interrupt request to the RCPU. When the RCPU acknowledges an interrupt request, it issues an external interrupt vector to the BBC. The BBC logic detects this address and replaces it with another address corresponding to the interrupt controller vector, which is defined by the highest priority interrupt request from a peripheral module or external interrupt request pin. See [Figure 4-3](#).

The external interrupt relocation table should be placed at the physical address defined in the external interrupt relocation table base address register. See [Section 4.6.2.5, “External Interrupt Relocation Table](#)

[Base Address Register \(EIBADR\)](#).” This is the base address of a branch table. See [Table 6-4](#) and [Figure 4-3](#).

Each table entry must contain a branch absolute (ba) instruction to the first instruction of an interrupt service routine. Each table entry occupies two words (eight bytes) to support decompression on mode, where a branch instruction can be more than 32 bits long.

The memory space allocated for the external interrupt relocation table is up to 2 Kbytes. If part of the external interrupt relocation table entry is not used, it may be utilized for another purpose such as instruction code space or data space.

In order to activate the external interrupt relocation feature, the following steps are required:

1. Program the EIBADR register to the external interrupt branch table base address. See [Section 4.6.2.5, “External Interrupt Relocation Table Base Address Register \(EIBADR\)”](#).
2. Set the MSR[IP] bit.
3. Set the BBCMCR[EIR] bit. See [Section 4.6.2.1, “BBC Module Configuration Register \(BBCMCR\)”](#) for programming details.

#### NOTE

If both the enhanced external interrupt relocation and exception table relocation functions are activated simultaneously, the final external interrupt vector is defined by EEIR mechanism.

When the EEIR function is activated, any branch instruction execution with the 0xFFFF0 0500 target address may cause unpredictable program execution.

Figure 4-3. External Interrupt Vectors Splitting

#### 4.4 Decompressor RAM (DECRAM) Functionality

Decompressor RAM (DECRAM) is a part of the ICDU. It occupies a 2-Kbyte physical RAM array block. It is mapped both in the ICDU internal address space and in the chip memory address space. It is a single port memory and may not be accessed simultaneously from the ICDU and U-bus.

**Figure 4-4. DECRAM Interfaces Block Diagram**

### 4.4.1 General-Purpose Memory Operation

In the case of decompression off mode, the DECRAM can serve as a two-clock access general-purpose RAM for U-bus instruction fetches or four-clock access for read/write data operations. The base address of the DECRAM is 0x2F 8000. See [Figure 4-6](#). The proper access rights to the DECRAM array may be defined by programming the R, D, and S bits of the BBCMCR register:

- Read/write or read only
- Instruction/data or data only
- Supervisor/user or supervisor only

U-bus access mode of the RAM is activated by the BBCMCR[DCAE] bit setting (see [Section 4.6.2.1](#), “BBC Module Configuration Register (BBCMCR)”). In this mode the DECRAM can be accessed from the U-bus and cannot be accessed by the ICDU logic.

In this mode:

- The DECRAM supports word, half-word and byte operations.
- The DECRAM is emulated to be 32 bits wide. For example: a load access from offset 0 in the DECRAM will deliver the concatenation of the first word in each of the DECRAM banks when RAM 1 contains the 16 LSB of the word and RAM 2 contains the 16 MSB.
- Load accesses at any width are supplied with 32 bits of valid data.
- The DECRAM communicates with the U-bus pipeline but does not support pipelined accesses to itself. If a store operation is second in the U-bus pipe, the store is carried out immediately and the U-bus acknowledgment is performed when the previous transaction in the pipe completes.
- Burst access is not supported.

#### NOTE

Instructions running from the DECRAM should not also perform store operations to the DECRAM.

### 4.4.1.1 Memory Protection Violations

The DECRAM module does not acknowledge U-bus accesses that violate the configuration defined in the BBCMCR. This causes the machine check exception for the internal RCPU or an error condition for the MPC561/MPC563 external master.

### 4.4.1.2 DECRAM Standby Operation Mode

The bus interface and DECRAM control logic are powered by  $V_{DD}$  supply. The memory array is supplied by a separate power pin (IRAMSTBY).

## 4.5 Branch Target Buffer

The burst buffer controller contains a branch target buffer (BTB) to reduce the impact of branches on processor performance. Following is a summary of the BTB features:

- Software controlled BTB enable/disable, inhibit, and invalidate
- User transparent — no user management required

The BTB consists of eight branch target entries (BTE). Refer to [Figure 4-5](#). All entries are managed as a fully associative cache. Each entry contains a tag and several data buffers related to this tag.

### 4.5.1 BTB Operation

When the RCPU generates a change of flow (COF) address for instruction fetch, the BTB control logic compares it to the tag values currently stored in the tag register file where the following events can happen:

- **BTE Miss** — The target address and instruction code data will be stored in one of the BTE entries defined by its control logic. Up to four instructions and their corresponding addresses subsequent to the COF target instruction may be saved in each BTE entry. The number of valid instructions currently stored in the BTE entry is written into the VDC field of the current BTE entry. The valid flag is set at the end of this process. The entry to be replaced upon miss is chosen based on FIFO replacement method. Thus the BTB can support up to eight different branch target addresses in a program loop.
- **BTE Hit** — When the target address of a branch matches one of the valid BTE entries, two activities take place in parallel:
  - The BTB supplies all the valid instructions in the matched entry to the RCPU.
  - The BIU starts to prefetch new instructions (and ICDU decompresses them in compressed mode) from the address following the last instruction that is stored in the matched BTB entry. The BBC will supply these new instructions to the RCPU after all the stored instructions in the matched BTB entry were delivered.

In case of a BTB hit, the impact of instruction decompression latency (in compressed mode) is eliminated as well as a latency of instruction storage memory device.

Figure 4-5. BTB Block Diagram

#### 4.5.1.1 BTB Invalidation

Write access to any BBC special purpose register invalidates all BTB entries.

#### NOTE

To guarantee that the BTB does not contain instructions that may have been changed, the BTB contents should be invalidated any time instruction memory is modified.

#### 4.5.1.2 BTB Enabling/Disabling

The BTB operation may be enabled or disabled by programming the BTEE bit in the BBCMCR register.

#### 4.5.1.3 BTB Inhibit Regions

The BTB operation may be inhibited regarding some memory regions. The BTB caching is inhibited for a region if the BTBINH bit is set in the region attribute register (or global region attribute register). See

Section 4.6.2.3, “Region Attribute Registers (MI\_RA[0:3]),” and Section 4.6.2.4, “Global Region Attribute Register (MI\_GRA)” for details.

## 4.6 BBC Programming Model

### 4.6.1 Address Map

The BBC consists of three separately addressable sections within the internal chip address space:

1. BBC and IMPU control registers. These are mapped in the SPR registers area and may be programmed by using the RCPU mtspr/mfspr instructions.
2. Decompressor vocabulary RAM (DECRAM). The DECRAM array occupies the 2-Kbyte physical memory (8 Kbytes of the MPC561/MPC563 address space is allocated for DECRAM).
3. Decompressor class configuration registers (DCCR) block. It consists of 15 decompression class configuration registers. These registers are available for word wide read/write accesses through U-bus. The registers occupy a 64-byte physical block (8-Kbyte chip address space is allocated for the register block).

|           |                    |
|-----------|--------------------|
| 0x2F 8000 |                    |
| 0x2F 87FF | DECRAM<br>2 Kbytes |
| 0x2F 8800 |                    |
| 0x2F 9FFF | Reserved           |
| 0x2F A000 |                    |
| 0x2F A03F | DCCR0 – DCCR15     |

Figure 4-6. MPC561/MPC563 Memory Map

#### 4.6.1.1 BBC Special Purpose Registers (SPRs)

Table 4-3. BBC SPRs

| SPR Number<br>(Decimal) | Address for<br>External<br>Master<br>Access (Hex) | Register Name                                                                                            |
|-------------------------|---------------------------------------------------|----------------------------------------------------------------------------------------------------------|
| 528                     | 0x2100                                            | IMPU Global Region Attribute Register (MI_GRA). See Table 4-8 for bits descriptions.                     |
| 529                     | 0x2300                                            | External Interrupt Relocation Table Base Address Register (EIBADR). See Table 4-9 for bits descriptions. |
| 560                     | 0x2110                                            | BBC Module Configuration Register (BBCMCR). See Table 4-4 for bits descriptions                          |

**Table 4-3. BBC SPRs (continued)**

| SPR Number (Decimal) | Address for External Master Access (Hex) | Register Name                                                                                       |
|----------------------|------------------------------------------|-----------------------------------------------------------------------------------------------------|
| 784                  | 0x2180                                   | IMPU Region Base Address Register 0 (MI_RBA0). See <a href="#">Table 4-5</a> for bits descriptions. |
| 785                  | 0x2380                                   | IMPU Region Base Address Register 1 (MI_RBA1). See <a href="#">Table 4-5</a> for bits descriptions. |
| 786                  | 0x2580                                   | IMPU Region Base Address Register 2 (MI_RBA2). See <a href="#">Table 4-5</a> for bits descriptions. |
| 787                  | 0x2780                                   | IMPU Region Base Address Register 3 (MI_RBA3). See <a href="#">Table 4-5</a> for bits descriptions. |
| 816                  | 0x2190                                   | IMPU Region Attribute Register 0 (MI_RA0). See <a href="#">Table 4-6</a> for bits descriptions.     |
| 817                  | 0x2390                                   | IMPU Region Attribute Register 1 (MI_RA1). See <a href="#">Table 4-6</a> for bits descriptions.     |
| 818                  | 0x2590                                   | IMPU Region Attribute Register 2 (MI_RA2). See <a href="#">Table 4-6</a> for bits descriptions.     |
| 819                  | 0x2790                                   | IMPU Region Attribute Register 3 (MI_RA3). See <a href="#">Table 4-6</a> for bits descriptions.     |

All the above registers may be accessed in the supervisor mode only. An exception is internally generated by the RCPU if there is an attempt to access them in user mode. An external master receives a transfer error acknowledge when attempting to access a register in user mode.

#### NOTE

If one of these registers is written within 4 instructions of a branch target, the user application may crash. To prevent this, ensure that any instruction writing to these registers is preceded by 4 instructions that are not the target of any branch, and is followed by an isync instruction.

#### 4.6.1.2 DECRAM and DCCR Block

The DECRAM occupies addresses from 0x2F 8000 to 0x2F 87FF. The DCCR block occupies addresses from 0x2F A000 to 0x2F A03F.

The address for non-implemented memory blocks is not acknowledged, and causes an error condition.

## 4.6.2 BBC Register Descriptions

### 4.6.2.1 BBC Module Configuration Register (BBCMCR)

|     |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  | |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  | **Figure 4-7. BBC Module Configuration Register (BBCMCR)**

<sup>1</sup> MPC562/MPC564 only.

<sup>2</sup> The reset value is a reset configuration word value extracted from the internal bus line. Refer to [Section 7.5.2, “Hard Reset Configuration Word \(RCW\).”](#)

**Table 4-4. BBCMCR Field Descriptions**

| Bits | Name            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|------|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0    | R               | Read Only. Any attempt to write to the DECRAM array while R is set is terminated with an error. This causes a machine check exception for RCPU.<br>0 DECRAM array is Readable and Writable.<br>1 DECRAM array is Read only.                                                                                                                                                                                                                                           |
| 1    | D               | Data Only. The DECRAM array may be used for Instructions and Data or for Data storage only. Any attempt to load instructions from the DECRAM array, while D is set, is terminated with an error This causes a machine check exception for the RCPU.<br>0 DECRAM array holds Data and/or Instruction.<br>1 DECRAM array holds Data only.                                                                                                                               |
| 2    | S               | Supervisor Only.<br>When the bit is set (S = 1), only a Supervisor program may access the DECRAM. If a Supervisor program is accessing the array, normal read/write operation will occur. If a User program is attempting to access the array, the access will be terminated with an error This causes a machine check exception for the RCPU.<br>If S = 0, the RAM array is placed in Unrestricted Space and access by both Supervisor and User programs is allowed. |
| 3:7  | TEST            | These bits can be set in Factory test mode only. The User should treat these bits as reserved and always write as zeros.                                                                                                                                                                                                                                                                                                                                              |
| 8:17 | —               | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

**Table 4-4. BBCMCR Field Descriptions (continued)**

| Bits  | Name                      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-------|---------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 19    | ETRE                      | Exception Table Relocation Enable<br>0 Exception Table Relocation is off: BBC does NOT map exception addresses.<br>1 Exception Table Relocation is on: BBC maps exception addresses to a table holding branch instructions two memory words apart from each other.<br>The reset value is taken from the reset configuration word bit 19.<br><b>Note:</b> On the MPC562/MPC564, do not put compressed code at addresses 0xFFFF0000 to 0xFFFF FFFF if ETRE = 1.                                                                                                                                                                                                                                  |
| 20    | EIR                       | Enhanced External Interrupt Relocation Enable— This bit activates the external interrupt relocation table mechanism. This bit is independent from the value of ETRE bit, but if EIR and ETRE are enabled, the mapping of external interrupt will be via EIR.<br>0 EIR function is disabled.<br>1 EIR function is active.                                                                                                                                                                                                                                                                                                                                                                       |
| 21    | EN_COMP <sup>2</sup>      | Enable Compression. This bit enables the operation of the MPC562/MPC564 in compression on mode.<br>NOTE: For Rev A and later versions of the MPC563 and rev B and later of the MPC561, the default state is defined by bit 21 of the reset configuration word, and is writable. In earlier versions, the bit can only be set by the reset configuration word.<br>0 decompression on mode is disabled.<br>1 decompression on mode is enabled.<br>The MPC561/MPC563 operates only in decompression off mode. The MPC562/MPC564 may operate with both decompression on and decompression off modes.                                                                                               |
| 22    | EXC_COMP <sup>2</sup>     | Exception Compression. This bit determines the operation of the MPC562/MPC564 with exceptions. If this bit is set, the MPC562/MPC564 assumes that the all exception routine codes are compressed; otherwise it is assumed that all exception routine codes are not compressed. The reset value is determined by reset configuration word bit 22.<br>0 The RCPU assumes that exception routines are noncompressed.<br>1 The RCPU assumes that all exception routines are compressed.<br>This bit has effects only when the EN_COMP bit is set. The MPC561/MPC563 operates only in decompression off mode. The MPC562/MPC564 may operate with both decompression on and decompression off modes. |
| 23    | DECOMP_SC_EN <sup>2</sup> | Decompression Show Cycle Enable. This bit determines the way the MPC562/MPC564 executes instruction show cycles.<br>The reset value is determined by configuration word bit 21. For further details regarding show cycles execution in “Decompression ON” mode see <a href="#">Section 4.2.1.2, “Decompression On Mode.”</a><br>0 Decompression Show Cycles do not include the bit pointer.<br>1 Decompression Show Cycles include the bit pointer information on the data bus.                                                                                                                                                                                                                |
| 24:25 | OERC[0:1]                 | Other Exceptions Relocation Control. These bits have effect only if ETRE was enabled; See details in <a href="#">Section 4.3.1, “ETR Operation.”</a><br>00: offset 0<br>01 Offset 64 Kbytes<br>10 Offset 512 Kbytes<br>11 Offset to 0x003FE000<br>The reset value is determined by reset configuration word bits 24 and 25                                                                                                                                                                                                                                                                                                                                                                     |
| 26    | BTEE <sup>1</sup>         | Branch Target Entries Enable. This bit enables Branch Target Entries of BTB operation<br>0 BTE operation is disabled<br>1 BTE operation is enabled                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

**Table 4-4. BBCMCR Field Descriptions (continued)**

| Bits  | Name | Description                                                                                                                                                                                                                                                                                                               |
|-------|------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 27:29 | —    | Reserved.<br>NOTE: Bit 27 was BCMEE and should be written as 0.                                                                                                                                                                                                                                                           |
| 30    | DCAE | Decompressor Configuration Access Enable. This bit enables DECRAM and DCCR registers access from the U-bus master (i.e., RCPU, external master).<br>0 DECRAM and DCCR registers are locked.<br>1 DECRAM allows accesses from the U-bus only.<br>DCAE bit should be set before vocabulary tables are loaded via the U-bus. |
| 31    | TST  | Reserved for BBC Test Operations.                                                                                                                                                                                                                                                                                         |

<sup>1</sup> BE and BTEE should not both be set at the same time, setting the BE bit disables the BTB.

<sup>2</sup> This bit is available on the MPC562/MPC564 only, software should write "0" to this bit for MPC561/MPC563.

### NOTE

When writing to the BBCMCR register, the following instruction after mtspr BBCMCR, Rx should be ISYNC, to make sure that the programmed value will come into effect before any further action.

## 4.6.2.2 Region Base Address Registers (MI\_RBA[0:3])

The following registers contain 32 bits and define the starting address of the protected regions. There is one register for each of four regions.

**Figure 4-8. Region Base Address Register (MI\_RBA[0:3])**
**Table 4-5. MI\_RBA[0:3] Registers Bit Descriptions**

| Bits  | Name | Description                                                                                                                                                                                                                       |
|-------|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0:19  | RA   | Region Base address. The RA field provides the base address of the region. The region base address should start on the memory block boundary for the corresponding region size, specified in the region attribute register MI_RA. |
| 20:31 | —    | Reserved                                                                                                                                                                                                                          |

## NOTE

When the MPC562/MPC564 operates in decompression on mode, a minimum of four unused words **MUST** be left after the last instruction in any region.

### 4.6.2.3 Region Attribute Registers (MI\_RA[0:3])

The following registers define protection attributes and size for four memory regions.

**Figure 4-9. Region Attribute Register (MI\_RA0[0:3])**

**Table 4-6. MI\_RA[0:3] Registers Bit Descriptions**

| Bits  | Name              | Description                                                                                                                                                                                                                                                                                          |

#### 4.6.2.4 Global Region Attribute Register (MI\_GRA)

The MI\_GRA register defines protection attributes for memory region, not covered by MI\_RB[0:3]/MI\_RBA[0:3] registers. It also contains protection regions 0-3 enable bits.

**Figure 4-10. Global Region Attribute Register (MI\_GRA)**

**Table 4-8. MI\_GRA Field Descriptions**

| Bits  | Name              | Description                                                                                                                                                                                                                                                                                         |

### NOTE

The MI\_GRA register should be programmed to enable fetch access (PP and G bits) before RCPU MSR[IR] is set.

### 4.6.2.5 External Interrupt Relocation Table Base Address Register (EIBADR)

Figure 4-11. External Interrupt Relocation Table Base Address Register (EIBADR)

Table 4-9. EIBADR External Interrupt Relocation Table Base Address Register Bit Descriptions

| Bits  | Name | Description                                                  |
|-------|------|--------------------------------------------------------------|
| 0:20  | BA   | External Interrupt Relocation Table Base Address bits [0:20] |
| 21:31 | —    | Reserved. EIBADR must be set on a 4K page boundary.          |

### 4.6.3 Decompressor Class Configuration Registers

See [Section A.4, “Decompressor Class Configuration Registers \(DCCR0-15\)”](#) for the registers of the ICDU.

## Chapter 5

# Unified System Interface Unit (USIU) Overview

The unified system interface unit (USIU) of the MPC561/MPC563 consists of several functional modules that control system start-up, system initialization and operation, system protection, and the external system bus. The MPC561/MPC563 USIU functions include the following and are discussed in the designated chapters:

- System configuration and protection with GPIO capability and an enhanced interrupt controller. Refer to [Chapter 6, “System Configuration and Protection.”](#)
- System reset monitoring and generation, refer to [Chapter 7, “Reset.”](#)
- Clock synthesis, power management, and debug support. Refer to [Chapter 8, “Clocks and Power Control.”](#)
- External bus interface (EBI), refer to [Chapter 9, “External Bus Interface.”](#)
- Memory controller that supports four memory banks. Refer to [Chapter 10, “Memory Controller.”](#)

The USIU provides system configuration and protection features that control the overall system configuration and supply various monitors and timers including the bus monitor, software watchdog timer, periodic interrupt timer, decremter, time base, and real-time clock. Freeze support and low power stop is provided. The interrupt controller supports up to eight external interrupts, eight levels for all internal USIU interrupt sources and 32 levels for internal peripheral modules on the IMB bus. It has an enhanced mode of operation, which simplifies the MPC561/MPC563 interrupt structure and speeds up interrupt processing.

Additionally, the USIU provides several pinout configurations that allow up to 64 general-purpose I/O, external 32-bit port that supports internal and external masters, and various debug functions.

Reset logic for the MPC561/MPC563 provides soft and hard resets, checkstop and watchdog resets, and other types of reset. The reset status register (RSR) reflects the most recent source to cause a reset.

The clock synthesizer generates the clock signals used by the USIU as well as the other modules and external devices. This circuitry can generate a system clock from a range of crystals, typically in the 4 MHz or 20 MHz range.

The USIU supports various low-power modes. Each one supplies a different range of power consumption, functionality and wake-up time. Refer to [Chapter 8, “Clocks and Power Control,”](#) for details.

The EBI handles the transfer of information between the internal busses and the memory or peripherals in the external address space. The MPC561/MPC563 is designed to allow external bus masters to request and obtain mastership of the system bus, and if required access the on-chip memory and registers. Refer to [Chapter 9, “External Bus Interface,”](#) for details.

The memory controller module provides glueless interface to many types of memory devices and peripherals. It supports up to four memory banks. Refer to [Chapter 10, “Memory Controller,”](#) for details.

The USIU supports the internal Flash censorship mechanism on the MPC561/MPC563 to protect the Flash contents. Refer to [Chapter 21, “CDR3 Flash \(UC3F\) EEPROM.”](#) It is not possible to operate the MPC561/MPC563 from the external world while the Flash is in censorship mode and in a censorship state. The internal Flash array will be either locked or accessible only after the entire array contents have been erased. The MPC561/MPC563 is in censored mode if one of the following events occurs:

- booting from external memory
- operating in peripheral mode or if accessed from an external master
- operating in debug mode (BDM or Nexus)

Figure 5-1 shows the USIU block diagram.

Figure 5-1. USIU Block Diagram

## 5.1 Memory Map and Registers

Table 5-1 is an address map of the USIU registers and, unless otherwise noted, registers are 32 bits wide. The address shown for each register is relative to the base address of the MPC561/MPC563 internal memory map. The internal memory block can reside in one of eight possible 4 Mbyte memory spaces. See Figure 1-3 for details.

**Table 5-1. USIU Address Map**

| Address                | Register                                                                                                                                          |

<sup>1</sup> 16-bit register.

### 5.1.1 USIU Special-Purpose Registers

[Table 5-2](#) lists the MPC561/MPC563 special purpose registers (SPR) used by the USIU. These registers reside in an alternate internal memory space that can only be accessed with the `mtspr` and `mfscr` instructions, or from an external master (refer to [Section 6.1.2, “External Master Modes,”](#) for details). All registers are 32 bits wide.

#### NOTE

RCPU special purpose registers cannot be accessed by an external master.  
Only SPRs in the USIU can be accessed by an external master.

**Table 5-2. USIU Special-Purpose Registers**

| Internal Address[0:31] | Register                                                                                                             | Decimal Address spr[5:9]:spr[0:4] <sup>1</sup> |
|------------------------|----------------------------------------------------------------------------------------------------------------------|------------------------------------------------|

## Chapter 6

# System Configuration and Protection

The MPC561/MPC563 incorporate many system functions that normally must be provided in external circuits. In addition, it is designed to provide maximum system safeguards against hardware and software faults. The system configuration and protection sub-module provides the following features:

- System Configuration ([Section 6.1.1, “System Configuration”](#))—The USIU allows the configuration of the system according to the particular requirements. The functions include control of show cycle operation, pin multiplexing, and internal memory map location. System configuration also includes a register containing part and mask number constants to identify the part in software.
- External Master Modes Support ([Section 6.1.2, “External Master Modes”](#))—External master modes are special modes of operation that allow an alternate master on the external bus to access the internal modules for debugging and backup purposes.
- General-Purpose I/O ([Section 6.1.3, “USIU General-Purpose I/O ”](#))—The USIU provides 64 pins for general-purpose I/O. The SGPIO pins are multiplexed with the address and data pins.
- Enhanced Interrupt Controller ([Section 6.1.4, “Enhanced Interrupt Controller”](#))—The interrupt controller receives interrupt requests from a number of internal and external sources and directs them on a single interrupt-request line to the RCP.
- Bus Monitor ([Section 6.1.5, “Hardware Bus Monitor”](#))—The SIU provides a bus monitor to watch internal to external accesses. It monitors the transfer acknowledge ( $\overline{TA}$ ) response time for internal to external transfers. A transfer error acknowledge ( $\overline{TEA}$ ) is asserted if the  $\overline{TA}$  response limit is exceeded. This function can be disabled.
- Decrementer ([Section 6.1.6, “Decrementer \(DEC\)”](#))—The DEC is a 32-bit decrementing counter defined by the MPC500 architecture to provide a decrementer interrupt. This binary counter is clocked by the same frequency as the time base (also defined by the MPC561/MPC563 architecture). The period for the DEC when driven by a 4-MHz oscillator can be up to 4295 seconds, which is approximately 71.6 minutes. Refer to [Table 6-6](#).
- Time Base Counter ([Section 6.1.7, “Time Base \(TB\)”](#))—The TB is a 64-bit counter defined by the MPC500 architecture to provide a time base reference for the operating system or application software. The TB has four independent reference registers that can generate a maskable interrupt when the time-base counter reaches the value programmed in one of the four reference registers. The associated bit in the TB status register will be set for the reference register which generated the interrupt.
- Real-Time Clock ([Section 6.1.8, “Real-Time Clock \(RTC\)”](#))—The RTC is used to provide time-of-day information to the operating system or application software. It is composed of a 45-bit counter and an alarm register. A maskable interrupt is generated when the counter reaches the value programmed in the alarm register. The RTC is clocked by the same clock as the PIT.

- Periodic Interrupt Timer ([Section 6.1.9, “Periodic Interrupt Timer \(PIT\)”](#))—The SIU provides a timer to generate periodic interrupts for use with a real-time operating system or the application software. The PIT provides a period from 1  $\mu$ s to 4 seconds with a four-MHz crystal or 200 ns to 0.8 ms with a 20-MHz crystal. The PIT function can be disabled.
- Software Watchdog Timer ([Section 6.1.10, “Software Watchdog Timer \(SWT\)”](#))—The SWT asserts a reset or non-maskable interrupt, as selected by the system protection control register (SYPCR), if the software fails to service the SWT for a designated period of time (e.g., because the software is trapped in a loop or lost). After a system reset, this function is enabled with a maximum time-out period and asserts a system reset if the time-out is reached. The SWT can be disabled or its time-out period can be changed in the SYPCR. Once the SYPCR is written, it cannot be written again until a system reset.
- Freeze Support ([Section 6.1.11, “Freeze Operation”](#))—The SIU allows control of whether the SWT, PIT, TB, DEC, and RTC should continue to run during freeze mode.
- Low Power Stop ([Section 6.1.12, “Low Power Stop Operation”](#))—In low power modes, specific timers are frozen but others are not.

Figure 6-1 shows a block diagram of the system configuration and protection logic.

Figure 6-1. System Configuration and Protection Logic

## 6.1 System Configuration and Protection Features

The system configuration and protection sub-module provides features described in the following sections.

### 6.1.1 System Configuration

The SIU allows the configuration of the system according to the particular requirements. The functions include control of show cycle operation, pin multiplexing, and internal memory map location. System configuration also includes a register containing part and mask number constants to identify the part in software.

System configuration registers include the SIU module configuration register (SIUMCR), and the internal memory mapping register (IMMR). Refer to [Section 6.2.2, “System Configuration and Protection Registers,”](#) for register diagrams and bit descriptions.

### 6.1.1.1 USIU Pin Multiplexing

Some of the functions defined in the various sections of the USIU (external bus interface, memory controller, and general-purpose I/O) share pins. [Table 6-1](#) summarizes how the pin functions of these multiplexed pins are assigned.

**Table 6-1. USIU Pin Multiplexing Control**

| Pin Name                                                                                                                                                                                                                                                                                                                                                                                                                                                           | Multiplexing Controlled by:                                                                                            |

| $\overline{\text{RSTCONF}}$ / TEXP                                                                                                                                                                                                                                                                                                                                                                                                                                 | At Power-On Reset: RSTCONF<br>Otherwise: Programmed in SIUMCR                                                          |

### 6.1.1.2 Arbitration Support

Two bits in the SIUMCR control USIU bus arbitration. The external arbitration (EARB) bit determines whether arbitration is performed internally or externally. If EARB is cleared (internal arbitration), the external arbitration request priority (EARP) bit determines the priority of an external master's arbitration request. The operation of the internal arbiter is described in [Section 9.5.7.4, "Internal Bus Arbiter."](#)

### 6.1.2 External Master Modes

External master modes are special modes of operation that allow an alternative master on the external bus to access the internal modules for debugging and backup purposes. They provide access to the internal buses (U-bus and L-bus) and to the intermodule bus (IMB3).

There are two external master modes:

- Peripheral mode (enabled by setting PRPM in the external master control (EMCR) register) uses a special slave mechanism that shuts down the RCPU and an alternative master on the external bus can perform accesses to any internal bus slave.

- Slave mode (enabled by setting EMCR[SLVM] and clearing EMCR[PRPM]) enables an external master to access any internal bus slave while the RCPU is fully operational.

Both modes can be enabled and disabled by software. In addition, peripheral mode can be selected from reset.

The internal bus is not capable of providing priority between internal RCPU accesses and external master accesses. If the bandwidth of external master accesses is large, it is recommended that the system force gaps between external master accesses in order to avoid suspension of internal RCPU activity.

The MPC561/MPC563 does not support burst accesses from an external master; only single accesses of 8, 16, or 32 bits can be performed. The MPC561/MPC563 asserts burst inhibit (BI) on any attempt to initiate a burst access to internal memory.

The MPC561/MPC563 provides memory controller services for external master accesses (single and burst) to external memories. See [Chapter 10, “Memory Controller,”](#) for details.

### 6.1.2.1 Operation in External Master Modes

The external master modes are controlled by the EMCR register, which contains the internal bus attributes. The default attributes in the EMCR allow an external master to configure the EMCR with the required attributes and access internal registers. The external master must be granted external bus ownership in order to initiate the external master access. The SIU compares the address on the external bus to the allocated internal address space. If the address is within the internal space, the access is performed with the internal bus. The internal address space is determined according to IMMR[ISB] (see [Section 6.2.2.1.2, “Internal Memory Map Register \(IMMR\),”](#) for details). The external master access is terminated by the  $\overline{TA}$ ,  $\overline{TEA}$ , or  $\overline{RETRY}$  signal on the external bus.

A deadlock situation might occur if an internal-to-external access is attempted on the internal bus while an external master access is initiated on the external bus. In this case, the SIU will assert  $\overline{RETRY}$  on the external bus in order to relinquish and retry the external access until the internal access is completed. The internal bus will deny other internal accesses for the next eight clocks in order to complete the pending accesses and prevent additional internal accesses from being initiated on the internal bus. The SIU will also mask internal accesses to support consecutive external accesses if the delay between the external accesses is less than four clocks. The external master access and retry timings are described in [Section 9.5.12, “Bus Operation in External Master Modes.”](#)

The external master may access the internal MPC561/MPC563 special registers that are located outside the RCPU. To access one of these special purpose registers (see [Section 5.1.1, “USIU Special-Purpose Registers”](#)), EMCR[CONT] must be set and EMCR[SUPU] must be cleared. The external master can then access the special register when it is provided the address according to the MPC561/MPC563 address map. Only the first external master access that follows EMCR setting will be assigned to the special register map; any subsequent accesses will be directed to the normal address map. This is done in order to enable access to the EMCR again after the required MPC561/MPC563 special register access.

Peripheral mode does not require external bus arbitration between the external master and the internal RCPU, since the internal RCPU is disabled. The  $\overline{BR}$  and  $\overline{BB}$  signals should be connected to ground, and the internal bus arbitration should be selected in order to prevent the “slave” MPC561/MPC563 from

occupying the external bus. Internal bus arbitration is selected by clearing SIUMCR[EARB] (see [Section 6.2.2.1.1, “SIU Module Configuration Register \(SIUMCR\)”](#)).

### 6.1.2.2 Address Decoding for External Accesses

During an external master access, the USIU compares the external address with the internal address block to determine if MPC561/MPC563 operation is required. Since only 24 of the 32 internal address bits are available on the external bus, the USIU assigns zeros to the most significant address bits (ADDR[0:7]).

The address compare sequence can be summarized as follows:

- Normal external access. If EMCR[CONT] is cleared, the address is compared to the internal address map. Refer to [Section 6.2.2.1.3, “External Master Control Register \(EMCR\)”](#).
  - MPC561/MPC563 special register external access. If EMCR[CONT] is set by the previous external master access, the address is compared to the MPC561/MPC563 special address range. See [Section 5.1.1, “USIU Special-Purpose Registers,”](#) for a list of the SPRs in the USIU.
  - Memory controller external access. If the first two comparisons do not match, the internal memory controller determines whether the address matches an address assigned to one of the regions. If it finds a match, the memory controller generates the appropriate chip select and attribute accordingly

When trying to fetch an MPC561/MPC563 special register from an external master, the address might be aliased to one of the external devices on the external bus. If this device is selected by the MPC561/MPC563 internal memory controller, this aliasing does not occur since the chip select is disabled. If the device has its own address decoding or is being selected by external logic, this case is resolved.

#### NOTE

This section does not address slave accesses to internal resources. For internal resources, the accesses compare against ADDR[8:9] = ISB[1:2]. ISB0 must be cleared.

### 6.1.3 USIU General-Purpose I/O

The USIU provides 64 general-purpose I/O (SGPIO) pins (See [Table 6-2](#)). The SGPIO pins are multiplexed with the address and data pins. In single-chip mode, where communicating with external devices is not required, all 64 SGPIO pins can be used. In multiple-chip mode, only eight SGPIO pins are available. Another configuration allows the use of the address bus for instruction show cycles while the data bus is dedicated to SGPIO functionality. The functionality of these pins is assigned by the single-chip (SC) bit in the SIUMCR. (See [Section 6.2.2.1.1, “SIU Module Configuration Register \(SIUMCR\)”](#).)

SGPIO pins are grouped as follows:

- Six groups of eight pins each, whose direction is set uniformly for the whole group
- 16 single pins whose direction is set separately for each pin

[Table 6-2](#) describes the SGPIO signals, and all available configurations. The SGPIO registers are described in [Section 6.2.2.5, “General-Purpose I/O Registers.”](#)

Table 6-2. SGPIO Configuration

| SGPIO Group Name         | Individual Pin Control | Direction Control | Available When SC = 00 (32-bit Port Size Mode) | Available When SC = 01 (16-bit Port Size Mode) | Available When SC = 10 (Single-Chip Mode with Trace) | Available When SC = 11 (Single-Chip Mode) |
|--------------------------|------------------------|-------------------|------------------------------------------------|------------------------------------------------|------------------------------------------------------|-------------------------------------------|

## 6.1.4 Enhanced Interrupt Controller

### 6.1.4.1 Key Features

- Significant interrupt latency reduction from that of the MPC555.
- Simplified interrupt structure
- Up to 48 different interrupt requests
- Splitting of single external interrupt vector into up to 48 vectors, one for each source
- Automatic lower priority requests masking
- Full backward compatibility with MPC555/MPC556 (enhanced mode is software programmable.)

### 6.1.4.2 Interrupt Configuration

An overview of the MPC561/MPC563 interrupt structure is shown in [Figure 6-3](#). The interrupt controller receives interrupts from USIU internal sources, such as PIT, RTC, from the UIMB module (which has its own interrupt controller) or from the IMB3 bus (directly from IMB modules) and from external pins  $\overline{\text{IRQ}}[0:7]$ .

## NOTE

The RCPU takes the system reset exception when an NMI is asserted, the external interrupt exception for any other asserted interrupt request, and the decremter exception when the decremter MSB changes from 0 to 1.

The decremter interrupt request is not a part of the interrupt controller. Each one of the external pins  $\overline{\text{IRQ}}[1:7]$  has its own dedicated assigned priority level.  $\overline{\text{IRQ}}0$  is also mapped, but it should be used only as a status bit indicating that  $\overline{\text{IRQ}}0$  was asserted and generated NMI interrupt. There are eight additional interrupt priority levels. Each one of the SIU internal interrupt sources, or any of the peripheral module interrupt sources can be assigned by software to any one of the eight interrupt priority levels. Thus, a very flexible interrupt scheme is implemented. The interrupt request signal generated by the interrupt controller is driven to the RPCU core and to the  $\overline{\text{IRQOUT}}$  pin (optionally). This pin may be used in peripheral mode, when the RPCU is disabled, and the internal modules are accessed externally. The IMB interrupts are controlled by the UIMB. The IMB provides 32 interrupt levels, and any interrupt source could be configured to any IMB interrupt level. The UIMB contains a 32-bit register that holds the IMB interrupt requests, and maps them to the USIU eight interrupt levels.

#### NOTE

If one interrupt level was configured to more than one interrupt source, the software should read the UIPEND register in the UIMB module, and the particular status bits in order to identify which interrupt was asserted.

The interrupt controller may be programmed to operate in two modes—a regular mode or an enhanced mode.

#### 6.1.4.3 Regular Interrupt Controller Operation (MPC555/MPC556-Compatible Mode)

In regular operation mode (default setting) the interrupt controller receives interrupt requests from internal sources, such as timers, PLL lock detector, IMB modules and from external pins  $\overline{\text{IRQ}}[0:7]$ . All the internal interrupt sources may be programmed to drive one or more of eight U-bus interrupt level lines while the RPCU, upon receiving an interrupt request, has to read the USIU and UIMB status register in order to determine the interrupt source.

The SIVC register contains an 8-bit code representing the unmasked interrupt request which has the highest priority level. The priority between all interrupt sources for the regular interrupt controller operation is shown in [Table 6-3](#).

**Table 6-3. Priority of Interrupt Sources—Regular Operation**

| Number | Priority Level | Interrupt Source Description  | Offset in Branch Table (Hex) | SIVC Interrupt Code <sup>1</sup> |
|--------|----------------|-------------------------------|------------------------------|----------------------------------|
| 0      | Highest        | $\overline{\text{EXT\_IRQ}}0$ | 0x0000                       | 00000000                         |
| 1      | —              | Level 0                       | 0x0008                       | 00000100                         |
| 2      | —              | $\overline{\text{EXT\_IRQ}}1$ | 0x0010                       | 00001000                         |
| 3      | —              | Level 1                       | 0x0018                       | 00001100                         |
| 4      | —              | $\overline{\text{EXT\_IRQ}}2$ | 0x0020                       | 00010000                         |
| 5      | —              | Level 2                       | 0x0028                       | 00010100                         |
| 6      | —              | $\overline{\text{EXT\_IRQ}}3$ | 0x0030                       | 00011000                         |
| 7      | —              | Level 3                       | 0x0038                       | 00011100                         |

**Table 6-3. Priority of Interrupt Sources—Regular Operation**

| Number | Priority Level | Interrupt Source Description | Offset in Branch Table (Hex) | SIVEC Interrupt Code <sup>1</sup> |
|--------|----------------|------------------------------|------------------------------|-----------------------------------|
| 8      | —              | EXT_IRQ4                     | 0x0040                       | 00100000                          |
| 9      | —              | Level 4                      | 0x0048                       | 00100100                          |
| 10     | —              | EXT_IRQ5                     | 0x0050                       | 00101000                          |
| 11     | —              | Level 5                      | 0x0058                       | 00101100                          |
| 12     | —              | EXT_IRQ6                     | 0x0060                       | 00110000                          |
| 13     | —              | Level 6                      | 0x0068                       | 00110100                          |
| 14     | —              | EXT_IRQ7                     | 0x0070                       | 00111000                          |
| 15     | Lowest         | Level 7                      | 0x0078                       | 00111100                          |

<sup>1</sup> This is the value in the 8 most significant bits of the SIVEC register (SIVEC[25:31]).

Each interrupt request from external lines and from USIU internal interrupt sources in the case of its assertion will set a corresponding bit in SIPEND register. The individual SIPEND bits may be masked by clearing an appropriate bit in SIMASK register.

#### 6.1.4.4 Enhanced Interrupt Controller Operation

The enhanced interrupt controller operation may be turned on by setting the EICEN control bit in the SIUMCR register. In this mode the 32 IMB interrupt levels will be latched by USIU using eight IMB interrupt lines and two lines of ilbs via the time multiplexing scheme defined by the UIMB module. In addition to the IMB interrupt sources the external interrupts and timer interrupts are available in the same way as in the regular scheme. In this mode, the UIMB module does not drive U-bus interrupt level lines. Each interrupt request will set a corresponding bit in SIPEND2 or SIPEND3 registers. SIPEND2 and SIPEND3 may be masked by clearing an appropriate bit in SIMASK2 or SIMASK3 registers.

The priority logic is provided in order to determine the highest unmasked interrupt request, and interrupt code is generated in the SIVEC register. See [Table 6-4](#).

#### NOTE

If the enhanced interrupt controller is enabled, a delay is required prior to re-enabling interrupts. Before clearing an interrupt related register, clear the MSR[EE] bit (EE = 0). Expect a vector offset of 0x0 if an interrupt is cleared or disabled while MSR[EE] = 1. This vector should be handled as if no interrupt has occurred, that is, perform an rfi instruction. After clearing an interrupt source, sufficient time must elapse before re-enabling the MSR[EE] bit (EE = 1). This time should take longer than the time needed for a load of the same register that was just cleared. To guarantee enough time, include this load instruction before the instruction that sets MSR[EE].

Table 6-4. Priority of Interrupt Sources—Enhanced Operation

| Number | Priority Level | Interrupt Source Description  | Offset in Branch Table (Hex) <sup>1,2</sup> | SIVC Interrupt Code <sup>3</sup> |
|--------|----------------|-------------------------------|---------------------------------------------|----------------------------------|
| 0      | Highest        | (see note above) <sup>4</sup> | 0x0000                                      | 00000000                         |
| 1      | —              | Level 0                       | 0x0008                                      | 00000100                         |
| 2      | —              | IMB_IRQ 0                     | 0x0010                                      | 00001000                         |
| 3      | —              | IMB_IRQ 1                     | 0x0018                                      | 00001100                         |
| 4      | —              | IMB_IRQ 2                     | 0x0020                                      | 00010000                         |

| 46     | —              | IMB_IRQ 30                   | 0x0170                                      | 10111000                          |
| 47     | Lowest         | IMB_IRQ 31                   | 0x0178                                      | 10111100                          |

<sup>1</sup> The branch table feature can be used only if the BBCMCR[EIR] is set.

<sup>2</sup> This offset is added to the table base address from the EIBDR register.

<sup>3</sup> This is the value in the 8 most significant bits of the SIVEC register.

<sup>4</sup> This vector is reserved and normally is not generated. It may be generated, if any other interrupt source disappears, before being acknowledged by the RCPU as a result of any change in the interrupt scheme, module stopping, masking interrupt sources in a module by application software while interrupts are enabled in the RCPU by setting MSR[EE].

The value of the SIVEC register is supplied internally to the BBC module and can be used as an offset to the branch table start address for the external interrupt relocation feature. Thus a fast way to a specific interrupt source routine is provided without software overhead. The BBCMCR (see [Section 4.6.2.1, “BBC Module Configuration Register \(BBCMCR\)”](#)) and EIBADR (see [Section 4.6.2.5, “External Interrupt Relocation Table Base Address Register \(EIBADR\)”](#)) registers must be programmed to enable this feature in the BBC. Additionally, the SIPEND2 and SIPEND3 registers contain the information about all the interrupt requests that are asserted at a given time, so that software can always read them.

### NOTE

When the enhanced interrupt controller is enabled the SIPEND and SIMASK registers are not used.

#### 6.1.4.4.1 Lower Priority Request Masking

This feature (if enabled) simplifies the masking of lower priority interrupt requests when a request of certain priority is in service in applications that require interrupt nesting. The highest (pending) request is also masked by itself. The masking is accomplished in the following way.

Upon asserting an interrupt request the BBC generates an acknowledge signal to notify the interrupt controller that the request and the branch table offset have been latched. The interrupt controller then sets a bit in the SISR register (interrupt in-service register), according to the asserted request. All other requests whose priority is lower than or equal to the one that is currently in-service, become masked. The mask remains set until the SISR bit is cleared by software (by the interrupt handler routine), writing a ‘1’ value to the corresponding bit. The lower priority request masking diagram is presented in Figure 6-4.

The lower priority request masking feature is disabled by  $\overline{\text{HRESET}}$  and it may be enabled by setting the LPMASK\_EN bit in the SIUMCR register.

#### NOTE

In the regular mode of the interrupt controller the lower priority request masking feature is not available.

The feature must be activated only together with exception table relocation in the BBC module.

Figure 6-4. Lower Priority Request Masking—One Bit Diagram

#### 6.1.4.4.2 Backward Compatibility with MPC555/MPC556

The enhanced interrupt controller is a feature that may be enabled according to a user’s application using the EICEN control bit in SIUMCR register, which can be set and cleared at any time by software. If the bit is cleared, the default interrupt controller operation is available, as described in Section 6.1.4.3, “Regular Interrupt Controller Operation (MPC555/MPC556-Compatible Mode).” The regular operation is fully compatible with the interrupt controller already implemented in MPC555/MPC556.

Figure 6-5 illustrates the interrupt controller functionality in the MPC561/MPC563.

**Figure 6-5. MPC561/MPC563 Interrupt Controller Block Diagram**

### 6.1.4.5 Interrupt Overhead Estimation for Enhanced Interrupt Controller Mode

The interrupt overhead consists of two main parts:

- Storage of general and special purpose registers
- Recognition of the interrupt source

The interrupt overhead can increase latency, and decrease the overall system performance. The overhead of register saving time can be reduced by improving the operating system. The number of registers that should be saved can be reduced if each interrupt event has its own interrupt vector. This solution solves the interrupt source recognition overhead. [Table 6-5](#) below illustrates the improvements.

Only registers required for the recognition routine are considered to be saved in the calculations below. Recognition of module internal events/channels is out of the scope of the calculations. See also the typical interrupt handler flowchart in [Figure 6-6](#).

**Table 6-5. Interrupt Latency Estimation for Three Typical Cases**

#### NOTE

Compiler and bus collision overhead are not included in the calculations.

Figure 6-6. Typical Interrupt Handler Routine

### 6.1.5 Hardware Bus Monitor

The bus monitor ensures that each bus cycle is terminated within a reasonable period of time. The USIU provides a bus monitor option to monitor internal to external bus accesses on the external bus. The monitor counts from transfer start to transfer acknowledge and from transfer acknowledge to transfer acknowledge within bursts. If the monitor times out, transfer error acknowledge (TEA) is asserted internally by the

MPC561/MPC563, and RCPU access is terminated with a data error, causing a machine check state or exception.

The bus monitor timing bit in the system protection control register (SYPCR[BMT]) defines the bus monitor time-out period. The programmability of the time-out allows for variation in system peripheral response time. The timing mechanism is clocked by the external bus clock divided by eight. The maximum value is 2040 system clock cycles.

SYPCR[BME] enables or disables the bus monitor. But regardless of the state of this bit the bus monitor is always enabled when freeze is asserted in debug mode.

### 6.1.6 Decrementer (DEC)

The decrementer (DEC) is a 32-bit decrementing counter defined by the MPC561/MPC563 architecture to provide a decrementer interrupt. This binary counter is clocked by the same frequency as the time base (also defined by the MPC500 architecture). The operation of the time base and decrementer are therefore coherent. The DEC is clocked by the TMBCLK clock. The decrementer period is computed as follows:

$$T_{DEC} = \frac{2^{32}}{F_{TMBCLK}}$$

The state of the DEC is not affected by any resets and should be initialized by software. The DEC runs continuously after power-up once the time base is enabled by setting the TBE bit of the TBSCR (see [Table 6-18](#)) (unless the clock module is programmed to turn off the clock). The decrementer continues counting while reset is asserted.

Reading from the decrementer has no effect on the counter value. Writing to the decrementer replaces the value in the decrementer with the value in the GPR.

Whenever bit 0 (the MSB) of the decrementer changes from zero to one, a decrementer exception occurs. If software alters the decrementer such that the content of bit 0 is changed to a value of 1, a decrementer exception occurs.

A decrementer exception causes a decrementer interrupt request to be pending in the RCPU. When the decrementer exception is taken, the decrementer interrupt request is automatically cleared.

[Table 6-6](#) illustrates some of the periods available for the decrementer, assuming a 4-MHz or 20-MHz crystal, and TBS = 0 which selects TMBCLK division to 4.

**NOTE**

Time base must be enabled to use the decrementer. See [Section 6.2.2.4.4](#), “Time Base Control and Status Register (TBSCR),” for more information.

**Table 6-6. Decrementer Time-Out Periods**

| Count Value | Time-Out @ 4 MHz | Time-Out @ 20 MHz |
|-------------|------------------|-------------------|
| 0           | 1.0 μs           | 0.2 μs            |
| 9           | 10 μs            | 2.0 μs            |

**Table 6-6. Decrementer Time-Out Periods (continued)**

| Count Value    | Time-Out @ 4 MHz | Time-Out @ 20 MHz |
|----------------|------------------|-------------------|
| 99             | 100 $\mu$ s      | 20 $\mu$ s        |
| 999            | 1.0 ms           | 200 $\mu$ s       |
| 9999           | 10.0 ms          | 2 ms              |
| 999999         | 1.0 s            | 200 ms            |
| 9999999        | 10.0 s           | 2.0 s             |
| 99999999       | 100.0 s          | 20 s              |
| 999999999      | 1000 s           | 200 s             |
| (hex) FFFFFFFF | 4295 s           | 859 s             |

Refer to [Section 3.9.5, “Decrementer Register \(DEC\),”](#) for more information.

### 6.1.7 Time Base (TB)

The time base (TB) is a 64-bit free-running binary counter defined by the MPC500 architecture. The TB has two independent reference registers which can generate a maskable interrupt when the time base counter reaches the value programmed in one of the two reference registers. The period of the TB depends on the driving frequency. The TB is clocked by the TMBCLK clock. The period for the TB is:

$$T_{TB} = \frac{2^{64}}{F_{TMBCLK}}$$

The state of TB is not affected by any resets and should be initialized by software. Reads and writes of the TB are restricted to special instructions. Separate special-purpose registers are defined in the MPC500 architecture for reading and writing the TB. For the MPC561/MPC563 implementation, it is not possible to read or write the entire TB in a single instruction. Therefore, the mttb and mftb instructions are used to move the lower half of the time base (TBL) while the mttbu and mftbu instructions are used to move the upper half (TBU).

Two reference registers are associated with the time base: TBREF0 and TBREF1. A maskable interrupt is generated when the TB count reaches to the value programmed in one of the two reference registers. Two status bits in the time base control and status register (TBSCR) indicate which one of the two reference registers generated the interrupt.

Refer to [Section 6.2.2.4, “System Timer Registers,”](#) for diagrams and bit descriptions of TB registers. Refer to [Section 3.9.4, “Time Base Facility \(TB\) — OEA,”](#) and to the *RCPU Reference Manual* for additional information.

### 6.1.8 Real-Time Clock (RTC)

The RTC is a 32-bit counter and pre-divider used to provide a time-of-day indication to the operating system and application software as show in [Figure 6-7](#). It is clocked by the PITRTCLK clock. The counter

is not affected by reset and operates in all low-power modes. It is initialized by software. The RTC can be programmed to generate a maskable interrupt when the time value matches the value programmed in its associated alarm register. It can also be programmed to generate an interrupt once a second. A control and status register is used to enable or disable the different functions and to report the interrupt source.

### NOTE

PITRTCLK can be divided by 4 or 256. See [Table 8-1](#) for default settings.

Figure 6-7. RTC Block Diagram

## 6.1.9 Periodic Interrupt Timer (PIT)

The periodic interrupt timer consists of a 16-bit counter clocked by the PITRTCLK clock signal supplied by the clock module as shown in [Figure 6-8](#).

The 16-bit counter counts down to zero when loaded with a value from the PITC register. After the timer reaches zero, the PS bit is set and an interrupt is generated if the PIE bit is a logic one. The software service routine should read the PS bit and then write a zero to terminate the interrupt request. At the next input clock edge, the value in the PITC is loaded into the counter, and the process starts over again.

When a new value is written into the PITC, the periodic timer is updated, the divider is reset, and the counter begins counting. If the PS bit is not cleared, an interrupt request is generated. The request remains pending until PS is cleared. If the PS bit is set again prior to being cleared, the interrupt remains pending until PS is cleared.

Any write to the PITC stops the current countdown, and the count resumes with the new value in PITC. If the PISCR[PTE] bit is not set, the PIT is unable to count and retains the old count value. Reads of the PIT have no effect on the counter value.

**Figure 6-8. PIT Block Diagram**

The timeout period is calculated as:

$$PIT_{PERIOD} = \frac{PITC + 1}{F_{PITRTCLK}} = \frac{PITC + 1}{\left\langle \frac{ExternalClock}{4 \text{ or } 256} \right\rangle}$$

Solving this equation using a 4-MHz external clock and a pre-divider of 256 gives:

$$PIT_{PERIOD} = \frac{PITC + 1}{15625}$$

This gives a range from 64 microseconds, with a PITC of 0x0000, to 4.19 seconds, with a PITC of 0xFFFF. When a 20-MHz crystal is used with a pre-divider of 256, the range is between 12.8 microseconds to 0.84 seconds.

### 6.1.10 Software Watchdog Timer (SWT)

The software watchdog timer (SWT) prevents system lockout in case the software becomes trapped in loops with no controlled exit. The SWT is enabled after system reset to cause a system reset if it times out. The SWT requires a special service sequence to be executed on a periodic basis. If this periodic servicing action does not occur, the SWT times out and issues a reset or a non-maskable interrupt (NMI), depending on the value of the SWRI bit in the SYPCR register.

The SWT can be disabled by clearing the SWE bit in the SYPCR. Once the SYPCR is written by software, the state of the SWE bit cannot be changed.

The SWT service sequence consists of the following two steps:

1. Write 0x556C to the software service register (SWSR)
2. Write 0xAA39 to the SWSR

The service sequence clears the watchdog timer and the timing process begins again. If any value other than 0x556C or 0xAA39 is written to the SWSR, the entire sequence must start over.

Although the writes must occur in the correct order prior to time-out, any number of instructions may be executed between the writes. This allows interrupts and exceptions to occur, if necessary, between the two writes.

**Figure 6-9. SWT State Diagram**

Although most software disciplines support the watchdog concept, different systems require different time-out periods. For this reason, the software watchdog provides a selectable range for the time-out period.

In [Figure 6-10](#), the range is determined by the value in the SWTC field. The value held in the SWTC field is then loaded into a 16-bit decremter clocked by the system clock. An additional divide by 2048 prescaler is used if necessary. The decremter begins counting when loaded with a value from the software watchdog timing count field (SWTC). After the timer reaches 0x0, a software watchdog expiration request is issued to the reset or NMI control logic.

Upon reset, the value in the SWTC is set to the maximum value and is again loaded into the software watchdog register (SWR), starting the process over. When a new value is loaded into the SWTC, the software watchdog timer is not updated until the servicing sequence is written to the SWSR. If the SWE is loaded with the value zero, the modulus counter does not count (i.e. SWTC is disabled).

Figure 6-10. SWT Block Diagram

### 6.1.11 Freeze Operation

When the FREEZE line is asserted, the clocks to the software watchdog, the periodic interrupt timer, the real-time clock, the time base counter, and the decremter can be disabled. This is controlled by the associated bits in the control register of each timer. If programmed to stop during FREEZE assertion, the counters maintain their values while FREEZE is asserted. The bus monitor remains enabled regardless of this signal.

### 6.1.12 Low Power Stop Operation

When the processor is set in a low-power mode (doze, sleep, or deep-sleep), the software watchdog timer is frozen. It remains frozen and maintains its count value until the processor exits this state and resumes executing instructions.

The periodic interrupt timer, decremter, and time base are not affected by these low-power modes. They continue to run at their respective frequencies. These timers are capable of generating an interrupt to bring the MCU out of these low-power modes.

## 6.2 Memory Map and Register Definitions

This section provides the MPC561/MPC563 memory map, register diagrams and bit descriptions of the system configuration and protection registers.

### 6.2.1 Memory Map

The MPC561/MPC563 internal memory space can be assigned to one of eight locations.

The internal memory map is organized as a single 4-Mbyte block. The user can assign this block to one of eight locations by programming the ISB field in the internal memory mapping register (IMMR). The eight possible locations are the first eight 4-Mbyte memory blocks starting with address 0x0000 0000. (Refer to Figure 6-11.)

Figure 6-11. MPC561/MPC563 Memory Map

### 6.2.2 System Configuration and Protection Registers

This section describes the MPC561/MPC563 registers.

#### 6.2.2.1 System Configuration Registers

System configuration registers include the SIUMCR, the IMMR, and the EMCR registers.

### 6.2.2.1.1 SIU Module Configuration Register (SIUMCR)

The SIUMCR contains bits which configure various features in the SIU module. The register contents are shown below.

| MSB    |                  |            |   |   |   |   |   |      |                       |   |    |                   |                   |     |     |    |

<sup>1</sup> Operates as MODCK1 during reset.

<sup>2</sup> This is true if MTSC is reset to 0. Otherwise,  $\overline{\text{IRQ2}}/\text{CR}/\text{SGPIOC2}/\text{MTS}$  will function as  $\overline{\text{MTS}}$ .

### 6.2.2.1.2 Internal Memory Map Register (IMMR)

The internal memory map register (IMMR) is a register located within the MPC561/MPC563 special register space. The IMMR contains identification of a specific device as well as the base for the internal memory map. Based on the value read from this register, software can deduce availability and location of any on-chip system resources.

This register can be read by the mfspr instruction. The ISB field can be written by the mtspr instruction. The PARTNUM and MASKNUM fields are mask programmed and cannot be changed.

<sup>1</sup> The reset value is 101 for MPC561 and 110 for MPC563.

<sup>2</sup> The reset value is a reset configuration word value extracted from the indicated bits of the internal data bus. Refer to [Section 7.5.2, “Hard Reset Configuration Word \(RCW\)”](#).

Figure 6-13. Internal Memory Mapping Register (IMMR)

**Table 6-12. IMMR Bit Descriptions**

| Bits  | Name    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-------|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0:7   | PARTNUM | This read-only field is mask programmed with a code corresponding to the part number of the part on which the SIU is located. It is intended to help factory test and user code which is sensitive to part changes. This changes when the part number changes. For example, it would change if any new module is added, if the size of any memory module is changed. It would not change if the part is changed to fix a bug in an existing module. The MPC561 has an ID of 0x35. The MPC563 has an ID of 0x36. |
| 8:15  | MASKNUM | This read-only field is mask programmed with a code corresponding to the mask number of the part. It is intended to help factory test and user code which is sensitive to part changes.                                                                                                                                                                                                                                                                                                                         |
| 16:19 | —       | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| 20    | FLEN    | Flash enable is a read-write bit. The default state of FLEN is negated, meaning that the boot is performed from external memory. This bit can be set at reset by the reset configuration word.<br>0 On-chip Flash memory is disabled, and all internal cycles to the allocated Flash address space are mapped to external memory<br>1 On-chip Flash memory is enabled                                                                                                                                           |

**Table 6-13. EMCRC Bit Descriptions**

| Bits  | Name | Description                                                                                                                                                                                                                                                                                                                              |
|-------|------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0:15  | —    | Reserved                                                                                                                                                                                                                                                                                                                                 |
| 16    | PRPM | Peripheral mode. In this mode, the internal RCPUCPU core is shut off and an alternative master on the external bus can access any internal slave module. The reset value of this bit is determined by the reset configuration word bit 16. The bit can also be written by software.<br>0 Normal operation<br>1 Peripheral mode operation |
| 17    | SLVM | Slave mode (valid only if PRPM = 0). In this mode, an alternative master on the external bus can access any internal slave module while the internal RCPUCPU core is fully operational. If PRPM is set, the value of SLVM is a “don’t care.”<br>0 Normal operation<br>1 Slave mode                                                       |
| 18    | —    | Reserved                                                                                                                                                                                                                                                                                                                                 |
| 19:20 | SIZE | Size attribute. If SIZEN = 1, the SIZE bits controls the internal bus attributes as follows:<br>00 Double word (8 bytes)<br>01 Word (4 bytes)<br>10 Half word (2 bytes)<br>11 Byte                                                                                                                                                       |
| 21    | SUPU | Supervisor/user attribute. SUPU controls the supervisor/user attribute as follows:<br>0 Supervisor mode access permitted to all registers<br>1 User access permitted to registers designated “user access”                                                                                                                               |
| 22    | INST | Instruction attribute. INST controls the internal bus instruction attribute as follows:<br>0 Instruction fetch<br>1 Operand or non-CPU access                                                                                                                                                                                            |
| 23:24 | —    | Reserved                                                                                                                                                                                                                                                                                                                                 |
| 25    | RESV | Reservation attribute. RESV controls the internal bus reservation attribute as follows:<br>0 Storage reservation cycle<br>1 Not a reservation                                                                                                                                                                                            |

**Table 6-13. EMCR Bit Descriptions (continued)**

| Bits  | Name  | Description                                                                                                                                                                                      |
|-------|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 26    | CONT  | Control attribute. CONT drives the internal bus control bit attribute as follows:<br>0 Access to MPC561/MPC563 control register, or control cycle access<br>1 Access to global address map       |
| 27    | —     | Reserved                                                                                                                                                                                         |
| 28    | TRAC  | Trace attribute. TRAC controls the internal bus program trace attribute as follows:<br>0 Program trace<br>1 Not program trace                                                                    |
| 29    | SIZEN | External size enable control bit. SIZEN determines how the internal bus size attribute is driven:<br>0 Drive size from external bus signals TSIZE[0:1]<br>1 Drive size from SIZE0, SIZE1 in EMCR |
| 30:31 | —     | Reserved                                                                                                                                                                                         |

### 6.2.2.2 SIU Interrupt Controller Registers

The SIU interrupt controller contains the following registers: SIPEND, SIPEND2 and SIPEND3 (interrupt pending registers), SIMASK, SIMASK2 and SIMASK3 (interrupt mask registers), SIEL, SIVEC, SISR2 and SISR3.

The SIPEND and SIMASK registers are used when the interrupt controller is configured for regular, MPC555/MPC556 compatible, operation. SIPEND2, SIPEND3, SIMASK2, SIMASK3, SISR2 and SISR3 registers are used only when the interrupt controller is operating in enhanced interrupt mode.

SIPEND, SIPEND2 and SIPEND3 are 32-bit registers. Each bit in the register corresponds to an interrupt request. The bits associated with internal exceptions indicate, if set, that an interrupt service is requested. These bits reflect the status of the internal requesting device, and will be cleared when the appropriate actions are initiated by software in the device itself. Writing to these bits has no effect.

The bits associated with the  $\overline{\text{IRQ}}$  pins have a different behavior depending on the sensitivity defined for them in the SIEL register. When the  $\overline{\text{IRQ}}$  is defined as a “level” interrupt the corresponding bit behaves in a manner similar to the bits associated with internal interrupt sources, (i.e., it reflects the status of the  $\overline{\text{IRQ}}$  pin). This bit can not be changed by software, it will be cleared when the external signal is negated. When the  $\overline{\text{IRQ}}$  is defined as an “edge” interrupt, if the corresponding bit is set, it indicates that a falling edge was detected on the line. The bit must be reset by software by writing a ‘1’ to it.

The following acronym definitions apply to the various bits implemented in the SIU interrupt controller registers.

**Table 6-14. SIU Interrupt Controller – Bit Acronym Definitions**

| Name       | Description                                 |
|------------|---------------------------------------------|
| IRQ $n$    | Interrupt Signal $n$ Request                |
| LVL $n$    | Interrupt Level $n$ Request                 |
| IMBIRQ $n$ | Intermodule Bus Interrupt Level $n$ Request |
| IRM $n$    | Interrupt Signal $n$ Mask                   |

**Table 6-14. SIU Interrupt Controller – Bit Acronym Definitions**

| Name    | Description                               |
|---------|-------------------------------------------|
| LVM $n$ | Interrupt Level $n$ Mask                  |
| ED $n$  | Falling Edge Detect, Interrupt Signal $n$ |
| WM $n$  | Wakeup Mask, Interrupt Signal $n$         |

Figure 6-17. SIU Interrupt Pending Register 3 (SIPEND3)

### 6.2.2.2.4 SIU Interrupt Mask Register (SIMASK)

SIMASK is a 32-bit read/write register. Each bit in the register corresponds to an interrupt request bit in the SIPEND register.

SIMASK2 is a 32-bit read/write register. Each bit in the register corresponds to an interrupt request bit in the SIPEND2 register.

SIMASK3 is a 32-bit read/write register. Each bit in the register corresponds to an interrupt request bit in the SIPEND3 register.

When the bit is set, it enables the generation of an interrupt request to the RCPU. SIMASK, SIMASK2, SIMASK3 are updated by software and cleared upon reset. It is the responsibility of the software to determine which of the interrupt sources are enabled at a given time.

#### NOTE

Disable external interrupts in the core prior to changing any interrupt controller related register (SIMASK, SIPEND, SIEL, or SISR). Refer to MSR[EE] bit description in [Table 3-11](#) and the note regarding special handling of the EIC in [Section 6.1.4.4, “Enhanced Interrupt Controller Operation.”](#)

Figure 6-20. SIU Interrupt Mask Register 3 (SIMASK3)

### 6.2.2.2.7 SIU Interrupt Edge Level Register (SIEL)

The SIEL is a 32-bit read/write register. Each pair of bits corresponds to an external interrupt request. The EDx bit, if set, specifies that a falling edge in the corresponding  $\overline{\text{IRQ}}$  line will be detected as an interrupt request. When the EDx bit is 0, a low logical level in the  $\overline{\text{IRQ}}$  line will be detected as an interrupt request. The WMx (wake-up mask) bit, if set, indicates that an interrupt request detection in the corresponding line causes the MPC561/MPC563 to exit low-power mode.

Figure 6-21. SIU Interrupt Edge Level Register (SIEL)

### 6.2.2.2.8 SIU Interrupt Vector Register (SIVEC)

The SIVEC is a 32-bit read-only register that contains an 8-bit code representing the unmasked interrupt source of the highest priority level. The SIVEC can be read as either a byte, half word, or word. When read as a byte, a branch table can be used in which each entry contains one instruction (branch). When read as a half-word, each entry can contain a full routine of up to 256 instructions. The interrupt code is defined such that its two least significant bits are 0, thus allowing indexing into the table. The two possible ways of the code usage are shown on [Figure 6-23](#).

Figure 6-22. SIU Interrupt Vector Register (SIVEC)

Figure 6-23. Example of SIVEC Register Usage for Interrupt Table Handling

SISR2, SISR3 are 32-bit read/write registers. Each bit in the register corresponds to an interrupt request. A bit is set if:

- There is a pending interrupt request (SIPEND2/3), that is not masked by (SIMASK2/3), and
- The BBC/IMPU acknowledges interrupt request and latches SIVEC value.

Once a bit is set, all requests with lower or equal priority become masked (i.e. they will not generate any interrupt request to the RCPU) until the bit is cleared. A bit is cleared by writing a '1' to it. Writing zero has no effect.

#### 6.2.2.3.1 System Protection Control Register (SYPCR)

The system protection control register (SYPCR) controls the system monitors, the software watchdog period, and the bus monitor timing. This register can be read at any time, but can be written only once after system reset.

**Figure 6-26. System Protection Control Register (SYPCR)**

**Table 6-15. SYPCR Bit Descriptions**

| Bits  | Name | Description                                                                                                                                                                             |
|-------|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0:15  | SWTC | Software watchdog timer count. This field contains the count value of the software watchdog timer.                                                                                      |
| 16:23 | BMT  | Bus monitor timing. This field specifies the time-out period, in eight-system-clock resolution, of the bus monitor. BMT must be set to non zero even if the bus monitor is not enabled. |

### 6.2.2.3.2 Software Service Register (SWSR)

The SWSR is the location to which the SWT servicing sequence is written. To prevent SWT time-out, a 0x556C followed by 0xAA39 should be written to this register. The SWSR can be written at any time but returns all zeros when read.

|       |                     |   |   |   |   |   |   |   |   |   |   |    |    |    |    |    |    |     |

| Bits | Name | Description                                                                                                                                                                                                       |
|------|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0:15 | SWSR | SWT servicing sequence is written to this register. To prevent SWT time-out, a 0x556C followed by 0xAA39 should be written to this register. The SWSR can be written at any time but returns all zeros when read. |

### 6.2.2.3.3 Transfer Error Status Register (TESR)

The transfer error status register contains a bit for each exception source generated by a transfer error. A bit set to logic 1 indicates what type of transfer error exception occurred since the last time the bits were cleared by reset or by the normal software status bit-clearing mechanism.

#### NOTE

These bits may be set due to canceled speculative accesses which do not cause an interrupt. The register has two identical sets of bit fields; one is associated with instruction transfers and the other with data transfers.

### 6.2.2.4 System Timer Registers

The following sections describe registers associated with the system timers. These facilities are powered by the KAPWR and can preserve their value when the main power supply is off. Refer to [Section 8.2.3, “Pre-Divider,”](#) for details on the required actions needed in order to guarantee this data retention.

A list of KAPWR registers affected by the key/lock mechanism is found in [Table 8-8](#).

#### 6.2.2.4.1 Decrementer Register (DEC)

The 32-bit decrementer register is defined by the PowerPC architecture. The values stored in this register are used by a down counter to cause decrementer exceptions. The decrementer causes an exception whenever bit zero changes from a logic zero to a logic one. A read of this register always returns the current count value from the down counter.

Contents of this register can be read or written to by the mfspr or the mtspr instruction. The decrementer register is reset by  $\overline{\text{PORESET}}$ .  $\overline{\text{HRESET}}$  and  $\overline{\text{SRESET}}$  do not affect this register. The decrementer is powered by standby power and can continue to count when standby power is applied.

Decrementer counts down the time base clock and the counting is enabled by TBE bit in TBCSR register [Section 6.2.2.4.4, “Time Base Control and Status Register \(TBSCR\).”](#)

Figure 6-29. Decrementer Register (DEC)

Refer to [Section 3.9.5, “Decrementer Register \(DEC\)”](#) for more information on this register.

#### 6.2.2.4.2 Time Base SPRs (TB)

The TB is a 64-bit register containing a 64-bit integer that is incremented periodically. There is no automatic initialization of the TB; the system software must perform this initialization. The contents of the

register may be written by the mttbl or the mttbu instructions, see [Section 3.9.4, “Time Base Facility \(TB\) — OEA.”](#)

Refer to [Section 3.8, “VEA Register Set — Time Base \(TB\)”](#) and [Section 3.9.4, “Time Base Facility \(TB\) — OEA”](#) for more information on reading and writing the TBU and TBL registers.

**Figure 6-30. Time Base (Reading) (TB)**

**Figure 6-31. Time Base (Writing) (TB)**

#### 6.2.2.4.3 Time Base Reference Registers (TBREF0 and TBREF1)

Two reference registers (TBREF0 and TBREF1) are associated with the lower part of the time base (TBL). Each is a 32-bit read/write register. Upon a match between the contents of TBL and the reference register, a maskable interrupt is generated.

**Figure 6-32. Time Base Reference Register 0 (TBREF0)**

**Figure 6-33. Time Base Reference Register 1 (TBREF1)**

#### 6.2.2.4.4 Time Base Control and Status Register (TBSCR)

The TBSCR is 16-bit read/write register. It controls the TB, decremter count enable, and interrupt generation and is used for reporting the source of the interrupts. The register can be read anytime. A status bit is cleared by writing a one to it. (Writing a zero has no effect.) More than one bit can be cleared at a time.

#### 6.2.2.4.5 Real-Time Clock Status and Control Register (RTCSC)

The RTCSC enables the different RTC functions and reports the source of the interrupts. The register can be read anytime. A status bit is cleared by writing a one to it. (Writing a zero does not affect a status bit’s value.) More than one status bit can be cleared at a time. This register is locked after reset by default. Unlocking is accomplished by writing 0x55CC AA33 to its associated key register. See [Section 8.8.3.2, “Keep-Alive Power Registers Lock Mechanism.”](#)

#### 6.2.2.4.6 Real-Time Clock Register (RTC)

The real-time clock register is a 32-bit read write register. It contains the current value of the real-time clock. A write to the RTC resets the seconds timer to zero. This register is locked after reset by default. Unlocking is accomplished by writing 0x55CC AA33 to its associated key register. See [Section 8.8.3.2, “Keep-Alive Power Registers Lock Mechanism.”](#)

|       |            |   |    |     |
|-------|------------|---|----|-----|
|       | MSB        | 0 | 31 | LSB |

| Reset | Unaffected |   |    |     |
| Addr  | 0x2F C224  |   |    |     |

**Figure 6-36. Real-Time Clock Register (RTC)**

### 6.2.2.4.7 Real-Time Clock Alarm Register (RTCAL)

The RTCAL is a 32-bit read/write register. When the value of the RTC is equal to the value programmed in the alarm register, a maskable interrupt is generated.

The alarm interrupt will be generated as soon as there is a match between the ALARM field and the corresponding bits in the RTC. The resolution of the alarm is 1 second. This register is locked after reset by default. Unlocking is accomplished by writing 0x55CC AA33 to its associated key register. See [Section 8.8.3.2, “Keep-Alive Power Registers Lock Mechanism.”](#)

| Addr  | 0x2F C22C  |  |     |

Figure 6-37. Real-Time Clock Alarm Register (RTCAL)

### 6.2.2.4.8 Periodic Interrupt Status and Control Register (PISCR)

The PISCR contains the interrupt request level and the interrupt status bit. It also contains the controls for the 16-bits to be loaded into a modulus counter. This register can be read or written at any time.

|         |                     |   |   |   |   |   |   |   |    |   |    |    |    |     |      |     |

Figure 6-38. Periodic Interrupt Status and Control Register (PISCR)

Table 6-20. PISCR Bit Descriptions

| Bits | Name | Description                                                                                                                                                                                                               |
|------|------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0:7  | PIRQ | Periodic interrupt request. These bits determine the interrupt priority level of the PIT. Refer to <a href="#">Section 6.1.4, “Enhanced Interrupt Controller”</a> for interrupt level encoding.                           |
| 8    | PS   | Periodic interrupt status. This bit is set if the PIT issues an interrupt. The PIT issues an interrupt after the modulus counter counts to zero. PS can be negated by writing a one to it. A write of zero has no affect. |
| 9:12 | —    | Reserved                                                                                                                                                                                                                  |
| 13   | PIE  | Periodic interrupt enable. If this bit is set, the time base generates an interrupt when the PS bit is set.                                                                                                               |
| 14   | PITF | PIT freeze. If this bit is set, the PIT stops while FREEZE is asserted.                                                                                                                                                   |
| 15   | PTE  | Periodic timer enable<br>0 PIT stops counting and maintains current value<br>1 PIT continues to decrement                                                                                                                 |

### 6.2.2.4.9 Periodic Interrupt Timer Count Register (PITC)

The PITC register contains the 16-bits to be loaded in a modulus counter. This register is readable and writable at any time.

**Figure 6-39. Periodic Interrupt Timer Count (PITC)**

**Table 6-21. PITC Bit Descriptions**

| Bits  | Name | Description                                                                                                                                                                                             |
|-------|------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0:15  | PITC | Periodic interrupt timing count. This field contains the 16-bit value to be loaded into the modulus counter that is loaded into the periodic timer. This register is readable and writable at any time. |
| 16:31 | —    | Reserved                                                                                                                                                                                                |

### 6.2.2.4.10 Periodic Interrupt Timer Register (PITR)

The periodic interrupt register is a read-only register that shows the current value in the periodic interrupt down counter. Read or writing this register does not affect the register.

**Figure 6-40. Periodic Interrupt Timer Register (PITR)**

**Table 6-22. PIT Bit Descriptions**

| Bits  | Name | Description                                                                                                                                  |

| Reset | 0000_0000_0000_0000 <sup>1</sup> |    |    |    |    |    |    |    |               |    |    |    |    |    |    |    |

<sup>1</sup> If the device is configured NOT in full bus mode (i.e., SIUMCR[SC]=0b01, 0x10, or 0b11), the GPIO pins will be in input mode and this register will reflect the state of the pins.

**Figure 6-41. SGPIO Data Register 1 (SGPIODT1)**

**Table 6-23. SGPIODT1 Bit Descriptions**

| Bits  | Name          | Description                                                                                                                                                                                                                                                                                                                  |
|-------|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0:7   | SGPIOD[0:7]   | SIU general-purpose I/O Group D[0:7]. This 8-bit register controls the data of general-purpose I/O pins SGPIOD[0:7]. The direction (input or output) of this group of pins is controlled by the GDDR0 bit in the SGPIO control register.                                                                                     |
| 8:15  | SGPIOD[8:15]  | SIU general-purpose I/O Group D[8:15]. This 8-bit register controls the data of general-purpose I/O pins SGPIOD[8:15]. The direction (input or output) of this group of pins is controlled by the GDDR1 bit in the SGPIO control register.                                                                                   |
| 16:23 | SGPIOD[16:23] | SIU general-purpose I/O Group D[16:23]. This 8-bit register controls the data of the general-purpose I/O pins SGPIOD[16:23]. The direction (input or output) of this group of pins is controlled by the GDDR2 bit in the SGPIO control register.                                                                             |
| 24:31 | SGPIOD[24:31] | SIU general-purpose I/O Group D[24:31]. This 8-bit register controls the data of the general-purpose I/O pins SGPIOD[24:31]. The direction of SGPIOD[24:31] is controlled by eight dedicated direction control signals SDDRD[24:31]. Each pin in this group can be configured separately as general-purpose input or output. |

### 6.2.2.5.2 SGPIO Data Register 2 (SGPIODT2)

<sup>1</sup> If the device is configured NOT in full bus mode (i.e., SIUMCR[SC]=0b01, 0x10, or 0b11), the GPIO pins will be in input mode and this register will reflect the state of the pins.

**Figure 6-42. SGPIO Data Register 2 (SGPIODT2)**

**Table 6-24. SGPIODT2 Bit Descriptions**

| Bits  | Name           | Description                                                                                                                                                                                                                                                                                                                                    |
|-------|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0:7   | SGPIOC[0:7]    | SIU general-purpose I/O Group C[0:7]. This 8-bit register controls the data of the general-purpose I/O pins SGPIOC[0:7]. The direction of SGPIOC[0:7] is controlled by 8 dedicated direction control signals SDDRC[0:7] in the SGPIO control register. Each pin in this group can be configured separately as general-purpose input or output. |
| 8:15  | SGPIOA[8:15]   | SIU general-purpose I/O Group A[8:15]. This 8-bit register controls the data of the general-purpose I/O pins SGPIOA[8:15]. The GDDR3 bit in the SGPIO control register configures these pins as a group as general-purpose input or output.                                                                                                    |
| 16:23 | SGPIOA [16:23] | SIU general-purpose I/O Group A[16:23]. This 8-bit register controls the data of the general-purpose I/O pins SGPIOA[16:23]. The GDDR4 bit in the SGPIO control register configures these pins as a group as general-purpose input or output.                                                                                                  |
| 24:31 | SGPIOA [24:31] | SIU general-purpose I/O Group A[24:31]. This 8-bit register controls the data of the general-purpose I/O pins SGPIOA[24:31]. The GDDR5 bit in the SGPIO control register configures these pins as a group as general-purpose input or output.                                                                                                  |

**Figure 6-43. SGPIO Control Register (SGPIOCR)**

**Table 6-25. SGPIOCR Bit Descriptions**

| Bits  | Name          | Description                                                                                                                            |
|-------|---------------|----------------------------------------------------------------------------------------------------------------------------------------|
| 0:7   | SDDRC[0:7]    | SGPIO data direction for SGPIOC[0:7]. Each SDDR bit zero to seven controls the direction of the corresponding SGPIOC pin zero to seven |
| 8:15  | —             | Reserved                                                                                                                               |
| 16    | GDDR0         | Group data direction for SGPIOD[0:7]                                                                                                   |
| 17    | GDDR1         | Group data direction for SGPIOD[8:15]                                                                                                  |
| 18    | GDDR2         | Group data direction for SGPIOD[16:23]                                                                                                 |
| 19    | GDDR3         | Group data direction for SGPIOA[8:15]                                                                                                  |
| 20    | GDDR4         | Group data direction for SGPIOA[16:23]                                                                                                 |
| 21    | GDDR5         | Group data direction for SGPIOA[24:31]                                                                                                 |
| 22:23 | —             | Reserved                                                                                                                               |
| 24:31 | SDDRD [24:31] | SGPIO data direction for SGPIOD[24:31]. Each SDDRD bits 24:31 controls the direction of the corresponding SGPIOD pin [24:31].          |

Table 6-26 describes the bit values for data direction control.

**Table 6-26. Data Direction Control**

| SDDR/GDDR | Operation                  |
|-----------|----------------------------|
| 0         | SGPIO configured as input  |
| 1         | SGPIO configured as output |

## Chapter 7

### Reset

This section describes the MPC561/MPC563 reset sources, operation, control, and status.

#### 7.1 Reset Operation

The MPC561/MPC563 has several inputs to the reset logic which include the following:

- Power-on reset
- External hard reset pin ( $\overline{\text{HRESET}}$ )
- External soft reset pin ( $\overline{\text{SRESET}}$ )
- Loss of PLL lock
- On-chip clock switch
- Software watchdog reset
- Checkstop reset
- Debug port hard reset
- Debug port soft reset
- JTAG reset
- Illegal bit change (ILBC)

All of these reset sources are fed into the reset controller. The control logic determines the cause of the reset, synchronizes it, and resets the appropriate logic modules, depending on the source of the reset. The memory controller, system protection logic, interrupt controller, and parallel I/O pins are initialized only on hard reset. External soft reset initializes internal logic while maintaining system configuration.

The reset status register (RSR) reflects the most recent source to cause a reset.

##### 7.1.1 Power-On Reset

The power-on reset pin,  $\overline{\text{PORESET}}$ , is an active low input. In a system with power-down low-power mode, this pin should be activated only as a result of a voltage failure on the KAPWR pin. After detecting the assertion of  $\overline{\text{PORESET}}$ , the MPC561/MPC563 enters the power-on reset state. During this state the MODCK[1:3] signals determine the oscillator frequency, PLL multiplication factor, and the PITRTCLK and TMBCLK clock sources. In addition, the MPC561/MPC563 asserts the  $\overline{\text{SRESET}}$  and  $\overline{\text{HRESET}}$  pins at the rising edge of  $\overline{\text{PORESET}}$ .

The  $\overline{\text{PORESET}}$  pin should be asserted for a minimum time of 100,000 of clock oscillator cycles after a valid level has been reached on the KAPWR supply. After detecting the assertion of  $\overline{\text{PORESET}}$ , the MPC561/MPC563 remains in the power-on reset state until the last of the following two events occurs:

- The Internal PLL enters the lock state and the system clock is active.
- The  $\overline{\text{PORESET}}$  pin is negated.

If limp mode is enabled, the internal PLL is not required to be locked before the chip exits power-on reset.

The internal MODCK[1:3] values are sampled at the rising edge of  $\overline{\text{PORESET}}$ . After exiting the power-on reset state, the MPC561/MPC563 continues to drive the  $\overline{\text{HRESET}}$  and  $\overline{\text{SRESET}}$  pins for 512 system clock cycles. When the timer expires (after 512 cycles), the configuration is sampled from data bus pins, if required (see [Section 7.5.1, “Hard Reset Configuration”](#)) and the MPC561/MPC563 stops driving the  $\overline{\text{HRESET}}$  and  $\overline{\text{SRESET}}$  pins.

The  $\overline{\text{PORESET}}$  pin has a glitch detector to ensure that low spikes of less than 20 ns are rejected. The internal  $\overline{\text{PORESET}}$  signal asserts only if the  $\overline{\text{PORESET}}$  pin asserts for more than 100 ns.

## 7.1.2 Hard Reset

$\overline{\text{HRESET}}$  (hard reset) is an active low, bidirectional I/O pin. The MPC561/MPC563 can detect an external assertion of  $\overline{\text{HRESET}}$  only if it occurs while the MPC561/MPC563 is not asserting  $\overline{\text{HRESET}}$ .

When the MPC561/MPC563 detects assertion of the external  $\overline{\text{HRESET}}$  pin or a cause to assert the internal  $\overline{\text{HRESET}}$  line is detected, the chip starts to drive the  $\overline{\text{HRESET}}$  and  $\overline{\text{SRESET}}$  for 512 cycles. When the timer expires (after 512 cycles) the configuration is sampled from data pins (refer to [Section 7.5.1, “Hard Reset Configuration”](#)) and the chip stops driving the  $\overline{\text{HRESET}}$  and  $\overline{\text{SRESET}}$  pins. An external pull-up resistor should drive the  $\overline{\text{HRESET}}$  and  $\overline{\text{SRESET}}$  pins high. After detecting the negation of  $\overline{\text{HRESET}}$  or  $\overline{\text{SRESET}}$ , the MPC561/MPC563 waits 16 clock cycles before testing the presence of an external hard or soft reset.

The  $\overline{\text{HRESET}}$  pin has a glitch detector to ensure that low spikes of less than 20 ns are rejected. The internal  $\overline{\text{HRESET}}$  will be asserted only if  $\overline{\text{HRESET}}$  is asserted for more than 100 ns.

The  $\overline{\text{HRESET}}$  is an open collector type pin.

## 7.1.3 Soft Reset

$\overline{\text{SRESET}}$  (soft reset) is an active low, bidirectional I/O pin. The MPC561/MPC563 can only detect an external assertion of  $\overline{\text{SRESET}}$  if it occurs while the MPC561/MPC563 is not asserting  $\overline{\text{SRESET}}$ .

When the MPC561/MPC563 detects the assertion of external  $\overline{\text{SRESET}}$  or a cause to assert the internal  $\overline{\text{SRESET}}$  line, the chip starts to drive the  $\overline{\text{SRESET}}$  for 512 cycles. When the timer expires (after 512 cycles) the debug port configuration is sampled from the DSDI and DSCK pins and the chip stops driving the  $\overline{\text{SRESET}}$  pin. An external pull-up resistor should drive the  $\overline{\text{SRESET}}$  pin high. After the MPC561/MPC563 detects the negation of  $\overline{\text{SRESET}}$ , it waits 16 clock cycles before testing the presence of an external soft reset.

The  $\overline{\text{SRESET}}$  is an open collector type pin.

## 7.1.4 Loss of PLL Lock

If the PLL detects a loss of lock, erroneous external bus operation will occur if synchronous external devices use the MPC561/MPC563 input clock. Erroneous operation could also occur if devices with a PLL

use the MPC561/MPC563 CLKOUT signal. This source of reset can be optionally asserted if the LOLRE bit in the PLL, low-power, and reset control register (PLPRCR) is set. The enabled PLL loss of lock event generates an internal hard reset sequence. Refer to [Chapter 8, “Clocks and Power Control,”](#) for more information on loss of PLL lock.

### 7.1.5 On-Chip Clock Switch

If the system clock is switched to the backup clock or switched from backup clock to another clock source an internal hard reset sequence is generated. Refer to [Chapter 8, “Clocks and Power Control.”](#)

### 7.1.6 Software Watchdog Reset

When the MPC561/MPC563 software watchdog counts to zero, a software watchdog reset is asserted. The enabled software watchdog event generates an internal hard reset sequence.

### 7.1.7 Checkstop Reset

When the RCPU enters a checkstop state, and the checkstop reset is enabled (the CSR bit in the PLPRCR is set), a checkstop reset is asserted. The enabled checkstop event generates an internal hard reset sequence. Refer to the *RCPU Reference Manual* for more information.

### 7.1.8 Debug Port Hard Reset

When the development port receives a hard reset request from the development tool, an internal hard reset sequence is generated. In this case the development tool must reconfigure the debug port. Refer to [Chapter 23, “Development Support,”](#) for more information.

### 7.1.9 Debug Port Soft Reset

When the development port receives a soft reset request from the development tool, an internal soft reset sequence is generated. In this case the development tool must reconfigure the debug port. Refer to [Chapter 23, “Development Support,”](#) for more information.

### 7.1.10 JTAG Reset

When the JTAG logic asserts the JTAG soft reset signal, an internal soft reset sequence is generated. Refer to [Chapter 25, “IEEE 1149.1-Compliant Interface \(JTAG\),”](#) for more information.

### 7.1.11 ILBC Illegal Bit Change

When locked bits in the PLPRCR register are changed, an internal hard reset sequence is generated. Refer to [Chapter 8, “Clocks and Power Control.”](#)

## 7.2 Reset Actions Summary

[Table 7-1](#) summarizes the action taken for each reset.

Table 7-1. Reset Action Taken for Each Reset Cause

| Reset Source                                                                                                                                                                                                                                                                                    | Reset Logic and PLL States Reset | System Configuration Reset | Clock Module Reset | $\overline{\text{HRESET}}$ Pin Driven | Debug Port Configuration | Other Internal Logic Reset | $\overline{\text{SRESET}}$ Pin Driven |

### 7.3 Data Coherency During Reset

The MPC561/MPC563 supports data coherency and avoids data corruption during reset. If a cycle is executing when any  $\overline{\text{SRESET}}$  or  $\overline{\text{HRESET}}$  source is detected, then the cycle will either complete or will not start before generating the corresponding reset control signal. There are reset sources, however, when the MPC561/MPC563 generates an internal reset due to special internal situations where this protection is not supported. See [Section 7.4, “Reset Status Register \(RSR\).”](#)

In the case of large operand size (32 or 16 bits) transactions to a smaller port size, the cycle is split into two 16-bit or four 8-bit cycles. In this case, data coherency is assured and data will not be corrupted.

In the case where the core executes an unaligned load/store cycle which is broken down into multiple cycles, data coherency is NOT assured between these cycles (i.e., data could be corrupted).

Contention may occur if a write access is in progress to external memory and  $\overline{\text{SRESET}}/\overline{\text{HRESET}}$  is asserted and the external reset configuration word (RCW) is used. In this case, the external RCW drivers, usually activated by  $\overline{\text{HRESET}}/\overline{\text{SRESET}}$  lines, will drive the data bus together with the MPC561/MPC563. Thus the data in the RAM may be corrupted regardless of the data coherency mechanism in the MPC561/MPC563.

Table 7-2. Reset Configuration Word and Data Corruption/Coherency

| Reset Driven               | Reset to Use for Data Coherency ( $\overline{\text{EXT\_RESET}}$ ) | Comments |
|----------------------------|--------------------------------------------------------------------|----------|
| $\overline{\text{HRESET}}$ | $\overline{\text{SRESET}}$                                         |          |

| $\overline{\text{HRESET}}$ & $\overline{\text{SRESET}}$ | $\overline{\text{HRESET}} \parallel \overline{\text{SRESET}}$ | Provided only one of them is driven into the MPC561/MPC563 at a time |

## 7.4 Reset Status Register (RSR)

All of the reset sources are fed into the reset controller. The 16-bit reset status register (RSR) reflects the most recent source, or sources, of reset. (Simultaneous reset requests can cause more than one bit to be set at the same time.) This register contains one bit for each reset source. A bit set to logic one indicates the type of reset that occurred.

Once set, individual bits in the RSR remain set until software clears them. Bits in the RSR can be cleared by writing a one to the bit. A write of zero has no effect on the bit. The register can be read at all times. The reset status register receives its default reset values during power-on reset. The RSR is powered by the KAPWR pin.

<sup>1</sup> In the USIU RSR, if both EHRS and ESRS are set, the reset source is internal. The EHRS and ESRS bits in RSR register are set for any internal reset source in addition to external  $\overline{\text{HRESET}}$  and external  $\overline{\text{SRESET}}$  events. If both internal and external indicator bits are set, then the reset source is internal.

## 7.5 Reset Configuration

### 7.5.1 Hard Reset Configuration

When a hard reset event occurs, the MPC561/MPC563 reconfigures its hardware system as well as the development port configuration. The logical value of the bits that determine its initial mode of operation, are sampled from the following:

- The external data bus pins DATA[0:31]
- An internal default constant (0x0000 0000)
- An internal NVM register value (UC3FCFIG). Available on the MPC563/MPC564 only.

If at the sampling time  $\overline{\text{RSTCONF}}$  is asserted, then the configuration is sampled from the external data bus. If  $\overline{\text{RSTCONF}}$  is negated and a valid NVM value exists ( $\text{UC3FCFIG}[\text{HC}]=0$ ), then the configuration is sampled from the NVM register in the UC3F module. If  $\overline{\text{RSTCONF}}$  is negated and no valid NVM value exists ( $\text{UC3FCFIG}[\text{HC}]=1$ ), then the configuration word is sampled from the internal default (all zeros). HC will be “1” if the internal Flash is erased. [Table 7-4](#) summarizes the reset configuration options.

**Table 7-4. Reset Configuration Options**

| $\overline{\text{RSTCONF}}$ | Has Configuration (HC) | Internal Configuration Word              |
|-----------------------------|------------------------|------------------------------------------|
| 0                           | x                      | DATA[0:31] pins                          |
| 1                           | 0                      | NVM Flash EEPROM register (UC3FCFIG)     |
| 1                           | 1                      | Internal data word default (0x0000 0000) |

If the PRDS control bit in the PDMCR register is cleared and  $\overline{\text{HRESET}}$  and  $\overline{\text{RSTCONF}}$  are asserted, the MPC561/MPC563 pulls the data bus low with a weak resistor. The user can overwrite this default by driving the appropriate bit high. See [Figure 7-2](#) for the basic reset configuration scheme.

**Figure 7-2. Reset Configuration Basic Scheme**

During the assertion of the  $\overline{\text{PORESET}}$  input signal, the chip assumes the default reset configuration. This assumed configuration changes if the input signal  $\overline{\text{RSTCONF}}$  is asserted when the  $\overline{\text{PORESET}}$  is negated or the CLKOUT starts to oscillate. To ensure that stable data is sampled, the hardware configuration is sampled every eight clock cycles on the rising edge of CLKOUT with a double buffer. The setup time required for the data bus is approximately 15 cycles (defined as  $T_{\text{sup}}$  in the following figures) and the maximum rise time of  $\overline{\text{HRESET}}$  should be less than six clock cycles. In systems where an external reset configuration word and the TEXP output function are both required,  $\overline{\text{RSTCONF}}$  should be asserted until  $\overline{\text{SRESET}}$  is negated.

Figure 7-3 to Figure 7-6 provide sample reset configuration timings.

### NOTE

Timing diagrams in the following figures are not to scale.

**Figure 7-3. Reset Configuration Sampling Scheme for "Short"  $\overline{\text{PORESET}}$  Assertion, Limp Mode Disabled**

**Figure 7-4. Reset Configuration Timing for "Short"  $\overline{\text{PORESET}}$  Assertion, Limp Mode Enabled**

**Figure 7-5. Reset Configuration Timing for “Long” PORESET Assertion, Limp Mode Disabled**

**Figure 7-6. Reset Configuration Sampling Timing Requirements**

## 7.5.2 Hard Reset Configuration Word (RCW)

Following is the hard reset configuration word that is sampled from the internal data bus, data\_sgpod(0:31) on the negation of HRESET. If the external reset config word is selected ( $\overline{\text{RSTCONF}} = 0$ ), the internal data bus will reflect the state of external data bus. If the internal reset config word is selected and neither of the Flash reset config words are enabled ( $\text{UC3FCFIG}[\text{HC}] = 1$ ), the internal data bus is internally driven with all zeros. The reset configuration word is not a register in the memory map. Most of the bits in the configuration are located in registers in the SIU. Refer to [Table 7-5](#) for a detailed description of each control bit.

**Figure 7-7. Reset Configuration Word (RCW)**

<sup>1</sup> Available only on the MPC562/MPC564, software should write "0" to this bit for MPC561/MPC563.

**Table 7-5. RCW Bit Descriptions**

| Bits | Name | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|------|------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0    | EARB | External Arbitration — Refer to <a href="#">Section 9.5.7, "Arbitration Phase,"</a> for a detailed description of Bus arbitration. The default value is that internal arbitration hardware is used.<br>0 Internal arbitration is performed<br>1 External arbitration is assumed                                                                                                                                                                                                                                                                                                                                                                                           |
| 1    | IP   | Initial Interrupt Prefix — This bit defines the initial value of MSR[IP] immediately after reset. MSR[IP] defines the Interrupt Table location. If IP is zero then the initial value of MSR[IP] is zero, If the IP is one, then the initial value of MSR[IP] is one. Default value is zero. See <a href="#">Table 3-11</a> for more information.<br>0 MSR[IP] = 0 after reset<br>1 MSR[IP] = 1 after reset                                                                                                                                                                                                                                                                |
| 2    | BDRV | Bus Pins Drive Strength — This bit determines the bus pins (address, data and control) driving capability to be either full or reduced drive. The bus default drive strength is full; Upon default, it also effects the CLKOUT drive strength to be full. See <a href="#">Table 6-7</a> for more information. BDRV controls the default state of COM1 in the SIUMCR.<br>0 Full drive<br>1 Reduced drive                                                                                                                                                                                                                                                                   |
| 3    | BDIS | Boot Disable — If the BDIS bit is set, then memory controller is not activated after reset. If it is cleared then the memory controller bank 0 is active immediately after reset such that it matches any addresses. If a write to the OR0 register occurs after reset this bit definition is ignored. The default value is that the memory controller is enabled to control the boot with the $\overline{\text{CS0}}$ pin. See <a href="#">Section 10.7, "Global (Boot) Chip-Select Operation,"</a> for more information.<br>0 Memory controller bank 0 is active and matches all addresses immediately after reset<br>1 Memory controller is not activated after reset. |

Table 7-5. RCW Bit Descriptions (continued)

| Bits              | Name                  | Description                                                                                                                                                                                                                                                                                                                                                           |
|-------------------|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 4:5               | BPS                   | Boot Port Size — This field defines the port size of the boot device on reset (BR0[PS]). If a write to the OR0 register occurs after reset this field definition is ignored. See <a href="#">Table 10-5</a> and <a href="#">Table 10-8</a> for more information.<br>00 32-bit port (default)<br>01 8-bit port<br>10 16-bit port<br>11 Reserved                        |
| 6:8               | —                     | Reserved. These bits must not be high in the reset configuration word.                                                                                                                                                                                                                                                                                                |
| 9:10              | DBGC[0:1]             | Debug Pins Configuration — See <a href="#">Section 6.2.2.1.1</a> , “SIU Module Configuration Register (SIUMCR),” for this field definition. The default value is that these pins function as: VFLS[0:1], $\overline{BI}$ , $\overline{BR}$ , $\overline{BG}$ and $\overline{BB}$ . See <a href="#">Table 6-8</a> .                                                    |
| 11                | —                     | Reserved.                                                                                                                                                                                                                                                                                                                                                             |
| 12                | ATWC                  | Address Type Write Enable Configuration — The default value is that these pins function as $\overline{WE}$ pins. See <a href="#">Table 6-7</a> .<br>0 $\overline{WE}[0:3]/\overline{BE}[0:3]/AT[0:3]$ functions as $\overline{WE}[0:3]/\overline{BE}[0:3]$<br>1 $\overline{WE}[0:3]/\overline{BE}[0:3]/AT[0:3]$ functions as AT[0:3]                                  |
| 13:14             | EBDF                  | External Bus Division Factor — This field defines the initial value of the external bus frequency. The default value is that CLKOUT frequency is equal to that of the internal clock (no division). See <a href="#">Table 8-9</a> .                                                                                                                                   |
| 15 <sup>1</sup>   | —                     | Reserved. This bit must be 0 in the reset configuration word.                                                                                                                                                                                                                                                                                                         |
| 16                | PRPM                  | Peripheral Mode Enable — This bit determines if the chip is in peripheral mode. A detailed description is in <a href="#">Table 6-13</a> The default value is no peripheral mode enabled.                                                                                                                                                                              |
| 17:18             | SC                    | Single Chip Select — This field defines the mode of theMPC562/MPC564. See <a href="#">Table 6-10</a> .<br>00 Extended chip, 32 bits data<br>01 Extended chip, 16 bits data<br>10 Single chip and show cycles (address)<br>11 Single chip                                                                                                                              |
| 19                | ETRE                  | Exception Table Relocation Enable — This field defines whether the Exception Table Relocation feature in the BBC is enabled or disabled; The default state for this field is disabled. For more details, see <a href="#">Table 4-4</a> .                                                                                                                              |
| 20 <sup>2,3</sup> | FLEN                  | Flash Enable — This field determines whether the on-chip Flash memory is enabled or disabled out of reset. The default state is disabled, which means that by default, the boot is from external memory. Refer to <a href="#">Table 6-12</a> for more details.<br>0 Flash disabled — boot is from external memory<br>1 Flash enabled                                  |
| 21                | EN_COMP <sup>4</sup>  | Enable Compression — This bit enables the operation of the MPC562/MPC564 with compressed code. The default state is disabled. See <a href="#">Table 4-4</a> and <XrefBlue>Appendix A, “MPC562/MPC564 Compression Features.”                                                                                                                                           |
| 22                | EXC_COMP <sup>4</sup> | Exception Compression — This bit determines the operation of the MPC562/MPC564 with exceptions. If this bit is set, then the MPC562/MPC564 assumes that ALL the exception routines are in compressed code. The default indicates the exceptions are all non-compressed. See <a href="#">Table 4-4</a> and <XrefBlue>Appendix A, “MPC562/MPC564 Compression Features.” |
| 23                | —                     | Reserved. This bit must not be high in the reset configuration word.                                                                                                                                                                                                                                                                                                  |

Table 7-5. RCW Bit Descriptions (continued)

| Bits  | Name | Description                                                                                                                                                                                                                                                                                                                |

| 31    | DME  | Dual Mapping Enable — This bit determines whether Dual mapping of the internal Flash is enabled. For a detailed description refer to <a href="#">Table 10-11</a> . The default state is that dual mapping is disabled.<br>0 Dual mapping disabled<br>1 Dual mapping enabled                                                |

- <sup>1</sup> Bit 15 always comes from the internal Flash Reset Configuration Word (MPC563 only).
- <sup>2</sup> This bit should not be set on the MPC561/MPC562.
- <sup>3</sup> This bit is  $\overline{HC}$  if read from the internal Flash Reset Configuration Word. See [Section 21.2.3.1, “Reset Configuration Word \(UC3FCFIG\)”](#).
- <sup>4</sup> Available only on the MPC562/MPC564, software should write "0" to this bit for MPC561/MPC563.

### 7.5.3 Soft Reset Configuration

When a soft reset event occurs, the MPC561/MPC563 reconfigures the development port. Refer to [Chapter 23, “Development Support,”](#) for details.

Reset

## Chapter 8

# Clocks and Power Control

The main timing reference for the MPC561/MPC563 can monitor any of the following:

- An external crystal with a frequency of 4 or 20 MHz
- An external frequency source with a frequency of 4 MHz
- An external frequency source at the system frequency

The system operating frequency is generated through a programmable phase-locked loop, the system PLL (SPLL). The SPLL runs at twice the system speed. The SPLL is programmable in integer multiples of the input frequency to generate the internal (VCO/2) operating frequency. A pre-divider before the SPLL enables the division of the high frequency crystal oscillator. The internal operating SPLL frequency should be at least 30 MHz. It can be divided by a power-of-two divider to generate the system operating frequencies.

In addition to the system clock, the clocks submodule provides the following:

- TMBCLK to the time base (TB) and decremter (DEC)
- PITRTCLK to the periodic interrupt timer (PIT) and real-time clock (RTC)

The oscillator, TB, DEC, RTC, and the PIT are powered from the keep alive power supply (KAPWR) pin. This allows the counters to continue to increment/decrement at the oscillator frequency even when the main power to the MCU is off. While the power is off, the PIT may be used to signal the power supply IC to enable power to the system at specific intervals. This is the power-down wake-up feature. When the chip is not in power-down low-power mode, the KAPWR is powered to the same voltage value as the voltage of the I/O buffers and logic.

The MPC561/MPC563 clock module consists of the main crystal oscillator, the SPLL, the low-power divider, the clock generator, the system low-power control block, and the limp mode control block. The clock module receives control bits from the system clock control register (SCCR), change of lock interrupt register (COLIR), the PLL low-power and reset-control register (PLPRCR), and the PLL.

Figure 8-1 is a functional block diagram of the clock unit.

Figure 8-1. Clock Unit Block Diagram

## 8.1 System Clock Sources

The system clock can be provided by the main system oscillator, an external clock input, or the backup clock (BUCLK) on-chip ring oscillator, see [Figure 8-1](#).

The main system oscillator uses either a 4-MHz or 20-MHz crystal to generate the PLL reference clock. When the main system oscillator output is the timing reference to the system PLL, skew elimination between the XTAL/EXTAL pins and CLKOUT is not guaranteed. There is also an on-chip crystal feedback resistor on the MPC561/MPC563; however, space should be reserved for an off-chip resistor to allow for future configurations. [Figure 8-2](#) illustrates the main system oscillator crystal configuration.

The external clock input (EXTCLK pin) can receive a clock signal from an external source. The clock frequency must be in the range of 3-5 MHz or, for 1:1 mode, at the system frequency of at least 15 MHz. When the external clock input is the timing reference to the system PLL, the skew between the EXTCLK pin and the CLKOUT is less than  $\pm 1$  ns.

The backup clock on-chip ring oscillator allows the MPC561/MPC563 to function with a less precise clock. When operating from the backup clock, the MPC561/MPC563 is in limp mode. This enables the system to continue minimum functionality until the system is fixed. The BUCLK frequency is approximately 11 MHz for the MPC561/MPC563 (see [Appendix F, “Electrical Characteristics”](#) for the complete frequency range).

For normal operation, at least one clock source (EXTCLK or main system oscillator) must be active. A configuration with both clock sources active is possible as well. At this configuration EXTCLK provides the system clock and main system oscillator provides the PITRTCLK. The input of an unused timing reference (EXTCLK or EXTAL) must be grounded.

1. Resistor is not currently required on the board but space should be available for its addition in the future.

**Figure 8-2. Main System Oscillator Crystal Configuration**

## 8.2 System PLL

The PLL allows the processor to operate at a high internal clock frequency using a low frequency clock input, a feature which offers two benefits: reduces the overall electromagnetic interference generated by the system, and the ability to oscillate at different frequencies reduces cost by eliminating the need to add an additional oscillator to a system.

The PLL can perform the following functions:

- Frequency multiplication
- Skew elimination
- Frequency division

## 8.2.1 Frequency Multiplication

The PLL can multiply the input frequency by any integer between one and 4096. The multiplication factor depends on the value of the MF[0:11] bits in the PLPRCR register. While any integer value from one to 4096 can be programmed, the resulting VCO output frequency must be at least 15 MHz. The multiplication factor is set to a predetermined value during power-on reset as defined in [Table 8-1](#).

## 8.2.2 Skew Elimination

The PLL is capable of eliminating the skew between the external clock entering the chip (EXTCLK) and both the internal clock phases and the CLKOUT pin, making it useful for tight synchronous timings. Skew elimination is active only when the PLL is enabled and programmed with a multiplication factor of one or two (MF = 0 or 1). The timing reference to the system PLL is the external clock input (EXTCLK pin).

## 8.2.3 Pre-Divider

A pre-divider before the phase comparator enables additional system clock resolution when the crystal oscillator frequency is 20 MHz. The division factor is determined by the DIVF[0:4] bits in the PLPRCR.

## 8.2.4 PLL Block Diagram

As shown in [Figure 8-3](#), the reference signal, OSCCLK, goes to the phase comparator. The phase comparator controls the direction (up or down) that the charge pump drives the voltage across the external filter capacitor (XFC). The direction depends on whether the feedback signal phase lags or leads the reference signal. The output of the charge pump drives the VCO. The output frequency of the VCO is divided down and fed back to the phase comparator for comparison with the reference signal, OSCCLK. The MF values, zero to 4095, are mapped to multiplication factors of one to 4096. Note that when the PLL is operating in 1:1 mode (refer to [Table 8-1](#)), the multiplication factor is one (MF = 0). The PLL output frequency is twice the maximum system frequency. This double frequency is needed to generate GCLK1 and GCLK2 clocks. On power-up, with a 4-MHz or 20-MHz crystal and the default MF settings, VCOOUT will be 40 MHz and the system clock will be 20 MHz.

The equation for VCOOUT is:

$$\text{VCOOUT} = \frac{\text{OSCCLK}}{\text{DIVF} + 1} \times (\text{MF} + 1) \times 2$$

### NOTE

When operating with the backup clock, the system clock (and CLKOUT) is one-half of the ring oscillator frequency, (i.e., the system clock is approximately 11 MHz). The time base and PIT clocks will be twice the system clock frequency.

In the case of initial system power up, or if KAPWR is lost, an external circuit must assert power on reset (PORESET). Once KAPWR is valid, PORESET must be asserted long enough to allow the external oscillator to start up and stabilize for the device to come out of reset in normal (non limp) mode.

If limp mode is enabled (by the MODCK[1:3] pins), and  $\overline{\text{PORESET}}$  is negated before the external oscillator has started up, the backup clock, BUCLK, will be used to clock the device. The device will start to run in limp mode. Software can then switch the clock mode from BUCLK to PLL. If an application requires that the device always comes out of reset in normal mode,  $\overline{\text{PORESET}}$  should be asserted long enough for the external oscillator to start up. The maximum start-up time of an external oscillator is given in [Appendix F, “Electrical Characteristics”](#) and  $\overline{\text{PORESET}}$  should be asserted for this time and at least an additional 100,000 input clock cycles.

If limp mode is disabled at reset, a short reset of at least 3  $\mu\text{s}$  is enough to obtain normal chip operation, because the BUCLK will not start. The system will wait for the external oscillator to start-up and stabilize.

The PLL will begin to lock once  $\overline{\text{PORESET}}$  has been negated, assuming stable KAPWR and VDDSYN power supplies and internal oscillator (or external clock). The PLL maximum lock time is determined by the input clock to the phase comparator. The PLL locks within 500 input clock cycles if the PLPRCR[MF]  $\leq 4$ . The PLL locks within 1000 input clock cycles if PLPRCR[MF]  $> 4$ .  $\overline{\text{HRESET}}$  will be released 512 system clock cycles after the PLL locks.

Whenever  $\overline{\text{PORESET}}$  is asserted, the MF bits are set according to [Table 8-1](#), and the division factor high frequency (DFNH) and division factor low frequency (DFNL) bits in SCCR are set to the value of 0 ( $\div 1$  for DFNH and  $\div 2$  for DFNL).

Figure 8-3. System PLL Block Diagram

## 8.2.5 PLL Pins

The following pins are dedicated to the PLL operation:

- **VDDSYN** — Drain voltage. This is the  $V_{DD}$  dedicated to the analog PLL circuits. The voltage should be well-regulated and the pin should be provided with an extremely low impedance path to the  $V_{DD}$  power rail. VDDSYN should be bypassed to VSSSYN by a 0.1  $\mu\text{F}$  capacitor located as close as possible to the chip package.
- **VSSSYN** — Source voltage. This is the  $V_{SS}$  dedicated to the analog PLL circuits. The pin should be provided with an extremely low impedance path to ground. VSSSYN should be bypassed to VDDSYN by a 0.1  $\mu\text{F}$  capacitor located as close as possible to the chip package.

- XFC — External filter capacitor. XFC connects to the off-chip capacitor for the PLL filter. One terminal of the capacitor is connected to XFC, and the other terminal is connected to VDDSYN.
    - The off-chip capacitor must have the following values:
      - $0 < MF + 1 < 4 (1130 \times (MF + 1) - 80) \text{ pF}$
      - $MF + 1 \geq 42100 \times (MF + 1) \text{ pF}$
- Where MF = the value stored on MF[0:11]. This is one less than the desired frequency multiplication.

## 8.3 System Clock During PLL Loss of Lock

At reset, until the SPLP is locked, the SPLP output clock is disabled.

During normal operation (once the PLL has locked), either the oscillator or an external clock source is generating the system clock. In this case, if loss of lock is detected and the LOLRE (loss of lock reset enable) bit in the PLPRCR is cleared, the system clock source continues to function as the PLL's output clock. The USIU timers can operate with the input clock to the PLL, so that these timers are not affected by the PLL loss of lock. Software can use these timers to measure the loss-of-lock period. If the timer reaches the user-preset software criterion, the MPC561/MPC563 can switch to the backup clock by setting the switch to backup clock (STBUC) bit in the SCCR, provided the limp mode enable (LME) bit in the SCCR is set.

If loss of lock is detected during normal operation, assertion of  $\overline{\text{HRESET}}$  (for example, if LOLRE is set) disables the PLL output clock until the lock condition is met. During hard reset, the STBUC bit is set as long as the PLL lock condition is not met and clears when the PLL is locked. If STBUC and LME are both set, the system clock switches to the backup clock (BUCLK), and the chip operates in limp mode until STBUC is cleared.

Every change in the lock status of the PLL can generate a maskable interrupt.

### NOTE

When the VCO is the system clock source, chip operation is unpredictable while the PLL is unlocked. Note further that a switch to the backup clock is possible only if the LME bit in the SCCR is set.

## 8.4 Low-Power Divider

The output of the PLL is sent to a low-power divider block. (In limp mode the BUCLK is sent to a low-power divider block.) This block generates all other clocks in normal operation, but has the ability to divide the output frequency of the VCO before it generates the general system clocks sent to the rest of the MPC561/MPC563. The PLL VCOOUT is always divided by at least two.

The purpose of the low-power divider block is to allow reduction and restoration of the operating frequencies of different sections of the MPC561/MPC563 without losing the PLL lock. Using the low-power divider block, full chip operation can still be obtained, but at a lower frequency. This is called gear mode. The selection and speed of gear mode can be changed at any time, with changes occurring immediately.

The low-power divider block is controlled in the system clock control register (SCCR). The default state of the low-power divider is to divide all clocks by one. Thus, for a 40-MHz system, the general system clocks are each 40 MHz. Whenever power-on reset is asserted, the MF bits are set according to [Table 8-1](#), and the division factor high frequency (DFNH) and division factor low frequency (DFNL) bits in SCCR are set to the value of 0 ( $\div 1$  for DFNH and  $\div 2$  for DFNL).

## 8.5 Internal Clock Signals

The internal clocks generated by the clocks module are shown in [Figure 8-4](#). The clocks module also generates the CLKOUT and ENGCLK external clock signals. The PLL synchronizes these signals to each other. The PITRTCLK frequency and source are specified by the RTDIV and RTSEL bits in the SCCR. When the backup clock is functioning as the system clock, the backup clock is automatically selected as the time base clock source and is twice the MPC561/MPC563 system clock.

**Figure 8-4. MPC561/MPC563 Clocks**

Note that GCLK1\_50, GCLK2\_50, and CLKOUT can have a lower frequency than GCLK1 and GCLK2. This is to enable the external bus operation at lower frequencies (controlled by EBDF in the SCCR). GCLK2\_50 always rises simultaneously with GCLK2. When DFNH = 0, GCLK2\_50 has a 50% duty cycle. With other values of DFNH or DFNL, the duty cycle is less than 50%. Refer to [Figure 8-7](#). GCLK1\_50 rises simultaneously with GCLK1. When the MPC561/MPC563 is not in gear mode, the falling edge of GCLK1\_50 occurs in the middle of the high phase of GCLK2\_50. EBDF determines the division factor between GCLK1/GCLK2 and GCLK1\_50/GCLK2\_50.

During power-on reset, the MODCK1, MODCK2, and MODCK3 pins determine the clock source for the PLL and the clock drivers. These pins are latched on the positive edge of PORESET. Their values must be stable as long as this line is asserted. The configuration modes are shown in [Table 8-1](#). MODCK1 specifies

the input source to the SPLL (main system oscillator or EXTCLK). MODCK1, MODCK2, and MODCK3 together determine the multiplication factor at reset and the functionality of limp mode.

If the configuration of PITRTCLK and TMBCLK and the SPLL multiplication factor is to remain unchanged in power-down low-power mode, the MODCK signals should not be sampled at wake-up from this mode. In this case the  $\overline{\text{PORESET}}$  pin should remain negated and  $\overline{\text{HRESET}}$  should be asserted during the power supply wake-up stage.

When MODCK1 is cleared, the output of the main oscillator is selected as the input to the SPLL. When MODCK1 is asserted, the external clock input (EXTCLK pin) is selected as the input to the SPLL. In all cases, the system clock frequency ( $\text{freq}_{\text{gclk2}}$ ) can be reduced by the DFNH[0:2] bits in the SCCR. Note that  $\text{freq}_{\text{gclk2}(\text{max})}$  occurs when the DFNH bits are cleared.

The TBS bit in the SCCR selects the time base clock to be either the SPLL input clock or GCLK2. When the backup clock is functioning as the system clock, the backup clock is automatically selected as the time base clock source.

The PITRTCLK frequency and source are specified by the RTDIV and RTSEL bits in the SCCR. When the backup clock is functioning as the system clock, the backup clock is automatically selected as the time base clock source.

When the  $\overline{\text{PORESET}}$  pin is negated (driven to a high value), the MODCK1, MODCK2, and MODCK3 values are not affected. They remain the same as they were defined during the most recent power-on reset.

Table 8-1 shows the clock configuration modes during power-on reset ( $\overline{\text{PORESET}}$  asserted).

### NOTE

The MODCK[1:3] are shared functions with IRQ[5:7]. If  $\overline{\text{IRQ}}[5:7]$  are used as interrupts, the interrupt source should be removed during  $\overline{\text{PORESET}}$  to insure the MODCK pins are in the correct state on the rising edge of  $\overline{\text{PORESET}}$ .

**Table 8-1. Reset Clocks Source Configuration**

| MODCK[1:3] <sup>1</sup> | Default Values after PORESET |       |       |        |                 |                 | SPLL Options                                                                                            |

<sup>1</sup> indicates MODCK pins value during power-on reset

### NOTE

The reset value of the PLL pre-divider is one.

The values of the PITRTCLK clock division and TMBCLK clock division can be changed by software. The RTDIV bit value in the SCCR register defines the division of PITRTCLK. All possible combinations of the TMBCLK divisions are listed in [Table 8-2](#).

**Table 8-2. TMBCLK Divisions<sup>1</sup>**

| SCCR[TBS] | MF + 1 | TMBCLK Division |
|-----------|--------|-----------------|
| 1         | —      | 16              |
| 0         | 1, 2   | 16              |
| 0         | > 2    | 4               |

<sup>1</sup> To ensure correct operation of the time base, keep the system clock to time base clock ratio above 4 and always set SCCR[TBS] = 1 when running on the backup clock (limp mode).

## 8.5.1 General System Clocks

The general system clocks (GCLK1C, GCLK2C, GCLK1, GCLK2, GCLK1\_50, and GCLK2\_50) are the basic clock supplied to all modules and sub-modules on the MPC561/MPC563. GCLK1C and GCLK2C are supplied to the RCPu and to the BBC. GCLK1C and GCLK2C are stopped when the chip enters the doze-low power mode. GCLK1 and GCLK2 are supplied to the SIU and the clock module. The external bus clock GCLK2\_50 is the same as CLKOUT. The general system clock defaults to VCO/2 = 20 MHz (assuming a 20-MHz system frequency) with default power-on reset MF values.

The general system clock frequency can be switched between different values. The highest operational frequency can be achieved when the system clock frequency is determined by DFNH (CSRC bit in the PLPRCR is cleared) and DFNH = 0 (division by one). The general system clock can be operated at a low frequency (gear mode) or a high frequency. The DFNL bits in SCCR define the low frequency. The DFNH bits in SCCR define the high frequency.

The frequency of the general system clock can be changed dynamically with the system clock control register (SCCR), as shown in Figure 8-5.

**Figure 8-5. General System Clocks Select**

The frequency of the general system clock can be changed “on the fly” by software. The user may simply cause the general system clock to switch to its low frequency. However, in some applications, there is a need for a high frequency during certain periods. Interrupt routines, for example, may require more performance than the low frequency operation provides, but must consume less power than in maximum frequency operation. The MPC561/MPC563 provides a method to automatically switch between low and high frequency operation whenever one of the following conditions exists:

- There is a pending interrupt from the interrupt controller. This option is maskable by the PRQEN bit in the SCCR.
- The (POW) bit in the MSR is clear in normal operation. This option is maskable by the PRQEN bit in the SCCR.

When neither of these conditions exists and the CSRC bit in PLPRCR is set, the general system clock switches automatically back to the low frequency.

Abrupt changes in the divide ratio can cause linear changes in the operating currents of the MPC561/MPC563.

When the multiplication factor (PLPRCR[MF]) for the PLL is changed, the PLL stops all internal clocks until the PLL adjusts to the new frequency. This includes stopping the clock to the watchdog timer, therefore SWT cannot reset the system during this period.

When the clock stops, the current consumed by the device from VDD will fall; it will then rise sharply when the PLL turns on the PLL output clocks at the new frequency. These abrupt changes in the divide ratio can cause linear changes in the operating currents of the device. Insure that the proper power supply filtering is available to handle changes instantaneously. The gear modes (DFNH and DFNL) can be used to temporarily decrease the system frequency to minimize the demand on the power supply when the MF or DIVF multiply/divide ratio is changed.

When the general system clock is divided, its duty cycle is changed. One phase remains the same (for example, 12.5 ns at 40 MHz) while the other becomes longer.

### NOTE

CLKOUT does not have a 50% duty cycle when the general system clock is divided. The CLKOUT wave form is the same as that of GCLK2\_50.

**Figure 8-6. Divided System Clocks Timing Diagram**

The system clocks GCLK1 and GCLK2 frequency is:

$$FREQ_{sys} = \frac{FREQ_{sysmax}}{(2^{DFNH})_{or}(2^{DFNL} + 1)}$$

where  $FREQ_{sysmax} = VCOOUT/2$

Therefore, the complete equation for determining the system clock frequency is:

$$\text{System Frequency} = \frac{OSCCLK}{DIVF + 1} \times \frac{(MF + 1)}{(2^{DNFH})_{or}(2^{DFNL} + 1)} \times \frac{2}{2}$$

The clocks GCLK1\_50 and GCLK2\_50 frequency is:

$$FREQ_{50} = \frac{FREQ_{sysmax}}{(2^{DFNH})_{or}(2^{DFNL+1})} \times \frac{1}{EBDF+1}$$

Figure 8-7 shows the timing of USIU clocks when DFNH = 1 or DFNL = 0.

Figure 8-7. Clocks Timing For DFNH = 1 (or DFNL = 0)

## 8.5.2 Clock Out (CLKOUT)

CLKOUT has the same frequency as the general system clock (GCLK2\_50). Unlike the main system clock GCLK1/GCLK2 however, CLKOUT (and GCLK2\_50) represents the external bus clock, and thus will be one-half of the main system clock if the external bus is running at half speed (EBDF = 0b01). The CLKOUT frequency (system frequency) defaults to VCO/2. CLKOUT can drive full, half, or quarter strength; it can also be disabled. The drive strength is controlled in the system clock and reset-control register (SCCR) by the COM[0:1] and CQDS bits. (See [Section 8.11.1, “System Clock Control Register \(SCCR\)”](#)). Disabling or decreasing the strength of CLKOUT can reduce power consumption, noise, and electromagnetic interference on the printed circuit board.

When the PLL is acquiring lock, the CLKOUT signal is disabled and remains in the low state (provided that BUCS = 0).

### 8.5.3 Engineering Clock (ENGCLK)

ENGCLK is an output clock with a 50% duty cycle. Its frequency defaults to VCO/128, which is 1/64 of the main system frequency. ENGCLK frequency can be programmed to the main system frequency divided by a factor from one to 64, as controlled by the ENGDIV[0:5] bits in the SCCR. ENGCLK can drive full- or half-strength, or it can also be disabled (remaining in the high state). The drive strength is controlled by the EECLK[0:1] bits in the SCCR. Disabling ENGCLK can reduce power consumption, noise, and electromagnetic interference on the printed circuit board.

#### NOTE

The full strength ENGCLK setting (SCCR[EECLK]=0b01) selects a 5-V driver while the half-strength selection (SCCR[EECLK]=0b00) is a 2.6-V driver.

When the PLL is acquiring lock, the ENGCLK signal is disabled and remains in the low state (provided that BUCS = 0).

#### NOTE

Skew elimination between CLKOUT and ENGCLK is not guaranteed.

## 8.6 Clock Source Switching

For limp mode support, clock source switching is supported. If for any reason the clock source for the chip is not functioning, the option is to switch the system clock to the backup clock ring oscillator, BUCLK.

This circuit consists of a loss-of-clock detector, which sets the LOCS status bit and LOCSS sticky bit in the PLPRCR. If the LME bit in the SCCR is set, whenever LOCS is asserted, the clock logic switches the system clock automatically to BUCLK and asserts hard reset to the chip. Switching the system clock to BUCLK is also possible by software setting the STBUC bit in SCCR. Switching from limp mode to normal system operation is accomplished by clearing STBUC and LOCSS bits. This operation also asserts hard reset to the chip.

At  $\overline{\text{HRESET}}$  assertion, if the PLL output clock is not valid, the BUCLK will be selected until software clears LOCSS bit in SCCR. At  $\overline{\text{HRESET}}$  assertion, if the PLL output clock is valid, the system will switch to oscillator/external clock. If during  $\overline{\text{HRESET}}$  the PLL loses lock or the clock frequency becomes slower than the required value, the system will switch to the BUCLK. After  $\overline{\text{HRESET}}$  negation the PLL lock condition does not effect the system clock source selection.

If the LME bit is clear, the switch to the backup clock is disabled and assertion of STBUC bit is ignored. If the chip is in limp mode, clearing the LME bit switches the system to normal operation and asserts hard reset to the chip.

Figure 8-8 describes the clock switching control logic. Table 8-3 summarizes the status and control for each state.

**Figure 8-8. Clock Source Switching Flow Chart**

### NOTE

buck\_enable = (STBUC | LOC) and LME lock indicates loss of lock status bit (LOCS) for all cases and loss of clock sticky bit (LOCSS) when state 3 is active. When buck\_enable is changed, the chip asserts  $\overline{\text{HRESET}}$  to switch the system clock to BUCLK or PLL.

At  $\overline{\text{PORESET}}$  negation, if the PLL is not locked, the loss-of-clock sticky bit (LOCSS) is asserted, and the chip should operate with BUCLK.

The switching from state three to state four is accomplished by clearing the STBUC and LOCSS bits. If the switching is done when the PLL is not locked, the system clock will not oscillate until lock condition is met.

**Table 8-3. Status of Clock Source**

| STATE          | $\overline{\text{PORESET}}$ | $\overline{\text{HRESET}}$ | LME | LOCS (status)  | LOCSS (sticky) | STBUC | BUCS | Chip Clock Source |
|----------------|-----------------------------|----------------------------|-----|----------------|----------------|-------|------|-------------------|
| 1              | 0                           | 0                          | 1   | 0              | 0              | 0     | 1    | BUCLK             |
| 2              | 1                           | 0                          | 1   | 0/1            | 0              | 0     | 1    | BUCLK             |
| 3 <sup>1</sup> | 1                           | 1                          | 1   | x <sup>2</sup> | 0/1            | 0/1   | 1    | BUCLK             |
| 4              | 1                           | 0                          | 0/1 | 0              | x <sup>2</sup> | 0     | 0    | Oscillator        |
| 5              | 1                           | 1                          | 0/1 | 0              | x <sup>2</sup> | 0     | 0    | Oscillator        |
| 6              | 1                           | 0                          | 1   | 0/1            | 1              | 0/1   | 1    | BUCLK             |

<sup>1</sup> At least one of the two bits, LOCSS or BUCS, must be asserted (one) in this state.

<sup>2</sup> X = don't care.

The default value of the LME bit is determined by MODCK[1:3] during assertion of the  $\overline{\text{PORESET}}$  line. The configuration modes are shown in [Table 8-1](#).

## 8.7 Low-Power Modes

The LPM and other bits in the PLPRCR are encoded to provide one normal operating mode and four low-power modes. In normal and doze modes the system can be in high state with frequency defined by the DFNH bits, or in the low state with frequency defined by the DFNL bits. The normal-high operating mode is the state out of reset. This is also the state of the bits after the low-power mode exit signal arrives.

There are four low-power modes:

- Doze mode
- Sleep mode
- Deep-sleep mode
- Power-down mode

### 8.7.1 Entering a Low-Power Mode

Low-power modes are enabled by setting the MSR[POW] and clearing the SCCR[LPML]. Once enabled, a low-power mode is entered by setting the LPM bits to the appropriate value. This can be done only in one of the normal modes. The user cannot change the PLPRCR[LPM or CSRC] when the MCU is in doze mode.

#### NOTE

Higher than desired currents during low-power mode can be avoided by executing a mullw instruction before entering the low-power mode, i.e., anytime after reset and prior to entering the low-power mode.

Table 8-6 summarizes the control bit settings for the different clock power modes.

**Table 8-4. Power Mode Control Bit Settings**

| Power Mode          | LPM[0:1] | CSRC | TEXPS |
|---------------------|----------|------|-------|
| Normal-high         | 00       | 0    | X     |
| Normal-low (“gear”) | 00       | 1    | X     |
| Doze-high           | 01       | 0    | X     |
| Doze-low            | 01       | 1    | X     |
| Sleep               | 10       | X    | X     |
| Deep-sleep          | 11       | X    | 1     |
| Power-down          | 11       | X    | 0     |

## 8.7.2 Power Mode Descriptions

Table 8-5 describes the clock frequency and chip functionality for each power mode.

**Table 8-5. Power Mode Descriptions**

| Operation Mode      | SPLL       | Clocks                           | Functionality                                                                         | Power Pins that Need to be Powered-Up      |
|---------------------|------------|----------------------------------|---------------------------------------------------------------------------------------|--------------------------------------------|
| Normal-high         | Active     | Full frequency $\div 2^{DFNH}$   | Full functions not in use are shut off                                                | All On                                     |
| Normal-low (“gear”) | Active     | Full frequency $\div 2^{DFNL+1}$ |                                                                                       | All On                                     |
| Doze-high           | Active     | Full frequency $\div 2^{DFNH}$   | Enabled: RTC, PIT, TB and DEC, controller<br>Disabled: extended core (RCPU, BBC, FPU) | KAPWR, VDDSYN, VDD, QVDDL, NVDDL, IRAMSTBY |
| Doze-low            | Active     | Full frequency $\div 2^{DFNL+1}$ |                                                                                       | KAPWR, VDDSYN, VDD, QVDDL, NVDDL, IRAMSTBY |
| Sleep               | Active     | Not active                       | Enabled: RTC, PIT, TB and DEC                                                         | KAPWR, VDDSYN, IRAMSTBY                    |
| Deep-sleep          | Not active | Not active                       |                                                                                       | KAPWR, IRAMSTBY                            |
| Power-down          | Not active | Not active                       |                                                                                       | KAPWR, IRAMSTBY                            |
| SRAM Standby        | Not active | Not active                       | SRAM data retention                                                                   | IRAMSTBY                                   |

## 8.7.3 Exiting from Low-Power Modes

Exiting from low-power modes occurs through an asynchronous interrupt or a synchronous interrupt generated by the interrupt controller. Any enabled asynchronous interrupt clears the LPM bits but does not change the PLPRCR[CSRC] bit.

The return to normal-high mode from normal-low, doze-high, low, and sleep mode is accomplished with the asynchronous interrupt. The sources of the asynchronous interrupt are:

- Asynchronous wake-up interrupt from the interrupt controller
- RTC, PIT, or time base interrupts (if enabled)
- Decrementer exception

The system responds quickly to asynchronous interrupts. The wake-up time from normal-low, doze-high, doze-low, and sleep mode caused by an asynchronous interrupt or a decrementer exception is only three to four clock cycles of maximum system frequency. In 40-MHz systems, this wake-up requires 75 to 100 ns. The asynchronous wake-up interrupt from the interrupt controller is level sensitive one. It will therefore be negated only after the reset of interrupt cause in the interrupt controller.

The timers' (RTC, PIT, time base, or decrementer) interrupts indications set status bits in the PLPRCR (TMIST). The clock module considers this interrupt to be pending asynchronous interrupt as long as the TMIST is set. The TMIST status bit should be cleared before entering any low-power mode.

Table 8-7 summarizes wake-up operation for each of the low-power modes.

**Table 8-6. Power Mode Wake-Up Operation**

| Operation Mode      | Wake-up Method        | Return Time from Wake-up Event to Normal-High                                                                |
|---------------------|-----------------------|--------------------------------------------------------------------------------------------------------------|
| Normal-low ("gear") | Software or Interrupt | Asynchronous interrupts:<br>3-4 maximum system cycles<br>Synchronous interrupts:<br>3-4 actual system cycles |
| Doze-high           | Interrupt             |                                                                                                              |
| Doze-low            | Interrupt             |                                                                                                              |
| Sleep               | Interrupt             | 3-4 maximum system clocks                                                                                    |
| Deep-sleep          | Interrupt             | < 500 Oscillator Cycles<br>125 $\mu$ s – 4 MHz<br>25 $\mu$ s – 20 MHz                                        |
| Power-down          | Interrupt             | < 500 oscillator cycles + power supply wake-up                                                               |
| IRAMSTBY            | External              | Power-on sequence                                                                                            |

## 8.7.3.1 Exiting from Normal-Low Mode

In normal mode (as well as doze mode), if the PLPRCR[CSRC] bit is set, the system toggles between low frequency (defined by PLPRCR[DFNL]) and high frequency (defined by PLPRCR[DFNH]). The system switches from normal-low mode to normal-high mode if either of the following conditions is met:

- An interrupt is pending from the interrupt controller; or
- The MSR[POW] bit is cleared (power management is disabled).

When neither of these conditions are met, the PLPRCR[CSRC] bit is set, and the asynchronous interrupt status bits are reset, the system returns to normal-low mode.

### 8.7.3.2 Exiting from Doze Mode

The system changes from doze mode to normal-high mode whenever an interrupt is pending from the interrupt controller.

### 8.7.3.3 Exiting from Deep-Sleep Mode

The system switches from deep-sleep mode to normal-high mode if any of the following conditions is met:

- An interrupt is pending from the interrupt controller
- An interrupt is requested by the RTC, PIT, or time base
- A decremter exception

In deep-sleep mode the PLL is disabled. The wake-up time from this mode is up to 500 PLL input frequency clocks. In one-to-one mode the wake-up time may be up to 100 PLL input frequency clocks. For a PLL input frequency of 4 MHz, the wake-up time is less than 125  $\mu$ s.

### 8.7.3.4 Exiting from Power-Down Mode

Exit from power-down mode is accomplished through hard reset. External logic should assert  $\overline{\text{HRESET}}$  in response to the TEXPS bit being set and TEXP pin being asserted. The TEXPS bit is set by an enabled RTC, PIT, time base, or decremter interrupt. The hard reset should be asserted for no longer than the time it takes for the power supply to wake-up in addition to the PLL lock time. When the TEXPS bit is cleared (and the TEXP signal is negated), assertion of hard reset sets the bit, causes the pin to be asserted, and causes an exit from power-down low-power mode. Refer to [Section 8.8.3, “Keep-Alive Power”](#) for more information.

### 8.7.3.5 Low-Power Modes Flow

[Figure 8-9](#) shows the flow among the different power modes.

<sup>1</sup>Software is active only in normal-high/low modes.

<sup>2</sup>TEXPS receives the zero value by writing one. Writing of zero has no effect on TEXPS.

<sup>3</sup>The switch from normal-high to normal-low is enable only if the conditions to asynchronous interrupt are cleared.

**Figure 8-9. Low-Power Modes Flow Diagram**

## 8.8 Basic Power Structure

### 8.8.1 General Power Supply Definitions

KAPWR and VSS power the following clock unit modules: oscillator, PITRTCLK and TMBCLK generation logic, timebase, decremter, RTC, PIT, system clock control register (SCCR), low-power and reset-control register (PLPRCR), and reset status register (RSR). All other circuits are powered by the normal supply pins: VDD, QVDDL, NVDDL, VDDF, VDDSYN, VFLASH, VDDH and VSS. The power supply for each block is listed in [Table 8-7](#).

**Table 8-7. Power Supplies**

| Circuit                                                                                                                          | Power Supply              |
|----------------------------------------------------------------------------------------------------------------------------------|---------------------------|
| CLKOUT<br>SPLL (digital),<br>System low-power control<br>Internal logic<br>Clock drivers                                         | NVDDL/QVDDL               |
| SPLL (analog)                                                                                                                    | VDDSYN                    |
| Main oscillator<br>Reset machine<br>Limp mode mechanism<br>Register control<br>SCCR, PLLRCR and RSR<br>PPC RTC, PIT, TB, and DEC | KAPWR                     |
| CALRAM, DPTRAM, DECRAM                                                                                                           | IRAMSTBY/VDD <sup>1</sup> |

<sup>1</sup> Keep-alive power is supplied by IRAMSTBY, but run current is provided through VDD

The following are the relations between different power supplies:

- $VDD = QVDDL = NVDDL = VDDSYN = VDDF = 2.6 \text{ V} \pm 0.1 \text{ V}$
- $KAPWR = VDD \pm 0.2 \text{ V}$  (during normal operation)
- $VDDH = VDDA = VFLASH = 5.0 \pm 5\%$
- $KAPWR = 2.6 \pm 0.1 \text{ V}$  (during standby operation)
- $IRAMSTBY = \text{current source} > 50 \mu\text{A}, < 1.75 \text{ mA}$  (average)

#### NOTE

The power supply inputs VDD, QVDDL, NVDDL, VDDSYN, and VDDF should all be connected to the same 2.6-V power supply. The KAPWR power supply can be connected to a 2.6-V standby power supply. If KAPWR is not connected to a standby power supply, it should be connected to the same power supply as VDD. IRAMSTBY is the input to an approximately 1.7 volt regulator. It must be connected through a resistor to a standby power supply. The power supply inputs VDDH and VFLASH should be connected to the same 5.0-V supply. VDDA can be isolated from VDDH, but should be the same approximate voltage.

## 8.8.2 Chip Power Structure

The MPC561/MPC563 provides a wide range of possibilities for power supply connections. [Figure 8-11](#) illustrates the different power supply sources for each of the basic units on the chip.

### 8.8.2.1 NVDDL

This supplies the final output stage of the 2.6-V pad output drivers.

### 8.8.2.2 QVDDL

This supplies all pad logic and pre-driver circuitry, except for the final output stage of the 2.6-V pad output drivers.

### 8.8.2.3 VDD

VDD powers the internal logic of the MPC561/MPC563, nominally 2.6V.

### 8.8.2.4 VDDSYN, VSSSYN

The charge pump and the VCO of the SPLL are fed by a separate 2.6-V power supply (VDDSYN) in order to improve noise immunity and achieve a high stability in its output frequency. VSSSYN provides an isolated ground reference for the PLL.

### 8.8.2.5 KAPWR

The oscillator, time base counter, decremter, periodic interrupt timer and the real-time clock are fed by the KAPWR rail. This allows the external power supply unit to disconnect all other sub-units of the MCU in low-power deep-sleep mode. The TEXP pin (fed by the same rail) can be used by the external power supply unit to switch between sources. The  $\overline{\text{IRQ}}[6:7]/\text{MODCK}[2:3]$ ,  $\overline{\text{IRQ}}5/\text{MODCK}1$ , XTAL, EXTAL, EXTCLK,  $\overline{\text{PORESET}}$ ,  $\overline{\text{HRESET}}$ ,  $\overline{\text{SRESET}}$ , and  $\overline{\text{RSTCONF}}/\text{TEXP}$  input pins are powered by KAPWR. Circuits, including pull-up resistors, driving these inputs should be powered by KAPWR.

### 8.8.2.6 VDDA, VSSA

VDDA supplies power to the analog subsystems of the QADC64E\_A and QADC64E\_B modules; it is nominally 5.0 V. VSSA is the ground reference for the analog subsystems.

### 8.8.2.7 VFLASH

VFLASH supplies the UC3F normal operating voltage. It is nominally 5.0 V. The MPC561 has no VFLASH signal.

### 8.8.2.8 VDDF, VSSF

VDDF provides internal core voltage to the UC3F Flash module; it should be a nominal 2.6V. VSSF provides an isolated ground for the UC3F Flash module. The MPC561 has no VDDF or VSSF signal.

### 8.8.2.9 VDDH

VDDH provides power for the 5-V I/O operations. It is a nominal 5.0 V.

### 8.8.2.10 IRAMSTBY

IRAMSTBY is the data retention power supply for all on-board RAM arrays (CALRAM, DPTRAM, DECRAM). It has a shunt regulator circuit of approximately 1.7 volts that diverts excess current to ground in order to regulate voltage on the IRAMSTBY power supply pin. Run current is supplied by normal VDD. IRAMSTBY must be connected to a positive power supply, via a register, and bypassed by a capacitor to ground (see [Figure 8-10](#)). The resistor should be sized according to the following equations:

$$\frac{(V_{\text{SUPPLYMIN}} - 1.95 \text{ V})}{R_{\text{SUPPLY}}} > 50 \mu\text{A}$$

$$\frac{(V_{\text{SUPPLYMAX}} - 1.35 \text{ V})}{R_{\text{SUPPLY}}} < 1.75 \text{ mA (average)}$$

where  $V_{\text{SUPPLYMIN}}$  is the lowest supply voltage and  $V_{\text{SUPPLYMAX}}$  is the highest possible supply voltage. See note in the VSRMCR[ZOREG] bit description.

**Figure 8-10. IRAMSTBY Regulator Circuit**

### 8.8.2.11 VSS

VSS provides the ground reference for the MPC561/MPC563.

Figure 8-11. Basic Power Supply Configuration

## 8.8.3 Keep-Alive Power

### 8.8.3.1 Keep-Alive Power Configuration

Figure 8-12 is an example of a switching scheme for an optimized low-power system. SW1 and SW2 can be unified in only one switch if VDDSYN and VDD/NVDDL/QVDDL are supplied by the same source.

**Figure 8-12. External Power Supply Scheme**

The MPC561/MPC563 asserts the TEXP signal, if enabled, when the RTC or TB time value matches the value programmed in the associated alarm register or when the PIT or DEC value reaches zero. The TEXP signal is negated when the TEXPS status bit is written to one.

The KAPWR power supply feeds the main crystal oscillator (OSCM). The condition for the main crystal oscillator stability is that the power supply value changes slowly. The maximum slope must be less than 5 mV per oscillation cycle ( $\tau > 200\text{-}300/\text{freq}_{\text{oscm}}$ ).

### 8.8.3.2 Keep-Alive Power Registers Lock Mechanism

The USIU timer, clocks, reset, power, decremter, and time base registers are powered by the KAPWR supply. When the main power supply is disconnected after power-down mode is entered, the value stored in any of these registers is preserved. If power-down mode is not entered before power disconnect, there is a chance of data loss in these registers. To minimize the possibility of data loss, the MPC561/MPC563 includes a key mechanism that ensures data retention as long as a register is locked. While a register is locked, writes to this register are ignored.

Each of the registers in the KAPWR region have a key that can be in one of two states: open or locked. At power-on reset the following keys are locked by default: RTC, RTSEC, RTCAL, and RTCSC. All other registers are unlocked. Each key has an address associated with it in the internal map.

A write of 0x55CAA33 to the associated key register changes the key to the open state. A write of any other data to this location changes the key to the locked state. The key registers are write-only. A read of the key register has undefined side effects and may be interpreted as a write that locks the associated register.

Table 8-8 lists the registers powered by KAPWR and the associated key registers.

**Table 8-8. KAPWR Registers and Key Registers**

| KAPWR Register        |                                                                                                                                                                                  | Associated Key Register |                                                        |

Figure 8-13 illustrates the process of locking or unlocking a register powered by KAPWR.

Figure 8-13. Keep-Alive Register Key State Diagram

## 8.9 IRAMSTBY Supply Failure Detection

A special circuit for IRAMSTBY supply failure detection is provided. In the case of supply failure detection, the dedicated sticky bits LVSRs in the VSRMCR register are asserted. Software can read or clear these bits. The user should enable the detector and then clear these bits. If any of the LVSR bits are read as one, then a power failure of IRAMSTBY has occurred. The circuit is capable of detecting supply failure below a voltage level to be determined. Also, enable/disable control bit for the IRAMSTBY detector may be used to disconnect the circuit and save the detector power consumption.

## 8.10 Power-Up/Down Sequencing

Figure 8-14 and Figure 8-15 detail the power-up sequencing for MPC561/MPC563 during normal operation. Note that for each of the conditions detailing the voltage relationships the absolute bounds of the minimum and maximum voltage supply cannot be violated; that is, the value of VDDL cannot fall below 2.5 V or exceed 2.7 V, and the value of VDDH cannot fall below 4.75 V or exceed 5.25 V for normal operation. Power consumption during power up sequencing will be below the operating power consumption.

During the power down sequence  $\overline{\text{PORESET}}$  needs to be asserted while VDD, NVDDL, and QVDDL are at a voltage greater than or equal to 2.5 V. Below this voltage the power supply chip can be turned off.

If the turn-off voltage of the power supply chip is greater than 0.74 V for the 2.6-V supply and greater than 0.8 V for the 5-V supply, then the circuitry inside the MPC561/MPC563 will act as a load to the respective supply and will discharge the supply line down to these values. Since the 2.6-V logic represents a larger load to the supply chip, the 2.6-V supply line will decay faster than the 5-V supply line.

- <sup>1</sup>  $\text{VDDH} \geq \text{QVDDL} - 0.5 \text{ V}$   
VDDA can lag VDDH, and VDDSYN can lag QVDDL, but both must be at a valid level before resets are negated.
- <sup>2</sup> If keep-alive functions are NOT used, then when system power is on:  $\text{KAPWR} = \text{QVDDL} \pm 0.1 \text{ V}$ ;  $\text{KAPWR} \leq 2.7 \text{ V}$
- <sup>3</sup> If keep-alive functions ARE used, then  $\text{KAPWR} = \text{QVDDL} = \text{NVDDL} = 2.6 \text{ V} \pm 0.1 \text{ V}$  when system power is on  $\text{KAPWR} = 2.6 \text{ V} \pm 0.1 \text{ V}$  when system power is off. IRAMSTBY should be powered prior to the other supplies. If IRAMSTBY is powered at the same time as the other supplies, it should be allowed to stabilize before  $\overline{\text{PORESET}}$  is negated. Normal system power is defined as  $\text{QVDDL} = \text{VDD} = \text{VDDF} = \text{VDDSYN} = \text{KAPWR} = 2.6 \pm 0.1 \text{ V}$  and  $\text{VDDA} = \text{VDDH} = \text{VFLASH} = 5.0 \pm 0.25 \text{ V}$ . Flash programming requirements are the same as normal system power. VFLASH should always be  $5.0 \pm 0.25 \text{ V}$ . Note: Flash is not implemented on the MPC561.
- <sup>4</sup> Do not hold the 2.6-V supplies at ground while VDDH/VDDA is ramping to 5 V.
- <sup>5</sup> If 5 V is applied before the 2.6-V supply, all 5-V outputs will be in indeterminate states until the 2.6-V supply reaches a level that allows reset to be distributed throughout the device. If 5 V is applied before the 2.6-V supply, all 5-V outputs will be in indeterminate states until the 2.6-V supply reaches a level that allows reset to be distributed throughout the device.

**Figure 8-14. No Standby, No KAPWR, All System Power-On/Off**

- <sup>1</sup>  $VDDH \geq QVDDL - 0.5 \text{ V}$   
VDDA can lag VDDH, and VDDSYN can lag QVDDL, but both must be at a valid level before resets are negated.
- <sup>2</sup> If keep-alive functions are NOT used, then when system power is on:  $KAPWR = QVDDL \pm 0.1 \text{ V}$ ;  $KAPWR \leq 2.7 \text{ V}$
- <sup>3</sup> If keep-alive functions ARE used, then  $KAPWR = QVDDL = NVDDL = 2.6 \text{ V} \pm 0.1 \text{ V}$  when system power is on  
 $KAPWR = 2.6 \text{ V} \pm 0.1 \text{ V}$  when system power is off. IRAMSTBY should be powered prior to the other supplies. If IRAMSTBY is powered at the same time as the other supplies, it should be allowed to stabilize before  $\overline{PORESET}$  is negated. Normal system power is defined as  $QVDDL = VDD = VDDF = VDDSYN = KAPWR = 2.6 \pm 0.1 \text{ V}$  and  $VDDA = VDDH = VFLASH = 5.0 \pm 0.25 \text{ V}$ . Flash programming requirements are the same as normal system power. VFLASH should always be  $5.0 \pm 0.25 \text{ V}$ . Note: Flash is not implemented on the MPC561.
- <sup>4</sup> Do not hold the 2.6-V supplies at ground while VDDH/VDDA is ramping to 5 V.
- <sup>5</sup> If 5 V is applied before the 2.6-V supply, all 5-V outputs will be in indeterminate states until the 2.6-V supply reaches a level that allows reset to be distributed throughout the device. If 5 V is applied before the 2.6-V supply, all 5-V outputs will be in indeterminate states until the 2.6-V supply reaches a level that allows reset to be distributed throughout the device

<sup>1</sup> The hard reset value is a reset configuration word value, extracted from the indicated internal data bus lines. Refer to [Section 7.5.2, “Hard Reset Configuration Word \(RCW\).”](#)

<sup>2</sup> EQ2 = MODCK1

<sup>3</sup> EQ3 = (MODCK1 AND MODCK2 AND MODCK3) | (MODCK1 AND MODCK2 AND MODCK3) | (MODCK1 AND MODCK2 AND MODCK3). See [Table 8-1](#).

<sup>4</sup> RTDIV will be 0 if MODCK[1:3] = 000.

**Figure 8-16. System Clock and Reset Control Register (SCCR)**

## NOTE

COM[1] bit default value is determined during by BDRV reset configuration bit; See [Section 7.5.2, “Hard Reset Configuration Word \(RCW\).”](#)

**Table 8-9. SCCR Bit Descriptions**

| Bits | Name | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|------|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0    | DBCT | Disable backup clock for timers. The DBCT bit controls the timers clock source while the chip is in limp mode. If DBCT is set, the timers clock (TMBLCK, PITRCLK) source will not be the backup clock, even if the system clock source is the backup clock ring oscillator. The real-time clock source will be EXTAL or EXTCLK according to RTSEL bit (see description in bit 11 below), and the time base clocks source will be determined according to TBS bit and MODCK1.<br>0 If the chip is in limp mode, the timer clock source is the backup (limp) clock<br>1 The timer clock source is either the external clock or the crystal (depending on the current clock mode selected) |
| 1:2  | COM  | Clock Output Mode – The COM and CQDS bits control the output buffer strength of the CLKOUT and external bus pins. When both COM bits are set the CLKOUT pin is held in the high (1) state and external bus pins are driven at reduced drive. These bits can be dynamically changed without generating spikes on the CLKOUT and external bus pins. If CLKOUT pin is not connected to external circuits, set both bits (disabling CLKOUT) to minimize noise and power dissipation. The default value for COM[1] is determined by the BDRV bit in the reset configuration word. See <a href="#">Table 7-5</a> . For CLKOUT control see <a href="#">Table 8-10</a> .                        |

**Table 8-9. SCCR Bit Descriptions (continued)**

| Bits | Name  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|------|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 3    | DCSLR | Disable clock switching at loss of lock during reset. When DCSLR is clear and limp mode is enabled, the chip will switch automatically to the backup clock if the PLL loses lock during $\overline{\text{HRESET}}$ . When DCSLR is asserted, a PLL loss-of-lock event does not cause clock switching. If $\overline{\text{HRESET}}$ is asserted and DCSLR is set, the chip will not negate $\overline{\text{HRESET}}$ until the PLL acquires lock.<br>0 Enable clock switching if the PLL loses lock during reset<br>1 Disable clock switching if the PLL loses lock during reset |
| 4    | MFPDL | MF and pre-divider lock. Setting this control bit disables writes to the MF and DIVF bits. This helps prevent runaway software from changing the VCO frequency and causing the SPILL to lose lock. In addition, to protect against hardware interference, a hardware reset will be asserted if these fields are changed while LPML is asserted. This bit is writable once after power-on reset.<br>0 MF and DIVF fields are writable<br>1 MF and DIVF fields are locked                                                                                                           |
| 5    | LPML  | LPM lock. Setting this control bit disables writes to the LPM and CSRC control bits. In addition, for added protection, a hardware reset is asserted if any mode is entered other than normal-high mode. This protects against runaway software causing the MCU to enter low-power modes. (The MSR[POW] bit provides additional protection). LPML is writable once after power-on reset.)<br>0 LPM and CSRC bits are writable<br>1 LPM and CSRC bits are locked and hard reset will occur if the MCU is not in normal-high mode                                                   |
| 6    | TBS   | Time base source.<br>0 Source is OSCCLK divided by either 4 or 16<br>1 Source is system clock divided by 16                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| 7    | RTDIV | RTC (and PIT) clock divider. At power-on reset this bit is cleared if MODCK[1:3] are all low; otherwise the bit is set.<br>0 RTC and PIT clock divided by 4<br>1 RTC and PIT clock divided by 256                                                                                                                                                                                                                                                                                                                                                                                 |
| 8    | STBUC | Switch to backup clock control. When software sets this bit, the system clock is switched to the on-chip backup clock ring oscillator, and the chip undergoes a hard reset. The STBUC bit is ignored if LME is cleared.<br>0 Do not switch to the backup clock ring oscillator<br>1 Switch to backup clock ring oscillator                                                                                                                                                                                                                                                        |
| 9    | CQDS  | Clock quarter drive strength — The COM and CQDS bits control the output buffer strength of the CLKOUT, see <a href="#">Table 8-10</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| 10   | PRQEN | Power management request enable<br>0 Remains in the lower frequency (defined by DFNL) even if the power management bit in the MSR is reset (normal operational mode) or if there is a pending interrupt from the interrupt controller<br>1 Switches to high frequency (defined by DFNH) when the power management bit in the MSR is reset (normal operational mode) or there is a pending interrupt from the interrupt controller                                                                                                                                                 |

**Table 8-9. SCCR Bit Descriptions (continued)**

| Bits  | Name        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-------|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 11    | RTSEL       | <p>RTC circuit input source select. At power-on reset RTSEL receives the value of the MODCK1 signal. Refer to <a href="#">Table 8-1</a>. Note that if the chip is operating in limp mode (BUCS = 0), the RTSEL bit is ignored, and the backup clock is the clock source for the RT and PIT clocks</p> <p>0 OSCM clock is selected as input to RTC and PIT<br/>1 EXTCLK clock is selected as the RTC and PIT clock source</p>                                                                                                                                                                                                                                                                                             |
| 12    | BUCS        | <p>Backup clock status. This status bit indicates the current system clock source. When loss of clock is detected and the LME bit is set, the clock source is the backup clock and this bit is set. When the STBUC bit and LME bit are set, the system switches to the backup clock and BUCS is set.</p> <p>0 System clock is not the backup clock<br/>1 System clock is the backup clock</p>                                                                                                                                                                                                                                                                                                                            |
| 13:14 | EBDF[0:1]   | <p>External bus division factor. These bits define the frequency division factor between (GCLK1 and GCLK2) and (GCLK1_50 and GCLK2_50). CLKOUT is similar to GCLK2_50. The GCLK2_50 and GCLK1_50 are used by the external bus interface and controller in order to interface to the external system. The EBDF bits are initialized during hard reset using the hard reset configuration mechanism.</p> <p>00 CLKOUT is GCLK2 divided by 1<br/>01 CLKOUT is GCLK2 divided by 2<br/>1x Reserved</p> <p>Note: If EBDF &gt; 0, an external burst access with short setup timing will corrupt any USIU register load/store. Refer to <a href="#">Section 10.2.6, “Reduced Data Setup Time.”</a></p>                           |
| 15    | LME         | <p>Limp mode enable. When LME is set, the loss-of-clock monitor is enabled and any detection of loss of clock will switch the system clock automatically to backup clock. It is also possible to switch to the backup clock by setting the STBUC bit.</p> <p>If LME is cleared, the option of using limp mode is disabled. The loss of clock detector is not active, and any write to STBUC is ignored.</p> <p>The LME bit is writable once, by software, after power-on reset, when the system clock is not backup clock (BUCS = 0).</p> <p>During power-on reset, the value of LME is determined by the MODCK[1:3] bits. (Refer to <a href="#">Table 8-1</a>.)</p> <p>0 Limp mode disabled<br/>1 Limp mode enabled</p> |
| 16:17 | EECLK[0:1]  | <p>Enable engineering clock. This field controls the output buffer voltage of the ENGCLK pin. When both bits are set the ENGCLK pin is held in the high state. These bits can be dynamically changed without generating spikes on the ENGCLK pin. If ENGCLK is not connected to external circuits, set both bits (disabling ENGCLK) to minimize noise and power dissipation. For measurement purposes the backup clock (BUCLK) can be driven externally on the ENGCLK pin.</p> <p>00 Engineering clock enabled, 2.6 V output buffer<br/>01 Engineering clock enabled (slew rate controlled), 5 V output buffer<br/>10 BUCLK is the output on the ENGCLK 2.6 V output buffer<br/>11 Engineering clock disabled</p>        |
| 18:23 | ENGDIV[0:5] | <p>Engineering clock division factor. These bits define the frequency division factor between VCO/2 and ENGCLK. Division factor can be from 1 (ENGDIV = 000000) to 64 (ENGDIV = 111111). These bits can be read and written at any time. They are not affected by hard reset but are cleared during power-on reset.</p> <p>NOTE: If the engineering clock division factor is not a power of two, synchronization between the system and ENGCLK is not guaranteed.</p>                                                                                                                                                                                                                                                    |

**Table 8-9. SCCR Bit Descriptions (continued)**

| Bits  | Name      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

### 8.11.2 PLL, Low-Power, and Reset-Control Register (PLPRCR)

The PLL, low-power, and reset-control register (PLPRCR) is a 32-bit register powered by the keep-alive power supply.

**Figure 8-17. PLL, Low-Power, and Reset-Control Register (PLPRCR)**

**Table 8-11. PLPRCR Bit Descriptions**

| Bits | Name  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|------|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0:11 | MF    | Multiplication factor bits. The output of the VCO is divided to generate the feedback signal to the phase comparator. The MF bits control the value of the divider in the SPLS feedback loop. The phase comparator determines the phase shift between the feedback signal and the reference clock. This difference results in either an increase or decrease in the VCO output frequency.<br>The MF bits can be read and written at any time. However, this field can be write-protected by setting the MF and pre-divider lock (MFPDL) bit in the SCCR. Changing the MF bits causes the SPLS to lose lock. Also, the MF field should not be modified when entering or exiting from low power mode (LPM change), or when back-up clock is active.<br>The normal reset value for the DFNH bits is zero (divide by 1). When the PLL is operating in one-to-one mode, the multiplication factor is set to x1 (MF = 0). |
| 12   | —     | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| 13   | LOCS  | Loss of clock status. When the oscillator or external clock source is not at the minimum frequency, the loss-of-clock circuit asserts the LOCS bit. This bit is cleared when the oscillator or external clock source is functioning normally. This bit is reset only on power-on reset. Writes to this bit have no effect.<br>0 No loss of oscillator is currently detected<br>1 Loss of oscillator is currently detected                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| 14   | LOCSS | Loss of clock sticky. If, after negation of $\overline{\text{PORESET}}$ , the loss-of-clock circuit detects that the oscillator or external clock source is not at a minimum frequency, the LOCSS bit is set. LOCSS remains set until software clears it by writing a one to it. A write of zero has no effect on this bit. The reset value is determined during hard reset. The STBUC bit will be set provided the PLL lock condition is not met when $\overline{\text{HRESET}}$ is asserted, and cleared if the PLL is locked when $\overline{\text{HRESET}}$ is asserted.<br>0 No loss of oscillator has been detected<br>1 Loss of oscillator has been detected                                                                                                                                                                                                                                                 |
| 15   | SPLS  | System PLL lock status bit<br>0 SPLS is currently not locked<br>1 SPLS is currently locked                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

**Table 8-11. PLPRCR Bit Descriptions (continued)**

| Bits  | Name     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-------|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 16    | SPLSS    | SPLL lock status sticky bit. An out-of-lock sets the SPLSS bit. The bit remains set until software clears it by writing a one to it. A write of zero has no effect on this bit. The bit is cleared at power-on reset. This bit is not affected due to a software initiated loss-of-lock (MF change and entering deep-sleep or power-down mode). The SPLSS bit is not affected by hard reset.<br>0 SPLL has remained in lock<br>1 SPLL has gone out of lock at least once (not due to software-initiated loss of lock)                                                                                                                                                                                                                                                                                                                                                     |
| 17    | TEXPS    | Timer expired status bit. This bit controls whether the chip negates the TEXP pin in deep-sleep mode, thus enabling external circuitry to switch off the VDD (power-down mode). When LPM = 11, CSRC = 0, and TEXPS is high, the TEXP pin remains asserted. When LPM = 11, CSRC = 0, and TEXPS is low, the TEXPS pin is negated.<br>To enable automatic wake-up TEXPS is asserted when one of the following occurs: <ul style="list-style-type: none"> <li>• The PIT is expired</li> <li>• The real-time clock alarm is set</li> <li>• The time base clock alarm is set</li> <li>• The decremter exception occurs</li> <li>• The bit remains set until software clears it by writing a one to it. A write of zero has no effect on this bit. TEXPS is set by power-on or hard reset.</li> </ul> 0 TEXP is negated in deep-sleep mode<br>1 TEXP pin remains asserted always |
| 18    | TEXP_INV | Timer Expired Pin Inversed Polarity – The TEXP_INV bit controls whether the polarity of the TEXP pin will be active high (normal default) or active low.<br>0 The TEXP pin is active high<br>1 The TEXP pin is active low                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| 19    | TMIST    | Timers interrupt status. TMIST is set when an interrupt from the RTC, PIT, TB or DEC occurs. The TMIST bit is cleared by writing a one to it. Writing a zero has no effect on this bit. The system clock frequency remains at its high frequency value (defined by DFNH) if the TMIST bit is set, even if the CSRC bit in the PLPRCR is set (DFNL enabled) and conditions to switch to normal-low mode do not exist. This bit is cleared during power-on or hard reset.<br>0 No timer expired event was detected<br>1 A timer expire event was detected                                                                                                                                                                                                                                                                                                                   |
| 20    | —        | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| 21    | CSRC     | Clock source. This bit is cleared at hard reset.<br>0 General system clock is determined by the DFNH value<br>1 General system clock is determined by the DFNL value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| 22:23 | LPM      | Low-power mode select. These bits are encoded to provide one normal operating mode and four low-power modes. In normal and doze modes, the system can be in high state (frequency determined by the DFNH bits) or low state (frequency defined by the DFNL bits). The LPM field can be write-protected by setting the LPM and CSRC lock (LPML) bit in the SCCR Refer to <a href="#">Table 8-4</a> and <a href="#">Table 8-5</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| 24    | CSR      | Checkstop reset enable. If this bit is set, then an automatic reset is generated when the RCPU signals that it has entered checkstop mode, unless debug mode was enabled at reset. If the bit is clear and debug mode is not enabled, then the USIU will not do anything upon receiving the checkstop signal from the RCPU. If debug mode is enabled, then the part enters debug mode upon entering checkstop mode. In this case, the RCPU will not assert the checkstop signal to the reset circuitry. This bit is writable once after soft reset.<br>0 No reset will occur when checkstop is asserted<br>1 Reset will occur when checkstop is asserted                                                                                                                                                                                                                  |

**Table 8-11. PLPRCR Bit Descriptions (continued)**

| Bits  | Name  | Description                                                                                                                                                                                                                                                                                                                              |
|-------|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 25    | LOLRE | Loss of lock reset enable<br>0 Loss of lock does not cause $\overline{\text{HRESET}}$ assertion<br>1 Loss of lock causes $\overline{\text{HRESET}}$ assertion<br>Note: if limp mode is enabled, use the COLIR feature instead of setting the LOLRE bit. See <a href="#">Section 8.11.3, “Change of Lock Interrupt Register (COLIR).”</a> |
| 26    | —     | Reserved                                                                                                                                                                                                                                                                                                                                 |
| 27:31 | DIVF  | The DIVF bits control the value of the pre-divider in the SPLL circuit. The DIVF bits can be read and written at any time. However, the DIVF field can be write-protected by setting the MF and pre-divider lock (MFPDL) bit in the SCCR. Changing the DIVF bits causes the SPLL to lose lock.                                           |

### 8.11.3 Change of Lock Interrupt Register (COLIR)

The COLIR is 16-bit read/write register. It controls the change of lock interrupt generation, and is used for reporting a loss of lock interrupt source. It contains the interrupt request level and the interrupt status bit. This register is readable and writable at any time. A status bit is cleared by writing a one (writing a zero does not affect a status bit's value). The COLIR is mapped into the MPC561/MPC563 USIU register map.

### 8.11.4 IRAMSTBY Control Register (VSRMCR)

This register contains control bits for enabling or disabling the IRAMSTBY supply detection circuit. There are also four bits that indicate the failure detection. All four bits have the same function and are required to improve the detection capability in extreme cases.

| 1:4  | LVSRs              | Loss of IRAMSTBY sticky. These status bits indicate whether a IRAMSTBY supply failure occurred. In addition, when the power is turned on for the first time, IRAMSTBY rises and these bits are set. The LVSRs bits are cleared by writing them to ones. A write of zero has no effect on these bits.<br>0 No IRAMSTBY supply failure was detected<br>1 IRAMSTBY supply failure was detected                                                                                                                                                                                                                                                                                                                                                                                                                          |
| 5    | VSRDE <sup>1</sup> | IRAMSTBY detector disable.<br>0 IRAMSTBY detection circuit is enabled<br>1 IRAMSTBY detection circuit is disabled                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 6    | LVDRS              | Loss of IRAMSTBY for DECRAM Sticky — The status bit, dedicated especially for the BBC DECRAM, which indicates if there was IRAMSTBY supply failure. When the power is turned on for the first time, IRAMSTBY rises also and the bits will be asserted. The LVDECRAM bit can be cleared by writing ones to LVDECRAM. A write of zero has no effect on this bit. The bit may be used by application software, to decide if there is need to load decompression vocabularies during reset routine.<br>0 IRAMSTBY supply failure was not detected<br>1 IRAMSTBY supply failure was detected<br>NOTE: The LVDRS bit is provided as a convenience for indicating that the DECRAM has lost power. It requires that the IRAMSTBY pins are connected to the same power supply. It actually only monitors the IRAMSTBY supply. |
| 7    | ZOREG <sup>2</sup> | This bit indicates the status of the internal IRAMSTBY supply. This bit is cleared by writing a 1 to it.<br>0 Internal IRAMSTBY zener regulator has not gone out of regulation<br>1 Internal IRAMSTBY zener regulator has gone out of regulation.<br><b>Note:</b> ZOREG may get set inadvertently if IRAMSTBY is not supplied with at least 150μA.                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| 8:15 | —                  | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

<sup>1</sup> Removed on all parts that have the ZOREG bit.

- <sup>2</sup> ZOREG is not in Rev 0 of the MPC561 but is in all later revisions. It is not in Rev 0 or 0A of the MPC563, but is in Rev A and later revisions.

## Chapter 9

# External Bus Interface

The MPC561/MPC563 external bus is a synchronous, burstable bus. Signals driven on this bus must adhere to the setup and hold time relative to the bus clock's rising edge. The bus has the ability to support multiple masters. The MPC561/MPC563 external bus interface architecture supports byte, half-word, and word operands allowing access to 8-, 16-, and 32-bit data ports through the use of synchronous cycles controlled by the size outputs (TSIZ0, TSIZ1). For accesses to 16- and 8-bit ports, the slave must be controlled by the memory controller. For more information, refer to [Appendix F, "Electrical Characteristics."](#)

### 9.1 Features

The external bus interface features are listed below:

- 32-bit address bus with transfer size indication (only 24 available on pins)
- 32-bit data bus
- Bus arbitration logic on-chip with external master support
- Chip-select and wait state generation to support peripheral or static memory devices through the memory controller
- Supports various memory (SRAM, EEPROM) types: synchronous and asynchronous, burstable and non-burstable
- Supports non-wrap bursts with up to four data beats
- Flash ROM programming support
- Implements the PowerPC ISA architecture
- Easy to interface to slave devices
- Bus is synchronous (all signals are referenced to rising edge of bus clock)
- Bus can operate at the same frequency as the internal RCPU core of MPC561/MPC563 or half the frequency.

### 9.2 Bus Transfer Signals

The bus transfers information between the MPC561/MPC563 and external memory of a peripheral device. External devices can accept or provide 8, 16, and 32 data bits in parallel and must follow the handshake protocol described in this section. The maximum number of bits accepted or provided during a bus transfer is defined as the port width.

The MPC561/MPC563 has non-multiplexed address and data buses. Control signals indicate the beginning and type of the cycle, as well as the address space and size of the transfer. The selected device

then controls the length of the cycle with the signal(s) used to terminate the cycle. A strobe signal for the address lines indicates the validity of the address.

The MPC561/MPC563 bus is synchronous with a synchronous support. The bus and control input signals must be timed to setup and hold times relative to the rising edge of the clock. Bus cycles can be completed in two clock cycles.

For all inputs, the MPC561/MPC563 latches the level of the input during a sample window around the rising edge of the clock signal. This window is illustrated in [Figure 9-1](#), where  $t_{su}$  and  $t_{ho}$  are the input setup and hold times, respectively. To ensure that an input signal is recognized on a specific rising edge of the clock, that input must be stable during the sample window. If an input makes a transition during the window time period, the level recognized by the MPC561/MPC563 is not predictable; however, the MPC561/MPC563 always resolves the latched level to either a logic high or low before using it. In addition to meeting input setup and hold times for deterministic operation, all input signals must obey the protocols described in this section.

**Figure 9-1. Input Sample Window**

## 9.3 Bus Control Signals

The MPC561/MPC563 initiates a bus cycle by driving the address, size, address type, cycle type, and read/write outputs. At the beginning of a bus cycle, TSIZ[0:1] are driven with the address type signals. TSIZ0 and TSIZ1 indicate the number of bytes remaining to be transferred during an operand cycle (consisting of one or more bus cycles). These signals are valid at the rising edge of the clock in which the transfer start ( $\overline{TS}$ ) signal is asserted.

The read/write ( $RD/\overline{WR}$ ) signal determines the direction of the transfer during a bus cycle. Driven at the beginning of a bus cycle,  $RD/\overline{WR}$  is valid at the rising edge of the clock in which  $\overline{TS}$  is asserted. The logic level of  $RD/\overline{WR}$  only changes when a write cycle is preceded by a read cycle or vice versa. The signal may remain low for consecutive write cycles.

Figure 9-2. MPC561/MPC563 Bus Signals

## 9.4 Bus Interface Signal Descriptions

Table 9-1 describes each signal in the bus interface unit. More detailed descriptions can be found in subsequent subsections. The buses are described in big endian manner, which means that bit 0 is the most significant bit in a bus (MSB), and bit 31 is the least significant bit (LSB).

**Table 9-1. MPC561/MPC563 BIU Signals**

| Signal Name                                     | Pins         | Active | I/O    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

Table 9-1. MPC561/MPC563 BIU Signals (continued)

| Signal Name                                        | Pins | Active | I/O | Description                                                                                                                                                                                                                                                                                                                                      |
|----------------------------------------------------|------|--------|-----|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $\overline{\text{BDIP}}$<br>Burst data in progress | 1    | Low    | O   | Driven by the MPC561/MPC563 when it owns the external bus. It is part of the burst protocol. When $\overline{\text{BDIP}}$ is asserted, the second beat in front of the current one is requested by the master. This signal is negated prior to the end of a burst to terminate the burst data phase early.                                      |
|                                                    |      |        | I   | Driven by an external master when it owns the external bus. When $\overline{\text{BDIP}}$ is asserted, the second beat in front of the current one is requested by the master. This signal is negated prior to the end of a burst to terminate the burst data phase early. The MPC561/MPC563 does not support burst accesses to internal slaves. |
| Transfer Start                                     |      |        |     |                                                                                                                                                                                                                                                                                                                                                  |
| $\overline{\text{TS}}$<br>Transfer start           | 1    | Low    | O   | Driven by the MPC561/MPC563 when it owns the external bus. Indicates the start of a transaction on the external bus.                                                                                                                                                                                                                             |
|                                                    |      |        | I   | Driven by an external master when it owns the external bus. It indicates the start of a transaction on the external bus or (in show cycle mode) signals the beginning of an internal transaction.                                                                                                                                                |
| Reservation Protocol                               |      |        |     |                                                                                                                                                                                                                                                                                                                                                  |
| $\overline{\text{CR}}$<br>Cancel reservation       | 1    | Low    | I   | Each MPC500 CPU has its own $\overline{\text{CR}}$ signal. Assertion of $\overline{\text{CR}}$ instructs the bus master to clear its reservation; some other master has touched its reserved space. This is a pulsed signal.                                                                                                                     |
| $\overline{\text{KR}}$<br>Kill reservation         | 1    | Low    | I   | In case of a bus cycle initiated by a STWCX instruction issued by the RCPU to a non-local bus on which the storage reservation has been lost, this signal is used by the non-local bus interface to back-off the cycle. Refer to <a href="#">Section 9.5.10, “Storage Reservation”</a> for details.                                              |

| I                                                         | Driven by the slave in a read transaction. For single beat transactions, the MPC561/MPC563 does not sample byte lanes that are not selected for the transfer by ADDR[30:31] and TSIZ[0:1]. In addition, an external master that owns the bus and initiated a write transaction to an internal slave module drives DATA[0:31]. |        |           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |           |           |           |   |            |   |             |   |             |   |

| $\overline{BI} / \overline{STS}$<br><br>Burst inhibit/<br>Special Transfer Start | 1    | Low    | I   | Burst Inhibit: Driven by the slave device to which the current transaction was addressed. Indicates that the current slave does not support burst mode.                                                                                                                                                                                                          |
|                                                                                  |      |        | O   | Burst Inhibit: Driven by the MPC561/MPC563 when the slave device is controlled by the on-chip Memory Controller. The MPC561/MPC563 also asserts BI for any external master burst access to internal MPC561/MPC563 memory space.                                                                                                                                  |
|                                                                                  |      |        |     | Special Transfer Start: Driven by the MPC561/MPC563 when it owns the external bus. Indicates the start of a transaction on the external bus or signals the beginning of an internal transaction in show cycle mode.                                                                                                                                              |
| Arbitration                                                                      |      |        |     |                                                                                                                                                                                                                                                                                                                                                                  |
| $\overline{BR}$<br><br>Bus request                                               | 1    | Low    | I   | When the internal arbiter is enabled, $\overline{BR}$ assertion indicates that an external master is requesting the bus.                                                                                                                                                                                                                                         |
|                                                                                  |      |        | O   | Driven by the MPC561/MPC563 when the internal arbiter is disabled and the chip is not parked.                                                                                                                                                                                                                                                                    |
| $\overline{BG}$<br><br>Bus grant                                                 | 1    | Low    | O   | When the internal arbiter is enabled, the MPC561/MPC563 asserts this signal to indicate that an external master may assume ownership of the bus and begin a bus transaction. The $\overline{BG}$ signal should be qualified by the master requesting the bus in order to ensure it is the bus owner:<br>Qualified bus grant = $BG \& \sim \overline{BB}$         |
|                                                                                  |      |        | I   | When the internal arbiter is disabled, $\overline{BG}$ is sampled and properly qualified by the MPC561/MPC563 when an external bus transaction is to be executed by the chip.                                                                                                                                                                                    |
| $\overline{BB}$<br><br>Bus busy                                                  | 1    | Low    | O   | When the internal arbiter is enabled, the MPC561/MPC563 asserts this signal to indicate that it is the current owner of the bus.<br>When the internal arbiter is disabled, the MPC561/MPC563 asserts this signal after the external arbiter has granted the ownership of the bus to the chip and it is ready to start the transaction.                           |
|                                                                                  |      |        | I   | When the internal arbiter is enabled, the MPC561/MPC563 samples this signal to get indication of when the external master ended its bus tenure ( $\overline{BB}$ negated).<br>When the internal arbiter is disabled, the $\overline{BB}$ is sampled to properly qualify the $\overline{BG}$ line when an external bus transaction is to be executed by the chip. |

**Table 9-1. MPC561/MPC563 BIU Signals (continued)**

| Signal Name                        | Pins | Active | I/O | Description                                                                                                                                                                                                                                  |
|------------------------------------|------|--------|-----|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $\overline{\text{RETRY}}$<br>Retry | 1    | Low    | I   | In the case of regular transaction, this signal is driven by the slave device to indicate that the MPC561/MPC563 must relinquish the ownership of the bus and retry the cycle.                                                               |
|                                    |      |        | O   | When an external master owns the bus and the internal MPC561/MPC563 bus initiates access to the external bus at the same time, this signal is used to cause the external master to relinquish the bus for one clock to solve the contention. |

## 9.5 Bus Operations

This section provides a functional description of the system bus, the signals that control it, and the bus cycles provided for data transfer operations. It also describes the error conditions, bus arbitration, and reset operation.

The MPC561/MPC563 generates a system clock output (CLKOUT). This output sets the frequency of operation for the bus interface directly. Internally, the MPC561/MPC563 uses a phase-lock loop (PLL) circuit to generate a master clock for all of the MPC561/MPC563 circuitry (including the bus interface) which is phase-locked to the CLKOUT output signal.

All signals for the MPC561/MPC563 bus interface are specified with respect to the rising edge of the external CLKOUT and are guaranteed to be sampled as inputs or changed as outputs with respect to that edge. Since the same clock edge is referenced for driving or sampling the bus signals, the possibility of clock skew could exist between various modules in a system due to routing or the use of multiple clock lines. It is the responsibility of the system to handle any such clock skew problems that could occur.

### 9.5.1 Basic Transfer Protocol

The basic transfer protocol defines the sequence of actions that must occur on the MPC561/MPC563 bus to perform a complete bus transaction. A simplified scheme of the basic transfer protocol is illustrated in [Figure 9-3](#).

**Figure 9-3. Basic Transfer Protocol**

The basic transfer protocol provides for an arbitration phase and an address and data transfer phase. The address phase specifies the address for the transaction and the transfer attributes that describe the transaction. The data phase performs the transfer of data (if any is to be transferred). The data phase may transfer a single beat of data (four bytes or less) for nonburst operations, a 4-beat burst of data (4 x 4 bytes), an 8-beat burst of data (8 x 2 bytes) or a 16-beat burst of data (16 x 1 bytes).

## 9.5.2 Single Beat Transfer

During the data transfer phase, the data is transferred from master to slave (in write cycles) or from slave to master (on read cycles).

During a write cycle, the master drives the data as soon as it can, but never earlier than the cycle following the address transfer phase. The master has to take into consideration the “one dead clock cycle” switching between drivers to avoid electrical contentions. The master can stop driving the data bus as soon as it samples the  $\overline{TA}$  line asserted on the rising edge of the CLKOUT.

During a read cycle, the master accepts the data bus contents as valid at the rising edge of the CLKOUT in which the  $\overline{TA}$  signal is sampled/asserted.

### 9.5.2.1 Single Beat Read Flow

The basic read cycle begins with bus arbitration, followed by the address transfer, then the data transfer. The handshakes illustrated in the following flow and timing figures (Figure 9-4, Figure 9-5, and Figure 9-6) are applicable to the fixed transaction protocol.

Figure 9-4. Basic Flow Diagram of a Single Beat Read Cycle

Figure 9-5. Single Beat Read Cycle – Basic Timing – Zero Wait States

Figure 9-6. Single Beat Read Cycle – Basic Timing – One Wait State

### 9.5.2.2 Single Beat Write Flow

The basic write cycle begins with a bus arbitration, followed by the address transfer, then the data transfer. The handshakes are illustrated in the following flow and timing diagrams as applicable to the fixed transaction protocol.

Figure 9-7. Basic Flow Diagram of a Single Beat Write Cycle

**Figure 9-8. Single Beat Basic Write Cycle Timing – Zero Wait States**

Figure 9-9. Single Beat Basic Write Cycle Timing – One Wait State

### 9.5.2.3 Single Beat Flow with Small Port Size

The general case of single beat transfers assumes that the external memory has a 32-bit port size. The MPC561/MPC563 provides an effective mechanism for interfacing with 16-bit and 8-bit port size memories, allowing transfers to these devices when they are controlled by the internal memory controller.

In this case, the MPC561/MPC563 attempts to initiate a transfer as in the normal case. If the bus interface receives a small port size (16 or 8 bits) indication before the transfer acknowledge to the first beat (through the internal memory controller), the MCU initiates successive transactions until the completion of the data transfer. Note that all the transactions initiated to complete the data transfer are considered to be part of an atomic transaction, so the MCU does not allow other unrelated master accesses or bus arbitration to intervene between the transfers. If any of the transactions except the first is re-tried during an access to a small port, then a machine-check exception is generated to the RCP.

1. For an illustration of device connections on the data bus, see [Figure 9-23](#).

**Figure 9-10. Single Beat 32-Bit Data Write Cycle Timing — 16-Bit Port Size**

### 9.5.3 Data Bus Pre-Discharge Mode

Pre-discharge mode is provided for applications that use 3.3-V/5-V external memories while the MPC561/MPC563 data bus pads are optimized to 2.6-V memories, and cannot tolerate more than 3.1 V. When connecting 3.3-V devices to the E-bus, and performing read and write operations, this mode should be invoked in order to avoid long term reliability issues of the data pads.

When the PDMCR2[PREDIS\_EN] bit is set, the MPC561/MPC563 will discharge the bus during the address phase of any write cycle prior to the data phase. The data bus will be discharged from up to 5 V to a level which is suitable to the low voltage drivers. In most cases, the ORx[EHTR] bit of the relevant memory bank, should be set along with the PREDIS\_EN bit in order to reserve sufficient time for the

memory to three-state the bus before the bus discharge is initiated. EHTR has a slight performance reduction impact since it adds a clock gap between some read and write cycles.

#### NOTE

EHTR also adds one idle clock for two consecutive read cycles from different memory banks.

#### NOTE

The pre-discharge will not occur, when using multiple processors with a common bus accessing an external device, if the processor that initiates a read is different from the processor that initiated the previous write. Perform a write to the external device to discharge the external bus, or read a value of 0x0 from the external device, prior to accessing another MCU on the same bus.

### 9.5.3.1 Operating Conditions

Pre-discharge mode should be enabled in the following cases:

- When external devices can charge the data bus to a higher voltage level than 3.1 volts
- And when one or more of the following occurs:
  - The MPC561/MPC563 uses write accesses to any external memory
  - Data show cycles are enabled
  - Instruction show cycles are enabled in code compression mode (MPC562/MPC564 only)

#### NOTE

In the case of code compression program tracking (3rd case above), the PREDIS\_EN bit should only be set when program tracking is not required since pre-discharge mode overwrites the compression show cycles data. The user should not set PREDIS\_EN bit when program tracking is required on development system, and set PREDIS\_EN bit on the production version. EHTR can always be set to keep the same system performance during development, and production phases.

### 9.5.3.2 Initialization Sequence

Systems that require pre-discharge operation should include the following steps:

- Execute boot sequence
- Set EHTR bit in all relevant memory banks during the memory controller initialization phase (configure ORx, and BRx) if it is required to extend the time between read cycles, and pre-discharge phase of write cycles.
- Set PREDIS\_EN in PDMCR2 register
- Start to write data to external devices

Refer to [Section 2.4, “Pad Module Configuration Register \(PDMCR2\),”](#) and [Section 10.9.4, “Memory Controller Option Registers \(OR0–OR3\),”](#) for more information on PREDIS\_EN, and EHTR configuration bits.

**Figure 9-11. Read Followed by Write when Pre-Discharge Mode is Enabled, and EHTR is Set**

## 9.5.4 Burst Transfer

The MPC561/MPC563 uses non-wrapping burst transfers to access operands of up to 32 bytes (eight words). A non-wrapping burst access stops accessing the external device when the word address is modulo four/eight. Burst configuration is determined by the value of BURST\_EN in the SIUMCR register. See [Chapter 5, “Unified System Interface Unit \(USIU\) Overview”](#) for further details. The MPC561/MPC563 begins the access by supplying a starting address that points to one of the words in the array and requires the memory to sequentially drive or sample each word on the data bus. The selected slave device must internally increment ADDR28 and ADDR29 (and ADDR30 in the case of a 16-bit port slave device, and also ADDR31 in the case of an 8-bit port slave device) of the supplied address for each transfer, causing the address to reach a four/eight word boundary, and then stop. The address and transfer attributes supplied by the MPC561/MPC563 remain stable during the transfers. The selected device terminates each transfer by driving or sampling the word on the data bus and asserting TA.

The MPC561/MPC563 also supports burst-inhibited transfers for slave devices that are unable to support bursting. For this type of bus cycle, the selected slave device supplies or samples the first word the MPC561/MPC563 points to and asserts the burst-inhibit signal with  $\overline{TA}$  for the first transfer of the burst access. The MPC561/MPC563 responds by terminating the burst and accessing the remainder of the 16-byte block. These remaining accesses use up to three read/write bus cycles (each one for a word) in the case of a 32-bit port width slave, up to seven read/write bus cycles in the case of a 16-bit port width slave, or up to fifteen read/write bus cycles in the case of a 8-bit port width slave.

The general case of burst transfers assumes that the external memory has a 32-bit port size. The MPC561/MPC563 provides an effective mechanism for interfacing with 16-bit and 8-bit port size memories, allowing bursts transfers to these devices when they are controlled by the internal memory controller.

In this case, the MPC561/MPC563 attempts to initiate a burst transfer as in the normal case. If the memory controller signals to the bus interface that the external device has a small port size (8 or 16 bits), and if the burst is accepted, the bus interface completes a burst of 16 or 8 beats respectively for four words. Eight words requires 32 or 16 beats. Each beat of the burst transfers only one or two bytes effectively. Note that this burst of 8 or 16 beats is considered an atomic transaction, so the MPC561/MPC563 does not allow other unrelated master accesses or bus arbitration to intervene between the transfers.

### 9.5.5 Burst Mechanism

In addition to the standard bus signals, the MPC561/MPC563 burst mechanism uses the following signals:

- The  $\overline{BURST}$  signal indicates that the cycle is a burst cycle.
- The burst data in progress ( $\overline{BDIP}$ ) signal indicates the duration of the burst data.
- The burst inhibit ( $\overline{BI}$ ) signal indicates whether the slave is burstable.

At the start of the burst transfer, the master drives the address, the address attributes, and the  $\overline{BURST}$  signal to indicate that a burst transfer is being initiated, and asserts  $\overline{TS}$ . If the slave is burstable, it negates the burst-inhibit ( $\overline{BI}$ ) signal. If the slave cannot burst, it asserts  $\overline{BI}$ . For additional details, refer to [Section 10.2.5, “Burst Support.”](#)

During the data phase of a burst-write cycle, the master drives the data. It also asserts  $\overline{BDIP}$  if it intends to drive the data beat following the current data beat. When the slave has received the data, it asserts  $\overline{TA}$  to indicate to the master that it is ready for the next data transfer. The master again drives the next data and asserts or negates the  $\overline{BDIP}$  signal. If the master does not intend to drive another data beat following the current one, it negates  $\overline{BDIP}$  to indicate to the slave that the next data beat transfer is the last data of the burst-write transfer.

$\overline{BDIP}$  has two basic timings: normal and late (see [Figure 9-14](#) and [Figure 9-15](#)). In the late timing mode, assertion of  $\overline{BDIP}$  is delayed by the number of wait states in the first data beat. This implies that for zero-wait-state cycles,  $\overline{BDIP}$  assertion time is identical in normal and late modes. Cycles with late  $\overline{BDIP}$  generation can occur only during cycles for which the memory controller generates  $\overline{TA}$  internally. Refer to [Chapter 10, “Memory Controller”](#) for more information.

In the MPC561/MPC563, no internal master initiates write bursts. The MPC561/MPC563 is designed to perform this kind of transaction in order to support an external master that is using the memory controller services. Refer to [Section 10.8, “Memory Controller External Master Support.”](#)

During the data phase of a burst-read cycle, the master receives data from the addressed slave. If the master needs more than one data beat, it asserts  $\overline{\text{BDIP}}$ . Upon receiving the second-to-last data beat, the master negates  $\overline{\text{BDIP}}$ . The slave stops driving new data after it receives the negation of the  $\overline{\text{BDIP}}$  signal at the rising edge of the clock.

Burst inputs (reads) in the MPC561/MPC563 are used only for instruction cycles. Data load cycles are not supported.

Figures 9-12 through 9-21 are examples of various burst cycles, including illustrations of burst-read and burst-write cycles for both the 16- and 32-bit port sizes.

## 9.5.6 Alignment and Packaging of Transfers

The MPC561/MPC563 external bus requires natural address alignment:

- Byte accesses allow any address alignment
- Half-word accesses require address bit 31 to equal zero

- Word accesses require address bits 30 – 31 to equal zero
- Burst accesses require address bits 30 – 31 to equal zero

The MPC561/MPC563 performs operand transfers through its 32-bit data port. If the transfer is controlled by the internal memory controller, the MPC561/MPC563 can support 8- and 16-bit data port sizes.

The bus requires that the portion of the data bus used for a transfer to or from a particular port size be fixed. A 32-bit port resides on DATA[0:31], a 16-bit port must reside on DATA[0:15], and an 8-bit port must reside on DATA[0:7]. The MPC561/MPC563 always tries to transfer the maximum amount of data on all bus cycles. For a word operation, it always assumes that the port is 32 bits wide when beginning the bus cycle.

In [Figure 9-22](#), [Figure 9-23](#), [Table 9-2](#), and [Table 9-3](#), the following conventions are used:

- OP0 is the most-significant byte of a word operand and OP3 is the least-significant byte.
- The two bytes of a half-word operand are either OP0 (most-significant) and OP1 or OP2 (most-significant) and OP3, depending on the address of the access.
- The single byte of a byte-length operand is OP0, OP1, OP2, or OP3, depending on the address of the access.

**Figure 9-22. Internal Operand Representation**

Figure 9-23 illustrates the device connections on the data bus.

Figure 9-23. Interface To Different Port Size Devices

Table 9-2 lists the bytes required on the data bus for read cycles.

Table 9-2. Data Bus Requirements For Read Cycles

| Transfer Size | TSIZE [0:1] | Address      | 32-bit Port Size |             |              |              | 16-bit Port Size |             | 8-bit Port Size |
|---------------|-------------|--------------|------------------|-------------|--------------|--------------|------------------|-------------|-----------------|
|               |             | ADDR [30:31] | DATA [0:7]       | DATA [8:15] | DATA [16:23] | DATA [24:31] | DATA [0:7]       | DATA [8:15] | DATA [0:7]      |
| Byte          | 01          | 00           | OP0              | —           | —            | —            | OP0              | —           | OP0             |
|               | 01          | 01           | —                | OP1         | —            | —            | —                | OP1         | OP1             |
|               | 01          | 10           | —                | —           | OP2          | —            | OP2              | —           | OP2             |
|               | 01          | 11           | —                | —           | —            | OP3          | —                | OP3         | OP3             |
| Half-word     | 10          | 00           | OP0              | OP1         | —            | —            | OP0              | OP1         | OP0             |
|               | 10          | 10           | —                | —           | OP2          | OP3          | OP2              | OP3         | OP2             |
| Word          | 00          | 00           | OP0              | OP1         | OP2          | OP3          | OP0              | OP1         | OP0             |

**Note:** “—” denotes a byte not required during that read cycle.

Table 9-3 lists the patterns of the data transfer for write cycles when the MPC561/MPC563 initiates an access.

**Table 9-3. Data Bus Contents for Write Cycles**

| Transfer Size | TSIZE[0:1] | Address      | External Data Bus Pattern |             |              |              |
|---------------|------------|--------------|---------------------------|-------------|--------------|--------------|
|               |            | ADDR [30:31] | DATA [0:7]                | DATA [8:15] | DATA [16:23] | DATA [24:31] |
| Byte          | 01         | 00           | OP0                       | —           | —            | —            |
|               | 01         | 01           | OP1                       | OP1         | —            | —            |
|               | 01         | 10           | OP2                       | —           | OP2          | —            |
|               | 01         | 11           | OP3                       | OP3         | —            | OP3          |
| Half-word     | 10         | 00           | OP0                       | OP1         | —            | —            |
|               | 10         | 10           | OP2                       | OP3         | OP2          | OP3          |
| Word          | 00         | 00           | OP0                       | OP1         | OP2          | OP3          |

**Note:** “—” denotes a byte not driven during that write cycle.

## 9.5.7 Arbitration Phase

The external bus design provides for a single bus master at any one time, either the MPC561/MPC563 or an external device. One or more of the external devices on the bus can have the capability of becoming bus master for the external bus. Bus arbitration may be handled either by an external central bus arbiter or by the internal on-chip arbiter. In the latter case, the system is optimized for one external bus master besides the MPC561/MPC563. The arbitration configuration (external or internal) is set at system reset.

Each bus master must have bus request ( $\overline{BR}$ ), bus grant ( $\overline{BG}$ ), and bus busy ( $\overline{BB}$ ) signals. The device that needs the bus asserts  $\overline{BR}$ . The device then waits for the arbiter to assert  $\overline{BG}$ . In addition, the new master must look at  $\overline{BB}$  to ensure that no other master is driving the bus before it can assert  $\overline{BB}$  to assume ownership of the bus. Any time the arbiter has taken the bus grant away from the master and the master wants to execute a new cycle, the master must re-arbitrate before a new cycle can be executed. The MPC561/MPC563, however, guarantees data coherency for access to a small port size and for decomposed bursts. This means that the MPC561/MPC563 will not release the bus before the completion of the transactions that are considered atomic. Figure 9-24 describes the basic protocol for bus arbitration.

Figure 9-24. Bus Arbitration Flowchart

### 9.5.7.1 Bus Request

The potential bus master asserts  $\overline{BR}$  to request bus mastership.  $\overline{BR}$  should be negated as soon as the bus is granted, the bus is not busy, and the new master can drive the bus. If more requests are pending, the master can keep asserting its bus request as long as needed. When configured for external central arbitration, the MPC561/MPC563 drives this signal when it requires bus mastership. When the internal on-chip arbiter is used, this signal is an input to the internal arbiter and should be driven by the external bus master.

### 9.5.7.2 Bus Grant

The arbiter asserts  $\overline{BG}$  to indicate that the bus is granted to the requesting device. This signal can be negated following the negation of  $\overline{BR}$  or kept asserted for the current master to park the bus.

When configured for external central arbitration,  $\overline{BG}$  is an input signal to the MPC561/MPC563 from the external arbiter. When the internal on-chip arbiter is used, this signal is an output from the internal arbiter to the external bus master.

### 9.5.7.3 Bus Busy

$\overline{BB}$  assertion indicates that the current bus master is using the bus. New masters should not begin transfer until this signal is negated. The bus owner should not relinquish or negate this signal until the transfer is complete. To avoid contention on the  $\overline{BB}$  line, the master should three-state this signal when it gets a logical one value. This requires the connection of an external pull-up resistor to ensure that a master that acquires the bus is able to recognize the  $\overline{BB}$  line negated, regardless of how many cycles have passed since the previous master relinquished the bus. Refer to [Figure 9-25](#).

Figure 9-25. Master Signals Basic Connection

Figure 9-26. Bus Arbitration Timing Diagram

### 9.5.7.4 Internal Bus Arbiter

The MPC561/MPC563 can be configured at system reset to use the internal bus arbiter. In this case, the MPC561/MPC563 will be parked on the bus. The parking feature allows the MPC561/MPC563 to skip the bus request phase, and if BB is negated, assert BB and initiate the transaction without waiting for BG from the arbiter.

The priority of the external device relative to the internal MPC561/MPC563 bus masters is programmed in the SIU module configuration register. If the external device requests the bus and the MPC561/MPC563 does not require it, or if the external device has higher priority than the current internal bus master, the MPC561/MPC563 grants the bus to the external device.

Table 9-4 describes the priority mechanism used by the internal arbiter.

**Table 9-4. Priority Between Internal and External Masters over External Bus<sup>1</sup>**

| Type                       | Direction                    | Priority                            |
|----------------------------|------------------------------|-------------------------------------|
| Parked access <sup>2</sup> | Internal → external          | 0                                   |
| Instruction access         | Internal → external          | 3                                   |
| Data access                | Internal → external          | 4                                   |
| External access            | external → external/internal | EARP (could be programmed to 0 – 7) |

<sup>1</sup> External master will be granted external bus ownership if EARP is greater than the internal access priority.

<sup>2</sup> Parked access is instruction or data access from the RCPU which is initiated on the internal bus without requesting it first in order to improve performance.

Figure 9-27 illustrates the internal finite-state machine that implements the arbiter protocol.

**Figure 9-27. Internal Bus Arbitration State Machine**

## 9.5.8 Address Transfer Phase Signals

Address transfer phase signals include the following:

- Transfer start
- Address bus
- Transfer attributes

Transfer attributes signals include  $\overline{\text{RD}}/\overline{\text{WR}}$ ,  $\overline{\text{BURST}}$ ,  $\text{TSIZ}[0:1]$ ,  $\text{AT}[0:3]$ ,  $\overline{\text{STS}}$ , and  $\overline{\text{BDIP}}$ . With the exception of the  $\overline{\text{BDIP}}$ , these signals are available at the same time as the address bus.

### 9.5.8.1 Transfer Start

This signal ( $\overline{\text{TS}}$ ) indicates the beginning of a transaction on the bus addressing a slave device. This signal should be asserted by a master only after the ownership of the bus was granted by the arbitration protocol. This signal is asserted for the first cycle of the transaction only and is negated in successive clock cycles until the end of the transaction. The master should three-state this signal when it relinquishes the bus to avoid contention between two or more masters in this line. This situation indicates that an external pull-up resistor should be connected to the  $\overline{\text{TS}}$  signal to avoid having a slave recognize this signal as asserted when no master drives it. Refer to [Figure 9-25](#).

### 9.5.8.2 Address Bus

The address bus consists of 32 bits, with  $\text{ADDR0}$  the most significant bit and  $\text{ADDR31}$  the least significant bit. Only 24 bits ( $\text{ADDR}[8:31]$ ) are available external to the MPC561/MPC563. The bus is byte-addressable, so each address can address one or more bytes. The address and its attributes are driven on the bus with the transfer start signal and kept valid until the bus master receives the transfer acknowledge signal from the slave. To distinguish the individual byte, the slave device must observe the  $\text{TSIZ}$  signals.

### 9.5.8.3 Read/Write

A high value on the  $\overline{\text{RD}}/\overline{\text{WR}}$  line indicates a read access. A low value indicates a write access.

### 9.5.8.4 Burst Indicator

$\overline{\text{BURST}}$  is driven by the bus master at the beginning of the bus cycle along with the address to indicate that the transfer is a burst transfer.

The MPC561/MPC563 supports a non-wrapping, 8-beat maximum (with 32-bit port), critical word first burst type. The maximum burst size is 32 bytes. For a 16-bit port, the burst includes 16 beats. For an 8-bit port, the burst includes 32 beats at most.

#### NOTE

8- and 16-bit ports must be controlled by the memory controller.

The actual size of the burst is determined by the address of the starting word of the burst. Refer to [Table 9-5](#) and [Table 9-6](#).

**Table 9-5. 4 Word Burst Length and Order**

| Starting Address<br>ADDR[28:29] | Burst Order (Assuming<br>32-bit Port Size) | Burst Length in<br>Words (Beats) | Burst Length<br>in Bytes | Comments                                |
|---------------------------------|--------------------------------------------|----------------------------------|--------------------------|-----------------------------------------|
| 00                              | word 0 → word 1 →<br>word 2 → word 3       | 4                                | 16                       |                                         |
| 01                              | word 1 → word 2 → word 3                   | 3                                | 12                       |                                         |
| 10                              | word 2 → word 3                            | 2                                | 8                        |                                         |
| 11                              | word 3                                     | 1                                | 4                        | $\overline{\text{BDIP}}$ never asserted |

### 9.5.8.5 Transfer Size

The transfer size signals (TSIZ[0:1]) indicate the size of the requested data transfer. During each transfer, the TSIZ signals indicate how many bytes are remaining to be transferred by the transaction. The TSIZ signals can be used with  $\overline{\text{BURST}}$  and ADDR[30:31] to determine which byte lanes of the data bus are involved in the transfer. For non-burst transfers, the TSIZ signals specify the number of bytes starting from the byte location addressed by ADDR[30:31]. In burst transfers, the value of TSIZ is always 00.

**Table 9-6.  $\overline{\text{BURST}}$ /TSIZE Encoding**

| $\overline{\text{BURST}}$ | TSIZ[0:1] | Transfer Size          |
|---------------------------|-----------|------------------------|
| Negated                   | 01        | Byte                   |
| Negated                   | 10        | Half-word              |
| Negated                   | 11        | x                      |
| Negated                   | 00        | Word                   |
| Asserted                  | 00        | Burst (16 or 32 bytes) |

### 9.5.8.6 Address Types

The address type (AT[0:3]), program trace ( $\overline{\text{PTR}}$ ), and reservation transfer ( $\overline{\text{RSV}}$ ) signals are outputs that indicate one of 16 address types. These types are designated as either a normal or alternate master cycle, user or supervisor, and instruction or data type. The address type signals are valid at the rising edge of the clock in which the special transfer start ( $\overline{\text{STS}}$ ) signal is asserted.

A special use of the  $\overline{\text{PTR}}$  and  $\overline{\text{RSV}}$  signals is for the reservation protocol described in [Section 9.5.10, “Storage Reservation.”](#) Refer to [Section 9.5.14, “Show Cycle Transactions”](#) for information on show cycles.

[Table 9-7](#) summarizes the pins used to define the address type. [Table 9-8](#) lists all the definitions achieved by combining these pins.

Table 9-7. Address Type Pins

| Pin              | Function                                |
|------------------|-----------------------------------------|
| $\overline{STS}$ | 0 Special transfer<br>1 Normal transfer |
| $\overline{TS}$  | 0 Start of transfer<br>1 No transfer    |
| AT0              | Must equal zero on MPC561/MPC563        |
| AT1              | 0 Supervisor mode<br>1 User mode        |
| AT2              | 0 Instruction<br>1 Data                 |
| AT3              | Reservation/Program Trace               |
| $\overline{PTR}$ | 0 Program trace<br>1 No program trace   |
| $\overline{RSV}$ | 0 Reservation data<br>1 No reservation  |

Table 9-8. Address Types Definition

| $\overline{STS}$ | $\overline{TS}$ | AT0 | AT1 | AT2 | AT3 | $\overline{PTR}$ | $\overline{RSV}$ | Address Space Definitions                                            |
|------------------|-----------------|-----|-----|-----|-----|------------------|------------------|----------------------------------------------------------------------|
| 1                | x               | x   | x   | x   | x   | 1                | 1                | No transfer                                                          |
| 0                | 0 <sup>1</sup>  | 0   | 0   | 0   | 0   | 0                | 1                | RCPU, normal instruction, program trace, supervisor mode             |
|                  |                 |     |     |     | 1   | 1                | 1                | RCPU, normal instruction, supervisor mode                            |
|                  |                 |     |     | 1   | 0   | 1                | 0                | RCPU, reservation data, supervisor mode                              |
|                  |                 |     |     |     | 1   | 1                | 1                | RCPU, normal data, supervisor mode                                   |
|                  |                 |     | 1   | 0   | 0   | 0                | 1                | RCPU, normal instruction, program trace, user mode                   |
|                  |                 |     |     |     | 1   | 1                | 1                | RCPU, normal instruction, user mode                                  |
|                  |                 |     |     | 1   | 0   | 1                | 0                | RCPU, reservation data, user mode                                    |
|                  |                 |     |     |     | 1   | 1                | 1                | RCPU, normal data, user mode                                         |
|                  |                 | 1   | ?   | ?   | ?   | 1                | 1                | Reserved                                                             |
|                  | 1               | 0   | 0   | 0   | 0   | 0                | 1                | RCPU, show cycle address instruction, program trace, supervisor mode |
|                  |                 |     |     |     | 1   | 1                | 1                | RCPU, show cycle address instruction, supervisor mode                |
|                  |                 |     |     | 1   | 0   | 1                | 0                | RCPU, reservation show cycle data, supervisor mode                   |
|                  |                 |     |     |     | 1   | 1                | 1                | RCPU, show cycle data, supervisor mode                               |
|                  |                 |     | 1   | 0   | 0   | 0                | 1                | RCPU, show cycle address instruction, program trace, user mode       |
|                  |                 |     |     |     | 1   | 1                | 1                | RCPU, show cycle address instruction, user mode                      |
|                  |                 |     |     | 1   | 0   | 1                | 0                | RCPU, reservation show cycle data, user mode                         |
|                  |                 |     |     |     | 1   | 1                | 1                | RCPU, show cycle data, user mode                                     |
|                  |                 | 1   | ?   | ?   | ?   | 1                | 1                | Reserved                                                             |

<sup>1</sup> Cases in which both  $\overline{TS}$  and  $\overline{STS}$  are asserted indicate normal cycles with the show cycle attribute.

### 9.5.8.7 Burst Data in Progress

This signal is sent from the master to the slave to indicate that there is a data beat following the current data beat. The master uses this signal to give the slave advance warning of the remaining data in the burst.  $\overline{BDIP}$  can also be used to terminate the burst cycle early. Refer to [Section 9.5.4, “Burst Transfer”](#) and [Section 9.5.5, “Burst Mechanism”](#) for more information. Refer to [Section 10.9.3, “Memory Controller Base Registers \(BR0–BR3\)”](#) for memory controller BDIP options.

## 9.5.9 Termination Signals

The EBI uses three termination signals:

- Transfer acknowledge ( $\overline{TA}$ )
- Burst inhibit ( $\overline{BI}$ )
- Transfer error acknowledge ( $\overline{TEA}$ )

### 9.5.9.1 Transfer Acknowledge

Transfer acknowledge ( $\overline{TA}$ ) indicates normal completion of the bus transfer. During a burst cycle, the slave asserts this signal with every data beat returned or accepted.

### 9.5.9.2 Burst Inhibit

A slave sends the  $\overline{BI}$  signal to the master to indicate that the addressed device does not have burst capability. If this signal is asserted, the master must transfer in multiple cycles and increment the address for the slave to complete the burst transfer. For a system that does not use the burst mode at all, this signal can be tied low permanently. Refer to [Section 10.9.3, “Memory Controller Base Registers \(BR0–BR3\)”](#) for  $\overline{BI}$  options.

### 9.5.9.3 Transfer Error Acknowledge

The  $\overline{TEA}$  signal terminates a bus cycle under one or more bus error conditions. The current bus cycle must be aborted. This signal overrides any other cycle termination signals, such as transfer acknowledge.

### 9.5.9.4 Termination Signals Protocol

The transfer protocol was defined to avoid electrical contention on lines that can be driven by various sources. To this end, a slave must not drive signals associated with the data transfer until the address phase is completed and it recognizes the address as its own. The slave must disconnect from signals immediately after it has acknowledged the cycle and no later than the termination of the next address phase cycle. This means that the termination signals must be connected to power through a pull-up resistor to avoid the situation in which a master samples an undefined value in any of these signals when no real slave is addressed.

Refer to [Figure 9-28](#) and [Figure 9-29](#).

**Figure 9-28. Termination Signals Protocol Basic Connection**

**Figure 9-29. Termination Signals Protocol Timing Diagram**

## 9.5.10 Storage Reservation

Reservation occurs when a master loads data from memory. The memory location must not be overwritten until the master finishes processing the data and writing the results back to the reserved location. The MPC561/MPC563 storage reservation protocol supports a multi-level bus structure. For each local bus, storage reservation is handled by the local reservation logic.

The protocol tries to optimize reservation cancellation such that an MPC500 processor is notified of storage reservation loss on a remote bus only when it has issued a conditional storeword (stwcx) cycle to that address. That is, the reservation loss indication comes as part of the stwcx cycle. This method avoids the need to have very fast storage reservation loss indication signals routed from every remote bus to every MPC500 master.

The storage reservation protocol makes the following assumptions:

- Each processor has, at most, one reservation flag
- lwarx sets the reservation flag
- lwarx by the same processor clears the reservation flag related to a previous lwarx instruction and again sets the reservation flag
- stwcx by the same processor clears the reservation flag
- Store by the same processor does not clear the reservation flag
- Some other processor (or other mechanism) store to the same address as an existing reservation clears the reservation flag
- In case the storage reservation is lost, it is guaranteed that stwcx will not modify the storage

The reservation protocol for a single-level (local) bus is illustrated in [Figure 9-30](#). The protocol assumes that an external logic on the bus carries out the following functions:

- Snoops accesses to all local bus slaves
- Holds one reservation for each local master capable of storage reservations
- Sets the reservation when that master issues a load and reserve request
- Clears the reservation when some other master issues a store to the reservation address

**Figure 9-30. Reservation on Local Bus**

The MPC561/MPC563 samples the  $\overline{CR}$  line at the rising edge of CLKOUT. When this signal is asserted, the reservation flag is reset (negated).

The external bus interface (EBI) samples the logical value of the reservation flag prior to externally starting a bus cycle initiated by the RCPU stwxc instruction. If the reservation flag is set, the EBI begins with the bus cycle. If the reservation flag is reset, no bus cycle is initiated externally, and this situation is reported to the RCPU.

The reservation protocol for a multi-level (local) bus is illustrated in [Figure 9-31](#). The system describes the situation in which the reserved location is sited in the remote bus.

**Figure 9-31. Reservation on Multi-level Bus Hierarchy**

In this case, the bus interface block implements a reservation flag for the local bus master. The reservation flag is set by the bus interface when a load with reservation is issued by the local bus master and the reservation address is located on the remote bus. The flag is reset (negated) when an alternative master on the remote bus accesses the same location in a write cycle. If the MPC561/MPC563 begins a memory cycle to the previously reserved address (located in the remote bus) as a result of an stwcx instruction, the following two cases can occur:

- If the reservation flag is set, the buses interface acknowledges the cycle in a normal way
- If the reservation flag is reset, the bus interface should assert the  $\overline{KR}$ . However, the bus interface should not perform the remote bus write-access or abort it if the remote bus supports aborted cycles. In this case the failure of the stwcx instruction is reported to the RCPU.

## 9.5.11 Bus Exception Control Cycles

The MPC561/MPC563 bus architecture requires assertion of  $\overline{TA}$  from an external device to signal that the bus cycle is complete.  $\overline{TA}$  is not asserted in the following cases:

- The external device does not respond
- Various other application-dependent errors occur

External circuitry can provide  $\overline{TEA}$  when no device responds by asserting  $\overline{TA}$  within an appropriate period of time after the MPC561/MPC563 initiates the bus cycle (it can be the internal bus monitor). This allows the cycle to terminate and the processor to enter exception-processing for the error condition (each one of the internal masters causes an internal interrupt under this situation). To properly control termination of a bus cycle for a bus error,  $\overline{TEA}$  must be asserted at the same time or before  $\overline{TA}$  is asserted.  $\overline{TEA}$  should be negated before the second rising edge after it was sampled as asserted to avoid the detection of an error for the next initiated bus cycle.  $\overline{TEA}$  is an open drain pin that allows the “wired-or” of any different sources of error generation.

### 9.5.11.1 Retrying a Bus Cycle

When an external device asserts the  $\overline{RETRY}$  signal during a bus cycle, the MPC561/MPC563 enters a sequence in which it terminates the current transaction, relinquishes the ownership of the bus, and retries the cycle using the same address, address attributes, and data (in the case of a write cycle).

Figure 9-32 illustrates the behavior of the MPC561/MPC563 when the  $\overline{RETRY}$  signal is detected as a termination of a transfer. As seen in this figure, in the case when the internal arbiter is enabled, the MPC561/MPC563 negates  $\overline{BB}$  and asserts  $\overline{BG}$  in the clock cycle following the retry detection. This allows any external master to gain bus ownership. In the next clock cycle, a normal arbitration procedure occurs again. As shown in the figure, the external master did not use the bus, so the MPC561/MPC563 initiates a new transfer with the same address and attributes as before.

In Figure 9-33, the same situation is shown except that the MPC561/MPC563 is working with an external arbiter. In this case, in the clock cycle after the  $\overline{RETRY}$  signal is detected asserted,  $\overline{BR}$  is negated together with  $\overline{BB}$ . One clock cycle later, the normal arbitration procedure occurs again.

**Figure 9-33. Retry Transfer Timing – External Arbiter**

When the MPC561/MPC563 initiates a burst access, the bus interface recognizes the  $\overline{\text{RETRY}}$  assertion as a retry termination only if it detects it before the first data beat was acknowledged by the slave device. When the  $\overline{\text{RETRY}}$  signal is asserted as a termination signal on any data beat of the access after the first (being the first data beat acknowledged by a normal  $\overline{\text{TA}}$  assertion), the MPC561/MPC563 recognizes  $\overline{\text{RETRY}}$  as a transfer error acknowledge.

**Figure 9-34. Retry on Burst Cycle**

If a burst access is acknowledged on its first beat with a normal  $\overline{TA}$  but with the  $\overline{BI}$  signal asserted, the following single-beat transfers initiated by the MPC561/MPC563 to complete the 16-byte transfer recognizes the  $\overline{RETRY}$  signal assertion as a transfer error acknowledge.

In the case in which a small port size causes the MPC561/MPC563 to break a bus transaction into several small transactions, terminating any transaction with  $\overline{RETRY}$  causes a transfer error acknowledge. See [Section 9.5.2.3, “Single Beat Flow with Small Port Size.”](#)

### 9.5.11.2 Termination Signals Protocol Summary

Table 9-9 summarizes how the MPC561/MPC563 recognizes the termination signals provided by the slave device that is addressed by the initiated transfer.

**Table 9-9. Termination Signals Protocol**

| $\overline{\text{TEA}}$ | $\overline{\text{TA}}$ | $\overline{\text{RETRY}}$ | Action                      |
|-------------------------|------------------------|---------------------------|-----------------------------|
| Asserted                | X                      | X                         | Transfer error termination  |
| Negated                 | Asserted               | X                         | Normal transfer termination |
| Negated                 | Negated                | Asserted                  | Retry transfer termination  |

### 9.5.12 Bus Operation in External Master Modes

When an external master takes ownership of the external bus and the MPC561/MPC563 is programmed for external master mode operation, the external master can access the internal space of the MPC561/MPC563 (see [Section 6.1.2, “External Master Modes”](#)). In external master mode, the external master owns the bus, and the direction of most of the bus signals is inverted, relative to its direction when the MPC561/MPC563 owns the bus.

The external master gets ownership of the bus and asserts  $\overline{\text{TS}}$  in order to initiate an external master access. The access is directed to the internal bus only if the input address matches the internal address space. The access is terminated with one of the following outputs:  $\overline{\text{TA}}$ ,  $\overline{\text{TEA}}$ , or  $\overline{\text{RETRY}}$ . If the access completes successfully, the MPC561/MPC563 asserts  $\overline{\text{TA}}$ , and the external master can proceed with another external master access or relinquish the bus. If an address or data error is detected internally, the MPC561/MPC563 asserts  $\overline{\text{TEA}}$  for one clock.  $\overline{\text{TEA}}$  should be negated before the second rising edge after it is sampled asserted in order to avoid the detection of an error for the next bus cycle initiated.  $\overline{\text{TEA}}$  is an open drain pin, and the negation timing depends on the attached pull-up. The MPC561/MPC563 asserts the  $\overline{\text{RETRY}}$  signal for one clock in order to retry the external master access.

If the address of the external access does not match the internal memory space, the internal memory controller can provide the chip-select and control signals for accesses that belong to one of the memory controller regions. This feature is explained in [Chapter 10, “Memory Controller.”](#)

[Figure 9-35](#) and [Figure 9-36](#) illustrate the basic flow of read and write external master accesses.

Figure 9-35. Basic Flow of an External Master Read Access

**Figure 9-36. Basic Flow of an External Master Write Access**

Figure 9-37, Figure 9-38, and Figure 9-39 describe read and write cycles from an external master accessing internal space in the MPC561/MPC563.

### NOTE

The minimum number of wait states for such access is two clocks. The accesses in these figures are valid for both peripheral mode and slave mode.

Figure 9-37. Peripheral Mode: External Master Reads from MPC561/MPC563 (Two Wait States)

Figure 9-38. Peripheral Mode: External Master Writes to MPC561/MPC563 (Two Wait States)

### 9.5.13 Contention Resolution on External Bus

When the MPC561/MPC563 is in slave mode, external master access to the MPC561/MPC563 internal bus can be terminated with relinquish and retry in order to allow a pending internal-to-external access to be executed. The  $\overline{RETRY}$  signal functions as an output that signals the external master to release the bus ownership and retry the access after one clock.

Figure 9-39 describes the flow of an external master retried access. Figure 9-40 shows the timing when an external access is retried and a pending internal-to-external access follows.

Figure 9-39. Flow of Retry of External Master Read Access

**Note:** the delay for the internal to external cycle may be one clock or greater.

**Figure 9-40. Retry of External Master Access (Internal Arbiter)**

## 9.5.14 Show Cycle Transactions

Show cycles are representations of RCPU accesses to internal devices of the MPC561/MPC563. These accesses are driven externally for emulation, visibility, and debugging purposes. A show cycle can have one address phase and one data phase, or just an address phase in the case of instruction show cycles. The cycle can be a write or a read access. The data for both the read and write accesses should be driven by the bus master. (This is different from normal bus read and write accesses.) The address and data of the show cycle must each be valid on the bus for one clock. The data phase must not require a transfer acknowledge to terminate the bus show cycle.

Show cycles are activated by properly setting the SIUMCR register bits. Refer to [Section 6.2.2.1.1, “SIU Module Configuration Register \(SIUMCR\)”](#). Construction visibility is controlled by the ISCT\_SER bits in the ICTRL register. Refer to [Table 23-26](#). Data visibility is controlled by the LSHOW bits of the L2U\_MCR register. Refer to [Table 11-7](#).

In a burst show cycle only the first data beat is shown externally. Refer to [Table 9-8](#) for show cycle transaction encodings.

Instruction show cycle bus transactions have the following characteristics (see [Figure 9-41](#)):

- One clock cycle
- Address phase only; in decompression on mode part of the compressed address is driven on data lines together with address lines. The external bus interface adds one clock delay between a read cycle and such show cycle.
- $\overline{STS}$  assertion only (no  $\overline{TA}$  assertion)

The compressed address is driven on the external bus in the following manner:

- ADDR[0:29] = the word base address;
- DATA[0] = operating mode:
  - 0 = decompression off mode;
  - 1 = decompression on mode;
- DATA[1:4] = bit pointer

See [Chapter 4, “Burst Buffer Controller 2 Module”](#) and [Appendix A, “MPC562/MPC564 Compression Features”](#) for more details about decompression mode.

**Figure 9-41. Instruction Show Cycle Transaction**

Both read and write data show cycles have the following characteristics: (see [Figure 9-42](#))

- Two clock cycle duration
- Address valid for two clock cycles
- Data is valid only in the second clock cycle
- $\overline{STS}$  signal only is asserted (no  $\overline{TA}$  or  $\overline{TS}$ )

Figure 9-42. Data Show Cycle Transaction

## Chapter 10

### Memory Controller

The memory controller generates interface signals to support a glueless interface to external memory and peripheral devices. It supports four regions, each with its own programmed attributes. The four regions are controlled by four chip-select signals. Read and write strobes are also provided.

The memory controller operates in parallel with the external bus interface to support external cycles. When an access to one of the memory regions is initiated, the memory controller takes ownership of the external signals and controls the access until its termination. Refer to [Figure 10-1](#).

**Figure 10-1. Memory Controller Function within the USIU**

### 10.1 Overview

The memory controller provides a glueless interface to external EPROM, static RAM (SRAM), Flash (EEPROM), and other peripherals. The general-purpose chip-selects are available on lines  $\overline{CS0}$  through  $\overline{CS3}$ .  $\overline{CS0}$  also functions as the global (boot) chip-select for accessing the boot Flash EEPROM. The chip select allows zero to 30 wait states.

[Figure 10-2](#) is a block diagram of the MPC561/MPC563 memory controller.

**Figure 10-2. Memory Controller Block Diagram**

Most memory controller features are common to all four banks. (For features unique to the  $\overline{CS0}$  bank, refer to [Section 10.7, “Global \(Boot\) Chip-Select Operation.”](#)) A full 32-bit address decode for each memory bank is possible with 17 bits having address masking. The full 32-bit decode is available, even if all 32 address bits are not MPC561/MPC563 signals connected to the external device.

Each memory bank includes a variable block size of 32 Kbytes, 64 Kbytes and up to four Gbytes. Each memory bank can be selected for read-only or read/write operation. The access to a memory bank can be restricted to certain address type codes for system protection. The address type comparison occurs with a mask option as well.

From 0 to 30 wait states can be programmed with  $\overline{TA}$  generation. Four write-enable and byte-enable signals ( $\overline{WE/BE}[0:3]$ ) are available for each byte that is written to memory. An output enable ( $\overline{OE}$ ) signal is provided to eliminate external glue logic. A memory transfer start ( $\overline{MTS}$ ) strobe permits one master on a bus to access external memory through the chip selects on another.

The memory controller functionality allows MPC561/MPC563-based systems to be built with little or no glue logic. A minimal system using no glue logic is shown in [Figure 10-3](#). In this example  $\overline{CS0}$  is used for

a 16-bit boot EPROM and  $\overline{\text{CS1}}$  is used for a 32-bit SRAM. The  $\overline{\text{WE}}/\overline{\text{BE}}[0:3]$  signals are used both to program the EPROM and to enable write access to various bytes in the RAM.

Figure 10-3. MPC561/MPC563 Simple System Configuration

## 10.2 Memory Controller Architecture

The memory controller consists of a basic machine that handles the memory access cycle: the general-purpose chip-select machine (GPCM).

When any of the internal masters request a new access to external memory, the address of the transfer (with 17 bits having a mask) and the address type (with three bits having a mask) are compared to each one of the valid banks defined in the memory controller. Refer to [Figure 10-4](#).

**Figure 10-4. Bank Base Address and Match Structure**

When a match is found on one of the memory banks, its attributes are selected for the functional operation of the external memory access:

- Read-only or read/write operations
- Number of wait states for a single memory access, and for any beat in a burst access
- Burst-inhibit indication. Internal burst requests are still possible during burst-inhibited cycles; the memory controller emulates the burst cycles
- Port size of the external device

Note that if more than one region matches the internal address supplied, then the lowest numbered region is selected to provide the attributes and the chip select. If the dual mapping region is matched, it has the highest priority (refer to [Section 10.5, “Dual Mapping of the Internal Flash EEPROM Array”](#)).

### 10.2.1 Associated Registers

Status bits for each memory bank are found in the memory control status register (MSTAT). The MSTAT reports write-protect violations for all the banks.

Each of the four memory banks has a base register (BR) and an option register (OR). The BR<sub>x</sub> and OR<sub>x</sub> registers contain the attributes specific to memory bank x. The base register contains a valid bit (V) that indicates the register information for that particular chip select is valid.

### 10.2.2 Port Size Configuration

The memory controller supports dynamic bus sizing. Defined 8-bit ports can be accessed as odd or even bytes. Defined 16-bit ports, when connected to data bus lines zero to 15, can be accessed as odd bytes, even bytes, or even half-words. Defined 32-bit ports can be accessed as odd bytes, even bytes, odd half-words, even half-words, or words on word boundaries. The port size is specified by the PS bits in the base register.

### 10.2.3 Write-Protect Configuration

The WP bit in each base register can restrict write access to its range of addresses. Any attempt to write this area results in the associated WPER bit being set in the MSTAT.

If an attempt to access an external device results in a write-protect violation, the memory controller considers the access to be no match. No chip-select line is asserted externally, and the memory controller does not terminate the cycle. The external bus interface generates a normal cycle on the external bus. Since the memory controller does not acknowledge the cycle internally, the cycle may be terminated by external logic asserting  $\overline{TA}$  or by the on-chip bus monitor asserting  $\overline{TEA}$ .

### 10.2.4 Address and Address Space Checking

The base address is written to the BRx. The address mask bits for the address are written to the OR. The address type access value, if desired, is written to the AT bits in the BRx. The ATM bits in the ORx can be used to mask this value. If address type checking is not desired, program the ATM bits to zero.

Each time an external bus cycle access is requested, the address and address type are compared with each one of the banks. If a match is found, the attributes defined for this bank in its BRx and ORx are used to control the memory access. If a match is found in more than one bank, the lowest bank matched handles the memory access (e.g., bank zero is selected over bank one).

#### NOTE

When an external master accesses a slave on the bus, the internal AT[0:2] lines reaching the memory controller are forced to 100.

### 10.2.5 Burst Support

The memory controller supports burst accesses of external burstable memory. To enable bursts, clear the burst inhibit ( $\overline{BI}$ ) bit in the appropriate base register. Burst support is for read only.

Bursts can be four or eight beats depending on the value of the BURST\_EN bit in the SIUMCR register and the BL bit in the BRx register. That is, the memory controller executes up to eight one-word accesses, but when a modulo eight limit is reached, the burst is terminated (even if fewer than eight words have been accessed).

When the SIU initiates a burst access, if no match is found in any of the memory controller's regions then a burst access is initiated to the external bus. The termination of each beat for this access is externally controlled.

To support different types of memory devices, the memory controller supports two types of timing for the BDIP signal: normal and late.

#### NOTE

The  $\overline{BDIP}$  signal itself is controlled by the external bus interface logic. Refer to [Figure 9-13](#) and [Figure 9-14](#) in [Chapter 9, "External Bus Interface."](#)

If the memory controller is used to support an external master accessing an external device with bursts, the  $\overline{BDIP}$  input signal is used to indicate to the memory controller when the burst is terminated.

For addition details, refer to [Section 9.5.4, “Burst Transfer.”](#)

### 10.2.6 Reduced Data Setup Time

In order to meet timing requirements when interfacing to external memories, the data setup time can be reduced. This mode can be selected by programming the BRx registers. Thus there is flexibility in how each region can be configured to operate. The operation mode will be determined dynamically according to a particular access type. This means that for a memory region with the reduced setup time mode enabled, the mode will automatically switch to disabled when there is no requirement for the reduced setup time, (e.g., a back-to-back load/store access). For a new access with burst length more than 1, the operation mode will be automatically switched back to the reduced setup time mode.

Reduced setup time can be selected via the SST bit in BR[0:3]. See [Section 10.9.3, “Memory Controller Base Registers \(BR0–BR3\)”](#) for more details. If SCCR[EBDF] is greater than 0, however, an external burst access with reduced data setup time will corrupt a load/store to any USIU register.

The reduced setup time mode may or may not have a performance impact, depending on the properties of the memory. Namely, there is always an additional empty cycle between two burst sequences. On the other hand, this additional cycle, under certain conditions, may be compensated for by reducing the number of cycles in initial data access and sequential burst beats.

**Table 10-1. Timing Requirements for Reduced Setup Time**

| CPU Specification                                                                             | Memory Device Requirements  |
|-----------------------------------------------------------------------------------------------|-----------------------------|
| Cycle time at 56 MHz = 17.9 ns                                                                | Initial access time = 49 ns |
| Short setup time = 3 ns                                                                       | Burst access time = 13 ns   |
| Normal setup time = 6 ns                                                                      |                             |
| Additional delay arising from on-board wires and clock skew between internal clock and CLKOUT |                             |

#### 10.2.6.1 Case 1: Normal Setup Time

Initial access:

$$\text{Initial access time of memory} + \text{Data setup time of CPU} + \text{Delays} = 49 + 6 + 1 = 56\text{ns}$$

To derive the number of clocks required, divide by the system clock cycle time:

$$\frac{56}{17.9} = 3.13 \quad \text{therefore 4 cycles are required}$$

Burst access:

$$\text{Burst access time of memory} + \text{Data setup time of CPU} + \text{Delays} = 13 + 6 + 1 = 20\text{ns}$$

$$\text{The number of clocks required} = \frac{20}{17.9} = 1.11 \quad \text{therefore 2 clocks are required.}$$

This case is illustrated in [Figure 10-5](#).

### 10.2.6.2 Case 2: Short Setup Time

Initial access:

Enabling short setup time requires one clock cycle:

$$\text{Initial access time of memory} + \text{Data setup time of CPU} + \text{Delays} = 49 + 3 + 1 = 53\text{ns}$$

The number of clocks required =  $\frac{53}{17.9} = 2.96 + 1 (\text{SST Enable Clock}) = 3.96$  therefore 4 clocks are required.

Burst access:

$$\text{Burst access time of memory} + \text{Data setup time of CPU} + \text{Delays} = 13 + 3 + 1 = 17\text{ns}$$

The number of clocks required =  $\frac{17}{17.9} = 0.95$  therefore 1 clock is required.

This case is illustrated in [Figure 10-6](#).

### 10.2.6.3 Summary of Short Setup Time

With normal setup time and a 4-beat burst, a 4-2-2-2 burst cycle is required which is reduced to a 4-1-1-1 burst cycle with a short setup time. Short setup time creates a saving of three clock cycles with a 4-beat burst and can result in even better performance with an 8-beat burst, saving seven clock cycles.

Figure 10-5. A 4-2-2-2 Burst Read Cycle (One Wait State Between Bursts)

**Figure 10-6. 4 Beat Burst Read with Short Setup Time (Zero Wait State)**

## NOTE

An extra clock cycle is required to enable short set-up time, resulting in a 4-1-1-1 cycle.

### 10.3 Chip-Select Timing

The general-purpose chip-select machine (GPCM) allows a glueless and flexible interface between the MPC561/MPC563 and external SRAM, EPROM, EEPROM, ROM peripherals. When an address and

address type match the values programmed in the BR and OR for one of the memory controller banks, the attributes for the memory cycle are taken from the OR and BR registers. These attributes include the following fields: CSNT, ACS, SCY, BSCY, WP, TRLX, BI, PS, and SETA. [Table 10-2](#) summarizes the chip-select timing options.

Byte write and read-enable signals ( $\overline{WE}/\overline{BE}[0:3]$ ) are available for each byte that is written to or read from memory. An output enable ( $\overline{OE}$ ) signal is provided to eliminate external glue logic for read cycles. Upon system reset, a global (boot) chip select is available. (Refer to [Section 10.7, “Global \(Boot\) Chip-Select Operation”](#) for more information on the global chip select.) This provides a boot ROM chip select before the system is fully configured.

**Table 10-2. Timing Attributes Summary**

| Timing Attribute                   | Bits/Fields           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|------------------------------------|-----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Access speed                       | TRLX                  | The TRLX (timing relaxed) bit determines strobe timing to be fast or relaxed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Intercycle space time              | EHTR                  | The EHTR (extended hold time on read accesses) bit is provided for devices that have long disconnect times from the data bus on read accesses. EHTR specifies whether the next cycle is delayed one clock cycle following a read cycle, to avoid data bus contentions. EHTR applies to all cycles following a read cycle except for another read cycle to the same region.                                                                                                                                                                                                          |
| Synchronous or asynchronous device | ACS, CSNT             | The ACS (address-to-chip-select setup) and CSNT (chip-select negation time) bits cause the timing of the strobes to be the same as the address bus timing, or cause the strobes to have setup and hold times relative to the address bus.                                                                                                                                                                                                                                                                                                                                           |
| Wait states                        | SCY, BSCY, SETA, TRLX | From zero to 15 wait states can be programmed for any cycle that the memory controller generates. The transfer is then terminated internally. In simplest case, the cycle length equals $(2 + \text{SCY})$ clock cycles, where SCY represents the programmed number of wait states (cycle length in clocks). The number of wait states is doubled if the TRLX bit is set $(2 + (\text{SCY} \times 2))$ .<br>When the SETA (external transfer acknowledge) bit is set, $\overline{TA}$ must be generated externally, so that external hardware determines the number of wait states. |

### NOTE

When a bank is configured for  $\overline{TA}$  to be generated externally (SETA bit is set) and the TRLX is set, the memory controller requires the external device to provide at least one wait state before asserting  $\overline{TA}$  to complete the transfer. In this case, the minimum transfer time is three clock cycles.

The internal  $\overline{TA}$  generation mode is enabled if the SETA bit in the OR register is cleared. However, if the  $\overline{TA}$  signal is asserted externally at least two clock cycles before the wait states counter has expired, this assertion terminates the memory cycle. When SETA is cleared, it is forbidden to assert external  $\overline{TA}$  less than two clocks before the wait states counter expires.

### 10.3.1 Memory Devices Interface Example

Figure 10-7 describes the basic connection between the MPC561/MPC563 and a static memory device. In this case  $\overline{CS}_x$  is connected directly to the chip enable ( $\overline{CE}$ ) of the memory device. The  $\overline{WE}/\overline{BE}[0:3]$  lines are connected to the respective  $\overline{WE}$  in the memory device where each  $\overline{WE}/\overline{BE}$  line corresponds to a different data byte.

Figure 10-7. GPCM-Memory Devices Interface

In Figure 10-8, the  $\overline{CS}_x$  timing is the same as that of the address lines output. The strobes for the transaction are supplied by the  $\overline{OE}$  and the  $\overline{WE}/\overline{BE}$  lines (if programmed as  $\overline{WE}/\overline{BE}$ ). When the ACS bits in the corresponding ORx register = 00,  $\overline{CS}$  is asserted at the same time that the address lines are valid.

**NOTE**

If CSNT is set, the  $\overline{WE}$  signal is negated a quarter of a clock earlier than normal.

**Note:** In this and subsequent timing diagrams in this section, the data bus refers to a read cycle. In a write cycle, the data immediately follows  $\overline{TS}$ .

**Figure 10-8. Memory Devices Interface Basic Timing (ACS = 00, TRLX = 0)**

### 10.3.2 Peripheral Devices Interface Example

Figure 10-9 illustrates the basic connection between the MPC561/MPC563 and an external peripheral device. In this case  $\overline{CSx}$  is connected directly to the chip enable ( $\overline{CE}$ ) of the memory device and the  $R/\overline{W}$  line is connected to the  $R/\overline{W}$  in the peripheral device. The  $\overline{CSx}$  line is the strobe output for the memory access.

**Figure 10-9. Peripheral Devices Interface**

The  $\overline{CS}_x$  timing is defined by the setup time required between the address lines and the  $\overline{CE}$  line. The memory controller allows specification of the  $\overline{CS}$  timing to meet the setup time required by the peripheral device. This is accomplished through the ACS field in the base register. In Figure 10-10, the ACS bits are set to 0b11, so  $\overline{CS}_x$  is asserted half a clock cycle after the address lines are valid.

Figure 10-10. Peripheral Devices Basic Timing (ACS = 11, TRLX = 0)

### 10.3.3 Relaxed Timing Examples

The TRLX field is provided for memory systems that need a more relaxed timing between signals. When TRLX is set and ACS = 0b00, the memory controller inserts an additional cycle between address and strobes ( $\overline{CS}$  line and  $\overline{WE}/\overline{OE}$ ).

When TRLX and CSNT are both set in a write to memory, the strobe lines ( $\overline{WE}/\overline{BE}[0:3]$  and  $\overline{CS}$ , if ACS = 0b00) are negated one clock earlier than in the regular case.

#### NOTE

In the case of a bank selected to work with external transfer acknowledge (SETA = 1) and TRLX = 1, the memory controller does not support external devices that provide  $\overline{TA}$  to complete the transfer with zero wait states. The minimum access duration in this case equals three clock cycles.

Figure 10-11 shows a read access with relaxed timing. Note the following:

- Strobes ( $\overline{OE}$  and  $\overline{CS}$ ) assertion time is delayed one clock relative to address (TRLX bit set effect).
- Strobe ( $\overline{CS}$ ) is further delayed (half-clock) relative to address due to ACS field being set to 11.

- Total cycle length = 5, is determined as follows:
  - Two clocks for basic cycle
  - $SCY = 1$  determines 1 wait state, which is multiplied by two due to  $TRLX$  being set ( $2 + (SCY \times 2)$ ).
  - Extra clock is added due to  $TRLX$  effect on the strobes.

**Figure 10-11. Relaxed Timing — Read Access ( $ACS = 11$ ,  $SCY = 1$ ,  $TRLX = 1$ )**

Figure 10-12 through Figure 10-14 are examples of write accesses using relaxed timing. In Figure 10-12, note the following points:

- Because  $TRLX$  is set, assertion of the  $\overline{CS}$  and  $\overline{WE}$  strobes is delayed by one clock cycle.
- $\overline{CS}$  assertion is delayed an additional one quarter clock cycle because  $ACS = 10$ .
- The total cycle length = three clock cycles, determined as follows:
  - The basic memory cycle requires two clock cycles.
  - An extra clock cycle is required due to the effect of  $TRLX$  on the strobes.

**Figure 10-12. Relaxed Timing — Write Access (ACS = 10, SCY = 0, CSNT = 0, TRLX = 1)**

In [Figure 10-13](#), note the following:

- Because the TRLX bit is set, the assertion of the  $\overline{CS}$  and  $\overline{WE}$  strobes is delayed by one clock cycle.
- Because ACS = 11, the assertion of  $\overline{CS}$  is delayed an additional half clock cycle.
- Because CSNT = 1,  $\overline{WE}$  is negated one clock cycle earlier than normal. (Refer to [Figure 10-8](#).) The total cycle length is four clock cycles, determined as follows:
  - The basic memory cycle requires two clock cycles.
  - Two extra clock cycles are required due to the effect of TRLX on the assertion and negation of the  $\overline{CS}$  and  $\overline{WE}$  strobes.

**Figure 10-13. Relaxed Timing — Write Access (ACS = 11, SCY = 0, CSNT = 1, TRLX = 1)**

In [Figure 10-14](#), notice the following:

- Because ACS = 0, TRLX being set does not delay the assertion of the  $\overline{CS}$  and  $\overline{WE}$  strobes.
- Because CSNT = 1,  $\overline{WE/BE}$  is negated one clock cycle earlier than normal. (Refer to [Figure 10-8](#)).
- $\overline{CS}$  is not negated one clock cycle earlier, since ACS = 00.
- The total cycle length is three clock cycles, determined as follows:
  - The basic memory cycle requires two clock cycles.
  - One extra clock cycle is required due to the effect of TRLX on the negation of the  $\overline{WE/BE}$  strobes.

Figure 10-14. Relaxed Timing — Write Access (ACS = 00, SCY = 0, CSNT = 1, TRLX = 1)

### 10.3.4 Extended Hold Time on Read Accesses

For devices that require a long disconnection time from the data bus on read accesses, the bit EHTR in the corresponding OR register can be set. In this case any MPC561/MPC563 access to the external bus following a read access to the referred memory bank is delayed by one clock cycle unless it is a read access to the same bank. Figure 10-15 through Figure 10-18 show the effect of the EHTR bit on memory controller timing.

Figure 10-15 shows a write access following a read access. Because EHTR = 0, no extra clock cycle is inserted between memory cycles.

**Figure 10-15. Consecutive Accesses (Write After Read, EHTR = 0)**

Figure 10-16 shows a write access following a read access when EHTR = 1. An extra clock is inserted between the cycles. For a write cycle following a read, this is true regardless of whether both accesses are to the same region.

**Figure 10-16. Consecutive Accesses (Write After Read, EHTR = 1)**

Figure 10-17 shows consecutive accesses from different banks. Because EHTR = 1 (and the accesses are to different banks), an extra clock cycle is inserted.

**Figure 10-17. Consecutive Accesses**  
(Read After Read From Different Banks, EHTR = 1)

Figure 10-18 shows two consecutive read cycles from the same bank. Even though EHTR = 1, no extra clock cycle is inserted between the memory cycles. (In the case of two consecutive read cycles to the same region, data contention is not a concern.)

Figure 10-18. Consecutive Accesses (Read After Read from Same Bank, EHTR = 1)

### 10.3.5 Summary of GPCM Timing Options

Table 10-3 summarizes the different combinations of timing options.

Table 10-3. Programming Rules for Timing Strokes

| TRLX | Access Type | ACS | CSNT | Address to CS Asserted | $\overline{CS}$ Negated to Add/Data Invalid | Address to $\overline{WE}/\overline{BE}$ or $\overline{OE}$ Asserted | $\overline{WE}/\overline{BE}$ Negated to Add/Data Invalid | $\overline{OE}$ Negated to Add/Data Invalid | Total Number of Cycles |
|------|-------------|-----|------|------------------------|---------------------------------------------|----------------------------------------------------------------------|-----------------------------------------------------------|---------------------------------------------|------------------------|
| 0    | read        | 00  | X    | 0                      | 1/4 * clock                                 | 3/4 * clock                                                          | X                                                         | 1/4 * clock                                 | 2 + SCY                |
| 0    | read        | 10  | X    | 1/4 * clock            | 1/4 * clock                                 | 3/4 * clock                                                          | X                                                         | 1/4 * clock                                 | 2 + SCY                |
| 0    | read        | 11  | X    | 1/2 * clock            | 1/4 * clock                                 | 3/4 * clock                                                          | X                                                         | 1/4 * clock                                 | 2 + SCY                |
| 0    | write       | 00  | 0    | 0                      | 1/4 * clock                                 | 3/4 * clock                                                          | 1/4 * clock                                               | X                                           | 2 + SCY                |
| 0    | write       | 10  | 0    | 1/4 * clock            | 1/4 * clock                                 | 3/4 * clock                                                          | 1/4 * clock                                               | X                                           | 2 + SCY                |
| 0    | write       | 11  | 0    | 1/2 * clock            | 1/4 * clock                                 | 3/4 * clock                                                          | 1/4 * clock                                               | X                                           | 2 + SCY                |
| 0    | write       | 00  | 1    | 0                      | 1/4 * clock                                 | 3/4 * clock                                                          | 1/2 * clock                                               | X                                           | 2 + SCY                |
| 0    | write       | 10  | 1    | 1/4 * clock            | 1/2 * clock                                 | 3/4 * clock                                                          | 1/2 * clock                                               | X                                           | 2 + SCY                |

Table 10-3. Programming Rules for Timing Strokes (continued)

| TRLX | Access Type | ACS | CSNT | Address to CS Asserted     | $\overline{\text{CS}}$ Negated to Add/Data Invalid | Address to $\overline{\text{WE/BE}}$ or $\overline{\text{OE}}$ Asserted | $\overline{\text{WE/BE}}$ Negated to Add/Data Invalid | $\overline{\text{OE}}$ Negated to Add/Data Invalid | Total Number of Cycles |

| 1    | write       | 10  | 1    | $(1 + 1/4) * \text{clock}$ | $(1 + 1/2) * \text{clock}$                         | $(1 + 3/4) \text{ clock}$                                               | $(1 + 1/2) * \text{clock}$                            | X                                                  | $4 + 2 * \text{SCY}$   |
| 1    | write       | 11  | 1    | $(1 + 1/2) * \text{clock}$ | $(1 + 1/2) * \text{clock}$                         | $(1 + 3/4) \text{ clock}$                                               | $(1 + 1/2) * \text{clock}$                            | X                                                  | $4 + 2 * \text{SCY}$   |

**Note:** Timing in this table refers to the typical timing only. Consult the electrical characteristics for exact worst-case timing values. 1/4 clock actually means 0 to 1/4 clock, 1/2 clock means 1/4 to 1/2 clock.

Additional timing rules not covered in Table 10-3 include the following:

- If SETA = 1, an external  $\overline{\text{TA}}$  signal is required to terminate the cycle.
- If TRLX = 1 and SETA = 1, the minimum cycle length = 3 clock cycles (even if SCY = 0000)
- If TRLX = 1, the number of wait states =  $2 * \text{SCY} \& 2 * \text{BSCY}$
- ACS = 01 is not defined (reserved).
- If EHTR = 1, an extra (idle) clock cycle is inserted between a read cycle and a following read cycle to another region, or between a read cycle and a following write cycle to any region.
- If LBDIP = 1 (late  $\overline{\text{BDIP}}$  assertion), the  $\overline{\text{BDIP}}$  signal is asserted only after the number of wait states for the first beat in a burst have elapsed. See Figure 9-13 in Chapter 9, “External Bus Interface,” as well as Section 9.5.5, “Burst Mechanism.”

### NOTE

The LBDIP/TBDIP function can operate only when the cycle termination is internal, using the number of wait states programmed in one of the ORx registers. The LBDIP/TBDIP function cannot be activated at the same time—results are unknown.

## 10.4 Write and Byte Enable Signals

The GPCM determines the timing and value of the  $\overline{WE}/\overline{BE}$  signals if allowed by the port size of the accessed bank, the transfer size of the transaction and the address accessed.

The functionality of the  $\overline{WE}/\overline{BE}[0:3]$  signals depends upon the value of the write enable/byte select (WEBS) bit in the corresponding BR register. Setting WEBS to 1 will enable these signals as  $\overline{BE}$ , while clearing it to zero will enable them as  $\overline{WE}$ .  $\overline{WE}$  is asserted only during write access, while  $\overline{BE}$  is asserted for both read and write accesses. The timing of the  $\overline{WE}/\overline{BE}$  signals remains the same in either case, and is determined by the TRLX, ACS and CSNT bits.

The upper  $\overline{WE}/\overline{BE}$  ( $\overline{WE0}/\overline{BE0}$ ) indicates that the upper eight bits of the data bus (D0–D7) contains valid data during a write/read cycle. The upper-middle write byte enable ( $\overline{WE1}/\overline{BE1}$ ) indicates that the upper-middle eight bits of the data bus (D8–D15) contains valid data during a write/read cycle. The lower-middle write byte enable ( $\overline{WE2}/\overline{BE2}$ ) indicates that the lower-middle eight bits of the data bus (D16–D23) contains valid data during a write/read cycle. The lower write/read enable ( $\overline{WE3}/\overline{BE3}$ ) indicates that the lower eight bits of the data bus contains valid data during a write cycle.

The write/byte enable lines affected in a transaction for 32-bit port (PS = 00), a 16-bit port (PS = 10) and a 8-bit port (PS = 01) are shown in Table 10-4.

**Table 10-4. Write Enable/Byte Enable Signals Function<sup>1</sup>**

| Transfer Size | TSIZ |   | Address |     | 32-bit Port Size                |                                 |                                 |                                 | 16-bit Port Size                |                                 |                                 |                                 | 8-bit Port Size                 |                                 |                                 |                                 |

| Half-Word     | 1    | 0 | 0       | 0   | X                               | X                               |                                 |                                 | X                               | X                               |                                 |                                 | X                               |                                 |                                 |                                 |
|               | 1    | 0 | 1       | 0   |                                 |                                 | X                               | X                               | X                               | X                               |                                 |                                 | X                               |                                 |                                 |                                 |
| Word          | 0    | 0 | 0       | 0   | X                               | X                               | X                               | X                               | X                               | X                               |                                 |                                 | X                               |                                 |                                 |                                 |

<sup>1</sup> This table shows which write enables are asserted (indicated with an 'X') for different combinations of port size and transfer size.

## 10.5 Dual Mapping of the Internal Flash EEPROM Array

The internal Flash EEPROM (UC3F) module can be mapped to an external memory region controlled by the memory controller. Only one region can be programmed to be dual-mapped. When dual mapping is enabled (DME bit is set in the DMBR register) and when an internal address matches the dual-mapped address range (as programmed in the DMBR) with the cycle type matching the AT/ATM field in DMBR/DMOR registers, the following occurs:

- The internal Flash memory does not respond to that address
- The memory controller takes control of the external access

- The attributes for the access are taken from one of the base and option registers of the appropriate chip select
- The chip-select region selected is determined by the  $\overline{\text{CS}}$  line select bit field ([Section 10.9.5, “Dual-Mapping Base Register \(DMBR\)”](#)).

With dual mapping, aliasing of address spaces may occur. This happens when the region is dual-mapped into a region which is also mapped into one of the four regions available in the memory controller. If code or data is written to the dual-mapped region, care must be taken to avoid overwriting this code or data by normal accesses of the chip-select region.

There is a match if:

$$\text{bus\_address}[0:16] == \{0000000, \text{ISB}[0:2], 0, \text{BA}[1:6]\} \quad \text{Eqn. 10-1}$$

$$\text{where BA represents the bit field in the DMBR register.} \quad \text{Eqn. 10-2}$$

Care must also be taken to avoid overwriting “normal” CSx data with dual-mapped code or data.

One way to avoid this situation is by disabling the chip-select region and enabling only the dual-mapped region ( $\text{DMBR}[\text{DME}] = 1$ , but  $\text{BRx}[\text{V}] = 0$ ). [Figure 10-19](#) illustrates the phenomenon.

**Figure 10-19. Aliasing Phenomenon Illustration**

### NOTE

The default state is to allow dual-mapping data accesses only; this means that dual mapping is possible only for data accesses on the internal bus. Also, the default state takes the lower 2 Mbytes of the MPC563 internal Flash memory. Hence, caution should be taken to change the dual-mapping setup before the first data access. Dual mapping is not supported for an external master when the memory controller serves the access; in such a case, the MPC561/MPC563 terminates the cycle by asserting  $\overline{TEA}$ .

## 10.6 Dual Mapping of an External Flash Region

The dual mapping feature also enables mapping of external memory to alternative memory regions controlled by the memory controller. When dual mapping is enabled and an external address matches a

dual mapped address, and the cycle type matches AT/ATM field in DMBR/DMOR register, then the following occur:

- The chip-select that is mapped to the access does not respond to that address (it remains negated)
- The chip-select region selected is determined by the DMCS bit field in the DMBR register
- The attributes for the access are taken from the corresponding chip select region

Dual mapping can only be enabled over memory addresses in the range 0x0000 0000 through 0x000F FFFF.

### NOTE

Internal Flash must be disabled to use dual mapping over an external memory.

## 10.7 Global (Boot) Chip-Select Operation

Global (boot) chip-select operation allows address decoding for a boot ROM before system initialization. If the global chip-select feature is enabled then the memory controller is enabled from reset.

The global chip select port size is programmable at system reset using RCW[BPS]. The global chip select does not provide write protection and responds to all address types, allowing a boot ROM to be located anywhere in the address space.

The memory controller will operate in this boot mode until the first write to any chip select option register (ORx). The chip select signal can be programmed to continue decoding a range of addresses after this write, provided the preferred address range is first loaded into the chip select base register (BRx). After the first write to ORx, the global chip select can only be restarted with a system reset.

Which chip-select line is used as the global chip select, and how it operates, is determined by the reset configuration parameters:

- FLEN – Internal Flash enable (bit 20)
- BDIS – Boot disable (bit 3)
- DME – Dual mapping enable (bit 31)

Table 10-6 summarizes global chip select operations for all combinations of values on these reset configuration word lines. In case 1, where FLEN, BDIS, DME = 0b000 (all cleared) at reset,  $\overline{CS0}$  is the global chip-select output. When the RCPU begins accessing memory after system reset,  $\overline{CS0}$  is asserted for every address, for accesses to both internal and external instructions and data.

In case 2, where FLEN, BDIS, DME = 0b001 at reset,  $\overline{CS0}$  is asserted for all external address accesses (instructions and data) and for internal instruction accesses. However,  $\overline{CS3}$  is asserted for all internal data accesses.  $\overline{CS3}$  is used in this case to allow dual mapping of loads/stores to/from an alternative bank which is not the memory bank normally used for instructions/data. In this way  $\overline{CS3}$  can be used to allow load/store from a different memory bank from reset. DME can then be disabled as required.

The global chip select feature is disabled by driving only the BDIS line of the RCW (FLEN, BDIS, DME = 0b010). This is shown in case 3 of Table 10-6.

Table 10-5 shows the initial values of the “boot bank” in the memory controller.

Table 10-5. Boot Bank Fields Values After Hard Reset

| Field     | Value (Binary)                                                                             |
|-----------|--------------------------------------------------------------------------------------------|

## 10.8 Memory Controller External Master Support

The memory controller in the MPC561/MPC563 supports accesses initiated by both internal and external bus masters to external memories. If the address of any master is mapped within the internal MPC561/MPC563 address space, the access will be directed to the internal device, and will be ignored by the memory controller. If the address is not mapped internally, but rather mapped to one of the memory controller regions, the memory controller will provide the appropriate chip select and strobes as programmed in the corresponding region (see [Section 6.2.2.1.3, “External Master Control Register \(EMCR\)”](#)).

The MPC561/MPC563 supports only synchronous external bus masters. This means that the external master works with CLKOUT and implements the MPC561/MPC563 bus protocol to access a slave device.

A synchronous master initiates a transfer by asserting  $\overline{TS}$ . The ADDR[0:31] signals must be stable from the rising edge of CLKOUT during which  $\overline{TS}$  is sampled, until the last  $\overline{TA}$  acknowledges the transfer. Since the external master works synchronously with the MPC561/MPC563, only setup and hold times around the rising edge of CLKOUT are important. Once the  $\overline{TS}$  is detected/asserted, the memory controller compares the address with each one of its defined valid banks to find a possible match. But, since the external address space is shorter than the internal space, the actual address that is used for comparing against the memory controller regions is in the format of: {00000000, bits [8:16] of the external address}. In the case where a match is found, the controls to the memory devices are generated and the transfer acknowledge indication ( $\overline{TA}$ ) is supplied to the master.

Because it takes two clocks for the external address to be recognized and handled by the memory controller, the  $\overline{TS}$  which is generated by the external master is ahead of the corresponding  $\overline{CS}$  and strobes which are asserted by the memory controller. This 2-clock delay might cause problems in some synchronous memories. To overcome this, the memory controller generates the  $\overline{MTS}$  (memory transfer start) strobe which can be used in the slave's memory instead of the external master's  $\overline{TS}$  signal. As seen in Figure 10-20, the  $\overline{MTS}$  strobe is synchronized to the assertion of  $\overline{CS}$  by the memory controller so that the external memory can latch the external master's address correctly. To activate this feature, the MTSC bit must be set in the SIUMCR register. Use external logic to control devices that can have burst accesses from an external master.

On the MPC563, when the external master accesses the internal Flash when it is disabled, the access is terminated with the transfer error acknowledge ( $\overline{TEA}$ ) signal asserted, and the memory controller does not support this access in any way.

When the memory controller serves an external master, the  $\overline{BDIP}$  signal becomes an input signal. This signal is watched by the memory controller to detect when the burst is terminated.

NOTE: The memory controller's BDIP line is used as a burst\_in\_progress signal.

**Figure 10-20. Synchronous External Master Configuration for GPCM-Handled Memory Devices**

**Figure 10-21. Synchronous External Master Basic Access (GPCM Controlled)**

**NOTE**

Because the MPC561/MPC563 has only 24 address signals, the eight most significant internal address lines are driven as 0b0000\_0000, and so compared in the memory controller's regions.

## 10.9 Programming Model

The registers in Table 10-6 are used to control the memory controller.

**Table 10-6. Memory Controller Address Map**

| Address               | Register                            |
|-----------------------|-------------------------------------|
| 0x2F C100             | Base Register Bank 0 (BR0)          |
| 0x2F C104             | Option Register Bank 0 (OR0)        |
| 0x2F C108             | Base Register Bank 1 (BR1)          |
| 0x2F C10C             | Option Register Bank 1 (OR1)        |
| 0x2F C110             | Base Register Bank 2 (BR2)          |
| 0x2F C114             | Option Register Bank 2 (OR2)        |
| 0x2F C118             | Base Register Bank 3 (BR3)          |
| 0x2F C11C             | Option Register Bank 3 (OR3)        |
| 0x2F C120 — 0x13F     | Reserved                            |
| 0x2F C140             | Dual-Mapping Base Register (DMBR)   |
| 0x2F C144             | Dual-Mapping Option Register (DMOR) |
| 0x2F C148 — 0x2F C174 | Reserved                            |
| 0x2F C178             | Memory Status Register (MSTAT)      |

### 10.9.1 General Memory Controller Programming Notes

1. In the case of an external master that accesses an internal MPC561/MPC563 module (in slave or peripheral mode), if that slave device address also matches one of the memory controller's regions, the memory controller will not issue any  $\overline{CS}$  for this access, nor will it terminate the cycle. Thus, this practice should be avoided. Be aware also that any internal slave access prevents memory controller operation.
2. If the memory controller serves an external master, then it can support accesses to 32-bit port devices only. This is because the MPC561/MPC563 external bus interface cannot initiate extra cycles to complete an access to a smaller port-size device as it does not own the external bus.
3. When the SETA bit in the base register is set, then the timing programming for the various strobes ( $\overline{CS}$ ,  $\overline{OE}$  and  $\overline{WE/BE}$ ) may become meaningless.
4. When configuring a chip select for a memory region with the intent to access that region immediately after configuration, then an ISYNC instruction should be executed in order to ensure that the configuration takes effect before any accesses are initiated.

## 10.9.2 Memory Controller Status Registers (MSTAT)

Figure 10-22. Memory Controller Status Register (MSTAT)

Table 10-7. MSTAT Bit Descriptions

| Bits  | Name          | Description                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-------|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0:7   | —             | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                       |
| 8:11  | WPER0 – WPER3 | Write protection error for bank x. This bit is asserted when a write-protect error occurs for the associated memory bank. A bus monitor (responding to $\overline{\text{TEA}}$ assertion) will, if enabled, prompt the read of this register if $\overline{\text{TA}}$ is not asserted during a write cycle. WPERx is cleared by writing one to the bit or by performing a system reset. Writing a zero has no effect on WPER. |
| 12:15 | —             | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                       |

## 10.9.3 Memory Controller Base Registers (BR0–BR3)

<sup>1</sup> The reset value is determined by the value on the internal data bus during reset (reset-configuration word).

<sup>2</sup> See Table 10-9 for reset value.

Figure 10-23. Memory Controller Base Registers 0–3 (BR0–BR3)

**Table 10-8. BR0–BR3 Bit Descriptions**

| Bits  | Name  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-------|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0:16  | BA    | Base address. These bits are compared to the corresponding unmasked address signals among ADDR[0:16] to determine if a memory bank controlled by the memory controller is being accessed by an internal bus master. (The address types are also compared.) These bits are used in conjunction with the AM[0:16] bits in the OR.                                                                                                                                                                                                                        |
| 17:19 | AT    | Address type. This field can be used to require accesses of the memory bank to be limited to a certain address space type. These bits are used in conjunction with the ATM bits in the OR. Note that the address type field uses only AT[0:2] and does not need AT3 to define the memory type space. For a full definition of address types, refer to <a href="#">Section 9.5.8.6, “Address Types.”</a>                                                                                                                                                |
| 20:21 | PS    | Port size<br>00 32-bit port<br>01 8-bit port<br>10 16-bit port<br>11 Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| 22    | SST   | Short Setup Time – This field specifies the setup time required for this memory region.<br>0 Normal setup time (like the MPC555)<br>1 Short Setup Time selected<br>Note that an external burst access with short setup timing will corrupt any USIU register load/store if SCCR[EBDF] is not 0b00. Refer to <a href="#">Table 8-9</a> .                                                                                                                                                                                                                |
| 23    | WP    | Write protect. An attempt to write to the range of addresses specified in a base address register that has this bit set can cause the $\overline{TEA}$ signal to be asserted by the bus-monitor logic (if enabled), causing termination of this cycle.<br>0 Both read and write accesses are allowed<br>1 Only read accesses are allowed. The $\overline{CSx}$ signal and $\overline{TA}$ are not asserted by the memory controller on write cycles to this memory bank. WPER is set in the MSTAT register if a write to this memory bank is attempted |

| 25    | BL    | Burst Length – This field specifies the maximum number of words that may comprise a burst access for this memory region. This field has an effect only in the case when the burst accesses are initiated by the USIU (SIUMCR[BURST_EN] = 1).<br>0 Burst access of up to 4 words<br>1 Burst access of up to 8 words                                                                                                                                                                                                                                     |
| 26    | WEBS  | Write-enable/byte-select. This bit controls the functionality of the $\overline{WE}/\overline{BE}$ pads.<br>0 The $\overline{WE}/\overline{BE}$ pads operate as $\overline{WE}$<br>1 The $\overline{WE}/\overline{BE}$ pads operate as $\overline{BE}$                                                                                                                                                                                                                                                                                                 |
| 27    | TBDIP | Toggle-burst data in progress. TBDIP determines how long the $\overline{BDIP}$ strobe will be asserted for each data beat in the burst cycles.                                                                                                                                                                                                                                                                                                                                                                                                         |
| 28    | LBDIP | Late-burst-data-in-progress (LBDIP). This bit determines the timing of the first assertion of the $\overline{BDIP}$ signal in burst cycles.<br>NOTE: Do not set both LBDIP and TBDIP bits in a region's base registers; behavior in such cases is unpredictable.<br>0 Normal timing for $\overline{BDIP}$ assertion (asserts one clock after negation of $\overline{TS}$ )<br>1 Late timing for $\overline{BDIP}$ assertion (asserts after the programmed number of wait states)                                                                       |
| 29    | SETA  | External transfer acknowledge<br>0 $\overline{TA}$ generated internally by memory controller<br>1 $\overline{TA}$ generated by external logic. Note that programming the timing of $\overline{CS}/\overline{WE}/\overline{OE}$ strobes may have no meaning when this bit is set                                                                                                                                                                                                                                                                        |

**Table 10-8. BR0–BR3 Bit Descriptions (continued)**

| Bits | Name | Description                                                                                                                                                                                                                                                                                                                                                      |
|------|------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 30   | BI   | Burst inhibit<br>0 Memory controller drives $\overline{BI}$ negated (high). The bank supports burst accesses.<br>1 Memory controller drives $\overline{BI}$ asserted (low). The bank does not support burst accesses.<br>NOTE: Following a system reset, the $\overline{BI}$ bit is set.                                                                         |
| 31   | V    | Valid bit. When set, this bit indicates that the contents of the base-register and option-register pair are valid. The $\overline{CS}$ signal does not assert until the V-bit is set.<br>NOTE: An access to a region that has no V-bit set may cause a bus monitor timeout. See <a href="#">Table 10-9</a> for the reset value of this bit in $\overline{BR0}$ . |

**Table 10-9. BRx[V] Reset Value**

| Branch Register | BRx[V] Reset Value                    |

| BR3             | $\overline{ID20}$ & $\overline{ID31}$ |

### 10.9.4 Memory Controller Option Registers (OR0–OR3)

<sup>1</sup> It is recommended that this field hold values that are the power of 2 minus 1 (e.g.,  $2^3 - 1 = 7$  [0b111]).

**Figure 10-24. Memory Controller Option Registers 1–3 (OR0–OR3)**

**Table 10-10. OR0–OR3 Bit Descriptions**

| Bits  | Name | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-------|------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0:16  | AM   | Address mask. This field allows masking of any corresponding bits in the associated base register. Masking the address bits independently allows external devices of different size address ranges to be used. Any clear bit masks the corresponding address bit. Any set bit causes the corresponding address bit to be used in comparison with the address signals. Address mask bits can be set or cleared in any order in the field, allowing a resource to reside in more than one area of the address map. This field can be read or written at anytime.<br>Following a system reset, the AM bits are cleared in OR0.                                                     |
| 17:19 | ATM  | Address type mask. This field masks selected address type bits, allowing more than one address space type to be assigned to a chip-select. Any set bit causes the corresponding address type code bits to be used as part of the address comparison. Any cleared bit masks the corresponding address type code bit. Clear the ATM bits to ignore address type codes as part of the address comparison. Note that the address type field uses only AT[0:2] and does not need AT3 to define the memory type space.<br>Following a system reset, the ATM bits are cleared in OR0.                                                                                                  |
| 20    | CSNT | Chip-select negation time. Following a system reset, the CSNT bit is reset in OR0.<br>0 $\overline{CS}/\overline{WE}$ are negated normally.<br>1 $\overline{CS}/\overline{WE}$ are negated a quarter of a clock earlier than normal<br>Following a system reset, the CSNT bit is cleared in OR0.                                                                                                                                                                                                                                                                                                                                                                                |
| 21:22 | ACS  | Address to chip-select setup. Following a system reset, the ACS bits are reset in OR0.<br>00 $\overline{CS}$ is asserted at the same time that the address lines are valid.<br>01 Reserved<br>10 $\overline{CS}$ is asserted a quarter of a clock after the address lines are valid.<br>11 $\overline{CS}$ is asserted half a clock after the address lines are valid<br>Following a system reset, the ACS bits are cleared in OR0.                                                                                                                                                                                                                                             |
| 23    | EHTR | Extended hold time on read accesses. This bit, when asserted, inserts an idle clock cycle after a read access from the current bank and any MPC561/MPC563 write accesses or read accesses to a different bank.<br>0 Memory controller generates normal timing<br>1 Memory controller generates extended hold timing<br>Following a system reset, the EHTR bits are cleared in OR0.                                                                                                                                                                                                                                                                                              |
| 24:27 | SCY  | Cycle length in clocks. This four-bit value represents the number of wait states inserted in the single cycle, or in the first beat of a burst, when the GPCM handles the external memory access. Values range from 0 (0b0000) to 15 (0b1111). This is the main parameter for determining the length of the cycle.<br>The total cycle length may vary depending on the settings of other timing attributes.<br>The total memory access length is (2 + SCY) x Clocks.<br>If an external $\overline{TA}$ response is selected for this memory bank (by setting the SETA bit), then the SCY field is not used.<br>Following a system reset, the SCY bits are set to 0b1111 in OR0. |

Table 10-10. OR0–OR3 Bit Descriptions (continued)

| Bits  | Name | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-------|------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 28:30 | BSCY | <p>Burst beats length in clocks. This field determines the number of wait states inserted in all burst beats except the first, when the GPCM starts handling the external memory access and thus using SCY[0:3] as the main parameter for determining the length of that cycle.</p> <p>The total cycle length may vary depending on the settings of other timing attributes.</p> <p>The total memory access length for the beat is (1 + BSCY) x Clocks.</p> <p>If an external <math>\overline{TA}</math> response has been selected for this memory bank (by setting the SETA bit) then BSCY[0:3] are not used.</p> <p>000 0-clock-cycle (1 clock per data beat)<br/> 001 1-clock-cycle wait states (2 clocks per data beat)<br/> 010 2-clock-cycle wait states (3 clocks per data beat)<br/> 011 3-clock-cycle wait states (4 clocks per data beat)<br/> 1xx Reserved</p> <p>Following a system reset, the BSCY bits are set to 0b011 in OR0.</p> |
| 31    | TRLX | <p>Timing relaxed. This bit, when set, modifies the timing of the signals that control the memory devices during a memory access to this memory region. Relaxed timing multiplies by two the number of wait states determined by the SCY and BSCY fields. Refer to <a href="#">Section 10.3.5, “Summary of GPCM Timing Options,”</a> for a full list of the effects of this bit on signals timing.</p> <p>0 Normal timing is generated by the GPCM.<br/> 1 Relaxed timing is generated by the GPCM</p> <p>Following a system reset, the TRLX bit is set in OR0.</p>                                                                                                                                                                                                                                                                                                                                                                                |

| Bits  | Name | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-------|------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0     | —    | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 1:6   | AM   | Address mask. The address mask field of each option register provides for masking any of the corresponding bits in the associated base register. By masking the address bits independently, external devices of different size address ranges can be used. Any clear bit masks the corresponding address bit. Any set causes the corresponding address bit to be used in the comparison with the address signals. Address mask bits can be set or cleared in any order in the field, allowing a resource to reside in more than one area of the address map. This field can be read or written at any time.                                                                  |
| 7:9   | —    | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 10:12 | ATM  | Address type mask. This field can be used to mask certain address type bits, allowing more than one address space type to be assigned to a chip select. Any set bit causes the corresponding address type code bits to be used as part of the address comparison. Any cleared bit masks the corresponding address type code bit.<br>To instruct the memory controller to ignore address type codes as part of the address comparison, clear the ATM bits.<br>NOTE: Following a system reset, the ATM bits are cleared in DMOR, except the ATM2 bit. This means that only data accesses are dual mapped. Refer to the address types definition in <a href="#">Table 9-8</a> . |
| 13:31 | —    | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

## Chapter 11

# L-Bus to U-Bus Interface (L2U)

The L-bus to U-bus interface unit (L2U) provides an interface between the load/store bus (L-bus) and the unified bus (U-bus). The L2U module includes the data memory protection unit (DMPU), which provides protection for data memory accesses.

The L2U is bidirectional. It allows load/store accesses not intended for the L-bus data RAM to go to the U-bus. It also allows code execution from the L-bus data RAM and read/write accesses from the U-bus to the L-bus.

The L2U directs bus traffic between the L-bus and the U-bus. When transactions start concurrently on both buses, the L2U interface arbitrates to select which transaction is handled. The top priority is assigned to U-bus to L-bus accesses; lower priority is assigned to the load/store accesses by the RCPU.

### 11.1 General Features

- Non-pipelined master and slave on U-bus
  - Does not start two back-to-back accesses on the U-bus
  - Supports U-bus pipelining
  - Retries back-to-back accesses from U-bus masters
- Non-pipelined master and slave on the L-bus
- Generates module selects for L-bus memory-mapped resources within a programmable, contiguous block of storage
- Programmable data memory protection unit (DMPU)
- L-bus and U-bus snoop logic for the reservation protocol compatible with the PowerPC ISA architecture
- Show cycles for RCPU accesses to the CALRAM (none, all, writes)
  - Protection for CALRAM accesses from the U-bus side (all accesses to the CALRAM from the U-bus side are blocked once the CALRAM protection bit is set)

### 11.2 Data Memory Protection Unit Features

- Supports four memory regions whose base address and size can be programmed
  - Available sizes are 4 Kbytes, 8 Kbytes, 16 Kbytes, 32 Kbytes, 64 Kbytes, 128 Kbytes, 256 Kbytes, 512 Kbytes, 1 Mbyte, 2 Mbytes, 4 Mbytes, 8 Mbytes, and 16 Mbytes
  - Region must start on the specified region size boundary (modulo addressing)
  - Overlap between regions is allowed
- Each of the four regions supports the following attributes:

- Access protection: user or supervisor
  - Guarded attribute: speculative or non-speculative
  - Enable/disable option
  - Read only option
- Supports a default global entry for memory space not covered by other regions:
  - Default access protection
  - Default guarded attribute
- Interrupt generated upon:
  - Access violation
  - Load from guarded region
  - Write to read-only region
- The MSR[DR] bit (data relocate) controls DMPU protection on/off operation
- Programming is done using the mtspr/mfspr instructions to/from implementation-specific special purpose registers.
- No protection for accesses to the CALRAM module on the L-bus (CALRAM has its own protection options)

### 11.3 L2U Block Diagram

Figure 11-1 shows a block diagram of the L-bus to U-bus interface as implemented in the overall MPC561/MPC563 bus architecture.

Figure 11-1. L2U Bus Interface Block Diagram

## 11.4 Modes Of Operation

The L2U module can operate in the following modes:

- Normal mode
- Reset operation
- Peripheral mode
- Factory test mode

### 11.4.1 Normal Mode

In normal mode (master or slave) the L2U module acts as a bidirectional protocol translator.

- In master mode the RCPU is fully operational, and there is no external master access to the U-bus.
- Slave mode enables an external master to access any internal bus slave while the RCPU is fully operational. The L2U transfers load/store accesses from the RCPU to the U-bus and the read/write accesses by the U-bus master to the L-bus.

In addition to the bus protocol translation, the L2U supports other functions such as show cycles, data memory protection, and MPC500 reservation protocol.

When a load to or store from the U-bus resource is issued by the RCPU, it is compared against the DMPU region access (address and attribute) comparators. If none of the access attributes are violated, the access is directed to the U-bus by the L2U module. If the DMPU detects an access violation, it informs the error status to the master initiating the cycle.

When show cycles are enabled, accesses to all of the L-bus resources by the RCPU are made visible on the U-bus side by the L2U.

The L2U is responsible for handling the effects of reservations on the L-bus and the U-bus. For the L-bus and the U-bus, the L2U detects reservation losses and updates the RCPU core with the reservation status.

### 11.4.2 Reset Operation

While hard or soft reset is asserted on the U-bus, the L2U asserts the corresponding L-bus reset signals. Upon soft reset assertion, the L2U goes to an idle state and all pending accesses are ignored. Additionally, the L2U module control registers are not initialized on soft reset, keeping the system configuration unchanged.

Upon assertion of hard reset, the L2U control registers are initialized to their reset states. The L2U also drives the reset configuration word from the U-bus to the L-bus upon hard reset.

### 11.4.3 Peripheral Mode

In the peripheral mode of operation the RCPU is shut down and an alternative master on the external bus can perform accesses to any internal bus (U-bus and L-bus) slave.

The external master can also access the internal MPC500 special registers that are located in the L2U module. In order to access one of these MPC500 registers the EMCR[CONT] bit in the USIU must be cleared.

### 11.4.4 Factory Test Mode

Factory test mode is a special mode of operation that allows access to the internal modules for testing. This mode is not intended for general use and is not supported for normal applications.

## 11.5 Data Memory Protection

The data memory protection unit (DMPU) in the L2U module provides access protection for the memory regions on the U-bus side from load/store accesses by the RCPU. (Only U-bus space is protected.) The DMPU does not protect MPC500 register accesses initiated by the RCPU on the L-bus. The user can assign up to four regions of access protection attributes and can assign global attributes to any space not included in the active regions. When it detects an access violation, the L2U generates an exception request to the CPU. A functional diagram of the DMPU is shown in [Figure 11-2](#).

Figure 11-2. DMPU Basic Functional Diagram

## 11.5.1 Functional Description

Data memory protection is assigned on a regional basis. Default manipulation of the DMPU is done on a global region. The DMPU has control registers that contain the following information: region protection on/off, region base address, region size, and the region's access permissions. Each region's protection attributes can be turned on or off by configuring the global region attribute register's enable attribute bit (L2U\_GRA[ENRx]).

During each load or store access from the RCPU to the U-bus, the address is compared to the value in the region base address register of each enabled region. Any access that matches the specific region within its appropriate size, as defined by the region attribute register's region size field (L2U\_RAx[RS]), sets a match indication.

When more than one match indication occurs, the effective region is the region with the highest priority. Priority is determined by region number; highest priority corresponds to the lowest region number, e.g. region 0 is highest priority, while region 3 is lowest.

When no match occurs, the effective region is the global region, which has the lowest priority.

The region attribute register also contains the region's protection fields. The protection field (PP) of the effective region is compared to the access attributes. If the attributes match, the access is permitted. When the access is permitted, a U-bus access may be generated according to the specific attribute of the effective region.

When the access by the RCPU is not permitted, the L2U module asserts a data memory storage exception to the RCPU.

For speculative load/store accesses from the RCPU to a region marked as guarded (G bit of region attribute register is set), the L2U asks the RCPU to retry the L-bus cycle until either the access is not speculative, or is canceled by the RCPU.

In the case of attempted accesses to a guarded region together with any other protection violation (no access), the L2U retries the access. The L2U handles this event as a data storage violation only when the access becomes non-speculative.

Note that access protection is active only when the MPC500's MSR[DR] = 1. When MSR[DR] = 0, DMPU exceptions are disabled, all accesses are considered to be to a guarded memory area, and no speculative accesses are allowed. In this case, if the L-bus master [RCPU] initiates a non-CALRAM cycle (access through the L2U) that is marked speculative, the L2U asks the RCPU to retry the L-bus cycle until either the access is not speculative, or it is canceled by the RCPU Core.

**NOTE**

The programmer must not overlap the CALRAM memory space with any enabled region. Overlapping an enabled region with CALRAM memory space disables the L2U data memory protection for that region.

If an enabled region overlaps with the L-bus space, the DMPU ignores all accesses to addresses within the L-bus space. If an enabled region overlaps with MPC500 register addresses, the DMPU ignores any access marked as an MPC500 access.

### 11.5.2 Associated Registers

Table 11-1 shows registers that are used to control the DMPU of the L2U module. All the registers are special purpose registers that are accessed via the MPC500 mtspr/mfspr instructions. The registers are also accessed by an external master when EMCR[CONT] = 0. See Section 11.8, “L2U Programming Model,” for register diagrams and bit descriptions.

**Table 11-1. DMPU Registers**

| Name     | Description                    |
|----------|--------------------------------|
| L2U_RBA0 | Region Base Address Register 0 |
| L2U_RBA1 | Region Base Address Register 1 |
| L2U_RBA2 | Region Base Address Register 2 |
| L2U_RBA3 | Region Base Address Register 3 |
| L2U_RA0  | Region Attribute Register 0    |
| L2U_RA1  | Region Attribute Register 1    |
| L2U_RA2  | Region Attribute Register 2    |
| L2U_RA3  | Region Attribute Register 3    |
| L2U_GRA  | Global Region Attribute        |

## NOTE

The appropriate DMPU registers must be programmed before the MSR[DR] bit is set. Otherwise, DMPU operation is not guaranteed.

Program the region base address in the L2U\_RBAx registers to the lower boundary of the region specified by the corresponding L2U\_RAx[RS] field. If the region base address does not correspond to the boundary of the block size programmed in the L2U\_RAx, the DMPU snaps the region base to the lower boundary of that block. For example, if the block size is programmed to 16 Kbytes for region zero (i.e., L2U\_RA0[RS] = 0x3) and the region base address is programmed to 0x1FFF(i.e., L2U\_RBA0[RBA] = 0x1), then the effective base address of region zero is 0x0. See [Figure 11-3](#).

**Figure 11-3. Region Base Address Example**

External action is required to program only legal region sizes. The L2U does not check whether the value is legal. If an illegal region size is programmed, the region calculation may not be successful.

## 11.5.3 L-Bus Memory Access Violations

All L-bus slaves have their own access protection logic. For consistency, all storage access violations have the same termination result. Thus access violations for load/store accesses started by the RCPU always have the same termination from all slaves: assertion of the data storage exception. All other L-bus masters cause machine check exceptions.

## 11.6 Reservation Support

In general terms, a reservation activity is the process whereby a load and store instruction pair is accompanied by a reservation of the data, the goal being to achieve an atomic operation. If a bus master other than the one holding the reservation accesses the data (or some other specific condition occurs as described in [Section 11.6.1, “Reservation Protocol”](#)) the reservation is lost and is indicated accordingly.

The RCPU storage reservation protocol supports a multi-level bus structure. For each local bus, storage reservation is handled by the local reservation logic. The protocol tries to optimize reservation cancellation such that an MPC500 processor (RCPU) is notified of storage reservation loss on a remote bus (U-bus, IMB or external bus) only when it has issued a stwex cycle to that address. That is, the reservation loss indication comes as part of the stwex cycle.

## 11.6.1 Reservation Protocol

The reservation protocol operates under the following assumptions:

- Each processor has at most 1 reservation flag
- A lwarx instruction sets the reservation flag
- Another lwarx instruction by same processor clears the reservation flag related to a previous lwarx instruction and sets again the reservation flag
- A stwcx instruction by the same processor clears the reservation flag
- A store instruction by the same processor does not clear the reservation flag
- Some other processor (or other mechanism) store to an address with an existing reservation clears the reservation flag
- In case the storage reservation is lost, it is guaranteed that stwcx will not modify the storage

## 11.6.2 L2U Reservation Support

The L2U is responsible for handling the effects of reservations on the L-bus and the U-bus. For the L-bus and the U-bus, the L2U detects reservation losses.

The reservation logic in the L2U performs the following functions:

- Snoops accesses to all L-bus and U-bus slaves
- Holds one reservation (address) for the core
- Sets the reservation flag when the RPCU issues a load-with-reservation request

The unit for reservation is one word. A byte or half-word store request by another master will clear the reservation flag.

A load-with-reservation request by the RPCU updates the reservation address related to a previous load-with-reservation request and sets the reservation flag for the new location. A store-with-reservation request by the RPCU clears the reservation flag. A store request by the RPCU does not clear the flag. A store request by some other master to the reservation address clears the reservation flag.

If the storage reservation is lost, it is guaranteed that a store-with-reservation request by the RPCU will not modify the storage.

The L2U does not start a store-with-reservation cycle on the U-bus if the reserved location on the U-bus has been touched by another master. The L2U drives the reservation status back to the core.

When the reserved location in the CALRAM on the L-bus is touched by an alternate master, on the following clock the L2U indicates to the RPCU that the reservation has been touched. On assertion of the cancel-reservation signal, the RPCU clears the internal reservation bit. If an stwcx cycle has been issued at the same time, the RPCU aborts the cycle. Software must check the CR0[EQ] bit to determine if the stwcx instruction completed successfully.

Storage reservation is set regardless of the termination status (address or data phase) of the lwarx access. Storage reservation is cleared regardless of the data phase termination status of the stwcx access if the address phase is terminated normally.

Storage reservation will be cleared regardless of the data phase termination status of the write requests by another master to the reserved address if the address phase of the write access is terminated normally on the destination (U-bus/L-bus) bus.

If the programmable memory map of the part is modified between a lwarx and a stwcx instruction, the reservation is not guaranteed.

### 11.6.3 Reserved Location (Bus) and Possible Actions

Once the RPCU core reserves a memory location, the L2U module is responsible for snooping the L-bus and U-bus for possible intrusion of the reserved location. Under certain circumstances, the L2U depends on the USIU or the UIMB to provide status of reservation on external bus and the IMB3 respectively.

Table 11-2 lists all reservation protocol cases supported by the L2U snooping logic.

**Table 11-2. Reservation Snoop Support**

| Reserved Location On | Intruding Alternate Master | Action Taken on stwcx cycle                     |
|----------------------|----------------------------|-------------------------------------------------|
| L-bus                | L-master                   | Request to cancel the reservation. <sup>1</sup> |
|                      | U-master                   | Request to cancel the reservation.              |
| U-bus                | L-master                   | Block stwcx <sup>2</sup>                        |
|                      | U-master                   | Block stwcx                                     |
| External Bus         | L-master                   | Block stwcx                                     |
|                      | U-master                   | Block stwcx                                     |
|                      | Ext-master                 | Transfer Status <sup>3</sup>                    |
| IMB3                 | L-master                   | Block stwcx                                     |
|                      | U-master                   | Block stwcx                                     |
|                      | IMB3-master                | Transfer Status                                 |

<sup>1</sup> If the RCPu tries to modify (stwcx) that location, the L2U does not have enough time to stop the write access from completing. In this case, the L2U will drive cancel-reservation signal back to the core as soon as it comes to know that the alternate master on the U-bus has touched the reserved location.

<sup>2</sup> If the RCPu tries to modify (stwcx) that location, the L2U does not start the cycle on the U-bus and it communicates to the core that the current write has been aborted by the slave with no side effects.

<sup>3</sup> If the RCPu tries to modify (stwcx) that location, the L2U runs a write-cycle-with-reservation request on the U-bus. The L2U samples the status of the reservation along with the U-bus cycle termination signals and it communicates to the core if the current write has been aborted by the slave with no side effects.

## 11.7 L-Bus Show Cycle Support

The L2U module provides support for L-bus show cycles. L-bus show cycles are external visibility cycles that reflect activity on the L-bus that would otherwise not be visible to the external bus. L-bus show cycles are software controlled.

## 11.7.1 Programming Show Cycles

L-bus show cycles are disabled during reset and must be configured by setting the LSHOW[0:1] bits in the L2U\_MCR. Table 11-3 shows the configurations of the LSHOW[0:1] bits.

**Table 11-3. L2U\_MCR LSHOW Modes**

| LSHOW | Action                                                         |
|-------|----------------------------------------------------------------|
| 00    | Disable L-bus show cycles                                      |
| 01    | Show address and data of all L-bus space write cycles          |
| 10    | Reserved (Disable L-bus show cycles)                           |
| 11    | Show address and data of all L-bus space read and write cycles |

## 11.7.2 Performance Impact

When show cycles are enabled in the L2U module, there is a performance penalty on the L-bus. This occurs because the L2U module does not support more than one access being processed at any time. To ensure that only one access at a time is processed, and not lose an L-bus access that would have been show cycled, the L2U module will arbitrate for the L-bus whenever it is processing any access. This L-bus arbitration will prevent any other L-bus master from starting a cycle that might turn out to be a qualifiable L-bus show cycle.

For L-bus show cycles, the minimum performance impact on the L-bus will be three clocks. This minimum impact assumes that the L-bus slave access is a 1-clock access, and the L2U module acquires immediate bus grant on the U-bus. The L2U has to wait two clocks before completing the show cycle on the U-Bus, thus using up five clocks for the complete process.

A retried access on the L-bus (no address acknowledge) that qualifies to be show cycled, will be accepted when it is actually acknowledged. This will cause a 1-clock delay before an L-bus master can retry the access on the L-bus, because the L2U module will release L-bus one clock later.

L2U asserts the internal bus request signal on the U-bus for a minimum of two clocks when starting a show cycle on the U-bus.

## 11.7.3 Show Cycle Protocol

The L2U module behaves as both a master and a slave on the U-bus during show cycles. The L2U starts the U-bus transfer as a bus master and then completes the address phase and data phase of the cycle as a slave. The L2U follows U-bus protocol of in-order termination of the data phase.

The USIU can control the start of show cycles on the U-bus by asserting the no-show cycle indicator. This will cause the L2U module to release the U-bus for at least one clock before retrying the show cycle.

## 11.7.4 L-Bus Write Show Cycle Flow

The L2U performs the following sequence of actions for an L-bus-write show cycle.

1. Arbitrates for the L-bus to prevent any other L-bus cycles from starting

2. Latches the address and the data of the L-bus access, along with all address attributes
3. Waits for the termination of the L-bus access and latches the termination status (data error)
4. Arbitrate for the U-bus, and when granted, starts the U-bus access, asserting show cycle request on the U-bus, along with address, attributes and the write data. The L2U module provides address recognition and acknowledgment for the address phase. If the no-show cycle indicator from the U-bus is asserted, the L2U does not start the show cycle. The L2U module releases the U-bus until the no-show cycle indicator is negated and then arbitrates for the U-bus again.
5. When the L2U module has U-bus data bus grant, it drives the data phase termination handshakes on the U-bus.
6. Releases the L-bus

### 11.7.5 L-Bus Read Show Cycle Flow

The L2U performs the following sequence of actions for an L-bus read show cycle.

1. Arbitrates for the L-bus to prevent any other L-bus cycle from starting
2. Latches the address of the L-bus access, along with all address attributes
3. Waits for the data phase termination on the L-bus and latches the read data, and the termination status from the L-bus
4. Arbitrates for the U-bus, and when granted, starts the U-bus access, asserting the show cycle request on the U-bus, along with address attributes. The L2U module provides address recognition/acknowledgment for the address phase. If the no-show cycle indicator from the U-bus is asserted, the L2U does not start the show cycle. The L2U module releases the U-bus until the no-show cycle indicator is negated and then arbitrates for the U-bus again.
5. When the L2U module has U-bus data bus grant, it drives the read data and the data phase termination handshakes on the U-bus
6. Release the L-bus.

### 11.7.6 Show Cycle Support Guidelines

The following are the guidelines for L2U show cycle support:

- The L2U module provides address and data for all qualifying L-bus cycles when the appropriate mode bits are set in the L2U\_MCR.
- The L2U-module-only provides show cycles L-bus activity that is not targeted for the U-bus or the L2U module internal registers, regardless of the termination status of such activity.
- The L2U module does not provide show cycle access to any MPC500 special purpose register.
- The L2U does not start a show cycle for an L-bus access that is retried. This decision to not start the show cycle causes a clock delay before the cycle can be retried, since the L2U module will have arbitrated away the L-bus immediately on detecting the show cycle, before the retry information is available.
- The L2U module does not show cycle any L-bus activity that is aborted.
- The L2U module does not access the U-bus if the USIU inhibits show cycle activity on the U-bus.

- The L2U does not provide show cycle for any L-bus addresses that fall in the L-bus CALRAM address space if the CALRAM protection [SP] bit is set in the L2U\_MCR.

Table 11-4 summarizes the L2U show cycle support.

**Table 11-4. L2U Show Cycle Support Chart**

| Case | Destination              | LB AACK | LB ABORT       | Comments                                                                |
|------|--------------------------|---------|----------------|-------------------------------------------------------------------------|
| 1    | L-bus Slave <sup>1</sup> | No      | X <sup>2</sup> | Not show cycled<br>[Cycle will be retried one clock later] <sup>3</sup> |
| 2    | L2U <sup>4</sup>         | X       | X              | Not show cycled                                                         |
| 3    | U-bus/E-bus <sup>5</sup> | X       | X              | Not show cycled                                                         |
| 4    | L-bus slave <sup>1</sup> | Yes     | No             | Show cycled                                                             |
| 5    | L-bus slave <sup>1</sup> | Yes     | Yes            | Not show cycled<br>[L-bus will be released next clock]                  |

<sup>1</sup> L-bus slave includes all address in the L-bus address space.

<sup>2</sup> X indicates don't care conditions.

<sup>3</sup> There will be a 1-clock turnaround because the L-bus retry information is not available in time to negate the L-bus arbitration.

<sup>4</sup> L2U indicates L2U registers.

<sup>5</sup> U-bus/E-bus refers to all destinations through the L2U interface.

## 11.8 L2U Programming Model

The L2U control registers control the L2U bus interface and the DMPU. They are accessible via the mtspr and mfspr instructions. They are also accessible by an external master when EMCR[CONT] bit is cleared. L2U control registers are accessible from both the L-bus side and the U-bus side in one clock cycle. As with all SPRs, L2U registers are accessible in supervisor mode only.

Any unimplemented bits in L2U registers return 0's on a read, and the writes to those register bits are ignored.

Table 11-5 shows L2U registers along with their SPR numbers and hexadecimal addresses that are used to access L2U registers during a peripheral mode access.

**Table 11-5. L2U (PPC) Register Decode**

| Name     | SPR # | SPR[5:9] | SPR[0:4] | Address for External Master Access <sup>1</sup> | Access | Description                       |
|----------|-------|----------|----------|-------------------------------------------------|--------|-----------------------------------|
| L2U_MCR  | 568   | 10001    | 11000    | 0x0000_3110                                     | SUPR   | L2U Module Configuration Register |
| L2U_RBA0 | 792   | 11000    | 11000    | 0x0000_3180                                     | SUPR   | Region Base Address Register 0    |
| L2U_RBA1 | 793   | 11000    | 11001    | 0x0000_3380                                     | SUPR   | Region Base Address Register 1    |
| L2U_RBA2 | 794   | 11000    | 11010    | 0x0000_3580                                     | SUPR   | Region Base Address Register 2    |
| L2U_RBA3 | 795   | 11000    | 11011    | 0x0000_3780                                     | SUPR   | Region Base Address Register 3    |
| L2U_RA0  | 824   | 11001    | 11000    | 0x0000_3190                                     | SUPR   | Region Attribute Register 0       |
| L2U_RA1  | 825   | 11001    | 11001    | 0x0000_3390                                     | SUPR   | Region Attribute Register 1       |

**Table 11-5. L2U (PPC) Register Decode (continued)**

| Name    | SPR # | SPR[5:9] | SPR[0:4] | Address for External Master Access <sup>1</sup> | Access | Description                 |
|---------|-------|----------|----------|-------------------------------------------------|--------|-----------------------------|
| L2U_RA2 | 826   | 11001    | 11010    | 0x0000_3590                                     | SUPR   | Region Attribute Register 2 |
| L2U_RA3 | 827   | 11001    | 11011    | 0x0000_3790                                     | SUPR   | Region Attribute Register 3 |
| L2U_GRA | 536   | 10000    | 11000    | 0x0000_3100                                     | SUPR   | Global Region Attribute     |

<sup>1</sup> When EMCR[CONT] = 0, for external master access only.

For these registers a bus cycle will be performed on the L-bus and the U-bus with the address as shown in [Table 11-6](#).

**Table 11-6. Hex Address For SPR Cycles**

| A[0:17] | A[18:22] | A[23:27] | A[28:31] |
|---------|----------|----------|----------|
| 0       | spr[5:9] | spr[0:4] | 0        |

### 11.8.1 U-Bus Access

The L2U registers are accessible from the U-bus side only if it is a supervisor mode data access and the register address is correct and it is indicated on the U-bus that it is a PPC register access.

A user mode access, or an access marked as instruction, to L2U registers from the U-bus side will cause a data error on the U-bus.

### 11.8.2 Transaction Size

All L2U registers are defined by MPC500 architecture as being 32-bit registers in normal mode. There is no MPC500 instruction to access either a half word or a byte of the special purpose register.

All L2U registers are only word accessible (read and write) in peripheral mode. A half-word or byte access in peripheral mode will result in a word transaction.

### 11.8.3 L2U Module Configuration Register (L2U\_MCR)

The L2U module configuration register (L2U\_MCR) is used to control the L2U module operation.

**Figure 11-4. L2U Module Configuration Register (L2U\_MCR)**

**Table 11-7. L2U\_MCR Bit Descriptions**

| Bits | Name  | Description                                                                                                                                                                                                                                                                                                                                                                                                         |
|------|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0    | SP    | CALRAM Protection (SP) bit is used to protect the CALRAM on the L-bus from U-bus accesses. Any attempt to set or clear the SP bit from the U-bus side has no affect. Once this bit is set, the L2U blocks all CALRAM accesses initiated by the U-bus masters and the access is terminated with a data error on the U-bus. If L-bus show cycles are enabled, setting this bit will disable L-bus CALRAM show cycles. |
| 1:2  | LSHOW | LSHOW bits are used to configure the show cycle mode for cycles accessing the L-bus slave e.g. CALRAM<br>00 Disable show cycles<br>01 Show address and data of all L-bus space write cycles<br>10 Reserved<br>11 Show address and data of all L-bus space read and write cycles                                                                                                                                     |

### 11.8.4 Region Base Address Registers (L2U\_RBx)

The L2U region base address register (L2U\_RBx) defines the base address of a specific region protected by the data memory protection unit. There are four registers (x = 0...3), one for each supported region.

**Figure 11-5. L2U Region x Base Address Register (L2U\_RBx)**

**Table 11-8. L2U\_RBAX Bit Descriptions**

| Bits  | Name | Description                                                                                                                                                                                                                             |
|-------|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0:19  | RBA  | Region base address. The RBA field provides the base address of the region. The region base address should start on the block boundary for the corresponding block size attribute specified in the region attribute register (L2U_RAx). |
| 20:31 | —    | Reserved                                                                                                                                                                                                                                |

### 11.8.5 Region Attribute Registers (L2U\_RAx)

Each L2U region attribute register defines the protection attributes associated with a specific region protected by the data memory protection unit. There are four registers (x = 0...3), one for each supported region.

**Figure 11-6. L2U Region X Attribute Register (L2U\_RAx)**
**Table 11-9. L2U\_RAx Bit Descriptions**

| Bits | Name | Description                                                                                                                                                                                                                                                                                                                                                                                                   |

## Chapter 12

# U-Bus to IMB3 Bus Interface (UIMB)

The U-bus to IMB3 bus interface (UIMB) structure is used to connect the CPU internal unified bus (U-bus) to the intermodule bus 3 (IMB3). It controls bus communication between the U-bus and the IMB3. The UIMB interface (see [Figure 12-1](#)) consists of seven submodules that control bus interface timing, address decode, data multiplexing, intrasystem communication (interrupts), and clock generation to allow communication between U-bus and the IMB3. The seven submodules are:

- U-bus interface
- IMB3 interface
- Address decoder
- Data multiplexer
- Interrupt synchronizer
- Clock control
- Scan control

### 12.1 Features

- Provides complete interfacing between the U-bus and the IMB3:
  - 15 bits (32 Kbytes) of address decode on IMB3
  - 32-bit data bus
  - Read/write access to IMB3 module registers
  - Interrupt synchronizer
  - Monitoring of accesses to unimplemented addresses within UIMB interface address range
  - Burst-inhibited accesses to the modules on IMB3
- Support of 32-bit and 16-bit bus interface units (BIUs) for IMB3 modules
- Half and full speed operation of IMB3 bus with respect to U-bus
- Simple “slave only” U-bus interface implementation
  - Transparent mode operation not supported
  - Relinquish and retry not supported
- Supports scan control for modules on the IMB3 and on the U-bus

#### NOTE

Modules on the IMB3 bus can only be reset by  $\overline{\text{SRESET}}$ . Some modules may have a module reset, as well.

**WARNING**

The user should not perform instruction fetches from modules on the IMB3.

## 12.2 UIMB Block Diagram

Figure 12-1. UIMB Interface Module Block Diagram

## 12.3 Clock Module

The clock module within the UIMB interface generates the IMB3 clock. The IMB3 clock is the main timing reference used within the IMB3 modules.

The IMB3 clock is generated based on the STOP and HSPEED bits in the UIMB module configuration register (UMCR). If the STOP = 1, the IMB3 clock is not generated. If the STOP = 0 and the HSPEED = 0, the IMB3 clock is generated as the inversion of the internal system clock. This is the same frequency as the CLKOUT if SCCR[EBDF] = 0b00 – full speed external bus. (See [Figure 12-2](#).) If the HSPEED = 1, then the IMB3 clock is one-half of the internal system frequency. (See [Figure 12-3](#).)

Table 12-1. STOP and HSPEED Bit Functionality

| STOP | HSPEED | Functionality                                           |
|------|--------|---------------------------------------------------------|
| 0    | 0      | IMB3 bus frequency is the same as U-bus frequency.      |
| 0    | 1      | IMB3 bus frequency is half that of the U-bus frequency. |
| 1    | X      | IMB3 clock is not generated.                            |

**Figure 12-2. IMB3 Clock – Full-Speed IMB3 Bus**

**Figure 12-3. IMB3 Clock – Half-Speed IMB3 Bus**

Table 12-2 shows the number of system clock cycles that the UIMB requires to perform each type of bus cycle. It is assumed that the IMB3 is available to the UIMB at all times (fastest possible case).

**Table 12-2. Bus Cycles and System Clock Cycles**

| Bus Cycle (from U-bus Transfer Start to U-bus Transfer Acknowledge) | Number of System Clock Cycles |            |
|---------------------------------------------------------------------|-------------------------------|------------|
|                                                                     | Full Speed                    | Half Speed |
| Normal write                                                        | 4                             | 6          |
| Normal read                                                         | 4                             | 6          |
| Dynamically-sized write                                             | 6                             | 10         |
| Dynamically-sized read                                              | 6                             | 10         |

### NOTE

The UIMB interface dynamically interprets the port size of the addressed module during each bus cycle, allowing bus transfers to and from 16-bit and 32-bit IMB3 modules. During a bus transaction, the slave module on the IMB3 signals its port size (16- or 32-bit) via an internal port size signal.

## 12.4 Interrupt Operation

The interrupts from the modules on the IMB3 are propagated to the interrupt controller in the USIU through the UIMB interface. The UIMB interrupt synchronizer latches the interrupts from the modules on the IMB3 and drives them onto the U-bus, where they are latched by the USIU interrupt controller.

### 12.4.1 Interrupt Sources and Levels on IMB3

The IMB3 has eight interrupt lines. There can be a maximum of 32 levels of interrupts from the modules on IMB3 bus. A single module can be a source for more than one interrupt. For example, the QSMCM can generate two interrupts (one for QSCI1/QSCI2 and another for QSPI). In this case, the QSMCM has two interrupt sources. Each of these two sources can assert the interrupt on any of the 32 levels.

It is possible for multiple interrupt sources to assert the same interrupt level. To reduce the latency, it is a good practice for each interrupt source to assert an interrupt on a level on which no other interrupt source is mapped.

## 12.4.2 IMB3 Interrupt Multiplexing

The IMB3 has 10 lines for interrupt support. Eight lines are for interrupts and two are for interrupt level byte select (ILBS). These lines will transfer the 32 interrupt levels to the interrupt synchronizer. A diagram of the interrupt flow is shown in [Figure 12-4](#).

**Figure 12-4. Interrupt Synchronizer Signal Flow**

Latching 32 interrupt levels using eight IMB3 interrupt lines is accomplished with a 4:1 time-multiplexing scheme. The UIMB drives two signals (ILBS[0:1]) with a multiplexer select code that tells all interrupting modules on the IMB3 about which group of signals to drive during the next clock. See [Figure 12-5](#).

## 12.4.3 ILBS Sequencing

The IMB3 interface drives the ILBS signals continuously, incrementing through a code sequence (0b00, 0b01, 0b10, 0b11) once every clock. The UMCR[IRQMUX] bits in the IMB3 module configuration register select which type of multiplexing the interrupt synchronizer will perform. The IRQMUX field can select time-multiplexing protocols for 8, 16, 24 or 32 interrupt sources. These protocols would take one, two, three or four clocks, respectively.

[Table 12-4](#) shows ILBS sequencing. Programming IRQMUX[0:1] to 0b00 disables time multiplexing. In this case the ILBS lines remain at 0b00 at all times. In this mode, no interrupts from IMB3 modules which assert on levels 8 through 31 are ever latched by the interrupt synchronizer.  $\overline{\text{SRESET}}$  will not clear the IRQMUX bits, so time multiplexing will be enabled with the previous setup after  $\overline{\text{SRESET}}$  is released.

The timing for the scheme and the values of ILBS and the interrupt levels driven onto the IMB3 IRQ lines are shown in [Figure 12-5](#). This scheme causes a maximum latency of four clocks and an average latency of two clocks before the interrupt request can reach the interrupt synchronizer.

**Note:** This diagram represents the ILBS behavior when IRQMUX[0:1] = 11

**Figure 12-5. Time-Multiplexing Protocol for IRQ Signals**

**Table 12-3. ILBS Signal Functionality**

| ILBS[0:1] | Description                                                                              |
|-----------|------------------------------------------------------------------------------------------|
| 00        | IMB3 interrupt sources mapped onto 0:7 levels will drive interrupts onto IMB3 LVL[0:7]   |
| 01        | IMB3 interrupt sources mapped onto 8:15 levels will drive interrupts onto IMB3 LVL[0:7]  |
| 10        | IMB3 interrupt sources mapped onto 16:23 levels will drive interrupts onto IMB3 LVL[0:7] |
| 11        | IMB3 interrupt sources mapped onto 24:31 levels will drive interrupts onto IMB3 LVL[0:7] |

The IRQMUX bits determine how many levels of IMB3 interrupts are sampled. Refer to [Table 12-4](#).

**Table 12-4. IRQMUX Functionality**

| IRQMUX[0:1] | ILBS sequence                       | Description                      |
|-------------|-------------------------------------|----------------------------------|
| 00          | 00, 00, 00,....                     | Latch 0:7 IMB3 interrupt levels  |
| 01          | 00, 01, 00, 01,....                 | Latch 0:15 IMB3 interrupt levels |
| 10          | 00, 01, 10, 00, 01, 10,....         | Latch 0:23 IMB3 interrupt levels |
| 11          | 00, 01, 10, 11, 00, 01, 10, 11,.... | Latch 0:31 IMB3 interrupt levels |

## 12.4.4 Interrupt Synchronizer

The interrupt synchronizer latches the 32 levels of interrupts from the IMB3 bus into a register which can be read by the CPU or other U-bus master. Since there are only eight lines for interrupts on the IMB3 and 32 levels of interrupts are possible, the 32 interrupt levels are multiplexed onto eight IMB3 interrupt lines. Apart from latching these interrupts in the register (UIPEND), the interrupt synchronizer drives the interrupts onto the U-bus, where they are latched by the interrupt controller in the USIU.

If IMB3 modules drive interrupts on any of the 24 levels (levels eight through 31), they will be latched in UIPEND in the UIMB. If any of the register bits 7 to 31 are set, then bit 7 will be set as well.

### NOTE

Software must poll this register to find out which of the levels 7 to 31 are asserted.

The UIPEND register contains a status bit for each of the 32 interrupt levels. Each bit of the register is a read-only status bit, reflecting the current state of the corresponding interrupt signal. For each of the 32 interrupt levels, a corresponding bit of the UIPEND register is set.

Figure 12-4 shows how the eight interrupt lines are connected to the UIPEND register to represent 32 levels of interrupts. Figure 12-6 shows the implementation of the interrupt synchronizer.

Figure 12-6. Interrupt Synchronizer Block Diagram

## 12.5 Programming Model

Table 12-5 lists the registers used for configuring and testing the UIMB module. The address offset shown in this table is from the start of the block reserved for UIMB registers. As shown in Figure 1-2, this block begins at offset 0x30 7F80 from the start of the MPC561/MPC563 internal memory map (the last 128-byte sub-block of the UIMB interface memory map).

<sup>1</sup> S = Supervisor mode only; T = Test mode only

Any word, half-word or byte access to a 32-bit location within the UIMB interface register decode block that is unimplemented (defined as reserved) causes the UIMB interface to assert a data error exception on the U-bus. The entire 32-bit location must be defined as reserved in order for a data error exception to be asserted.

Unimplemented bits in a register return zero when read.

## 12.5.1 UIMB Module Configuration Register (UMCR)

The UIMB module configuration register (UMCR) is accessible in supervisor mode only.

Software must also ensure that all IMB3 interrupts have been serviced before setting this bit.                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| 1:2  | IRQMUX | Interrupt request multiplexing. These bits control the multiplexing of the 32 possible interrupt requests onto the eight IMB3 interrupt request lines.<br>00 Disables the multiplexing scheme on the interrupt controller within this interface. What this means is that the IMB3 IRQ [0:7] signals are non-multiplexed, only providing 8 [0:7] interrupt request lines to the interrupt controller<br>01 Enables the IMB3 IRQ control logic to perform a 2-to-1 multiplexing to allow transferring of 16 [0:15] interrupt sources<br>10 Enables the IMB3 IRQ control logic to perform a 3-to-1 multiplexing to allow transferring of 24 [0:23] interrupt sources<br>11 Enables the IMB3 IRQ control logic to perform a 4-to-1 multiplexing to allow transferring of 32 [0:31] interrupt sources |
| 3    | HSPEED | Half speed. The HSPEED bit controls the frequency at which the IMB3 runs with respect to the U-bus. This is a modify-once bit. Software can write the reset value of this bit any number of times. However, once logic 0 is written to this location, any attempt to rewrite this bit to a logic 1 will have no effect.<br>0 IMB3 frequency is the same as that of the U-bus<br>1 IMB3 frequency is one half that of the U-bus                                                                                                                                                                                                                                                                                                                                                                   |
| 4:31 | —      | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

## 12.5.2 Test Control Register (UTSTCREG)

The UTSTCREG register is used for factory testing only.

## 12.5.3 Pending Interrupt Request Register (UIPEND)

The UIPEND register is a read-only status register which reflects the state of the 32 interrupt levels. The state of IRQ0 is shown in bit 0, the state of IRQ1 is shown in bit 1 and so on. This register is accessible only in supervisor mode.

Figure 12-8. Pending Interrupt Request Register (UIPEND)

Table 12-7. UIPEND Bit Descriptions

| Bits | Name | Description                                                                                                                                              |
|------|------|----------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0:31 | LVLx | Pending interrupt request level. Accessible only in supervisor mode. LVLx identifies the interrupt source as UIMB LVLx, where x is the interrupt number. |

# Chapter 13

## QADC64E Legacy Mode Operation

The two queued analog-to-digital converter (QADC) modules on MPC561/MPC563 devices are 10-bit, unipolar, successive approximation converters. The modules can be configured to operate in one of two modes, legacy mode (MPC555 compatible) and enhanced mode. This chapter describes how the modules operate in legacy mode, which is the default mode of operation. Refer to [Chapter 14, “QADC64E Enhanced Mode Operation,”](#) for information regarding the QADC64E functionality in enhanced mode.

For this revision of the QADC, the name QADC64E implies the enhanced version of the QADC module, not just enhanced mode of operation. For simplicity, the names QADC and QADC64E may be used interchangeably throughout this document.

### 13.1 QADC64E Block Diagram

Figure 13-1 displays the major components of the QADC64E modules on the MPC561/MPC563.

Figure 13-1. QADC64E Block Diagram

## 13.2 Key Features and Quick Reference Diagrams

This section gives an overview of the implementation of the two QADC64E modules on MPC561/MPC563. It can also be used as a quick reference guide while programming the modules.

### 13.2.1 Features of the QADC64E Legacy Mode Operation

- Internal sample and hold
- Directly supports up to four external multiplexers (for example the MC14051)
- Up to 41 analog input channels using QADC64E external multiplexing
- Programmable input sample time for various source impedances
- Minimum conversion time of 7  $\mu$ s (with typical QCLK frequency, 2 MHz)
- Two conversion command queues with a total of 64 entries
- Sub-queues possible using pause mechanism
- Queue complete and pause software interrupts available on both queues
- Queue pointers indicate current location for each queue
- Automated queue modes initiated by
  - External edge trigger
  - Periodic/Interval timer, within QADC64E module
  - Software command
  - External gated trigger (Queue 1 only)
- Single-scan or continuous-scan of queues
- 64 result registers in each QADC64E module
- Output readable in three formats
  - Right-justified unsigned
  - Left-justified signed
  - Left-justified unsigned
- Unused analog channels on Port A can be used as digital input/output signals, unused analog channels on Port B can be used as digital input signals.

The analog section includes input signals, an analog multiplexer, and the sample and hold circuits. The analog conversion is performed by the digital-to-analog converter (DAC) resistor-capacitor array and a high-gain comparator.

The digital control section contains queue control logic to sequence the conversion process and interrupt generation logic. Also included are the periodic/interval timer, control and status registers, the conversion command word (CCW) table RAM, and the result table RAM.

The bus interface unit (BIU) allows the QADC64E to operate with the applications software through the IMB3 environment.

## 13.2.2 Memory Map

The QADC64E occupies 1 Kbyte, or 512 16-bit entries, of address space. Ten 16-bit registers are control, port, and status registers, 64 16-bit entries are the CCW table, and 64 16-bit entries are the result table, and occupy 192 16-bit address locations because the result data is readable in three data alignment formats.

Each QADC64E module on the MPC561/MPC563 has its own memory space. Table 13-1 shows the memory map for QADC64E module A, it occupies 0x30 4800 to 0x30 4BFF. Table 13-2 displays the memory map for module B. Module B has the same offset scheme starting at 0x30 4C00. QADC64E B occupies 0x30 4C00 to 0x30 4FFF.

**Table 13-1. QADC64E\_A Address Map**

| Address                    | MSB                     |                       |          |         |          |          |                          |            |        |         |         |    |     |     |           | LSB            | Register                       |                   |

<sup>1</sup>Registers are accessible only as supervisor data space

Accesses to supervisor-only data space is permitted only when the bus master is operating in supervisor access mode. Assignable data space can be either restricted to supervisor-only access or unrestricted to both supervisor and user data space addresses. See [Section 13.3.1.4, “Supervisor/Unrestricted Address Space.”](#)

### 13.2.3 Legacy and Enhanced Modes of Operation

The QADC64E modules can be configured to operate in legacy or enhanced mode. Legacy mode is the default state out of reset. Configuring bits in the QADC64E module configuration register enables

enhanced mode. This will be described in [Section 13.3.1.3, “Switching Between Legacy and Enhanced Modes of Operation.”](#)

### 13.2.4 Using the Queue and Result Word Table

The heart of the QADC is its conversion command word (CCW) queues. This is where the module is programmed to convert a particular channel according to a particular requirement. The queues are created by writing CCWs into the CCW table in the register memory. The queues are controlled by the three control registers, and their status can be read from the two status registers. As conversions are completed the digital value is written into the result word table. [Figure 13-2](#) shows the CCW queue and the result word table.

Figure 13-2. QADC64E Conversion Queue Operation

### 13.2.5 External Multiplexing

The QADC can use from one to four 8-input external multiplexer chips to expand the number of analog signals that may be converted. The externally multiplexed channels are automatically selected from the

channel field of the conversion command word (CCW) table. External Multiplex mode is software selectable, by setting the EMUX bit of control register 0, QACR0.

Figure 13-3 shows the maximum configuration of four external multiplexer chips connected to the QADC. The QADC provides three multiplexer address signals – MA[0], MA[1], MA[2] – to select one of the multiplexer chips. These outputs are the multiplexer control lines and they are connected to all external multiplexer chips.

The analog output of each of the four multiplexer chips is connected to four separate QADC inputs – ANw, ANx, ANy, ANz. These signals are the first four signals of port B and each one can represent eight analog input channels. The QADC converts the proper input channel (ANw, ANx, ANy, ANz) by interpreting the channel number in the CCW. Refer to Table 13-3.

Figure 13-3. Example of External Multiplexing

In the external multiplexed mode, four of the port B signals are redefined to each represent eight input channels. Refer to Table 13-3 for more information.

**Table 13-3. Multiplexed Analog Input Channels**

| Multiplexed Analog Input | Channels                       |
|--------------------------|--------------------------------|
| ANw (AN[0])              | 0, 2, 4, 6, 8, 10, 12, 14      |
| ANx (AN[1])              | 1, 3, 5, 7, 9, 11, 13, 15      |
| ANY (AN[2])              | 16, 18, 20, 22, 24, 26, 28, 30 |
| ANz (AN[3])              | 17, 19, 21, 23, 25, 27, 29, 31 |

Table 13-4 shows the total number of analog input channels supported with zero to four external multiplexer chips using one QADC module.

**Table 13-4. Analog Input Channels**

| Number of Analog Input Channels Available<br>Directly Connected + External Multiplexed = Total Channels |                       |                        |                          |                         |
|---------------------------------------------------------------------------------------------------------|-----------------------|------------------------|--------------------------|-------------------------|
| No External MUX Chips                                                                                   | One External MUX Chip | Two External MUX Chips | Three External MUX Chips | Four External MUX Chips |
| 16                                                                                                      | 20                    | 27                     | 34                       | 41                      |

**NOTE: QADC64E External MUX Users**

If either QADC64E\_A or QADC64E\_B is in external multiplexing (EMUX) mode then the multiplexer address signal channels, AN[52:54] should *not* be programmed into queues.

### 13.3 Programming the QADC64E Registers

The QADC64E has three global registers for configuring module operation:

- Module configuration register (Section 13.3.1, “QADC64E Module Configuration Register (QADMCR)”)
- Interrupt register (Section 13.3.2, “QADC64E Interrupt Register (QADCINT)”)
- Test register (QADCTEST) for factory tests.

The global registers are always defined to be in supervisor-only data space. Refer to Table 13-1 for the QADC64E\_A address map and Table 13-2 for the QADC64E\_B address map. See Section 13.3.1.4, “Supervisor/Unrestricted Address Space” for access modes of these registers.

The remaining five registers in the control register block control the operation of the queuing mechanism, and provide a means of monitoring the operation of the QADC64E.

- Control register 0 (QACR0) contains hardware configuration information (Section 13.3.5, “Control Register 0 (QACR0)”)
- Control register 1 (QACR1) is associated with queue 1 (Section 13.3.6, “Control Register 1 (QACR1)”)
- Control register 2 (QACR2) is associated with queue 2 (Section 13.3.7, “Control Register 2 (QACR2)”)

- Status registers (QASR0 and QASR1) provide visibility on the status of each queue and the particular conversion that is in progress ([Section 13.3.8, “Status Registers \(QASR0 and QASR1\)”](#))

The CCW table follows the register block in the address map. There are 64 table entries to hold the desired analog conversion sequences. Each CCW table entry is 16-bits, with ten implemented bits in four fields.

The final block of address space belongs to the result word table, which appears in three places in the memory map. Each result word table location holds one 10-bit conversion value.

### 13.3.1 QADC64E Module Configuration Register (QADMCR)

The QADMCR contains five implemented bits that control the operating modes of the QADC64E module. The configurable modes are freeze, stop and supervisor. The QADMCR also implements a pair of bits that together select either legacy or enhanced mode for the QADC module, and lock that operating mode.

### 13.3.1.1 Low Power Stop Mode

When the STOP bit in the QADCMCR is set, the QADC64E clock (QCLK) which clocks the A/D converter, is disabled and the analog circuitry is powered down. This results in a static, low power consumption, idle condition. The stop mode aborts any conversion sequence in progress. Because the bias currents to the analog circuits are turned off in stop mode, the QADC64E requires some recovery time ( $T_{SR}$  in [Appendix F, “Electrical Characteristics”](#)) to stabilize the analog circuits after the stop enable bit is cleared.

In stop mode:

- BIU state machine and logic do not shut down
- The CCW and result is not reset and is not accessible
- The module configuration register (QADCMCR), the interrupt register (QADCINT), and the test register (QADCTEST) are fully accessible and are not reset
- The data direction register (DDRQA), port data register (PORTQA/PORTQB), and control register 0 (QACR0) are not reset and are read-only accessible
- Control register 1 (QACR1), control register 2 (QACR2), and the status registers (QASR0 and QASR1) are reset and are read-only accessible
- In addition, the periodic/interval timer is held in reset during stop mode

If the STOP bit is clear, stop mode is disabled.

### 13.3.1.2 Freeze Mode

Freeze mode occurs when the background debug mode is enabled in the USIU and a breakpoint is encountered. This is indicated by the assertion of the internal FREEZE line on the IMB3. The FRZ bit in the QADCMCR determines whether or not the QADC64E responds to an IMB3 internal FREEZE signal assertion. Freeze is very useful when debugging an application.

When the internal FREEZE signal is asserted and the FRZ bit is set, the QADC64E finishes any conversion in progress and then freezes.

Depending on when the FREEZE signal is asserted, there are three possible queue "freeze" scenarios:

- When a queue is not executing, the QADC64E freezes immediately
- When a queue is executing, the QADC64E completes the conversion in progress and then freezes

- If, during the execution of the current conversion, the queue operating mode for the active queue is changed, or a queue 2 abort occurs, the QADC64E freezes immediately

During freeze mode, both the analog clock, QCLK, and periodic/interval timer are held in reset. When the QADC64E enters the freeze mode while a queue is active, the current CCW location of the queue pointer is saved.

During freeze, the analog clock, QCLK, is held in reset and the periodic/interval timer is held in reset. External trigger events that occur during the freeze mode are not captured. The BIU remains active to allow IMB3 access to all QADC64E registers and RAM. Although the QADC64E saves a pointer to the next CCW in the current queue, the software can force the QADC64E to execute a different CCW by writing new queue operating modes for normal operation. The QADC64E looks at the queue operating modes, the current queue pointer, and any pending trigger events to decide which CCW to execute when exiting freeze.

If the FRZ bit is clear, the internal FREEZE signal is ignored.

### 13.3.1.3 Switching Between Legacy and Enhanced Modes of Operation

The LOCK and FLIP bits of the QADCMCR register control the operating mode of the QADC64E modules. Out of reset, the QADC64E modules are in legacy mode (FLIP = 0) and the LOCK bit is clear, indicating that the module is locked in legacy mode. In order to change the value of the FLIP bit, the operating mode must first be unlocked, by setting the LOCK bit. Only then can the FLIP bit be changed. Finally, the LOCK bit must be cleared again to protect the state of the FLIP bit from future writes.

1. Write LOCK = 1 to unlock operating mode bit.
2. Modify the value of FLIP as required.
  - FLIP = 0 Legacy mode enabled
  - FLIP = 1 Enhanced mode enabled
3. Write LOCK = 0 and new FLIP bit value to preserve the value of FLIP bit
  - Example 1 Switching from legacy mode to enhanced mode
    - QADCMCR = 0x280; LOCK = 1, SUPV = 1
    - QADCMCR = 0x380; LOCK = 1, write FLIP = 1, SUPV = 1
    - QADCMCR = 0x180; LOCK = 0, FLIP = 1, SUPV = 1
 Subsequent writes to the FLIP bit will have no effect while LOCK = 0.
  - Example 2 Switching from enhanced mode to legacy mode
    - QADCMCR = 0x280 or 0x380; LOCK = 1, SUPV = 1  
(Can write FLIP = x because value will not change)
    - QADCMCR = 0x280; LOCK = 1, FLIP = 0, SUPV = 1
    - QADCMCR = 0x080; LOCK = 0, FLIP = 0, SUPV = 1

### 13.3.1.4 Supervisor/Unrestricted Address Space

The QADC64E memory map is divided into two segments: supervisor-only data space and assignable data space. Access to supervisor-only data space is permitted only when the software is operating in supervisor

access mode. Assignable data space can be either restricted to supervisor-only access or unrestricted to both supervisor and user data space accesses. The SUPV bit in the QADCMCR designates the assignable space as supervisor or unrestricted.

The following information applies to accesses to address space located within the module's 16-bit boundaries and where the response is a bus error. See [Table 13-6](#) for more information.

- Attempts to read a supervisor-only data space when not in the supervisor access mode and SUPV = 1, causes the bus master to assert a bus error condition. No data is returned. If SUPV = 0, the QADC64E asserts a bus error condition and no data is returned.
- Attempts to write to supervisor-only data space when not in the supervisor access mode and SUPV = 1, causes the bus master to assert a bus error condition. No data is written. If SUPV = 0, the QADC64E asserts a bus error condition and the register is not written.
- Attempts to read unimplemented data space in the unrestricted access mode and SUPV = 1, causes the bus master to assert a bus error condition and no data is returned. In all other attempts to read unimplemented data space, the QADC64E causes a bus error condition and no data is returned.
- Attempts to write unimplemented data space in the unrestricted access mode and SUPV = 1, causes the bus master to assert a bus error condition and no data is written. In all other attempts to write unimplemented data space, the QADC64E causes a bus error condition and no data is written.
- Attempts to read assignable data space in the unrestricted access mode when the space is programmed as supervisor space causes the bus master to assert a bus error condition and no data is returned.
- Attempts to write assignable data space in the unrestricted access mode when the space is programmed as supervisor space causes the bus master to assert a bus error condition and the register is not written.

**Table 13-6. QADC64E Bus Error Response**

| S/U <sup>1</sup><br>Mode | SUPV Bit | Supervisor-Only<br>Register    | Supervisor/<br>Unrestricted Register | Reserved/<br>Unimplemented<br>Register |
|--------------------------|----------|--------------------------------|--------------------------------------|----------------------------------------|
| U                        | 0        | QADC64E bus error <sup>2</sup> | Valid access <sup>4</sup>            | QADC64E bus error <sup>2</sup>         |
| U                        | 1        | Master bus error <sup>3</sup>  | Master bus error <sup>3</sup>        | Master bus error <sup>3</sup>          |
| S                        | 0        | Valid access                   | Valid access                         | QADC64E bus error <sup>2</sup>         |
| S                        | 1        | Valid access                   | Valid access                         | QADC64E bus error <sup>2</sup>         |

<sup>1</sup> S/U = Supervisor/Unrestricted

<sup>2</sup> QADC64E bus error = Caused by QADC64E

<sup>3</sup> Master bus error = Caused by bus master

<sup>4</sup> Access to QADCTEST register will act as a reserved/unimplemented register unless in factory test mode

The bus master indicates the supervisor and user space access with the function code bits (FC[2:0]) on the IMB3. For privilege violations, refer to the [Chapter 9, "External Bus Interface"](#) to determine the consequence of a bus error cycle termination.

The supervisor-only data space segment contains the QADC64E global registers, which include the QADCMCR, the QADCTEST, and the QADCINT. The supervisor/unrestricted space designation for the CCW table, the result word table, and the remaining QADC64E registers is programmable.

### 13.3.2 QADC64E Interrupt Register (QADCINT)

QADCINT specifies the priority level of QADC64E interrupt requests. The interrupt level for queue 1 and queue 2 may be different. The interrupt register is read/write accessible in supervisor data space only. The implemented interrupt register fields can be read and written, reserved bits read zero and writes have no effect. They are typically written once when the software initializes the QADC64E, and not changed afterwards.

Figure 13-5. QADC Interrupt Register (QADCINT)

Table 13-7. QADCINT Bit Descriptions

| Bit(s) | Name | Description                                                                                                                                                                                                                                                                                                                    |
|--------|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0:4    | IRL1 | Queue 1 Interrupt Request Level. The IRL1 field establishes the queue 1 interrupt request level. The 00000 state provides a level 0 interrupt, while 11111 provides a level 31 interrupt. All interrupts are presented on the IMB3. Interrupt level priority software determines which level has the highest priority request. |
| 5:9    | IRL2 | Queue 2 Interrupt Request Level. The IRL2 field establishes the queue 2 interrupt request level. The 00000 state provides a level 0 interrupt, while 11111 provides a level 31 interrupt. All interrupts are presented on the IMB3. Interrupt level priority software determines which level has the highest priority request. |
| 10:15  | —    | Reserved.                                                                                                                                                                                                                                                                                                                      |

The QADC64E conditionally generates interrupts to the bus master via the IMB3 IRQ signals. When the QADC64E sets a status bit assigned to generate an interrupt, the QADC64E drives the IRQ bus. The value driven onto IRQ[7:0] represents the interrupt level assigned to the interrupt source. Under the control of ILBS, each interrupt request level is driven during the time multiplexed bus during one of four different time slots, with eight levels communicated per time slot. No hardware priority is assigned to interrupts. Furthermore, if more than one source on a module requests an interrupt at the same level, the system software must assign a priority to each source requesting at that level. [Figure 13-6](#) displays the interrupt levels on IRQ with ILBS. Refer to [Chapter 12, “U-Bus to IMB3 Bus Interface \(UIMB\),”](#) for more information.

Figure 13-6. Interrupt Levels on IRQ with ILBS

### 13.3.3 Port Data Register (PORTQA and PORTQB)

QADC64E ports A and B are accessed through two 8-bit port data registers (PORTQA and PORTQB) in each QADC64E.

Port A signals are referred to as PQA[7:0] when used as 8-bit general-purpose digital input or output signals. It is configured as a digital input or digital output using the data direction register, DDRQA. When Port A is configured as an input, a read of the PORTQA register returns the actual PQA[7:0] signal values. When Port A is configured as an output, the contents of port register PQA are driven on the port A signals. Port A can also be used as analog inputs AN[59:52] and external multiplexer address outputs MA[2:0].

Port B signals are referred to as PQB[7:0] when used as 8-bit general-purpose digital input-only signals. Digital input signal states are read from the 8-bit PORTQB register. Port B can also be used as non-multiplexed analog inputs AN[51:48] and AN[3:0], and external multiplexer analog inputs, ANw, ANx, ANy, ANz.

During a port data register read, the actual value of the signal is reported when its corresponding bit in the data direction register defines the signal to be an input. When the data direction bit specifies the signal to be an output, the content of the port data register is read. PORTQA and PORTQB are not initialized by reset.

|                              | MSB                            | 1        | 2        | 3        | 4        | 5        | 6        | 7        | 8                             | 9        | 10       | 11       | 12       | 13       | 14       | LSB      |

| Bits | Name     | Description                                                                                                                                                                                  |
|------|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0:7  | PQA[7:0] | Port A signals are referred to as PQA when used as an 8-bit input/output port. Port A can also be used for analog inputs (AN[59:52]), and external multiplexer address outputs (MA[2:0]).    |
| 8:15 | PQB[7:0] | Port B signals are referred to as PQB when used as an 8 input-only port. Port B can also be used for non-multiplexed (AN[51:48]/AN[3:0]) and multiplexed (ANz, ANy, ANx, ANw) analog inputs. |

### 13.3.4 Port Data Direction Register (DDRQA)

The port data direction register, DDRQA, is associated with port A digital input/output signals only. Any bit set in this register configures the corresponding signal as an output. Any bit cleared in this register configures the corresponding signal as an input. The software is responsible for ensuring that DDR bits are not set on signals used for analog inputs. When the DDR bit is set, thereby selecting the signal for analog conversion, the voltage sampled is that of the output digital driver as influenced by the load.

#### NOTE

Caution should be exercised when mixing digital and analog inputs. This should be isolated as much as possible. Rise and fall times should be as large as possible to minimize AC coupling effects.

There are two special cases to consider for the digital I/O port operation. When QACR0[EMUX] is set, enabling external multiplexing, the data direction register settings are ignored for the bits corresponding to PORTQA[2:0], which are the three multiplexed address (MA[2:0]) output signals. The MA[2:0] signals are forced to be digital outputs, regardless of the data direction setting, and the multiplexed address outputs are driven. The data returned during a port data register read is the value of the multiplexed address latches which drive MA[2:0], regardless of the data direction setting.

Figure 13-8. Port A Data Direction Register (DDRQA)

### 13.3.5 Control Register 0 (QACR0)

Control Register 0 is used to define whether external multiplexing is enabled, assign external triggers to the conversion queues and to sets up the QCLK prescaler parameter field. All of the implemented control

register fields can be read or written but reserved fields read zero and writes have no effect. Typically, they are written once when software initializes the QADC64E and are not changed afterwards.

|-------|------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0     | EMUX | Externally multiplexed mode. The EMUX bit configures the QADC64E for externally multiplexed mode, which affects the interpretation of the channel numbers and forces the MA[2:0] signals to be outputs. See <a href="#">Table 13-7</a> for more information.<br>0 Internally multiplexed, 16 possible channels<br>1 Externally multiplexed, 41 possible channels |
| 1:2   | —    | Reserved                                                                                                                                                                                                                                                                                                                                                         |
| 3     | TRG  | Trigger assignment. TRG allows the software to assign the ETRIG[2:1] signals to queue 1 and queue 2.<br>0 ETRIG1 triggers queue 1; ETRIG2 triggers queue 2<br>1 ETRIG1 triggers queue 2; ETRIG2 triggers queue 1<br>Refer to <a href="#">Section 13.7.2, “External Trigger Input Signals.”</a>                                                                   |
| 4:6   | —    | Reserved                                                                                                                                                                                                                                                                                                                                                         |
| 7:11  | PSH  | Prescaler clock high time. The PSH field selects the QCLK high time in the prescaler. PSH value plus 1 represents the high time in IMB3 clocks                                                                                                                                                                                                                   |
| 12    | PSA  | Note that this bit location is maintained for software compatibility with previous versions of the QADC64E. It serves no functional benefit in the MPC561/MPC563 and is not operational.                                                                                                                                                                         |
| 13:15 | PSL  | Prescaler clock low time. The PSL field selects the QCLK low time in the prescaler. PSL value plus 1 represents the low time in IMB3 clocks                                                                                                                                                                                                                      |

**NOTE**

Details of how to calculate values for PSH, PSA, and PSL, as well as examples, are given in [Section 13.5.5, “QADC64E Clock \(QCLK\) Generation.”](#)

### 13.3.6 Control Register 1 (QACR1)

Control register 1 is the mode control register for the operation of queue 1. The application software defines the queue operating mode for the queue, and may enable a completion and/or pause interrupt. All of the control register fields are read/write data. However, the SSE1 bit always reads as zero. Most of the bits are typically written once when the software initializes the QADC64E, and not changed afterwards.

| 1    | PIE1 | Queue 1 Pause Interrupt Enable. PIE1 enables an interrupt when queue 1 enters the pause state. The interrupt request is initiated when conversion is complete for a CCW that has the pause bit set.<br>0 Disable the pause interrupt associated with queue 1<br>1 Enable an interrupt after the conversion of the sample requested by a CCW in queue 1 which has the pause bit set                                                                                                                                                                                                                                                                                                                                      |
| 2    | SSE1 | Queue 1 Single-Scan Enable Bit. SSE1 enables a single-scan of queue 1 to start after a trigger event occurs. The SSE1 bit may be set to a one during the same write cycle when the MQ1 bits are set for one of the single-scan queue operating modes. The single-scan enable bit can be written as a one or a zero, but is always read as a zero. The SSE1 bit enables a trigger event to initiate queue execution for any single-scan operation on queue 1. The QADC64E clears the SSE1 bit when the single-scan is complete. Refer to <a href="#">Table 13-11</a> for more information.<br>0 Trigger events are not accepted for single-scan modes<br>1 Accept a trigger event to start queue 1 in a single-scan mode |
| 3:7  | MQ1  | Queue 1 Operating Mode. The MQ1 field selects the queue operating mode for queue 1. <a href="#">Table 13-11</a> shows the bits in the MQ1 field which enable different queue 1 operating mode                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| 8:15 | —    | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

### 13.3.7 Control Register 2 (QACR2)

Control register 2 is the mode control register for the operation of queue 2. Software specifies the queue operating mode of queue 2, and may enable a completion and/or a pause interrupt. All control register fields are read/write data, except the SSE2 bit, which is readable only when the test mode is enabled. Most of the bits are typically written once when the software initializes the QADC64E, and not changed afterwards.

| Bits | Name | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|------|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 9:15 | BQ2  | <p>Beginning of queue 2. The BQ2 field indicates the CCW location where queue 2 begins. To allow the length of queue 1 and queue 2 to vary, a programmable pointer identifies the CCW table location where queue 2 begins. The BQ2 field also serves as an end-of-queue condition for queue 1. Setting BQ2 beyond physical CCW table memory space allows queue 1 all 64 entries.</p> <p>Software defines the beginning of queue 2 by programming the BQ2 field in QACR2. BQ2 is usually programmed before or at the same time as the queue operating mode for queue 2 is selected. If BQ2 is 64 or greater, queue 2 has no entries, and the entire CCW table is dedicated to queue 1 and CCW63 is the end-of-queue 1. If BQ2 is zero, the entire CCW table is dedicated to queue 2. As a special case, when a queue operating mode for queue 1 is selected and a trigger event occurs for queue 1 with BQ2 set to zero, queue 1 execution is terminated after CCW0 is read. Conversions do not occur.</p> <p>The BQ2 pointer may be changed dynamically, to alternate between queue 2 scan sequences. A change in BQ2 after queue 2 has begun or if queue 2 has a trigger pending does not affect queue 2 until queue 2 is started again. For example, two scan sequences could be defined as follows: the first sequence starts at CCW10, with a pause after CCW11 and an EOQ programmed in CCW15; the second sequence starts at CCW16, with a pause after CCW17 and an EOQ programmed in CCW39.</p> <p>With BQ2 set to CCW10 and the continuous-scan mode selected, queue execution begins. When the pause is encountered in CCW11, a software interrupt routine can redefine BQ2 to be CCW16. Therefore, after the end-of-queue is recognized in CCW15, an internal retrigger event is generated and execution restarts at CCW16. When the pause software interrupt occurs again, software can change BQ2 back to CCW10. After the end-of-queue is recognized in CCW39, an internal retrigger event is created and execution now restarts at CCW10.</p> <p>If BQ2 is changed while queue 1 is active, the effect of BQ2 as an end-of-queue indication for queue 1 is immediate. However, beware of the risk of losing the end-of-queue 1 through moving BQ2. Recommend use of EOQ (chan63) to end queue 1.</p> <p><b>Note:</b> Be sure to do a mode change when changing BQ2 and setting SSE2. Setting BQ2 first is recommended.</p> |

Table 13-13 shows the bits in the MQ2 field that enable different queue 2 operating modes.

### NOTE

If BQ2 was assigned to the CCW that queue 1 is currently working on, then that conversion is completed before BQ2 takes effect.

Each time a CCW is read for queue 1, the CCW location is compared with the current value of the BQ2 pointer to detect a possible end-of-queue condition. For example, if BQ2 is changed to CCW3 while queue 1 is converting CCW2, queue 1 is terminated after the conversion is completed. However, if BQ2 is changed to CCW1 while queue 1 is converting CCW2, the QADC64E would not recognize a BQ2 end-of-queue condition until queue 1 execution reached CCW1 again, presumably on the next pass through the queue.

### 13.3.8 Status Registers (QASR0 and QASR1)

The status registers contains information about the state of each queue and the current A/D conversion. Except for the four flag bits (CF1, PF1, CF2, and PF2) and the two trigger overrun bits (TOR1 and TOR2),

all of the status register fields contain read-only data. The four flag bits and the two trigger overrun bits are cleared by writing a zero to the bit after the bit was previously read as a one.

|------|------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0    | CF1  | <p>Queue 1 Completion Flag. CF1 indicates that a queue 1 scan has been completed. The scan completion flag is set by the QADC64E when the input channel sample requested by the last CCW in queue 1 is converted, and the result is stored in the result table.</p> <p>The end-of-queue 1 is identified when execution is complete on the CCW in the location prior to that pointed to by BQ2, when the current CCW contains an end-of-queue code instead of a valid channel number, or when the currently completed CCW is in the last location of the CCW RAM.</p> <p>When CF1 is set and interrupts are enabled for that queue completion flag, the QADC64E asserts an interrupt request at the level specified by IRL1 in the interrupt register (QADCINT). The software reads the completion flag during an interrupt service routine to identify the interrupt request. The interrupt request is cleared when the software writes a zero to the completion flag bit, when the bit was previously read as a one. Once set, only software or reset can clear CF1.</p> <p>CF1 is maintained by the QADC64E regardless of whether the corresponding interrupt is enabled. The software polls for CF1 bit to see if it is set. This allows the software to recognize that the QADC64E is finished with a queue 1 scan. The software acknowledges that it has detected the completion flag being set by writing a zero to the completion flag after the bit was read as a one.</p> |

**Table 13-14. QASR0 Bit Descriptions (continued)**

| Bits | Name | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|------|------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1    | PF1  | <p>Queue 1 Pause Flag. PF1 indicates that a queue 1 scan has reached a pause. PF1 is set by the QADC64E when the current queue 1 CCW has the pause bit set, the selected input channel has been converted, and the result has been stored in the result table.</p> <p>Once PF1 is set, the queue enters the paused state and waits for a trigger event to allow queue execution to continue. However, if the CCW with the pause bit set is the last CCW in a queue, the queue execution is complete. The queue status becomes idle, not paused, and both the pause and completion flags are set. Another exception occurs in software controlled mode, where the PF1 can be set but queue 1 never enters the pause state since queue 1 continues without pausing.</p> <p>When PF1 is set and interrupts are enabled for the corresponding queue, the QADC64E asserts an interrupt request at the level specified by IRL1 in the interrupt register. The software may read PF1 during an interrupt service routine to identify the interrupt request. The interrupt request is cleared when the software writes a zero to PF1, when the bit was previously read as a one. Once set, only software or reset can clear PF1.</p> <p>In external gated single-scan and continuous-scan mode the definition of PF1 has been redefined. When the gate closes before the end-of-queue 1 is reached, PF1 becomes set to indicate that an incomplete scan has occurred. In single-scan mode, setting PF1 can be used to cause an interrupt and software can then determine if queue 1 should be enabled again. In either external gated mode, setting PF1 indicates that the results for queue 1 have not been collected during one scan (coherently).</p> <p>NOTE: If a pause in a CCW is encountered in external gated mode for either single-scan and continuous-scan mode, the pause flag <i>will not set</i>, and execution continues without pausing. This has allowed for the added definition of PF1 in the external gated modes.</p> <p>PF1 is maintained by the QADC64E regardless of whether the corresponding interrupts are enabled. The software may poll PF1 to find out when the QADC64E has reached a pause in scanning a queue. The software acknowledges that it has detected a pause flag being set by writing a zero to PF1 after the bit was last read as a one.</p> <p>0 = queue 1 has not reached a pause (or gate has not closed before end-of-queue in gated mode)</p> <p>1 = queue 1 has reached a pause (or gate closed before end-of-queue in gated mode)</p> <p>Refer to <a href="#">Table 13-15</a> for a summary of pause response in all scan modes.</p> |
| 2    | CF2  | <p>Queue 2 Completion Flag. CF2 indicates that a queue 2 scan has been completed. CF2 is set by the QADC64E when the input channel sample requested by the last CCW in queue 2 is converted, and the result is stored in the result table.</p> <p>The end-of-queue 2 is identified when the current CCW contains an end-of-queue code instead of a valid channel number, or when the currently completed CCW is in the last location of the CCW RAM.</p> <p>When CF2 is set and interrupts are enabled for that queue completion flag, the QADC64E asserts an interrupt request at the level specified by IRL2 in the interrupt register (QADCINT). The software reads CF2 during an interrupt service routine to identify the interrupt request. The interrupt request is cleared when the software writes a zero to the CF2 bit, when the bit was previously read as a one. Once set, only software or reset can clear CF2.</p> <p>CF2 is maintained by the QADC64E regardless of whether the corresponding interrupts are enabled. The software polls for CF2 to see if it is set. This allows the software to recognize that the QADC64E is finished with a queue 2 scan. The software acknowledges that it has detected the completion flag being set by writing a zero to the completion flag after the bit was read as a one.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

**Table 13-14. QASR0 Bit Descriptions (continued)**

| Bits | Name | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|------|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 3    | PF2  | <p>Queue 2 Pause Flag. PF2 indicates that a queue 2 scan has reached a pause. PF2 is set by the QADC64E when the current queue 2 CCW has the pause bit set, the selected input channel has been converted, and the result has been stored in the result table.</p> <p>Once PF2 is set, the queue enters the paused state and waits for a trigger event to allow queue execution to continue. However, if the CCW with the pause bit set is the last CCW in a queue, the queue execution is complete. The queue status becomes idle, not paused, and both the pause and completion flags are set. Another exception occurs in software controlled mode, where the PF2 can be set but queue 2 never enters the pause state.</p> <p>When PF2 is set and interrupts are enabled for the corresponding queue, the QADC64E asserts an interrupt request at the level specified by IRL2 in the interrupt register. The software reads PF2 during an interrupt service routine to identify the interrupt request. The interrupt request is cleared when the software writes a zero to PF2, when the bit was previously read as a one. Once set, only software or reset can clear PF2.</p> <p>PF2 is maintained by the QADC64E regardless of whether the corresponding interrupts are enabled. The software may poll PF2 to find out when the QADC64E has reached a pause in scanning a queue. The software acknowledges that it has detected a pause flag being set by writing a zero to PF2 after the bit was last read as a one.</p> <p>0 queue 2 has not reached a pause<br/>1 queue 2 has reached a pause</p> <p>Refer to <a href="#">Table 13-15</a> for a summary of pause response in all scan modes.</p>                                                                                                                                                                                                  |
| 4    | TOR1 | <p>Queue 1 Trigger Overrun. TOR1 indicates that an unexpected trigger event has occurred for queue 1. TOR1 can be set only while queue 1 is in the active state.</p> <p>A trigger event generated by a transition on the external trigger signal or by the periodic/interval timer may be captured as a trigger overrun. TOR1 cannot occur when the software initiated single-scan mode or the software initiated continuous-scan mode are selected.</p> <p>TOR1 occurs when a trigger event is received while a queue is executing and before the scan has completed or paused. TOR1 has no effect on the queue execution.</p> <p>After a trigger event has occurred for queue 1, and before the scan has completed or paused, additional queue 1 trigger events are not retained. Such trigger events are considered unexpected, and the QADC64E sets the TOR1 error status bit. An unexpected trigger event may be a system overrun situation, indicating a system loading mismatch.</p> <p>In external gated continuous-scan mode the definition of TOR1 has been redefined. In the case when queue 1 reaches an end-of-queue condition for the second time during an open gate, TOR1 becomes set. This is considered an overrun condition. In this case CF1 has been set for the first end-of-queue 1 condition and then TOR1 becomes set for the second end-of-queue 1 condition. For TOR1 to be set, software must not clear CF1 before the second end-of-queue 1.</p> <p>The software acknowledges that it has detected a trigger overrun being set by writing a zero to the trigger overrun, after the bit was read as a one. Once set, only software or reset can clear TOR1.</p> <p>0 No unexpected queue 1 trigger events have occurred<br/>1 At least one unexpected queue 1 trigger event has occurred (or queue 1 reaches an end-of-queue condition for the second time in gated mode)</p> |

**Table 13-14. QASR0 Bit Descriptions (continued)**

| Bits  | Name | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-------|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 5     | TOR2 | <p>Queue 2 Trigger Overrun. TOR2 indicates that an unexpected trigger event has occurred for queue 2. TOR2 can be set when queue 2 is in the active, suspended, and trigger pending states.</p> <p>The TOR2 trigger overrun can only occur when using an external trigger mode or a periodic/interval timer mode. Trigger overruns cannot occur when the software initiated single-scan mode and the software initiated continuous-scan mode are selected.</p> <p>TOR2 occurs when a trigger event is received while queue 2 is executing, suspended, or a trigger is pending. TOR2 has no effect on the queue execution. A trigger event that causes a trigger overrun is not retained since it is considered unexpected.</p> <p>An unexpected trigger event may be a system overrun situation, indicating a system loading mismatch. The software acknowledges that it has detected a trigger overrun being set by writing a zero to the trigger overrun, after the bit was read as a one. Once set, only software or reset can clear TOR2.</p> <p>0 No unexpected queue 2 trigger events have occurred<br/>1 At least one unexpected queue 2 trigger event has occurred</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| 6:9   | QS   | <p>Queue Status. The 4-bit read-only QS field indicates the current condition of queue 1 and queue 2. The following are the five queue status conditions:</p> <ul style="list-style-type: none"> <li>• Idle</li> <li>• Active</li> <li>• Paused</li> <li>• Suspended</li> <li>• Trigger pending</li> </ul> <p>The two most significant bits are associated primarily with queue 1, and the remaining two bits are associated with queue 2. Since the priority scheme between the two queues causes the status to be interlinked, the status bits are considered as one 4-bit field.</p> <p><a href="#">Table 13-16</a> shows the bits in the QS field and how they affect the status of queue 1 and queue 2. Refer to <a href="#">Section 13.6, “Trigger and Queue Interaction Examples,”</a> which shows the 4-bit queue status field transitions in typical situations.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| 10:15 | CWP  | <p>Command Word Pointer. The CWP allows the software to know which CCW is executing at present, or was last completed. The command word pointer is a software read-only field, and write operations have no effect. The CWP allows software to monitor the progress of the QADC64E scan sequence. The CWP field is a CCW word pointer with a valid range of 0 to 63.</p> <p>When a queue enters the paused state, the CWP points to the CCW with the pause bit set. While in pause, the CWP value is maintained until a trigger event occurs on the same queue or the other queue. Usually, the CWP is updated a few clock cycles before the queue status field shows that the queue has become active. For example, software may read a CWP pointing to a CCW in queue 2, and the status field shows queue 1 paused, queue 2 trigger pending.</p> <p>When the QADC64E finishes the scan of the queue, the CWP points to the CCW where the end-of-queue (EOQ) condition was detected. Therefore, when the end-of-queue condition is a CCW with the EOQ code (channel 63), the CWP points to the CCW containing the EOQ.</p> <p>When the last CCW in a queue is in the last CCW table location (CCW63), and it does not contain the EOQ code, the end-of-queue is detected when the following CCW is read, so the CWP points to word CCW0.</p> <p>Finally, when queue 1 operation is terminated after a CCW is read that is defined as BQ2, the CWP points to the same CCW as BQ2.</p> <p>During the stop mode, the CWP is reset to zero, since the control registers and the analog logic are reset. When the freeze mode is entered, the CWP is unchanged; it points to the last executed CCW.</p> |

**Table 13-15. Pause Response**

| Scan Mode                                   | Q Operation | PF Asserts? |
|---------------------------------------------|-------------|-------------|
| External Trigger Single-scan                | Pauses      | Yes         |
| External Trigger Continuous-scan            | Pauses      | Yes         |
| Periodic/Interval Timer Trigger Single-scan | Pauses      | Yes         |
| Periodic/Interval Timer Continuous-scan     | Pauses      | Yes         |
| Software Initiated Single-scan              | Continues   | Yes         |
| Software Initiated Continuous-scan          | Continues   | Yes         |
| External Gated Single-scan                  | Continues   | No          |
| External Gated Continuous-scan              | Continues   | No          |

**Table 13-16. Queue Status**

| QS[9:6] | Queue 1/Queue 2 States                  |
|---------|-----------------------------------------|
| 0000    | queue 1 idle, queue 2 idle              |
| 0001    | queue 1 idle, queue 2 paused            |
| 0010    | queue 1 idle, queue 2 active            |
| 0011    | queue 1 idle, queue 2 trigger pending   |
| 0100    | queue 1 paused, queue 2 idle            |
| 0101    | queue 1 paused, queue 2 paused          |
| 0110    | queue 1 paused, queue 2 active          |
| 0111    | queue 1 paused, queue 2 trigger pending |
| 1000    | queue 1 active, queue 2 idle            |
| 1001    | queue 1 active, queue 2 paused          |
| 1010    | queue 1 active, queue 2 suspended       |
| 1011    | queue 1 active, queue 2 trigger pending |
| 1100    | Reserved                                |
| 1101    | Reserved                                |
| 1110    | Reserved                                |
| 1111    | Reserved                                |

One or both queues may be in the idle state. When a queue is idle, CCWs are not being executed for that queue, the queue is not in the pause state, and there is not a trigger pending.

The idle state occurs when a queue is disabled, when a queue is in a reserved mode, or when a queue is in a valid queue operating mode awaiting a trigger event to initiate queue execution.

A queue is in the active state when a valid queue operating mode is selected, when the selected trigger event has occurred, or when the QADC64E is performing a conversion specified by a CCW from that queue.

Only one queue can be active at a time. Either or both queues can be in the paused state. A queue is paused when the previous CCW executed from that queue had the pause bit set. The QADC64E does not execute any CCWs from the paused queue until a trigger event occurs. Consequently, the QADC64E can service queue 2 while queue 1 is paused.

Only queue 2 can be in the suspended state. When a trigger event occurs on queue 1 while queue 2 is executing, the current queue 2 conversion is aborted. The queue 2 status is reported as suspended. Queue 2 transitions back to the active state when queue 1 becomes idle or paused.

A trigger pending state is required since both queues cannot be active at the same time. The status of queue 2 is changed to trigger pending when a trigger event occurs for queue 2 while queue 1 is active. In the opposite case, when a trigger event occurs for queue 1 while queue 2 is active, queue 2 is aborted and the status is reported as queue 1 active, queue 2 suspended. So due to the priority scheme, only queue 2 can be in the trigger pending state.

There are two transition cases which cause the queue 2 status to be trigger pending before queue 2 is shown to be in the active state. When queue 1 is active and there is a trigger pending on queue 2, after queue 1 completes or pauses, queue 2 continues to be in the trigger pending state for a few clock cycles. The following are fleeting status conditions:

- Queue 1 idle with queue 2 trigger pending
- Queue 1 paused with queue 2 trigger pending

Figure 13-13 displays the status conditions of the queue status field as the QADC64E goes through the transition from queue 1 active to queue 2 active.

**Figure 13-13. QADC64E Queue Status Transition**

The queue status field is affected by the stop mode. Because all of the analog logic and control registers are reset, the queue status field is reset to queue 1 idle, queue 2 idle.

During the freeze mode, the queue status field is not modified. The queue status field retains the status it held prior to freezing. As a result, the queue status can show queue 1 active, queue 2 idle, even though neither queue is being executed during freeze.

### 13.3.9 Conversion Command Word Table

The conversion command word (CCW) table is a RAM, 64 words long on 16-bit address boundaries where 10-bits of each entry are implemented. A CCW can be programmed by the software to request a conversion of one analog input channel. The CCW table is written by software and is not modified by the QADC64E. Each CCW requests the conversion of an analog channel to a digital result. The CCW specifies the analog channel number, the input sample time, and whether the queue is to pause after the current CCW. The ten implemented bits of the CCW word are read/write data, where they may be written when the software initializes the QADC64E. The remaining 6-bits are unimplemented so these read as zeros, and write

operations have no effect. Each location in the CCW table corresponds to a location in the result word table. When a conversion is completed for a CCW entry, the 10-bit result is written in the corresponding result word entry. The QADC64E provides 64 CCW table entries.

The beginning of queue 1 is the first location in the CCW table. The first location of queue 2 is specified by the beginning of queue 2 pointer (BQ2) in QACR2. To dedicate the entire CCW table to queue 1, queue 2 is programmed to be in the disabled mode, and BQ2 is programmed to 64 or greater. To dedicate the entire CCW table to queue 2, queue 1 is programmed to be in the disabled mode, and BQ2 is specified as the first location in the CCW table. Figure 13-15 illustrates the operation of the queue structure.

Note 1: These offsets must be added to the module base address: A = 0x30 4800 or B = 0x30 4C00.

**Figure 13-15. QADC64E Conversion Queue Operation**

To prepare the QADC64E for a scan sequence, the software writes to the CCW table to specify the desired channel conversions. The software also establishes the criteria for initiating the queue execution by programming the queue operating mode. The queue operating mode determines what type of trigger event causes queue execution to begin. A “trigger event” is used to refer to any of the ways to cause the QADC64E to begin executing the CCWs in a queue or sub-queue. An “external trigger” is only one of the possible “trigger events.”

A scan sequence may be initiated by the following:

- A software command
- Expiration of the periodic/interval timer
- External trigger signal
- External gated signal (queue 1 only)

The software also specifies whether the QADC64E is to perform a single pass through the queue or is to scan continuously. When a single-scan mode is selected, the software selects the queue operating mode and sets the single-scan enable bit. When a continuous-scan mode is selected, the queue remains active in the selected queue operating mode after the QADC64E completes each queue scan sequence.

During queue execution, the QADC64E reads each CCW from the active queue and executes conversions in three stages:

- Initial sample - During initial sample, a buffered version of the selected input channel is connected to the sample capacitor at the input of the sample buffer amplifier.
- Final sample - During the final sample period, the sample buffer amplifier is bypassed, and the multiplexer input charges the sample capacitor directly. Each CCW specifies a final input sample time of 2, 4, 8, or 16 cycles.
- Resolution - When an analog-to-digital conversion is complete, the result is written to the corresponding location in the result word table. The QADC64E continues to sequentially execute each CCW in the queue until the end of the queue is detected or a pause bit is found in a CCW.

When the pause bit is set in the current CCW, the QADC64E stops execution of the queue until a new trigger event occurs. The pause status flag bit is set, which may cause an interrupt to notify the software that the queue has reached the pause state. After the trigger event occurs, the paused state ends and the QADC64E continues to execute each CCW in the queue until another pause is encountered or the end of the queue is detected.

The following indicate the end-of-queue condition:

- The CCW channel field is programmed with 63 (0x3F) to specify the end of the queue
- The end-of-queue 1 is implied by the beginning of queue 2, which is specified in the BQ2 field in QACR2
- The physical end of the queue RAM space defines the end of either queue

When any of the end-of-queue conditions is recognized, a queue completion flag is set, and if enabled, an interrupt is issued to the software.

The following situations prematurely terminate queue execution:

- Because queue 1 is higher in priority than queue 2, when a trigger event occurs on queue 1 during queue 2 execution, the execution of queue 2 is suspended by aborting the execution of the CCW in progress, and the queue 1 execution begins. When queue 1 execution is completed, queue 2 conversions restart with the first CCW entry in queue 2 or the first CCW of the queue 2 sub-queue being executed when queue 2 was suspended. Alternately, conversions can restart with the aborted queue 2 CCW entry. The RESUME bit in QACR2 allows the software to select where queue 2 begins after suspension. By choosing to re-execute all of the suspended queue 2 queue and

sub-queue CCWs, all of the samples are guaranteed to have been taken during the same scan pass. However, a high trigger event rate for queue 1 can prohibit the completion of queue 2. If this occurs, the software may choose to begin execution of queue 2 with the aborted CCW entry.

- Software can change the queue operating mode to disabled mode. Any conversion in progress for that queue is aborted. Putting a queue into the disabled mode does not power down the converter.
- Software can change the queue operating mode to another valid mode. Any conversion in progress for that queue is aborted. The queue restarts at the beginning of the queue, once an appropriate trigger event occurs.
- For low power operation, software can set the stop mode bit to prepare the module for a loss of clocks. The QADC64E aborts any conversion in progress when the stop mode is entered.
- When the freeze enable bit is set by software and the IMB3 internal FREEZE line is asserted, the QADC64E freezes at the end of the conversion in progress. When internal FREEZE is negated, the QADC64E resumes queue execution beginning with the next CCW entry. Refer to [Section 13.5.7, “Configuration and Control Using the IMB3 Interface”](#) for more information.

| Bits | Name | Description                                                                                                                                                                                                                                                                                                                                                                                                                            |
|------|------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0:5  | —    | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                               |
| 6    | P    | Pause. The pause bit allows the creation of sub-queues within queue 1 and queue 2. The QADC64E performs the conversion specified by the CCW with the pause bit set, and then the queue enters the pause state. Another trigger event causes execution to continue from the pause to the next CCW.<br>0 Do not enter the pause state after execution of the current CCW.<br>1 Enter the pause state after execution of the current CCW. |
| 7    | BYP  | Sample amplifier bypass. Setting BYP enables the amplifier bypass mode for a conversion, and subsequently changes the timing. Refer to <a href="#">Section 13.4.1.2, “Amplifier Bypass Mode Conversion Timing,”</a> for more information.<br>0 Amplifier bypass mode disabled.<br>1 Amplifier bypass mode enabled.                                                                                                                     |

**Table 13-18. CCW Bit Descriptions (continued)**

| Bits  | Name | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-------|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 8:9   | IST  | Input sample time. The IST field specifies the length of the sample window. Longer sample times permit more accurate A/D conversions of signals with higher source impedances, especially if $BYP = 1$ .<br>00 QCKL period x 2<br>01 QCKL period x 4<br>10 QCKL period x 8<br>11 QCKL period x 16                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| 10:15 | CHAN | Channel number. The CHAN field selects the input channel number corresponding to the analog input signal to be sampled and converted. The analog input signal channel number assignments and the signal definitions vary depending on whether the QADC64E is operating in multiplexed or non-multiplexed mode. The queue scan mechanism sees no distinction between an internally or externally multiplexed analog input.<br>If CHAN specifies a reserved channel number (channels 32 to 47) or an invalid channel number (channels 4 to 31 in non-multiplexed mode), the low reference level (VRL) is converted.<br>Programming the channel field to channel 63 indicates the end of the queue. Channels 60 to 62 are special internal channels. When one of these channels is selected, the sample amplifier is not used. The value of VRL, VRH, or $(V_{RH} - V_{RL})/2$ is placed directly into the converter.<br>Programming the input sample time to any value other than two for one of the internal channels has no benefit except to lengthen the overall conversion time.<br><a href="#">Table 13-19</a> shows the channel number assignments for non-multiplexed mode. <a href="#">Table 13-20</a> shows the channel number assignments for multiplexed mode. |

**Table 13-19. Non-Multiplexed Channel Assignments and Signal Designations**

| PQA5                      | AN57               | —                                      | I/O               | 111001                 | 57            |
| PQA6                      | AN58               | —                                      | I/O               | 111010                 | 58            |
| PQA7                      | AN59               | —                                      | I/O               | 111011                 | 59            |
| —                         | V <sub>RL</sub>    | —                                      | I                 | 111100                 | 60            |
| —                         | V <sub>RH</sub>    | —                                      | I                 | 111101                 | 61            |
| —                         | —                  | (V <sub>RH</sub> - V <sub>RL</sub> )/2 | —                 | 111110                 | 62            |
| —                         | —                  | End of Queue Code                      | —                 | 111111                 | 63            |

The channel field is programmed for channel 63 to indicate the end of the queue. Channels 60 to 62 are special internal channels. When one of the special channels is selected, the sampling amplifier is not used. The value of V<sub>RL</sub>, V<sub>RH</sub>, or (V<sub>RH</sub> - V<sub>RL</sub>)/2 is placed directly onto the converter. Also for the internal special channels, programming any input sample time other than two has no benefit except to lengthen the overall conversion time.

### 13.3.10 Result Word Table

The result word table is a RAM, 64 words long and 10 bits wide. An entry is written by the QADC64E after completing an analog conversion specified by the corresponding CCW table entry. Software can read

or write the result word table, but in normal operation, the software reads the result word table to obtain analog conversions from the QADC64E. Unimplemented bits are read as zeros, and write operations do not have any effect. See Figure 13-17 for a diagram of the result word table

While there is only one result word table, the data can be accessed in three different data formats:

- Right justified in the 16-bit word, with zeros in the higher order unused bits
- Left justified, with the most significant bit inverted to form a sign bit, and zeros in the unused lower order bits
- Left justified, with zeros in the lower order unused bits

The left justified, signed format corresponds to a half-scale, offset binary, two's complement data format. The data is routed onto the IMB3 according to the selected format. The address used to access the table determines the data alignment format. All write operations to the result word table are right justified.

**Figure 13-19. Left Justified, Unsigned Result Register (LJURR)**

The three result data formats are produced by routing the RAM bits onto the data bus. The software chooses among the three formats by reading the result at the memory address which produces the desired data alignment.

The result word table is read/write accessible by software. During normal operation, application software only needs to read the result table. Write operations to the table may occur during test or debug breakpoint operation. When locations in the CCW table are not used by an application, software could use the

## NOTE

## 13.4 Analog Subsystem

### 13.4.1 Analog-to-Digital Converter Operation

The diagram illustrates the internal architecture of the AD7714 ADC. Key components and their interconnections include:

- Inputs:** Analog inputs AN44 through AN59 are connected to a **Decoder** block. Reference voltages  $V_{RH}$  and  $V_{RL}$  are provided to the **RDAC (7 BIT)** and **CDAC (4 BIT)** blocks.
- Sampling and Buffering:** A **Sample** signal (input 6) controls a switch in the **Decoder** and a **Buffer AMP**. The **Buffer AMP** output passes through **Final** and **Buffer** switches (controlled by a **STOP** signal) to a **Sample CAP Array Equals CDAC**.
- Conversion and Comparison:** The **Sample CAP Array** is connected to the **COMP.** (Comparator) block. The **RDAC** output passes through a **CONV.** switch to the **COMP.** block. The **CDAC** output is also connected to the **COMP.** block. The **COMP.** block has a **Zero** output.
- Control and Data:** A **CHAN** input and **IST REF** signal are connected to the **State Mach, SAR and SAR Buffer** block. This block also receives a **CCW Buffer** signal and outputs **WCCW**, **EOS/EOC**, and **CLK** signals. It is connected to a **Data Bus** (input 10) and a **Standard Converter Interface**.
- Other Blocks:** A **BIAS** block is connected to the **STOP** signal and the **Sample CAP Array**. A **CRH CRL** block is connected to the **CDAC** and the **State Mach, SAR and SAR Buffer** block.

**Figure 13-20. QADC64E Analog Subsystem Block Diagram**

### 13.4.1.1 Conversion Cycle Times

Total conversion time is made up of initial sample time, final sample time, and resolution time. Initial sample time refers to the time during which the selected input channel is coupled through the buffer amplifier to the sample capacitor. This buffer is used to quickly reproduce its input signal on the sample capacitor and minimize charge sharing errors. During the final sampling period the amplifier is bypassed, and the multiplexer input charges the sample capacitor array directly for improved accuracy. During the resolution period, the voltage in the sample capacitor is converted to a digital value and stored in the SAR.

Initial sample time is fixed at two QCLK cycles. Final sample time can be 2, 4, 6, 8, or 16 QCLK cycles, depending on the value of the IST field in the CCW. Resolution time is ten QCLK cycles.

Therefore, conversion time requires a minimum of 14 QCLK clocks (7  $\mu$ s with a 2.0-MHz QCLK). If the maximum final sample time period of 16 QCLKs is selected, the total conversion time is 28 QCLKs or 14  $\mu$ s (with a 2.0-MHz QCLK)

Figure 13-21 illustrates the timing for conversions.

Figure 13-21. Conversion Timing

### 13.4.1.2 Amplifier Bypass Mode Conversion Timing

If the amplifier bypass mode is enabled for a conversion by setting the amplifier bypass (BYP) bit in the CCW, the timing changes to that shown in Figure 13-22. The buffered sample time is eliminated, reducing the potential conversion time by two QCLKs. However, due to internal RC effects, a minimum final sample time of four QCLKs must be allowed. This results in no savings of QCLKs. When using the bypass mode, the external circuit should be of low source impedance, typically less than 10 k $\Omega$ . Also, the loading effects of the external circuitry by the QADC64E need to be considered, since the benefits of the sample amplifier are not present.

#### NOTE

Because of internal RC time constants, a sample time of two QCLKs in bypass mode for high frequency operation is not recommended.

**Figure 13-22. Bypass Mode Conversion Timing**

### 13.4.2 Channel Decode and Multiplexer

The internal multiplexer selects one of the 16 analog input signals for conversion. The selected input is connected to the sample buffer amplifier. The multiplexer also includes positive and negative stress protection circuitry, which prevents deselected channels from affecting the selected channel when current is injected into the deselected channels. Refer to [Appendix F, “Electrical Characteristics,”](#) for specific current levels.

### 13.4.3 Sample Buffer Amplifier

The sample buffer is used to raise the effective input impedance of the A/D converter, so that external components (higher bandwidth or higher impedance) are less critical to accuracy. The input voltage is buffered onto the sample capacitor to reduce crosstalk between channels.

### 13.4.4 Digital-to-Analog Converter (DAC) Array

The digital to analog converter (DAC) array consists of binary-weighted capacitors and a resistor-divider chain. The reference voltages,  $V_{RH}$  and  $V_{RL}$ , are used by the DAC to perform ratiometric conversions. The DAC also converts the following three internal channels:

- $V_{RH}$  — Reference voltage high
- $V_{RL}$  — Reference voltage low
- $(V_{RH} - V_{RL})/2$  — Reference voltage

The DAC array serves to provide a mechanism for the successive approximation A/D conversion.

Resolution begins with the most significant bit (MSB) and works down to the least significant bit (LSB). The switching sequence is controlled by the comparator and successive-approximation register (SAR) logic.

- Sample capacitor — The sample capacitor is employed to sample and hold the voltage to be converted.

### 13.4.5 Comparator

The comparator is used during the approximation process to sense whether the digitally selected arrangement of the DAC array produces a voltage level higher or lower than the sampled input. The comparator output feeds into the SAR which accumulates the A/D conversion result sequentially, beginning with the MSB.

### 13.4.6 Bias

The bias circuit is controlled by the STOP signal to power-up and power-down all the analog circuits.

### 13.4.7 Successive Approximation Register

The input of the successive approximation register (SAR) is connected to the comparator output. The SAR sequentially receives the conversion value one bit at a time, starting with the MSB. After accumulating the 10 bits of the conversion result, the SAR data is transferred to the appropriate result location, where it may be read from the IMB3 by user software.

### 13.4.8 State Machine

The state machine receives the QCLK, RST, STOP, BYP, IST, CHAN[5:0], and START CONV signals, from which it generates all timing to perform an A/D conversion. The start convert (START CONV) signal indicates to the A/D converter that the desired channel has been sent to the MUX. IST indicates the desired sample time. BYP indicates whether to bypass the sample amplifier. The end of conversion (EOC) signal, notifies the queue control logic that a result is available for storage in the result RAM.

## 13.5 Digital Subsystem

The digital control subsystem includes the control logic to sequence the conversion activity, the clock and periodic/interval timer, control and status registers, the conversion command word table RAM, and the result word table RAM.

The central element for control of the QADC64E conversions is the 64-entry CCW table. Each CCW specifies the conversion of one input channel. Depending on the application, one or two queues can be established in the CCW table. A queue is a scan sequence of one or more input channels. By using a pause mechanism, sub-queues can be created in the two queues. Each queue can be operated using one of several different scan modes. The scan modes for queue 1 and queue 2 are programmed in QACR1 and QACR2 (control registers 1 and 2). Once a queue has been started by a trigger event (any of the ways to cause the QADC64E to begin executing the CCWs in a queue or sub-queue), the QADC64E performs a sequence of conversions and places the results in the result word table.

### 13.5.1 Queue Priority

Queue 1 has priority over queue 2 execution. The following cases show the conditions under which queue 1 asserts its priority:

- When a queue is not active, a trigger event for queue 1 or queue 2 causes the corresponding queue execution to begin.
- When queue 1 is active and a trigger event occurs for queue 2, queue 2 cannot begin execution until queue 1 reaches completion or the paused state. The status register records the trigger event by reporting the queue 2 status as trigger pending. Additional trigger events for queue 2, which occur before execution can begin, are captured as trigger overruns.
- When queue 2 is active and a trigger event occurs for queue 1, the current queue 2 conversion is aborted. The status register reports the queue 2 status as suspended. Any trigger events occurring for queue 2 while queue 2 is suspended are captured as trigger overruns. Once queue 1 reaches the completion or the paused state, queue 2 begins executing again. The programming of the RESUME bit in QACR2 determines which CCW is executed in queue 2. Refer to [Section 13.3.7, “Control Register 2 \(QACR2\)”](#) for more information.
- When simultaneous trigger events occur for queue 1 and queue 2, queue 1 begins execution and the queue 2 status is changed to trigger pending.

### 13.5.2 Paused Sub-Queues

The pause feature can be used to divide queue 1 and/or queue 2 into multiple sub-queues. A sub-queue is defined by setting the pause bit in the last CCW of the sub-queue.

[Figure 13-23](#) shows the CCW format and an example of using pause to create sub-queues. Queue 1 is shown with four CCWs in each sub-queue and queue 2 has two CCWs in each sub-queue.

Trigger events which occur during the execution of a sub-queue are ignored, except that the trigger overrun flag is set. When a continuous-scan mode is selected, a trigger event occurring after the completion of the

last sub-queue (after the queue completion flag is set), causes the execution to continue with the first sub-queue, starting with the first CCW in the queue.

When the QADC64E encounters a CCW with the pause bit set, the queue enters the paused state after completing the conversion specified in the CCW with the pause bit. The pause flag is set and a pause software interrupt may optionally be issued. The status of the queue is shown to be paused, indicating completion of a sub-queue. The QADC64E then waits for another trigger event to again begin execution of the next sub-queue.

### 13.5.3 Boundary Conditions

The following are queue operation boundary conditions:

- The first CCW in a queue contains channel 63, the end-of-queue (EOQ) code. The queue becomes active and the first CCW is read. The end-of-queue is recognized, the completion flag is set, and the queue becomes idle. A conversion is not performed.
- BQ2 (beginning of queue 2) is set at the end of the CCW table (63) and a trigger event occurs on queue 2. Refer to [Section 13.3.7, “Control Register 2 \(QACR2\),”](#) for more information on BQ2. The end-of-queue condition is recognized, a conversion is performed, the completion flag is set, and the queue becomes idle.
- BQ2 is set to CCW0 and a trigger event occurs on queue 1. After reading CCW0, the end-of-queue condition is recognized, the completion flag is set, and the queue becomes idle. A conversion is not performed.
- BQ2 is set beyond the end of the CCW table (64 – 127) and a trigger event occurs on queue 2. The end-of-queue condition is recognized immediately, the completion flag is set, and the queue becomes idle. A conversion is not performed.

#### NOTE

Multiple end-of-queue conditions may be recognized simultaneously, although there is no change in the QADC64E behavior. For example, if BQ2 is set to CCW0, CCW0 contains the EOQ code, and a trigger event occurs on queue 1, the QADC64E reads CCW0 and detects both end-of-queue conditions. The completion flag is set and queue 1 becomes idle.

Boundary conditions also exist for combinations of pause and end-of-queue. One case is when a pause bit is in one CCW and an end-of-queue condition is in the next CCW. The conversion specified by the CCW with the pause bit set completes normally. The pause flag is set. However, since the end-of-queue condition is recognized, the completion flag is also set and the queue status becomes idle, not paused. Examples of this situation include:

- The pause bit is set in CCW5 and the EOQ code is in CCW6
- The pause is set in CCW63
- During queue 1 operation, the pause bit is set in CCW20 and BQ2 points to CCW21

Another pause and end-of-queue boundary condition occurs when the pause and an end-of-queue condition occur in the same CCW. Both the pause and end-of-queue conditions are recognized simultaneously. The end-of-queue condition has precedence so a conversion is not performed for the CCW

and the pause flag is not set. The QADC64E sets the completion flag and the queue status becomes idle. Examples of this situation are:

- The pause bit is set in CCW10 and EOQ is programmed into CCW10
- During queue 1 operation, the pause bit set in CCW32, which is also BQ2

### 13.5.4 Scan Modes

The QADC64E queuing mechanism allows the application to utilize different requirements for automatically scanning input channels.

In single-scan mode, a single pass through a sequence of conversions defined by a queue is performed. In continuous-scan mode, multiple passes through a sequence of conversions defined by a queue are executed. The possible modes are:

- Disabled and reserved mode
- Single-scan modes
  - Software initiated single-scan mode
  - External trigger single-scan mode
  - External gated single-scan mode
  - Periodic/Interval timer single-scan mode
- Continuous-scan modes
  - Software initiated continuous-scan mode
  - External trigger continuous-scan mode
  - External gated continuous-scan mode
  - Periodic/Interval timer continuous-scan mode

The following paragraphs describe single-scan and continuous-scan operations.

#### 13.5.4.1 Disabled Mode

When the disabled mode is selected, the queue is not active. Trigger events cannot initiate queue execution. When both queue 1 and queue 2 are disabled, wait states are not encountered for IMB3 accesses of the RAM. When both queues are disabled, it is safe to change the QCLK prescaler values.

#### 13.5.4.2 Reserved Mode

Reserved mode allows for future mode definitions. When the reserved mode is selected, the queue is not active. It functions the same as disabled mode.

#### CAUTION

Do not use a reserved mode. Unspecified operations may result.

### 13.5.4.3 Single-Scan Modes

When the application software wants to execute a single pass through a sequence of conversions defined by a queue, a single-scan queue operating mode is selected. By programming the MQ field in QACR1 or QACR2, the following modes can be selected:

- Software initiated single-scan mode
- External trigger single-scan mode
- External gated single-scan mode
- Periodic/Interval timer single-scan mode

#### NOTE

Queue 2 cannot be programmed for external gated single-scan mode.

In all single-scan queue operating modes, the software must also enable the queue to begin execution by writing the single-scan enable bit to a one in the queue's control register. The single-scan enable bits, SSE1 and SSE2, are provided for queue 1 and queue 2 respectively.

Until the single-scan enable bit is set, any trigger events for that queue are ignored. The single-scan enable bit may be set to a one during the write cycle, which selects the single-scan queue operating mode. The single-scan enable bit is set through software, but will always read as a zero. Once set, writing the single-scan enable bit to zero has no effect. Only the QADC64E can clear the single-scan enable bit. The completion flag, completion interrupt, or queue status are used to determine when the queue has completed.

After the single-scan enable bit is set, a trigger event causes the QADC64E to begin execution with the first CCW in the queue. The single-scan enable bit remains set until the queue is completed. After the queue reaches completion, the QADC64E resets the single-scan enable bit to zero. If the single-scan enable bit is written to a one or a zero by the software before the queue scan is complete, the queue is not affected. However, if the software changes the queue operating mode, the new queue operating mode and the value of the single-scan enable bit are recognized immediately. The conversion in progress is aborted and the new queue operating mode takes effect.

In the software-initiated single-scan mode, the writing of a one to the single-scan enable bit causes the QADC64E to internally generate a trigger event and the queue execution begins immediately. In the other single-scan queue operating modes, once the single-scan enable bit is written, the selected trigger event must occur before the queue can start. The single-scan enable bit allows the entire queue to be scanned once. A trigger overrun is captured if a trigger event occurs during queue execution in an edge-sensitive external trigger mode or a periodic/interval timer mode.

In the periodic/interval timer single-scan mode, the next expiration of the timer is the trigger event for the queue. After the queue execution is complete, the queue status is shown as idle. The software can restart the queue by setting the single-scan enable bit to a one. Queue execution begins with the first CCW in the queue.

#### 13.5.4.3.1 Software Initiated Single-Scan Mode

Software can initiate the execution of a scan sequence for queue 1 or 2 by selecting the software initiated single-scan mode, and writing the single-scan enable bit in QACR1 or QACR2. A trigger event is

generated internally and the QADC64E immediately begins execution of the first CCW in the queue. If a pause occurs, another trigger event is generated internally, and then execution continues without pausing.

The QADC64E automatically performs the conversions in the queue until an end-of-queue condition is encountered. The queue remains idle until the software again sets the single-scan enable bit. While the time to internally generate and act on a trigger event is very short, software can momentarily read the status conditions, indicating that the queue is paused. The trigger overrun flag is never set while in the software initiated single-scan mode.

The software initiated single-scan mode is useful in the following applications:

- Allows software complete control of the queue execution
- Allows the software to easily alternate between several queue sequences.

#### 13.5.4.3.2 External Trigger Single-Scan Mode

The external trigger single-scan mode is available on both queue 1 and queue 2. The software programs the polarity of the external trigger edge that is to be detected, either a rising or a falling edge. The software must enable the scan to occur by setting the single-scan enable bit for the queue.

The first external trigger edge causes the queue to be executed one time. Each CCW is read and the indicated conversions are performed until an end-of-queue condition is encountered. After the queue is completed, the QADC64E clears the single-scan enable bit. Software may set the single-scan enable bit again to allow another scan of the queue to be initiated by the next external trigger edge.

The external trigger single-scan mode is useful when the input trigger rate can exceed the queue execution rate. Analog samples can be taken in sync with an external event, even though the software is not interested in data taken from every edge. The software can start the external trigger single-scan mode and get one set of data, and at a later time, start the queue again for the next set of samples.

When a pause bit is encountered during external trigger single-scan mode, another trigger event is required for queue execution to continue. Software involvement is not needed to enable queue execution to continue from the paused state.

#### 13.5.4.3.3 External Gated Single-Scan Mode

The QADC64E provides external gating for queue 1 only. When external gated single-scan mode is selected, the input level on the associated external trigger signal enables and disables queue execution. The polarity of the external gated signal is fixed so only a high level opens the gate and a low level closes the gate. Once the gate is open, each CCW is read and the indicated conversions are performed until the gate is closed. Software must enable the scan to occur by setting the single-scan enable bit for queue 1. If a pause in a CCW is encountered, the pause flag will not set, and execution continues without pausing.

While the gate is open, queue 1 executes one time. Each CCW is read and the indicated conversions are performed until an end-of-queue condition is encountered. When queue 1 completes, the QADC64E sets the completion flag (CF1) and clears the single-scan enable bit. Software may set the single-scan enable bit again to allow another scan of queue 1 to be initiated during the next open gate.

If the gate closes before queue 1 completes execution, the current CCW completes, execution of queue 1 stops, the single-scan enable bit is cleared, and the PF1 bit is set. Software can read the CWPQ1 to

determine the last valid conversion in the queue. Software must set the single-scan enable bit again and should clear the PF1 bit before another scan of queue 1 is initiated during the next open gate. The start of queue 1 is always the first CCW in the CCW table.

Since the condition of the gate is only sampled after each conversion during queue execution, closing the gate for a period less than a conversion time interval does not guarantee the closure will be captured.

#### **13.5.4.3.4 Periodic/Interval Timer Single-Scan Mode**

Both queues can use the periodic/interval timer in a single-scan queue operating mode. The timer interval can range from 128- to 128-Kbyte QCLK cycles in binary multiples. When the periodic/ interval timer single-scan mode is selected and the software sets the single-scan enable bit in QACR1 or QACR2, the timer begins counting. When the time interval elapses, an internal trigger event is created to start the queue and the QADC64E begins execution with the first CCW.

The QADC64E automatically performs the conversions in the queue until a pause or an end-of-queue condition is encountered. When a pause occurs, queue execution stops until the timer interval elapses again, and then queue execution continues. When the queue execution reaches an end-of-queue situation, the single-scan enable bit is cleared. Software may set the single-scan enable bit again, allowing another scan of the queue to be initiated by the periodic/interval timer.

The periodic/interval timer generates a trigger event whenever the time interval elapses. The trigger event may cause the queue execution to continue following a pause, or may be considered a trigger overrun. Once the queue execution is completed, the single-scan enable bit must be set again to enable the timer to count again.

Normally only one queue will be enabled for periodic/interval timer single-scan mode and the timer will reset at the end-of-queue. However, if both queues are enabled for either single-scan or continuous periodic/interval timer mode, the end-of-queue condition will not reset the timer while the other queue is active. In this case, the timer will reset when both queues have reached end-of-queue. See [Section 13.5.6, “Periodic / Interval Timer”](#) for a definition of periodic/interval timer reset conditions.

The periodic/interval timer single-scan mode can be used in applications which need coherent results, for example:

- When it is necessary that all samples are guaranteed to be taken during the same scan of the analog signals
- When the interrupt rate in the periodic/interval timer continuous-scan mode would be too high
- In sensitive battery applications, where the single-scan mode uses less power than the software initiated continuous-scan mode

#### **13.5.4.4 Continuous-Scan Modes**

When the application software wants to execute multiple passes through a sequence of conversions defined by a queue, a continuous-scan queue operating mode is selected.

By programming the MQ1 field in QACR1 or the MQ2 field in QACR2, the following software initiated modes can be selected:

- Software initiated continuous-scan mode

- External trigger continuous-scan mode
- External gated continuous-scan mode
- Periodic/interval timer continuous-scan mode

When a queue is programmed for a continuous-scan mode, the single-scan enable bit in the queue control register does not have any meaning or effect. As soon as the queue operating mode is programmed, the selected trigger event can initiate queue execution.

In the case of the software-initiated continuous-scan mode, the trigger event is generated internally and queue execution begins immediately. In the other continuous-scan queue operating modes, the selected trigger event must occur before the queue can start. A trigger overrun is captured if a trigger event occurs during queue execution in the external trigger continuous-scan mode and the periodic/interval timer continuous-scan mode.

After the queue execution is complete, the queue status is shown as idle. Since the continuous-scan queue operating modes allow the entire queue to be scanned multiple times, software involvement is not needed to enable queue execution to continue from the idle state. The next trigger event causes queue execution to begin again, starting with the first CCW in the queue.

#### NOTE

Coherent samples are guaranteed. The time between consecutive conversions has been designed to be consistent. However, there is one exception. For queues that end with a CCW containing EOQ code (channel 63), the last queue conversion to the first queue conversion requires 1 additional CCW fetch cycle. Therefore continuous samples are not coherent at this boundary.

In addition, the time from trigger to first conversion cannot be guaranteed since it is a function of clock synchronization, programmable trigger events, queue priorities, and so on.

#### 13.5.4.4.1 Software Initiated Continuous-Scan Mode

When the software initiated continuous-scan mode is programmed, the trigger event is generated automatically by the QADC64E. Queue execution begins immediately. If a pause is encountered, another trigger event is generated internally, and then execution continues without pausing. When the end-of-queue is reached, another internal trigger event is generated, and queue execution begins again from the beginning of the queue.

While the time to internally generate and act on a trigger event is very short, software can momentarily read the status conditions, indicating that the queue is idle. The trigger overrun flag is never set while in the software-initiated continuous-scan mode.

The software initiated continuous-scan mode keeps the result registers updated more frequently than any of the other queue operating modes. The software can always read the result table to get the latest converted value for each channel. The channels scanned are kept up to date by the QADC64E without software involvement. Software can read a result value at any time.

The software initiated continuous-scan mode may be chosen for either queue, but is normally used only with queue 2. When the software initiated continuous-scan mode is chosen for queue 1, that queue operates

continuously and queue 2, being lower in priority, never gets executed. The short interval of time between a queue 1 completion and the subsequent trigger event is not sufficient to allow queue 2 execution to begin.

The software initiated continuous-scan mode is a useful choice with queue 2 for converting channels that do not need to be synchronized to anything, or for the slow-to-change analog channels. Interrupts are normally not used with the software initiated continuous-scan mode. Rather, the software reads the latest conversion result from the result table at any time. Once initiated, software action is not needed to sustain conversions of channel.

#### 13.5.4.4.2 External Trigger Continuous-Scan Mode

The QADC64E provides external trigger signals for both queues. When the external trigger software initiated continuous-scan mode is selected, a transition on the associated external trigger signal initiates queue execution. The polarity of the external trigger signal is programmable, so that the software can select a mode which begins queue execution on the rising or falling edge. Each CCW is read and the indicated conversions are performed until an end-of-queue condition is encountered. When the next external trigger edge is detected, the queue execution begins again automatically. Software initialization is not needed between trigger events.

When a pause bit is encountered in external trigger continuous-scan mode, another trigger event is required for queue execution to continue. Software involvement is not needed to enable queue execution to continue from the paused state.

Some applications need to synchronize the sampling of analog channels to external events. There are cases when it is not possible to use software initiation of the queue scan sequence, since interrupt response times vary.

#### 13.5.4.4.3 External Gated Continuous-Scan Mode

The QADC64E provides external gating for queue 1 only. When external gated continuous-scan mode is selected, the input level on the associated external trigger signal enables and disables queue execution. The polarity of the external gated signal is fixed so a high level opens the gate and a low level closes the gate. Once the gate is open, each CCW is read and the indicated conversions are performed until the gate is closed. When the gate opens again, the queue execution automatically begins again from the beginning of the queue. Software initialization is not needed between trigger events. If a pause in a CCW is encountered, the pause flag *will not set*, and execution continues without pausing.

The purpose of external gated continuous-scan mode is to continuously collect digitized samples while the gate is open and to have the most recent samples available. It is up to the programmer to ensure that the queue is large enough so that a maximum gate open time will not reach an end-of-queue. However it is useful to take advantage of a smaller queue in the manner described in the next paragraph.

In the event that the queue completes before the gate closes, a completion flag will be set and the queue will roll over to the beginning and continue conversions until the gate closes. If the gate remains open and the completion flag is not cleared, when the queue completes a second time the trigger overrun flag will be set and the queue will roll-over again. The queue will continue to execute until the gate closes or the mode is disabled.

If the gate closes before queue 1 completes execution, the current CCW completes execution of queue 1 stops and QADC64E sets the PF1 bit to indicate an incomplete queue. Software can read the CWPQ1 to determine the last valid conversion in the queue. In this mode, if the gate opens again, execution of queue 1 begins again. The start of queue 1 is always the first CCW in the CCW table.

Since the condition of the gate is only sampled after each conversion during queue execution, closing the gate for a period less than a conversion time interval does not guarantee the closure will be captured.

#### 13.5.4.4 Periodic/Interval Timer Continuous-Scan Mode

The QADC64E includes a dedicated periodic/interval timer for initiating a scan sequence on queue 1 and/or queue 2. Software selects a programmable timer interval ranging from 128 to 128 Kbytes times the QCLK period in binary multiples. The QCLK period is prescaled down from the IMB3 MCU clock.

When a periodic/interval timer continuous-scan mode is selected for queue 1 and/or queue 2, the timer begins counting. After the programmed interval elapses, the timer generated trigger event starts the appropriate queue. Meanwhile, the QADC64E automatically performs the conversions in the queue until an end-of-queue condition or a pause is encountered. When a pause occurs, the QADC64E waits for the periodic interval to expire again, then continues with the queue. Once end-of-queue has been detected, the next trigger event causes queue execution to begin again with the first CCW in the queue.

The periodic/interval timer generates a trigger event whenever the time interval elapses. The trigger event may cause the queue execution to continue following a pause or queue completion, or may be considered a trigger overrun. As with all continuous-scan queue operating modes, software action is not needed between trigger events. Since both queues may be triggered by the periodic/interval timer, see [Section 13.5.6, “Periodic / Interval Timer”](#) for a summary of periodic/interval timer reset conditions.

Software enables the completion interrupt when using the periodic/interval timer continuous-scan mode. When the interrupt occurs, the software knows that the periodically collected analog results have just been taken. The software can use the periodic interrupt to obtain non-analog inputs as well, such as contact closures, as part of a periodic look at all inputs.

### 13.5.5 QADC64E Clock (QCLK) Generation

[Figure 13-24](#) is a block diagram of the clock subsystem. The QCLK provides the timing for the A/D converter state machine which controls the timing of the conversion. The QCLK is also the input to a 17-stage binary divider which implements the periodic/interval timer. To retain the specified analog conversion accuracy, the QCLK frequency ( $F_{QCLK}$ ) must be within the tolerance specified in [Appendix F, “Electrical Characteristics.”](#)

Before using the QADC64E, the software must initialize the prescaler with values that put the QCLK within the specified range. Though most software applications initialize the prescaler once and do not change it, write operations to the prescaler fields are permitted.

For software compatibility with earlier versions of QADC64E, the definition of PSL, PSH, and PSA have been maintained. However, the requirements on minimum time and minimum low time no longer exist.

## NOTE

A change in the prescaler value while a conversion is in progress is likely to corrupt the result from any conversion in progress. Therefore, any prescaler write operation should be done only when both queues are in the disabled modes.

**Figure 13-24. QADC64E Clock Subsystem Functions**

To accommodate wide variations of the main MCU clock frequency (IMB3 clock —  $f_{SYS}$ ), QCLK is generated by a programmable prescaler which divides the MCU IMB3 clock to a frequency within the specified QCLK tolerance range. To allow the A/D conversion time to be maximized across the spectrum of IMB3 clock frequencies, the QADC64E prescaler permits the frequency of QCLK to be software selectable. It also allows the duty cycle of the QCLK waveform to be programmable.

The software establishes the basic high phase of the QCLK waveform with the PSH (prescaler clock high time) field in QACR0, and selects the basic low phase of QCLK with the prescaler clock low time (PSL) field. The combination of the PSH and PSL parameters establishes the frequency of the QCLK.

## NOTE

The guideline for selecting PSH and PSL is select is to maintain approximately 50% duty cycle. So for prescaler values less then 16, or PSH  $\approx$  PSL. For prescaler values greater than 16 keep PSL as large as possible.

Figure 13-24 shows that the prescaler is essentially a variable pulse width signal generator. A 5-bit down counter, clocked at the IMB3 clock rate, is used to create both the high phase and the low phase of the QCLK signal. At the beginning of the high phase, the 5-bit counter is loaded with the 5-bit PSH value. When the zero detector finds that the high phase is finished, the QCLK is reset. A 3-bit comparator looks for a one's complement match with the 3-bit PSL value, which is the end of the low phase of the QCLK. The PSA bit was maintained for software compatibility, but has no effect on QADC64E.

The following equations define QCLK frequency:

$$\begin{aligned}\text{High QCLK Time} &= (\text{PSH} + 1) \div f_{\text{SYS}} \\ \text{Low QCLK Time} &= (\text{PSL} + 1) \div f_{\text{SYS}} \\ \text{FQCLK} &= 1 \div (\text{High QCLK Time} + \text{Low QCLK Time})\end{aligned}$$

Where:

- PSH = 0 to 31, the prescaler QCLK high cycles in QACR0
- PSL = 0 to 7, the prescaler QCLK low cycles in QACR0
- $f_{\text{SYS}}$  = IMB3 clock frequency
- FQCLK = QCLK frequency

The following are equations for calculating the QCLK high/low phases in Example 1:

$$\begin{aligned}\text{High QCLK Time} &= (19 + 1) \div 56 \times 10^6 = 357 \text{ ns} \\ \text{Low QCLK Time} &= (7 + 1) \div 56 \times 10^6 = 143 \text{ ns} \\ \text{FQCLK} &= 1 / (357 + 143) = 2 \text{ MHz}\end{aligned}$$

The following are equations for calculating the QCLK high/low phases in Example 2:

$$\begin{aligned}\text{High QCLK Time} &= (11 + 1) \div 40 \times 10^6 = 300 \text{ ns} \\ \text{Low QCLK Time} &= (7 + 1) \div 40 \times 10^6 = 200 \text{ ns} \\ \text{FQCLK} &= 1 / (300 + 200) = 2 \text{ MHz}\end{aligned}$$

The following are equations for calculating the QCLK high/low phases in Example 3:

$$\begin{aligned}\text{High QCLK Time} &= (7 + 1) \div 32 \times 10^6 = 250 \text{ ns} \\ \text{Low QCLK Time} &= (7 + 1) \div 32 \times 10^6 = 250 \text{ ns} \\ \text{FQCLK} &= 1 / (250 + 250) = 2 \text{ MHz}\end{aligned}$$

Figure 13-25 and Table 13-21 show examples of QCLK programmability. The examples include conversion times based on the following assumption:

- Input sample time is as fast as possible (IST = 0, 2 QCLK cycles).

Figure 13-25 and Table 13-21 also show the conversion time calculated for a single conversion in a queue. For other MCU IMB3 clock frequencies and other input sample times, the same calculations can be made.

Figure 13-25. QADC64E Clock Programmability Examples

Table 13-21. QADC64E Clock Programmability

| Control Register 0 Information |           |     |     |     | Input Sample Time (IST) =0b00 |                      |
|--------------------------------|-----------|-----|-----|-----|-------------------------------|----------------------|
| Example Number                 | Frequency | PSH | PSA | PSL | QCLK (MHz)                    | Conversion Time (μs) |
| 1                              | 56 MHz    | 19  | 0   | 7   | 2.0                           | 7.0                  |
| 2                              | 40 MHz    | 11  | 0   | 7   | 2.0                           | 7.0                  |
| 3                              | 32 MHz    | 7   | 0   | 7   | 2.0                           | 7.0                  |

**NOTE**

PSA is maintained for software compatibility but has no functional benefit to this version of the module.

The MCU IMB3 clock frequency is the basis of the QADC64E timing. The QADC64E requires that the IMB3 clock frequency be at least twice the QCLK frequency. The QCLK frequency is established by the combination of the PSH and PSL parameters in QACR0. The 5-bit PSH field selects the number of IMB3 clock cycles in the high phase of the QCLK wave. The 3-bit PSL field selects the number of IMB3 clock cycles in the low phase of the QCLK wave.

Example 1 in Table 13-21 shows that when the PSH = 19, the QCLK remains high for 20 cycles if the IMB3 clock and with PSL = 7 the QCLK remains low for 8 IMB3 clock cycles. Example 2 shows that when PSH = 11, QCLK is high for 12 IMB3 clock cycles and with PSL = 7, QCLK is low for 8 IMB3 clock cycles. Finally, example 3 shows that with PSH = 7 and PSL = 7, QCLK alternates between high and low every 8 IMB3 cycles.

## 13.5.6 Periodic / Interval Timer

The on-chip periodic/interval timer can be used to generate trigger events at a programmable interval, initiating execution of queue 1 and/or queue 2. The periodic/interval timer stays reset under the following conditions:

- Both queue 1 and queue 2 are programmed to any mode which does not use the periodic/interval timer
- IMB3 system reset or the master reset is asserted
- Stop mode is selected
- Freeze mode is selected

### NOTE

Interval timer single-scan mode does not use the periodic/interval timer until the single-scan enable bit is set.

The following two conditions will cause a pulsed reset of the periodic/interval timer during use:

- A queue 1 operating mode change to a mode which uses the periodic/interval timer, even if queue 2 is already using the timer
- A queue 2 operating mode change to a mode which uses the periodic/interval timer, provided queue 1 is not in a mode which uses the periodic/interval timer
- Roll over of the timer

During the low power stop mode, the periodic timer is held in reset. Since low power stop mode causes QACR1 and QACR2 to be reset to zero, a valid periodic or interval timer mode must be written after stop mode is exited to release the timer from reset.

When the IMB3 internal FREEZE line is asserted and a periodic or interval timer mode is selected, the timer counter is reset after the conversion in progress completes. When the periodic or interval timer mode has been enabled (the timer is counting), but a trigger event has not been issued, the freeze mode takes effect immediately, and the timer is held in reset. When the internal FREEZE line is negated, the timer counter starts counting from the beginning. Refer to [Section 13.5.7, “Configuration and Control Using the IMB3 Interface,”](#) for more information.

## 13.5.7 Configuration and Control Using the IMB3 Interface

The QADC64E module communicates with other microcontroller modules via the IMB3. The QADC64E bus interface unit (BIU) coordinates IMB3 activity with internal QADC64E bus activity. This section describes the operation of the BIU, IMB3 read/write accesses to QADC64E memory locations, module configuration, and general-purpose I/O operation.

### 13.5.7.1 QADC64E Bus Interface Unit

The BIU is designed to act as a slave device on the IMB3. The BIU has the following functions:

- Respond with the appropriate bus cycle termination
- Supply IMB3 interface timing to all internal module signals

BIU components consist of:

- IMB3 buffers
- Address match and module select logic
- The BIU state machine
- Clock prescaler logic
- Data bus routing logic
- Interface to the internal module data bus

## NOTE

Normal accesses from the IMB3 to the QADC64E require two clocks. However, if the CPU tries to access table locations while the QADC64E is accessing them, the QADC64E produces IMB3 wait states. From one to four IMB3 wait states may be inserted by the QADC64E in the process of reading and writing.

### 13.5.7.2 QADC64E Bus Accessing

The QADC64E supports 8-bit, 16-bit, and 32-bit data transfers, at even and odd addresses. Coherency of results read (ensuring that all results read were taken consecutively in one scan) is not guaranteed. For example, if a read of two consecutive 16-bit locations in a result area is made, the QADC64E could change one 16-bit location in the result area between the bus cycles. There is no holding register for the second 16-bit location. All read and write accesses that require more than one 16-bit access to complete occur as two or more independent bus cycles. Depending on bus master protocol, these accesses could include misaligned and 32-bit accesses.

Figure 13-26 shows the three bus cycles which are implemented by the QADC64E. The following paragraphs describe how the three types of accesses are used, including misaligned 16-bit and 32-bit accesses.

**Figure 13-26. Bus Cycle Accesses**

Byte access to an even address of a QADC64E location is shown in the top illustration of [Figure 13-26](#). In the case of write cycles, byte 1 of the register is not disturbed. In the case of a read cycle, the QADC64E provides both byte 0 and byte 1.

Byte access to an odd address of a QADC64E location is shown in the center illustration of [Figure 13-26](#). In the case of write cycles, byte 0 of the register is not disturbed. In the case of read cycles, the QADC64E provides both byte 0 and byte 1.

16-bit accesses to an even address read or write byte 0 and byte 1 as shown in the lowest illustration of [Figure 13-26](#). The full 16 bits of data is written to and read from the QADC64E location with each access.

16-bit accesses to an odd address require two bus cycles; one byte of two different 16-bit QADC64E locations is accessed. The first bus cycle is treated by the QADC64E as an 8-bit read or write of an odd address. The second cycle is an 8-bit read or write of an even address. The QADC64E address space is organized into 16-bit even address locations, so a 16-bit read or write of an odd address obtains or provides the lower half of one QADC64E location, and the upper half of the following QADC64E location.

32-bit accesses to an even address require two bus cycles to complete the access, and two full 16-bit QADC64E locations are accessed. The first bus cycle reads or writes the addressed 16-bit QADC64E location and the second cycle reads or writes the following 16-bit location.

32-bit accesses to an odd address require three bus cycles. Portions of three different QADC64E locations are accessed. The first bus cycle is treated by the QADC64E as an 8-bit access of an odd address, the second cycle is a 16-bit aligned access, and the third cycle is an 8-bit access of an even address. The QADC64E address space is organized into 16-bit even address locations, so a 32-bit read or write of an odd address provides the lower half of one QADC64E location, the full 16-bit content of the following QADC64E location, and the upper half of the third QADC64E location.

### 13.6 Trigger and Queue Interaction Examples

This section contains examples describing queue priority and conversion timing schemes.

#### 13.6.1 Queue Priority Schemes

Since there are two conversion command queues and only one A/D converter, there is a priority scheme to determine which conversion is to occur. Each queue has a variety of trigger events that are intended to initiate conversions, and they can occur asynchronously in relation to each other and other conversions in progress. For example, a queue can be idle awaiting a trigger event, a trigger event can have occurred but the first conversion has not started, a conversion can be in progress, a pause condition can exist awaiting another trigger event to continue the queue, and so on.

The following paragraphs and figures outline the prioritizing criteria used to determine which conversion occurs in each overlap situation.

**NOTE**

The situations in [Figure 13-27](#) through [Figure 13-45](#) are labeled S1 through S19. In each diagram, time is shown increasing from left to right. The execution of queue 1 and queue 2 (Q1 and Q2) is shown as a string of rectangles representing the execution time of each CCW in the queue. In most of the situations, there are four CCWs (labeled C1 to C4) in both queue 1 and queue 2. In some of the situations, CCW C2 is presumed to have the pause bit set, to show the similarities of pause and end-of-queue as terminations of queue execution.

Trigger events are described in [Table 13-22](#).

**Table 13-22. Trigger Events**

| Trigger | Events                                                                                                                                                                            |
|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| T1      | Events that trigger queue 1 execution (external trigger, software initiated single-scan enable bit, or completion of the previous continuous loop)                                |
| T2      | Events that trigger queue 2 execution (external trigger, software initiated single-scan enable bit, timer period/interval expired, or completion of the previous continuous loop) |

When a trigger event causes a CCW execution in progress to be aborted, the aborted conversion is shown as a ragged end of a shortened CCW rectangle.

The situation diagrams also show when key status bits are set. [Table 13-23](#) describes the status bits.

**Table 13-23. Status Bits**

| Bit                         | Function                                                                                            |
|-----------------------------|-----------------------------------------------------------------------------------------------------|
| CF Flag                     | Set when the end of the queue is reached                                                            |
| PF Flag                     | Set when a queue completes execution up through a pause bit                                         |
| Trigger Overrun Error (TOR) | Set when a new trigger event occurs before the queue is finished serving the previous trigger event |

Below the queue execution flows are three sets of blocks that show the status information that is made available to the software. The first two rows of status blocks show the condition of each queue as:

- Idle
- Active
- Pause
- Suspended (queue 2 only)
- Trigger pending

The third row of status blocks shows the 4-bit QS status register field that encodes the condition of the two queues. Two transition status cases, QS = 0011 and QS = 0111, are not shown because they exist only very briefly between stable status conditions.

The first three examples in [Figure 13-27](#) through [Figure 13-29](#) (S1, S2, and S3) show what happens when a new trigger event is recognized before the queue has completed servicing the previous trigger event on the same queue.

In situation S1 ([Figure 13-27](#)), one trigger event is being recognized on each queue while that queue is still working on the previously recognized trigger event. The trigger overrun error status bit is set, and otherwise, the premature trigger event is ignored. A trigger event that occurs before the servicing of the previous trigger event is completed does not disturb the queue execution in progress.

Figure 13-27. CCW Priority Situation 1

In situation S2 (Figure 13-27), more than one trigger event is recognized before servicing of a previous trigger event is complete, the trigger overrun bit is again set, but otherwise, the additional trigger events are ignored. After the queue is complete, the first newly detected trigger event causes queue execution to begin again. When the trigger event rate is high, a new trigger event can be seen very soon after completion of the previous queue, leaving software little time to retrieve the previous results. Also, when trigger events are occurring at a high rate for queue 1, the lower priority queue 2 channels may not get serviced at all.

Figure 13-28. CCW Priority Situation 2

Situation S3 (Figure 13-28) shows that when the pause feature is in use, the trigger overrun error status bit is set the same way, and that queue execution continues unchanged.

**Figure 13-29. CCW Priority Situation 3**

The next two situations consider trigger events that occur for the lower priority queue 2, while queue 1 is actively being serviced.

Situation S4 (Figure 13-30) shows that a queue 2 trigger event that is recognized while queue 1 is active is saved, and as soon as queue 1 is finished, queue 2 servicing begins.

**Figure 13-30. CCW Priority Situation 4**

Situation S5 (Figure 13-31) shows that when multiple queue 2 trigger events are detected while queue 1 is busy, the trigger overrun error bit is set, but queue 1 execution is not disturbed. Situation S5 also shows that the effect of queue 2 trigger events during queue 1 execution is the same when the pause feature is in use in either queue.

Figure 13-31. CCW Priority Situation 5

The remaining situations, S6 through S11, show the impact of a queue 1 trigger event occurring during queue 2 execution. Queue 1 is higher in priority the conversion taking place in queue 2 is aborted, so that there is not a variable latency time in responding to queue 1 trigger events.

In situation S6 (Figure 13-32), the conversion initiated by the second CCW in queue 2 is aborted just before the conversion is complete, so that queue 1 execution can begin. Queue 2 is considered suspended. After queue 1 is finished, queue 2 starts over with the first CCW, when the RES (resume) control bit is set to 0. Situation S7 (Figure 13-33) shows that when pause operation is not in use with queue 2, queue 2 suspension works the same way.

Figure 13-32. CCW Priority Situation 6

Figure 13-33. CCW Priority Situation 7

Situations S8 and S9 (Figure 13-34 and Figure 13-35) repeat the same two situations with the resume bit set to a one. When the RES bit is set, following suspension, queue 2 resumes execution with the aborted CCW, not the first CCW in the queue.

Figure 13-34. CCW Priority Situation 8

Figure 13-35. CCW Priority Situation 9

Situations S10 and S11 (Figure 13-36 and Figure 13-37) show that when an additional trigger event is detected for queue 2 while the queue is suspended, the trigger overrun error bit is set, the same as if queue 2 were being executed when a new trigger event occurs. Trigger overrun on queue 2 thus permits the software to know that queue 1 is taking up so much QADC64E time that queue 2 trigger events are being lost.

Figure 13-36. CCW Priority Situation 10

Figure 13-37. CCW Priority Situation 11

The above situations cover normal overlap conditions that arise with asynchronous trigger events on the two queues. An additional conflict to consider is that the freeze condition can arise while the QADC64E is actively executing CCWs. The conventional use for the freeze mode is for software/hardware debugging. When the CPU background debug mode is enabled and a breakpoint occurs, the freeze signal is issued, which can cause peripheral modules to stop operation. When freeze is detected, the QADC64E completes the conversion in progress, unlike queue 1 suspending queue 2. After the freeze condition is removed, the QADC64E continues queue execution with the next CCW in sequence.

Trigger events that occur during freeze are not captured. When a trigger event is pending for queue 2 before freeze begins, that trigger event is remembered when the freeze is passed. Similarly, when freeze occurs while queue 2 is suspended, after freeze, queue 2 resumes execution as soon as queue 1 is finished.

Situations 12 through 19 (Figure 13-38 to Figure 13-45) show examples of all of the freeze situations.

## 13.6.2 Conversion Timing Schemes

This section contains some conversion timing examples. Example 1 below shows the timing for basic conversions where the following is assumed:

- Q1 begins with CCW0 and ends with CCW3
- CCW0 has pause bit set
- CCW1 does not have pause bit set
- External trigger rise-edge for Q1
- CCW4 = BQ2 and Q2 is disabled

- Q1 RES shows relative result register updates

**Figure 13-46. External Trigger Mode (Positive Edge) Timing with Pause**

Recall  $QS = 0 \Rightarrow$  Queues disabled;  $QS = 8 \Rightarrow$  Q1 active, Q2 disabled;  $QS = 4 \Rightarrow$  Q1 paused, Q2 disabled.

A time separator was provided between the triggers and end of conversion (EOC). The relationship to QCLK displayed is not guaranteed.

CWPQ1 and CWPQ2 typically lag CWP and only match CWP when the associated queue is inactive. Another way to view CWPQ1 and CWPQ2 is that these registers update when EOC triggers the result register to be written.

When the pause bit is set (CCW0), please note that CWP does not increment until triggered. When the pause is not set (CCW1), the CWP increments with EOC.

The conversion results Q1 RES(x) show the result associated with CCW(x). So that R0 represents the result associated with CCW0.

Example 2 below shows the timing for conversions in gated mode single-scan with the same assumptions as example 1 except:

- No pause bits set in any CCW
- External trigger gated single-scan mode for Q1
- Single-scan bit is set

When the gate closes and opens again the conversions start with the first CCW in Q1.

When the gate closes the active conversion completes before the queue goes idle.

When Q1 completes both the CF1 bit sets and the SSE bit clears.

**Figure 13-47. Gated Mode, Single-Scan Timing**

Example 3 below shows the timing for conversions in gated continuous-scan mode with the same assumptions in the amended definition for the PF bit in this mode to reflect the condition that a gate closing occurred before the queue completed is a proposal under consideration at this time as example 2.

**NOTE**

At the end of Q1, the completion flag CF1 sets and the queue restarts. Also, note that if the queue starts a second time and completes, the trigger overrun flag TOR1 sets.

The QADC64E requires accurate, noise-free input signals for proper operation. This section discusses the design of external circuitry to maximize QADC64E performance.

### 13.7.1 Port Digital Input/Output Signals

Port A signals are referred to as PQA[7:0] when used as a bidirectional 8-bit digital input/output port. These eight signals may be used for general-purpose digital input signals or push-pull digital output signals. Port B signals are referred to as PQB[7:0] when used as digital input signals.

Port A and B signals are connected to a digital input synchronizer during reads and may be used as general purpose digital inputs when the applied voltages meet high voltage input ( $V_{IH}$ ) and low voltage input ( $V_{IL}$ ) requirements. Refer to [Appendix F, “Electrical Characteristics,”](#) for more information on voltage requirements.

Port A signals are configured as inputs or outputs by programming the port data direction register, DDRQA. The digital input signal states are read from the port data register, PORTQA, when the port data direction register specifies that the signals are inputs. The digital data in the port data register is driven onto the port A signals when the corresponding bit in the port data direction register specifies that the signals are outputs. Refer to [Appendix B, “Internal Memory Map,”](#) for more information. Since the outputs are configured as push-pull drivers, external pull-up provisions are not necessary when the output is used to drive another integrated circuit.

### 13.7.2 External Trigger Input Signals

The QADC64E uses two external trigger signals (ETRIG[2:1]). Each of the two input external trigger signals is associated with one of the scan queues, queue 1 or queue 2. The assignment of ETRIG[2:1] to a queue is made in the QACR0 register by the TRG bit. When TRG=0, ETRIG[1] triggers queue 1 and ETRIG[2] triggers queue 2. When TRG=1, ETRIG[1] triggers queue 2 and ETRIG[2] triggers queue 1.

#### NOTE

The ETRIG[2:1] pins on the MPC561/MPC563 are multiplexed with the PCS[7:6] pins.

### 13.7.3 Analog Power Signals

$V_{DDA}$  and  $V_{SSA}$  signals supply power to the analog subsystems of the QADC64E module. Dedicated power is required to isolate the sensitive analog circuitry from the normal levels of noise present on the digital power supply. Refer to [Appendix F, “Electrical Characteristics,”](#) for more information.

The analog supply signals ( $V_{DDA}$  and  $V_{SSA}$ ) define the limits of the analog reference voltages ( $V_{RH}$  and  $V_{RL}$ ) and of the analog multiplexer inputs. [Figure 13-49](#) is a diagram of the analog input circuitry.

**Figure 13-49. Equivalent Analog Input Circuitry**

Since the sample amplifier is powered by  $V_{DDA}$  and  $V_{SSA}$ , it can accurately transfer input signal levels up to but not exceeding  $V_{DDA}$  and down to but not below  $V_{SSA}$ . If the input signal is outside of this range, the output from the sample amplifier is clipped.

In addition,  $V_{RH}$  and  $V_{RL}$  must be within the range defined by  $V_{DDA}$  and  $V_{SSA}$ . As long as  $V_{RH}$  is less than or equal to  $V_{DDA}$  and  $V_{RL}$  is greater than or equal to  $V_{SSA}$  and the sample amplifier has accurately transferred the input signal, resolution is ratiometric within the limits defined by  $V_{RL}$  and  $V_{RH}$ . If  $V_{RH}$  is greater than  $V_{DDA}$ , the sample amplifier can never transfer a full-scale value. If  $V_{RL}$  is less than  $V_{SSA}$ , the sample amplifier can never transfer a zero value.

Figure 13-50 shows the results of reference voltages outside the range defined by  $V_{DDA}$  and  $V_{SSA}$ . At the top of the input signal range,  $V_{DDA}$  is 10 mV lower than  $V_{RH}$ . This results in a maximum obtainable 10-bit conversion value of 0x3FE. At the bottom of the signal range,  $V_{SSA}$  is 15 mV higher than  $V_{RL}$ , resulting in a minimum obtainable 10-bit conversion value of three.

**Figure 13-50. Errors Resulting from Clipping**

### 13.7.3.1 Analog Supply Filtering and Grounding

Two important factors influencing performance in analog integrated circuits are supply filtering and grounding. Generally, digital circuits use bypass capacitors on every VDD/VSS signal pair. This applies to analog sub-modules also. The distribution of power and ground is equally important.

Analog supplies should be isolated from digital supplies as much as possible. This necessity stems from the higher performance requirements often associated with analog circuits. Therefore, deriving an analog supply from a local digital supply is not recommended. However, if for economic reasons digital and analog power are derived from a common regulator, filtering of the analog power is recommended in addition to the bypassing of the supplies already mentioned.

For example, an RC low pass filter could be used to isolate the digital and analog supplies when generated by a common regulator. If multiple high precision analog circuits are locally employed (i.e., two A/D converters), the analog supplies should be isolated from each other as sharing supplies introduces the potential for interference between analog circuits.

Grounding is the most important factor influencing analog circuit performance in mixed signal systems (or in stand-alone analog systems). Care must be taken to not introduce additional sources of noise into the analog circuitry. Common sources of noise include ground loops, inductive coupling, and combining digital and analog grounds together inappropriately.

The problem of how and when to combine digital and analog grounds arises from the large transients which the digital ground must handle. If the digital ground is not able to handle the large transients, the current from the large transients can return to ground through the analog ground. It is the excess current overflowing into the analog ground which causes performance degradation by developing a differential voltage between the true analog ground and the microcontroller's ground signal. The end result is that the ground observed by the analog circuit is no longer true ground and often ends in skewed results.

Two similar approaches designed to improve or eliminate the problems associated with grounding excess transient currents involve star-point ground systems. One approach is to star-point the different grounds at the power supply origin, thus keeping the ground isolated. Refer to [Figure 13-51](#).

Another approach is to star-point the different grounds near the analog ground signal on the microcontroller by using small traces for connecting the non-analog grounds to the analog ground. The small traces are meant only to accommodate DC differences, not AC transients.

### NOTE

This star-point scheme still requires adequate grounding for digital and analog subsystems in addition to the star-point ground.

Other suggestions for PCB layout in which the QADC64E is employed include:

- Analog ground must be low impedance to all analog ground points in the circuit.
- Bypass capacitors should be as close to the power signals as possible.

The analog ground should be isolated from the digital ground. This can be done by cutting a separate ground plane for the analog ground

- Non-minimum traces should be utilized for connecting bypass capacitors and filters to their corresponding ground/power points.
- Distance for trace runs should be minimized where possible

Figure 13-51. Star-Ground at the Point of Power Supply Origin

### 13.7.4 Analog Reference Signals

$V_{RH}$  and  $V_{RL}$  are the dedicated input signals for the high and low reference voltages. Separating the reference inputs from the power supply signals allows for additional external filtering, which increases reference voltage precision and stability, and subsequently contributes to a higher degree of conversion accuracy.

No A/D converter can be more accurate than its analog reference. Any noise in the reference can result in at least that much error in a conversion. The reference for the QADC64E, supplied by signals  $V_{RH}$  and  $V_{RL}$ , should be low-pass filtered from its source to obtain a noise-free, clean signal. In many cases, simple capacitive bypassing may suffice. In extreme cases, inductors or ferrite beads may be necessary if noise or RF energy is present. Series resistance is not advisable since there is an effective DC current requirement from the reference voltage by the internal resistor string in the RC DAC array. External resistance may introduce error in this architecture under certain conditions. Any series devices in the filter network should contain a minimum amount of DC resistance.

### 13.7.5 Analog Input Signals

Analog inputs should have low AC impedance at the signals. Low AC impedance can be realized by placing a capacitor with good high frequency characteristics at the input signal of the part. Ideally, that capacitor should be as large as possible (within the practical range of capacitors that still have good high frequency characteristics). This capacitor has two effects:

- It helps attenuate any noise that may exist on the input.

- It sources charge during the sample period when the analog signal source is a high-impedance source.

Series resistance can be used with the capacitor on an input signal to implement a simple RC filter. The maximum level of filtering at the input signals is application dependent and is based on the bandpass characteristics required to accurately track the dynamic characteristics of an input. Simple RC filtering at the signal may be limited by the source impedance of the transducer or circuit supplying the analog signal to be measured. Refer to [Section 13.7.5.3, “Error Resulting from Leakage,”](#) for more information. In some cases, the size of the capacitor at the signal may be very small.

[Figure 13-52](#) is a simplified model of an input channel. Refer to this model in the following discussion of the interaction between the external circuitry and the circuitry inside the QADC64E.

**Figure 13-52. Electrical Model of an A/D Input Signal**

In [Figure 13-52](#),  $R_F$ ,  $R_{SRC}$  and  $C_F$  comprise the external filter circuit.  $C_P$  is the internal parasitic capacitor.  $C_{SAMP}$  is the capacitor array used to sample and hold the input voltage.  $V_I$  is an internal voltage source used to provide charge to  $C_{SAMP}$  during sample phase.

The following paragraphs provide a simplified description of the interaction between the QADC64E and the external circuitry. This circuitry is assumed to be a simple RC low-pass filter passing a signal from a source to the QADC64E input signal. The following simplifying assumptions are made:

- The external capacitor is perfect (no leakage, no significant dielectric absorption characteristics, etc.)
- All parasitic capacitance associated with the input signal is included in the value of the external capacitor
- Inductance is ignored

- The “on” resistance of the internal switches is 0  $\Omega$  and the “off” resistance is infinite

#### 13.7.5.1 Analog Input Considerations

The source impedance of the analog signal to be measured and any intermediate filtering should be considered whether external multiplexing is used or not. [Figure 13-53](#) shows the connection of eight typical analog signal sources to one QADC64E analog input signal through a separate multiplexer chip. Also, an example of an analog signal source connected directly to a QADC64E analog input channel is displayed.

1 Typical Value

2 RFILTER typically 10KW–20KW

**Figure 13-53. External Multiplexing of Analog Signal Sources**

### 13.7.5.2 Settling Time for the External Circuit

The values for  $R_{SRC}$ ,  $R_F$  and  $C_F$  in the external circuitry determine the length of time required to charge  $C_F$  to the source voltage level ( $V_{SRC}$ ). At time  $t = 0$ ,  $V_{SRC}$  changes in [Figure 13-52](#) while S1 is open, disconnecting the internal circuitry from the external circuitry. Assume that the initial voltage across  $C_F$  is zero. As  $C_F$  charges, the voltage across it is determined by the following equation, where  $t$  is the total charge time:

$$V_{CF} = V_{SRC} \left( 1 - e^{\left( \frac{-t}{(R_F + R_{SRC})C_F} \right)} \right) \quad \text{Eqn. 13-1}$$

As  $t$  approaches infinity,  $V_{CF}$  will equal  $V_{SRC}$ . (This assumes no internal leakage.) With 10-bit resolution, 1/2 of a count is equal to 1/2048 full-scale value. Assuming worst case ( $V_{SRC}$  = full scale), [Table 13-24](#) shows the required time for  $C_F$  to charge to within 1/2 of a count of the actual source voltage during 10-bit conversions. [Table 13-24](#) is based on the RC network in [Figure 13-52](#).

#### NOTE

The following times are completely independent of the A/D converter architecture (assuming the QADC64E is not affecting the charging).

**Table 13-24. External Circuit Settling Time to 1/2 LSB (10-Bit Conversions)**

| Filter Capacitor<br>(CF) | Source Resistance ( $R_F + R_{SRC}$ ) |              |               |                |
|--------------------------|---------------------------------------|--------------|---------------|----------------|
|                          | 100 $\Omega$                          | 1 k $\Omega$ | 10 k $\Omega$ | 100 k $\Omega$ |
| 1 $\mu$ F                | 760 $\mu$ s                           | 7.6 ms       | 76 ms         | 760 ms         |
| .1 $\mu$ F               | 76 $\mu$ s                            | 760 $\mu$ s  | 7.6 ms        | 76 ms          |
| .01 $\mu$ F              | 7.6 $\mu$ s                           | 76 $\mu$ s   | 760 $\mu$ s   | 7.6 ms         |
| .001 $\mu$ F             | 760 ns                                | 7.6 $\mu$ s  | 76 $\mu$ s    | 760 $\mu$ s    |
| 100 pF                   | 76 ns                                 | 760 ns       | 7.6 $\mu$ s   | 76 $\mu$ s     |

The external circuit described in [Table 13-24](#) is a low-pass filter. A user interested in measuring an AC component of the external signal must take the characteristics of this filter into account.

### 13.7.5.3 Error Resulting from Leakage

A series resistor limits the current to a signal, therefore input leakage acting through a large source impedance can degrade A/D accuracy. The maximum input leakage current is specified in [Appendix F, “Electrical Characteristics.”](#) Input leakage is greater at higher operating temperatures. In the temperature range from 125° C to 50° C, the leakage current is halved for every 8 – 12° C reduction in temperature.

Assuming  $V_{RH} - V_{RL} = 5.12$  V, one count (assuming 10-bit resolution) corresponds to 5 mV of input voltage. A typical input leakage of 200 nA acting through 10 k $\Omega$  of external series resistance results in an error of 0.4 count (2.0 mV). If the source impedance is 100 k $\Omega$  and a typical leakage of 100 nA is present, an error of two counts (10 mV) is introduced.

In addition to internal junction leakage, external leakage (e.g., if external clamping diodes are used) and charge sharing effects with internal capacitors also contribute to the total leakage current. [Table 13-25](#) illustrates the effect of different levels of total leakage on accuracy for different values of source impedance. The error is listed in terms of 10-bit counts.

### CAUTION

Leakage from the part below 200 nA is obtainable only within a limited temperature range.

**Table 13-25. Error Resulting from Input Leakage (IOFF)**

| Source Impedance | Leakage Value (10-bit Conversions) |            |            |            |
|------------------|------------------------------------|------------|------------|------------|
|                  | 100 nA                             | 200 nA     | 500 nA     | 1000 nA    |
| 1 k $\Omega$     | —                                  | —          | 0.1 counts | 0.2 counts |
| 10 k $\Omega$    | 0.2 counts                         | 0.4 counts | 1 counts   | 2 counts   |
| 100 k $\Omega$   | 2 counts                           | 4 count    | 10 counts  | 20 counts  |

#### 13.7.5.4 Accommodating Positive/Negative Stress Conditions

Positive or negative stress refers to conditions which exceed nominally defined operating limits. Examples include applying a voltage exceeding the normal limit on an input (for example, voltages outside of the suggested supply/reference ranges) or causing currents into or out of the signal which exceed normal limits. QADC64E specific considerations are voltages greater than  $V_{DDA}$ ,  $V_{RH}$  or less than  $V_{SSA}$  applied to an analog input which cause excessive currents into or out of the input. Refer to [Appendix F, “Electrical Characteristics,”](#) to for more information on exact magnitudes.

Either stress condition can potentially disrupt conversion results on neighboring inputs. Parasitic devices, associated with CMOS processes, can cause an immediate disruptive influence on neighboring signals. Common examples of parasitic devices are diodes to substrate and bipolar devices with the base terminal tied to substrate ( $V_{SS1}/V_{SSA}$  ground). Under stress conditions, current injected on an adjacent signal can cause errors on the selected channel by developing a voltage drop across the selected channel's impedances.

[Figure 13-54](#) shows an active parasitic bipolar NPN transistor when an input signal is subjected to negative stress conditions. [Figure 13-55](#) shows positive stress conditions can activate a similar PNP transistor.

**Figure 13-54. Input Signal Subjected to Negative Stress**

QADC64E PAR

**Figure 13-55. Input Signal Subjected to Positive Stress**

The current into the signal ( $I_{INJN}$  or  $I_{INJP}$ ) under negative or positive stress is determined by the following equations:

$$I_{INJN} = \frac{-(V_{STRESS} - V_{BE})}{R_{STRESS}} \quad \text{Eqn. 13-2}$$

$$I_{INJP} = \frac{V_{STRESS} - V_{EB} - V_{DDA}}{R_{STRESS}} \quad \text{Eqn. 13-3}$$

where:

$V_{STRESS}$  = Adjustable voltage source

$V_{EB}$  = Parasitic PNP emitter/base voltage

(refer to  $V_{NEGCLAMP}$  in [Appendix F, “Electrical Characteristics”](#))

$V_{BE}$  = Parasitic NPN base/emitter voltage

(refer to  $V_{NEGCLAMP}$  in [Appendix F, “Electrical Characteristics”](#))

$R_{STRESS}$  = Source impedance

(10-k $\Omega$  resistor in [Figure 13-54](#) and [Figure 13-55](#) on stressed channel)

$R_{SELECTED}$  = Source impedance on channel selected for conversion

The current into ( $I_{IN}$ ) the neighboring signal is determined by the  $K_N$  (current coupling ratio) of the parasitic bipolar transistor ( $K_N \ll 1$ ). The  $I_{IN}$  can be expressed by the following equation:

$$I_{IN} = -K_N * I_{INJ}$$

where  $I_{INJ}$  is either  $I_{INJN}$  or  $I_{INJP}$ .

A method for minimizing the impact of stress conditions on the QADC64E is to strategically allocate QADC64E inputs so that the lower accuracy inputs are adjacent to the inputs most likely to see stress conditions.

Also, suitable source impedances should be selected to meet design goals and minimize the effect of stress conditions.

# Chapter 14

## QADC64E Enhanced Mode Operation

The two queued analog-to-digital converter (QADC) modules on the MPC561/MPC563 devices are 10-bit, unipolar, successive approximation converters. The modules can be configured to operate in one of two modes, legacy mode (for MPC555 compatibility) and enhanced mode. This chapter describes how the module operates in enhanced mode. Refer to [Chapter 13, “QADC64E Legacy Mode Operation,”](#) for information regarding the QADC64E functionality in legacy mode.

For this revision of the QADC, the name QADC64E implies the enhanced version of the QADC64 module, not just enhanced mode of operation. For simplicity, the names QADC and QADC64E may be used interchangeably throughout this document.

### 14.1 QADC64E Block Diagram

[Figure 14-1](#) displays the major components of the QADC64E modules on the MPC561/MPC563.

**Figure 14-1. QADC64E Block Diagram**

## 14.2 Key Features and Quick Reference Diagrams

This section gives an overview of the implementation of the two QADC64E modules on the MPC561/MPC563. It can also be used for a quick reference while programming the modules.

### 14.2.1 Features of the QADC64E Enhanced Mode Operation

- Internal sample and hold
- Directly supports up to four external multiplexers (for example, the MC14051)
- Up to 41 analog input channels using QADC64 external multiplexing
- Programmable input sample time for various source impedances
- Minimum conversion time of 7 $\mu$ s (with typical QCLK frequency, 2 MHz)
- Two conversion command queues with a total of 64 entries
- Sub-queues possible using pause mechanism
- Queue complete and pause software interrupts available on both queues
- Queue pointers indicate current location for each queue
- Automated queue modes initiated by
  - External edge trigger
  - Periodic/Interval timer, within QADC64E module
  - Software command
  - External gated trigger (queue 1 only)
- Single-scan or continuous-scan of queues
- 64 result registers in each QADC64E module
- Output readable in three formats
  - Right-justified unsigned
  - Left-justified signed
  - Left-justified unsigned
- Unused analog channels can be used as digital input/output signals
- Modulus prescaler can divide the system clock for the converter by two to 128
- Alternate reference input, with control in the conversion command word (CCW)

The analog section includes input signals, an analog multiplexer, and the sample and hold circuits. The analog conversion is performed by the digital-to-analog converter (DAC) resistor-capacitor array and a high-gain comparator.

The digital control section contains queue control logic to sequence the conversion process and interrupt generation logic. Also included are the periodic/interval timer, control and status registers, the conversion command word (CCW) table RAM, and the result table RAM.

The bus interface unit (BIU) allows the QADC64E to operate with the applications software through the IMB3 environment.

## 14.2.2 Memory Map

The QADC64E occupies one Kbyte, or 512 16-bit entries, of address space. Ten 16-bit registers are control, port, and status registers, 64 16-bit entries are the CCW table, and 64 16-bit entries are the result table, and occupy 192 16-bit address locations because the result data is readable in three data alignment formats.

Each QADC64E module on MPC561/MPC563 has its own memory space. Table 14-1 shows the memory map for QADC64E module A, it occupies 0x30 4800 to 0x30 4BFF. Table 14-2 shows the memory map for QADC64E module B. Module B has the same offset scheme starting at 0x30 4C00. QADC64E\_B occupies 0x30 4C00 to 0x30 4FFF.

<sup>1</sup> Registers are accessible only as supervisor data space

Accesses to supervisor-only data space is permitted only when the bus master is operating in supervisor access mode. Assignable data space can be either restricted to supervisor-only access or unrestricted to both supervisor and user data space addresses. See [Section 14.3.1.4, “Supervisor/Unrestricted Address Space.”](#)

### 14.2.3 Legacy and Enhanced Modes of Operation

The QADC64E modules can be configured to operate in Legacy or Enhanced mode. Legacy mode is the default state out of reset. The QADC64E modules are configured for Enhanced mode by a series of writes

to the LOCK and FLIP bits of the module configuration register. This will be described in [Section 14.3.1.3](#), “Switching Between Legacy and Enhanced Modes of Operation.”

## 14.2.4 Using the Queue and Result Word Table

The heart of the QADC is its conversion command word (CCW) queues. This is where the module is programmed to convert a particular channel according to a particular requirement. The queues are created by writing CCWs into the CCW table in the register memory. The queues are controlled by the three control registers, and their status can be read from the two status registers. As conversions are completed the digital value is written into the result word table. [Figure 14-2](#) shows the CCW queue and the result word table.

NOTE 1: These offsets must be added to the module base address: A = 0x30 4800 or B = 0x30 4C00

**Figure 14-2. CCW Queue and Result Table Block Diagram**

## 14.2.5 External Multiplexing

The QADC can use from one to four 8-input external multiplexer chips to expand the number of analog signals that may be converted. The externally multiplexed channels are automatically selected from the

channel field of the conversion command word (CCW) table. External Multiplex mode is software selectable, by setting the EMUX bit of control register 0 (QACR0).

Figure 14-3 shows the maximum configuration of four external multiplexer chips connected to the QADC. The QADC provides three multiplexer address signals – MA0, MA1, MA2 – to select one of the multiplexer chips. These outputs are the multiplexer control lines and they are connected to all external multiplexer chips.

The analog output of each of the four multiplexer chips is connected to four separate QADC inputs – ANw, ANx, ANy, ANz. These signals are the first four signals of port B and each one can represent eight analog input channels. The QADC converts the proper input channel (ANw, ANx, ANy, ANz) by interpreting the channel number in the CCW. Refer to Table 14-3.

**Figure 14-3. Example of External Multiplexing**

**Table 14-3. Multiplexed Analog Input Channels**

| Multiplexed Analog Input | Channels      |
|--------------------------|---------------|
| ANw (AN44)               | 0 through 7   |
| ANx (AN45)               | 8 through 15  |
| ANy (AN46)               | 16 through 23 |
| ANz (AN47)               | 24 through 31 |

Table 14-4 shows the total number of analog input channels supported with zero to four external multiplexer chips using one QADC module.

**Table 14-4. Analog Input Channels**

| Number of Analog Input Channels Available<br>Directly Connected + External Multiplexed = Total Channels |                       |                        |                          |                         |
|---------------------------------------------------------------------------------------------------------|-----------------------|------------------------|--------------------------|-------------------------|
| No External MUX Chips                                                                                   | One External MUX Chip | Two External MUX Chips | Three External MUX Chips | Four External MUX Chips |
| 16                                                                                                      | 20                    | 27                     | 34                       | 41                      |

**NOTE: QADC64E External MUX Users**

If a QADC64E module is in external multiplexing (EMUX) mode then the multiplexer address signal channels AN[52:54] should *not* be programmed into queues.

## 14.3 Programming the QADC64E Registers

The QADC64E has three global registers for configuring module operation.

- The module configuration register, QADCMCR (Section 14.3.1, “QADC64E Module Configuration Register”)
- The interrupt register, QADCINT (Section 14.3.2, “QADC64E Interrupt Register”)
- The test register, QADCTEST. This register is used for factory test only.

These global registers are always defined to be in supervisor-only data space. Refer to Table 14-1 for the QADC64E\_A Address Map and Table 14-2 for QADC64E\_B Address Map. See Section 14.3.1.4, “Supervisor/Unrestricted Address Space” for access modes for these registers.

The remaining five registers in the control register block control the operation of the queuing mechanism, and provide a means of monitoring the operation of the QADC64E.

- Control register 0 (QACR0) contains hardware configuration information (Section 14.3.5, “Control Register 0”)
- Control register 1 (QACR1) is associated with queue 1 (Section 14.3.6, “Control Register 1”)
- Control register 2 (QACR2) is associated with queue 2 (Section 14.3.7, “Control Register 2”)
- Status registers (QASR0 and QASR1) provide visibility on the status of each queue and the particular conversion that is in progress (Section 14.3.8, “Status Registers (QASR0 and QASR1)”)

The Conversion Command Word (CCW) table contains 64 entries to hold the software programmable analog conversion sequences. Each CCW table entry is a 16-bit entry, though only 10 bits are used.

The final block of address space belongs to the result word table, which appears in three places in the memory map. Each result word table location holds one 10-bit conversion value.

## 14.3.1 QADC64E Module Configuration Register

The QADCMCR contains fields and bits that control freeze and stop modes, operating mode of the QADC64E module, determine the privilege level required to access most registers and master/slave operation.

### 14.3.1.1 Low Power Stop Mode

When the STOP bit in the QADCMCR is set, the QADC64E clock (QCLK) which clocks the A/D converter, is disabled and the analog circuitry is powered down. This results in a static, low power consumption, idle condition. The stop mode aborts any conversion sequence in progress. Because the bias currents to the analog circuits are turned off in stop mode, the QADC64E requires some recovery time ( $T_{SR}$  in Appendix F: Electrical Characteristics) to stabilize the analog circuits after the stop enable bit is cleared.

In stop mode:

- BIU state machine and logic do not shut down
- The CCW and Result RAM is not reset and is not accessible
- The module configuration register (QADCMCR), the interrupt register (QADCINT), and the test register (QADCTEST) are fully accessible and are not reset
- The data direction register (DDRQA), port data register (PORTQA/PORTQB), and control register 0 (QACR0) are not reset and are read-only accessible
- Control register 1 (QACR1), control register 2 (QACR2), and the status registers (QASR0 and QASR1) are reset and are read-only accessible
- In addition, the periodic/interval timer is held in reset during stop mode

If the STOP bit is clear, stop mode is disabled.

### 14.3.1.2 Freeze Mode

Freeze mode occurs when background debug mode is enabled in the USIU and a breakpoint is encountered. This is indicated by the assertion of the internal FREEZE line on the IMB3. The FRZ bit in the QADCMCR determines whether or not the QADC64E responds to an IMB3 internal FREEZE signal assertion. Freeze is very useful when debugging an application.

When the internal FREEZE signal is asserted and the FRZ bit is set, the QADC64E finishes any conversion in progress and then freezes.

Depending on when the FREEZE signal is asserted, there are three possible queue "freeze" scenarios:

- When a queue is not executing, the QADC64E freezes immediately
- When a queue is executing, the QADC64E completes the conversion in progress and then freezes
- If, during the execution of the current conversion, the queue operating mode for the active queue is changed, or a queue 2 abort occurs, the QADC64E freezes immediately

During freeze mode, both the analog clock, QCLK, and periodic/interval timer are held in reset. When the QADC64E enters the freeze mode while a queue is active, the current CCW location of the queue pointer is saved.

During freeze, the analog clock, QCLK, is held in reset and the periodic/interval timer is held in reset. External trigger events that occur during the freeze mode are not captured. The BIU remains active to allow IMB3 access to all QADC64E registers and RAM. Although the QADC64E saves a pointer to the next CCW in the current queue, the software can force the QADC64E to execute a different CCW by writing new queue operating modes for normal operation. The QADC64E looks at the queue operating modes, the current queue pointer, and any pending trigger events to decide which CCW to execute when exiting freeze.

If the FRZ bit is clear, the internal FREEZE signal is ignored.

### 14.3.1.3 Switching Between Legacy and Enhanced Modes of Operation

The LOCK and FLIP bits of the QADCMCR register control the operating mode of the QADC64E modules. Out of reset, the QADC64E modules are in legacy mode (FLIP = 0) and the LOCK bit is clear,

indicating that the module is locked in legacy mode. In order to change the value of the FLIP bit, the operating mode must first be unlocked by setting the LOCK bit. Only then can the FLIP bit be changed. Finally, the LOCK bit must be cleared again to protect the state of the FLIP bit from future writes.

1. Write LOCK = 1 to unlock operating mode bit.
2. Modify the value of FLIP as required.
  - FLIP = 0 legacy mode enabled
  - FLIP = 1 enhanced mode enabled
3. Write LOCK = 0 and new FLIP bit value to preserve the value of FLIP bit
  - Example 1: switching from legacy mode to enhanced mode
    - QADCMCR = 0x280; LOCK = 1, SUPV = 1
    - QADCMCR = 0x380; LOCK = 1, write FLIP = 1, SUPV = 1
    - QADCMCR = 0x180; LOCK = 0, FLIP = 1, SUPV = 1
 Subsequent writes to the FLIP bit will have no effect while LOCK = 0.
  - Example 2: switching from enhanced mode to legacy mode
    - QADCMCR = 0x280 or 0x380; LOCK = 1, SUPV = 1 (Can write FLIP = x since value will not change)
    - QADCMCR = 0x280; LOCK = 1, FLIP = 0, SUPV = 1
    - QADCMCR = 0x080; LOCK = 0, FLIP = 0, SUPV = 1

#### 14.3.1.4 Supervisor/Unrestricted Address Space

The QADC64E memory map is divided into two segments: supervisor-only data space and assignable data space. Access to supervisor-only data space is permitted only when the software is operating in supervisor access mode. Assignable data space can be either restricted to supervisor-only access or unrestricted to both supervisor and user data space accesses. The SUPV bit in the QADCMCR designates the assignable space as supervisor or unrestricted.

The following information applies to accesses to address space located within the module's 16-bit boundaries and where the response is a bus error. See [Table 14-6](#) for more information.

- Attempts to read a supervisor-only data space when not in the supervisor access mode and SUPV = 1, causes the bus master to assert a bus error condition. No data is returned. If SUPV = 0, the QADC64E asserts a bus error condition and no data is returned.
- Attempts to write to supervisor-only data space when not in the supervisor access mode and SUPV = 1, causes the bus master to assert a bus error condition. No data is written. If SUPV = 0, the QADC64E asserts a bus error condition and the register is not written.
- Attempts to read unimplemented data space in the unrestricted access mode and SUPV = 1, causes the bus master to assert a bus error condition and no data is returned. In all other attempts to read unimplemented data space, the QADC64E causes a bus error condition and no data is returned.
- Attempts to write unimplemented data space in the unrestricted access mode and SUPV = 1, causes the bus master to assert a bus error condition and no data is written. In all other

attempts to write unimplemented data space, the QADC64E causes a bus error condition and no data is written.

- Attempts to read assignable data space in the unrestricted access mode when the space is programmed as supervisor space causes the bus master to assert a bus error condition and no data is returned.
- Attempts to write assignable data space in the unrestricted access mode when the space is programmed as supervisor space causes the bus master to assert a bus error condition and the register is not written.

**Table 14-6. QADC64E Bus Error Response**

| S/U <sup>1</sup><br>Mode | SUPV Bit | Supervisor-Only<br>Register    | Supervisor/<br>Unrestricted Register | Reserved/<br>Unimplemented<br>Register |
|--------------------------|----------|--------------------------------|--------------------------------------|----------------------------------------|
| U                        | 0        | QADC64E bus error <sup>2</sup> | Valid access <sup>4</sup>            | QADC64E bus error <sup>2</sup>         |
| U                        | 1        | Master bus error <sup>3</sup>  | Master bus error <sup>3</sup>        | Master bus error <sup>3</sup>          |
| S                        | 0        | Valid access                   | Valid access                         | QADC64E bus error <sup>2</sup>         |
| S                        | 1        | Valid access                   | Valid access                         | QADC64E bus error <sup>2</sup>         |

<sup>1</sup> S/U = Supervisor/Unrestricted

<sup>2</sup> QADC64E bus error = Caused by QADC64E

<sup>3</sup> Master bus error = Caused by bus master

<sup>4</sup> Access to QADCTEST register will act as a reserved/unimplemented register unless in factory test mode

The bus master indicates the supervisor and user space access with the function code bits (FC[2:0]) on the IMB3. For privilege violations, refer to [Chapter 9, “External Bus Interface”](#) to determine the consequence of a bus error cycle termination.

The supervisor-only data space segment contains the QADC64E global registers, which include the QADCMCR, QADCINT and QADCTEST. The supervisor/unrestricted space designation for the CCW table, the result word table and the remaining QADC64E registers is programmable.

### 14.3.2 QADC64E Interrupt Register

QADCINT specifies the priority level of QADC64E interrupt requests. The interrupt level for queue 1 and queue 2 may be different. The interrupt register is read/write accessible in supervisor data space only. The implemented interrupt register fields can be read and written, reserved bits read zero and writes have no effect. They are typically written once when the software initializes the QADC64E, and not changed afterwards.

**Table 14-7. QADCINT Bit Descriptions**

| Bits  | Name | Description                                                                                                                                                                                                                                                                                                                   |
|-------|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0:4   | IRL1 | Queue 1 Interrupt Request Level. The IRL1 field establishes the queue 1 interrupt request level. The 00000 state provides a level 0 interrupt while 11111 provides a level 31 interrupt. All interrupts are presented on the IMB3. Interrupt level priority software determines which level has the highest priority request. |
| 5:9   | IRL2 | Queue 2 Interrupt Request Level. The IRL2 field establishes the queue 2 interrupt request level. The 00000 state provides a level 0 interrupt while 11111 provides a level 31 interrupt. All interrupts are presented on the IMB3. Interrupt level priority software determines which level has the highest priority request. |
| 10:15 | —    | Reserved.                                                                                                                                                                                                                                                                                                                     |

The QADC64E conditionally generates interrupts to the bus master via the IMB3 IRQ signals. When the QADC64E sets a status bit assigned to generate an interrupt, the QADC64E drives the IRQ bus. The value driven onto IRQ[7:0] represents the interrupt level assigned to the interrupt source. Under the control of ILBS, each interrupt request level is driven during the time multiplexed bus during one of four different time slots, with eight levels communicated per time slot. No hardware priority is assigned to interrupts. Furthermore, if more than one source on a module requests an interrupt at the same level, the system software must assign a priority to each source requesting at that level. [Figure 14-6](#) displays the interrupt levels on IRQ with ILBS. Refer to [Chapter 12, “U-Bus to IMB3 Bus Interface \(UIMB\)”](#) for more information.

**Figure 14-6. Interrupt Levels on IRQ with ILBS**

### 14.3.3 Port Data Register

QADC64E ports A and B are accessed through two 8-bit port data registers, PORTQA and PORTQB.

Port A signals are referred to as PQA[7:0] when used as 8-bit general-purpose digital input or output signals. It is configured as a digital input or digital output using the data direction register, DDRQA. When Port A is configured as an input, a read of the PORTQA register returns the actual PQA[7:0] signal values. When Port A is configured as an output, the contents of port register PQA are driven on the port A signals. Port A can also be used as analog inputs AN[59:52] and external multiplexer address outputs MA[2:0].

Port B signals are referred to as PQB[7:0] when used as 8-bit general-purpose digital input or output signals. It is configured as a digital input or digital output using the data direction register, DDRQB. When Port B is configured as an input, a read of the PORTQB register returns the actual PQB[7:0] signal values. When Port B is configured as an output, the contents of port register PQB are driven on the port B signals. Port B can also be used as non-multiplexed analog inputs AN[51:44]. In external multiplexed mode four signals can be used as multiplexer analog inputs, ANw, ANx, ANy, ANz.

During a port data register read, the actual value of the signal is reported when its corresponding bit in the data direction register defines the signal to be an input. When the data direction bit specifies the signal to be an output, the content of the port data register is read. PORTQA and PORTQB are not initialized by reset..

| Bits | Name     | Description                                                                                                                                                                                |
|------|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0:7  | PQA[7:0] | Port A signals are referred to as PQA when used as an 8-bit input/output port. Port A can also be used for analog inputs (AN[59:52]), and external multiplexer address outputs (MA[2:0]).  |
| 8:15 | PQB[7:0] | Port B signals are referred to as PQB when used as an 8-bit input/output port. Port B can also be used for non-multiplexed (AN[51:44]) and multiplexed (ANz, ANy, ANx, ANw) analog inputs. |

### 14.3.4 Port Data Direction Register

The port data direction registers (DDRQA and DDRQB) are associated with the Port A and Port B digital I/O signals. Refer to [Appendix F, “Electrical Characteristics,”](#) for more information. Any bit set to one in this register configures the corresponding signal as an output. Any bit cleared to zero in this register

configures the corresponding signal as an input. The software is responsible for ensuring that DDR bits are not set to one on signals used for analog inputs. When the DDR bit is set to one and the signal is selected for analog conversion, the voltage sampled is that of the output digital driver as influenced by the load.

### NOTE

Caution should be exercised when mixing digital and analog inputs. This should be isolated as much as possible. Rise and fall times should be as large as possible to minimize AC coupling effects.

There are two special cases to consider for the digital I/O port operation. When QACR0[EMUX] bit is set, enabling external multiplexing, the data direction register settings are ignored for the bits corresponding to PORTQA[2:0], which are the three multiplexed address output signals, MA[2:0]. The MA[2:0] signals are forced to be digital outputs, regardless of the data direction setting, and the multiplexed address outputs are driven. The data returned during a port data register read is the value of the multiplexed address latches which drive MA[2:0], regardless of the data direction setting.

## 14.3.5 Control Register 0

Control Register 0 defines whether external multiplexing is enabled, assigns external triggers to the conversion queues and sets up the QCLK prescaler parameter field. All of the implemented control register fields can be read or written but reserved fields read zero and writes have no effect. Typically, they are written once when software initializes the QADC64E and are not changed afterwards.

| 9:15 | PRESCALER | Prescaler Value. The PRESCALER value determines the QCLK frequency ( $f_{QCLK}$ ). Refer to <a href="#">Appendix F, “Electrical Characteristics,”</a> for more information on the QADC64E operating clock frequency ( $f_{QCLK}$ ) values. $f_{QCLK}$ can range from 2-to-128 system clock cycles ( $f_{SYSCLK}$ ). To keep $f_{QCLK}$ within the specified range, the value of PRESCALER+1 is the $f_{SYSCLK}$ divisor. Refer to <a href="#">Section 14.4.5, “QADC64E Clock (QCLK) Generation”</a> for more information on selecting a PRESCALER value. |

[Table 14-10](#) displays the bits in PRESCALER field which enable a range of QCLK frequencies

### 14.3.6 Control Register 1

Control register 1 is the mode control register for the operation of queue 1. The applications software defines the queue operating mode for the queue, and may enable a completion and/or pause interrupt. All of the control register fields are read/write data. However, the SSE1 bit always reads as zero unless the test mode is enabled. Most of the bits are typically written once when the software initializes the QADC64E, and not changed afterwards.

**Table 14-11. QACR1 Bit Descriptions**

| Bits | Name | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|------|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0    | CIE1 | Queue 1 Completion Interrupt Enable. CIE1 enables an interrupt upon completion of queue 1. The interrupt request is initiated when the conversion is complete for the CCW in queue 1.<br>0 Disable the queue completion interrupt associated with queue 1<br>1 Enable an interrupt after the conversion of the sample requested by the last CCW in queue 1                                                                                                                                                                                                                                                                                                                                                              |
| 1    | PIE1 | Queue 1 Pause Interrupt Enable. PIE1 enables an interrupt when queue 1 enters the pause state. The interrupt request is initiated when conversion is complete for a CCW that has the pause bit set.<br>0 Disable the pause interrupt associated with queue 1<br>1 Enable an interrupt after the conversion of the sample requested by a CCW in queue 1 which has the pause bit set                                                                                                                                                                                                                                                                                                                                      |
| 2    | SSE1 | Queue 1 Single-Scan Enable Bit. SSE1 enables a single-scan of queue 1 to start after a trigger event occurs. The SSE1 bit may be set to a one during the same write cycle when the MQ1 bits are set for one of the single-scan queue operating modes. The single-scan enable bit can be written as a one or a zero, but is always read as a zero. The SSE1 bit enables a trigger event to initiate queue execution for any single-scan operation on queue 1. The QADC64E clears the SSE1 bit when the single-scan is complete. Refer to <a href="#">Table 14-12</a> for more information.<br>0 Trigger events are not accepted for single-scan modes<br>1 Accept a trigger event to start queue 1 in a single-scan mode |
| 3:7  | MQ1  | Queue 1 Operating Mode. The MQ1 field selects the queue operating mode for queue 1. <a href="#">Table 14-12</a> shows the bits in the MQ1 field which enable different queue 1 operating mode                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| 8:15 | —    | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| 11110    | Periodic timer continuous-scan mode: time = QCLK period x $2^{17}$    |
| 11111    | External gated continuous-scan mode                                   |

### 14.3.7 Control Register 2

Control register 2 is the mode control register for the operation of queue 2. Software specifies the queue operating mode of queue 2, and may enable a completion and/or a pause interrupt. All control register fields are read/write data, except the SSE2 bit, which is readable only when the test mode is enabled. Most of the bits are typically written once when the software initializes the QADC64E, and not changed afterwards.

**Table 14-13. QACR2 Bit Descriptions (continued)**

| Bits | Name | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|------|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 9:15 | BQ2  | <p>Beginning of queue 2. The BQ2 field indicates the CCW location where queue 2 begins. To allow the length of queue 1 and queue 2 to vary, a programmable pointer identifies the CCW table location where queue 2 begins. The BQ2 field also serves as an end-of-queue condition for queue 1. Setting BQ2 beyond physical CCW table memory space allows queue 1 all 64 entries.</p> <p>Software defines the beginning of queue 2 by programming the BQ2 field in QACR2. BQ2 is usually programmed before or at the same time as the queue operating mode for queue 2 is selected. If BQ2 is 64 or greater, queue 2 has no entries, and the entire CCW table is dedicated to queue 1 and CCW63 is the end-of-queue 1. If BQ2 is zero, the entire CCW table is dedicated to queue 2. As a special case, when a queue operating mode for queue 1 is selected and a trigger event occurs for queue 1 with BQ2 set to zero, queue 1 execution is terminated after CCW0 is read. Conversions do not occur.</p> <p>The BQ2 pointer may be changed dynamically, to alternate between queue 2 scan sequences. A change in BQ2 after queue 2 has begun or if queue 2 has a trigger pending does not affect queue 2 until queue 2 is started again. For example, two scan sequences could be defined as follows: the first sequence starts at CCW10, with a pause after CCW11 and an EOQ programmed in CCW15; the second sequence starts at CCW16, with a pause after CCW17 and an EOQ programmed in CCW39.</p> <p>With BQ2 set to CCW10 and the continuous-scan mode selected, queue execution begins. When the pause is encountered in CCW11, a software interrupt routine can redefine BQ2 to be CCW16. Therefore, after the end-of-queue is recognized in CCW15, an internal retrigger event is generated and execution restarts at CCW16. When the pause software interrupt occurs again, software can change BQ2 back to CCW10. After the end-of-queue is recognized in CCW39, an internal retrigger event is created and execution now restarts at CCW10.</p> <p>If BQ2 is changed while queue 1 is active, the effect of BQ2 as an end-of-queue indication for queue 1 is immediate. However, beware of the risk of losing the end-of-queue 1 through moving BQ2. Recommend use of EOQ (chan63) to end queue 1.</p> <p><b>Note:</b> Be sure to do a mode change when changing BQ2 and setting SSE2. Setting BQ2 first is recommended.</p> |

Table 14-14 shows the bits in the MQ2 field which enable different queue 2 operating modes.

**Table 14-14. Queue 2 Operating Modes**

| MQ2[3:7] | Operating Modes                                                       |

### NOTE

If BQ2 was assigned to the CCW that queue 1 is currently working on, then that conversion is completed before BQ2 takes effect.

Each time a CCW is read for queue 1, the CCW location is compared with the current value of the BQ2 pointer to detect a possible end-of-queue condition. For example, if BQ2 is changed to CCW3 while queue 1 is converting CCW2, queue 1 is terminated after the conversion is completed. However, if BQ2 is changed to CCW1 while queue 1 is converting CCW2, the QADC64E would not recognize a BQ2 end-of-queue condition until queue 1 execution reached CCW1 again, presumably on the next pass through the queue.

### 14.3.8 Status Registers (QASR0 and QASR1)

The status registers contains information about the state of each queue and the current A/D conversion. Except for the four flag bits (CF1, PF1, CF2, and PF2) and the two trigger overrun bits (TOR1 and TOR2), all of the status register fields contain read-only data. The four flag bits and the two trigger overrun bits are cleared by writing a zero to the bit after the bit was previously read as a one.

**Figure 14-12. Status Register 0 (QASR0)**

**Table 14-15. QASR0 Bit Descriptions**

| Bits | Name | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|------|------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0    | CF1  | <p>Queue 1 Completion Flag. CF1 indicates that a queue 1 scan has been completed. The scan completion flag is set by the QADC64E when the input channel sample requested by the last CCW in queue 1 is converted, and the result is stored in the result table.</p> <p>The end-of-queue 1 is identified when execution is complete on the CCW in the location prior to that pointed to by BQ2, when the current CCW contains an end-of-queue code instead of a valid channel number, or when the currently completed CCW is in the last location of the CCW RAM.</p> <p>When CF1 is set and interrupts are enabled for that queue completion flag, the QADC64E asserts an interrupt request at the level specified by IRL1 in the interrupt register (QADCINT). The software reads the completion flag during an interrupt service routine to identify the interrupt request. The interrupt request is cleared when the software writes a zero to the completion flag bit, when the bit was previously read as a one. Once set, only software or reset can clear CF1.</p> <p>CF1 is maintained by the QADC64E regardless of whether the corresponding interrupt is enabled. The software polls for CF1 bit to see if it is set. This allows the software to recognize that the QADC64E is finished with a queue 1 scan. The software acknowledges that it has detected the completion flag being set by writing a zero to the completion flag after the bit was read as a one.</p> |

**Table 14-15. QASR0 Bit Descriptions (continued)**

| Bits | Name | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|------|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1    | PF1  | <p>Queue 1 Pause Flag. PF1 indicates that a queue 1 scan has reached a pause. PF1 is set by the QADC64E when the current queue 1 CCW has the pause bit set, the selected input channel has been converted, and the result has been stored in the result table.</p> <p>Once PF1 is set, the queue enters the paused state and waits for a trigger event to allow queue execution to continue. However, if the CCW with the pause bit set is the last CCW in a queue, the queue execution is complete. The queue status becomes idle, not paused, and both the pause and completion flags are set. Another exception occurs in software controlled mode, where the PF1 can be set but queue 1 never enters the pause state since queue 1 continues without pausing.</p> <p>When PF1 is set and interrupts are enabled for the corresponding queue, the QADC64E asserts an interrupt request at the level specified by IRL1 in the interrupt register. The software may read PF1 during an interrupt service routine to identify the interrupt request. The interrupt request is cleared when the software writes a zero to PF1, when the bit was previously read as a one. Once set, only software or reset can clear PF1.</p> <p>In external gated single-scan and continuous-scan mode the definition of PF1 has been redefined. When the gate closes before the end-of-queue 1 is reached, PF1 becomes set to indicate that an incomplete scan has occurred. In single-scan mode, setting PF1 can be used to cause an interrupt and software can then determine if queue 1 should be enabled again. In either external gated mode, setting PF1 indicates that the results for queue 1 have not been collected during one scan (coherently).</p> <p>NOTE: If a pause in a CCW is encountered in external gated mode for either single-scan and continuous-scan mode, the pause flag <b>will not set</b>, and execution continues without pausing. This has allowed for the added definition of PF1 in the external gated modes. PF1 is maintained by the QADC64E regardless of whether the corresponding interrupts are enabled. The software may poll PF1 to find out when the QADC64E has reached a pause in scanning a queue. The software acknowledges that it has detected a pause flag being set by writing a zero to PF1 after the bit was last read as a one.</p> <p>0 = queue 1 has not reached a pause (or gate has not closed before end-of-queue in gated mode)</p> <p>1 = queue 1 has reached a pause (or gate closed before end-of-queue in gated mode)</p> <p>Refer to <a href="#">Table 14-16</a> for a summary of pause response in all scan modes.</p> |
| 2    | CF2  | <p>Queue 2 Completion Flag. CF2 indicates that a queue 2 scan has been completed. CF2 is set by the QADC64E when the input channel sample requested by the last CCW in queue 2 is converted, and the result is stored in the result table.</p> <p>The end-of-queue 2 is identified when the current CCW contains an end-of-queue code instead of a valid channel number, or when the currently completed CCW is in the last location of the CCW RAM.</p> <p>When CF2 is set and interrupts are enabled for that queue completion flag, the QADC64E asserts an interrupt request at the level specified by IRL2 in the interrupt register (QADCINT). The software reads CF2 during an interrupt service routine to identify the interrupt request. The interrupt request is cleared when the software writes a zero to the CF2 bit, when the bit was previously read as a one. Once set, only software or reset can clear CF2.</p> <p>CF2 is maintained by the QADC64E regardless of whether the corresponding interrupts are enabled. The software polls for CF2 to see if it is set. This allows the software to recognize that the QADC64E is finished with a queue 2 scan. The software acknowledges that it has detected the completion flag being set by writing a zero to the completion flag after the bit was read as a one.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

**Table 14-15. QASR0 Bit Descriptions (continued)**

| Bits | Name | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|------|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 3    | PF2  | <p>Queue 2 Pause Flag. PF2 indicates that a queue 2 scan has reached a pause. PF2 is set by the QADC64E when the current queue 2 CCW has the pause bit set, the selected input channel has been converted, and the result has been stored in the result table.</p> <p>Once PF2 is set, the queue enters the paused state and waits for a trigger event to allow queue execution to continue. However, if the CCW with the pause bit set is the last CCW in a queue, the queue execution is complete. The queue status becomes idle, not paused, and both the pause and completion flags are set. Another exception occurs in software controlled mode, where the PF2 can be set but queue 2 never enters the pause state.</p> <p>When PF2 is set and interrupts are enabled for the corresponding queue, the QADC64E asserts an interrupt request at the level specified by IRL2 in the interrupt register. The software reads PF2 during an interrupt service routine to identify the interrupt request. The interrupt request is cleared when the software writes a zero to PF2, when the bit was previously read as a one. Once set, only software or reset can clear PF2.</p> <p>PF2 is maintained by the QADC64E regardless of whether the corresponding interrupts are enabled. The software may poll PF2 to find out when the QADC64E has reached a pause in scanning a queue. The software acknowledges that it has detected a pause flag being set by writing a zero to PF2 after the bit was last read as a one.</p> <p>0 queue 2 has not reached a pause<br/>1 queue 2 has reached a pause</p> <p>Refer to <a href="#">Table 14-16</a> for a summary of pause response in all scan modes.</p>                                                                                                                                                                                                  |
| 4    | TOR1 | <p>Queue 1 Trigger Overrun. TOR1 indicates that an unexpected trigger event has occurred for queue 1. TOR1 can be set only while queue 1 is in the active state.</p> <p>A trigger event generated by a transition on the external trigger signal or by the periodic/interval timer may be captured as a trigger overrun. TOR1 cannot occur when the software initiated single-scan mode or the software initiated continuous-scan mode are selected.</p> <p>TOR1 occurs when a trigger event is received while a queue is executing and before the scan has completed or paused. TOR1 has no effect on the queue execution.</p> <p>After a trigger event has occurred for queue 1, and before the scan has completed or paused, additional queue 1 trigger events are not retained. Such trigger events are considered unexpected, and the QADC64E sets the TOR1 error status bit. An unexpected trigger event may be a system overrun situation, indicating a system loading mismatch.</p> <p>In external gated continuous-scan mode the definition of TOR1 has been redefined. In the case when queue 1 reaches an end-of-queue condition for the second time during an open gate, TOR1 becomes set. This is considered an overrun condition. In this case CF1 has been set for the first end-of-queue 1 condition and then TOR1 becomes set for the second end-of-queue 1 condition. For TOR1 to be set, software must not clear CF1 before the second end-of-queue 1.</p> <p>The software acknowledges that it has detected a trigger overrun being set by writing a zero to the trigger overrun, after the bit was read as a one. Once set, only software or reset can clear TOR1.</p> <p>0 No unexpected queue 1 trigger events have occurred<br/>1 At least one unexpected queue 1 trigger event has occurred (or queue 1 reaches an end-of-queue condition for the second time in gated mode)</p> |

**Table 14-15. QASR0 Bit Descriptions (continued)**

| Bits  | Name | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-------|------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 5     | TOR2 | <p>Queue 2 Trigger Overrun. TOR2 indicates that an unexpected trigger event has occurred for queue 2. TOR2 can be set when queue 2 is in the active, suspended, and trigger pending states.</p> <p>The TOR2 trigger overrun can only occur when using an external trigger mode or a periodic/interval timer mode. Trigger overruns cannot occur when the software initiated single-scan mode and the software initiated continuous-scan mode are selected.</p> <p>TOR2 occurs when a trigger event is received while queue 2 is executing, suspended, or a trigger is pending. TOR2 has no effect on the queue execution. A trigger event that causes a trigger overrun is not retained since it is considered unexpected.</p> <p>An unexpected trigger event may be a system overrun situation, indicating a system loading mismatch. The software acknowledges that it has detected a trigger overrun being set by writing a zero to the trigger overrun, after the bit was read as a one. Once set, only software or reset can clear TOR2.</p> <p>0 No unexpected queue 2 trigger events have occurred<br/>1 At least one unexpected queue 2 trigger event has occurred</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| 6:9   | QS   | <p>Queue Status. The 4-bit read-only QS field indicates the current condition of queue 1 and queue 2. The following are the five queue status conditions:</p> <ul style="list-style-type: none"> <li>• Idle</li> <li>• Active</li> <li>• Paused</li> <li>• Suspended</li> <li>• Trigger pending</li> </ul> <p>The two most significant bits are associated primarily with queue 1, and the remaining two bits are associated with queue 2. Since the priority scheme between the two queues causes the status to be interlinked, the status bits are considered as one 4-bit field.</p> <p><a href="#">Table 14-17</a> shows the bits in the QS field and how they affect the status of queue 1 and queue 2. Refer to <a href="#">Section 14.5, “Trigger and Queue Interaction Examples,”</a> which shows the 4-bit queue status field transitions in typical situations.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 10:15 | CWP  | <p>Command Word Pointer. The CWP allows the software to know which CCW is executing at present, or was last completed. The command word pointer is a software read-only field, and write operations have no effect. The CWP allows software to monitor the progress of the QADC64E scan sequence. The CWP field is a CCW word pointer with a valid range of 0 to 63.</p> <p>When a queue enters the paused state, the CWP points to the CCW with the pause bit set. While in pause, the CWP value is maintained until a trigger event occurs on the same queue or the other queue. Usually, the CWP is updated a few clock cycles before the queue status field shows that the queue has become active. For example, software may read a CWP pointing to a CCW in queue 2, and the status field shows queue 1 paused, queue 2 trigger pending.</p> <p>When the QADC64E finishes the scan of the queue, the CWP points to the CCW where the end-of-queue condition was detected. Therefore, when the end-of-queue condition is a CCW with the EOQ code, the CWP points to the CCW containing the EOQ.</p> <p>When the last CCW in a queue is in the last CCW table location (CCW63), and it does not contain the EOQ code, the end-of-queue is detected when the following CCW is read, so the CWP points to word CCW0.</p> <p>Finally, when queue 1 operation is terminated after a CCW is read that is defined as BQ2, the CWP points to the same CCW as BQ2.</p> <p>During the stop mode, the CWP is reset to zero, since the control registers and the analog logic are reset. When the freeze mode is entered, the CWP is unchanged; it points to the last executed CCW.</p> |

**Table 14-16. Pause Response**

| Scan Mode                                   | Q Operation | PF Asserts? |
|---------------------------------------------|-------------|-------------|
| External Trigger Single-scan                | Pauses      | Yes         |
| External Trigger Continuous-scan            | Pauses      | Yes         |
| Periodic/Interval Timer Trigger Single-scan | Pauses      | Yes         |
| Periodic/Interval Timer Continuous-scan     | Pauses      | Yes         |
| Software Initiated Single-scan              | Continues   | Yes         |
| Software Initiated Continuous-scan          | Continues   | Yes         |
| External Gated Single-scan                  | Continues   | No          |
| External Gated Continuous-scan              | Continues   | No          |

**Table 14-17. Queue Status**

| QS[9:6] | Queue 1/Queue 2 States                  |
|---------|-----------------------------------------|
| 0000    | queue 1 idle, queue 2 idle              |
| 0001    | queue 1 idle, queue 2 paused            |
| 0010    | queue 1 idle, queue 2 active            |
| 0011    | queue 1 idle, queue 2 trigger pending   |
| 0100    | queue 1 paused, queue 2 idle            |
| 0101    | queue 1 paused, queue 2 paused          |
| 0110    | queue 1 paused, queue 2 active          |
| 0111    | queue 1 paused, queue 2 trigger pending |
| 1000    | queue 1 active, queue 2 idle            |
| 1001    | queue 1 active, queue 2 paused          |
| 1010    | queue 1 active, queue 2 suspended       |
| 1011    | queue 1 active, queue 2 trigger pending |
| 1100    | Reserved                                |
| 1101    | Reserved                                |
| 1110    | Reserved                                |
| 1111    | Reserved                                |

One or both queues may be in the idle state. When a queue is idle, CCWs are not being executed for that queue, the queue is not in the pause state, and there is not a trigger pending.

The idle state occurs when a queue is disabled, when a queue is in a reserved mode, or when a queue is in a valid queue operating mode awaiting a trigger event to initiate queue execution.

A queue is in the active state when a valid queue operating mode is selected, when the selected trigger event has occurred, or when the QADC64E is performing a conversion specified by a CCW from that queue.

Only one queue can be active at a time. Either or both queues can be in the paused state. A queue is paused when the previous CCW executed from that queue had the pause bit set. The QADC64E does not execute any CCWs from the paused queue until a trigger event occurs. Consequently, the QADC64E can service queue 2 while queue 1 is paused.

Only queue 2 can be in the suspended state. When a trigger event occurs on queue 1 while queue 2 is executing, the current queue 2 conversion is aborted. The queue 2 status is reported as suspended. Queue 2 transitions back to the active state when queue 1 becomes idle or paused.

A trigger pending state is required since both queues cannot be active at the same time. The status of queue 2 is changed to trigger pending when a trigger event occurs for queue 2 while queue 1 is active. In the opposite case, when a trigger event occurs for queue 1 while queue 2 is active, queue 2 is aborted and the status is reported as queue 1 active, queue 2 suspended. So due to the priority scheme, only queue 2 can be in the trigger pending state.

There are two transition cases which cause the queue 2 status to be trigger pending before queue 2 is shown to be in the active state. When queue 1 is active and there is a trigger pending on queue 2, after queue 1 completes or pauses, queue 2 continues to be in the trigger pending state for a few clock cycles. The following are fleeting status conditions:

- Queue 1 idle with queue 2 trigger pending
- Queue 1 paused with queue 2 trigger pending

Figure 14-13 displays the status conditions of the queue status field as the QADC64E goes through the transition from queue 1 active to queue 2 active.

QADC64E QUEUE STATUS

**Figure 14-13. Queue Status Transition**

The queue status field is affected by the stop mode. Since all of the analog logic and control registers are reset, the queue status field is reset to queue 1 idle, queue 2 idle.

During the freeze mode, the queue status field is not modified. The queue status field retains the status it held prior to freezing. As a result, the queue status can show queue 1 active, queue 2 idle, even though neither queue is being executed during freeze.

### 14.3.9 Conversion Command Word Table

The conversion command word (CCW) table is a RAM, 64 words long on 16-bit address boundaries where 10-bits of each entry are implemented. A CCW can be programmed by the software to request a conversion of one analog input channel. The CCW table is written by software and is not modified by the QADC64E. Each CCW requests the conversion of an analog channel to a digital result. The CCW specifies the analog channel number, the input sample time, and whether the queue is to pause after the current CCW. The ten implemented bits of the CCW word are read/write data, where they may be written when the software

initializes the QADC64E. The remaining 6-bits are unimplemented so these read as zeros, and write operations have no effect. Each location in the CCW table corresponds to a location in the result word table. When a conversion is completed for a CCW entry, the 10-bit result is written in the corresponding result word entry. The QADC64E provides 64 CCW table entries.

The beginning of queue 1 is the first location in the CCW table. The first location of queue 2 is specified by the beginning of queue 2 pointer (BQ2) in QACR2. To dedicate the entire CCW table to queue 1, queue 2 is programmed to be in the disabled mode, and BQ2 is programmed to 64 or greater. To dedicate the entire CCW table to queue 2, queue 1 is programmed to be in the disabled mode, and BQ2 is specified as the first location in the CCW table

Figure 14-15 illustrates the operation of the queue structure.

NOTE 1: These offsets must be added to the module base address: A = 0x30 4800 or B = 0x30 4C00

**Figure 14-15. QADC64E Conversion Queue Operation**

To prepare the QADC64E for a scan sequence, the software writes to the CCW table to specify the desired channel conversions. The software also establishes the criteria for initiating the queue execution by programming the queue operating mode. The queue operating mode determines what type of trigger event causes queue execution to begin. A “trigger event” is used to refer to any of the ways to cause the

QADC64E to begin executing the CCWs in a queue or sub-queue. An “external trigger” is only one of the possible “trigger events.”

A scan sequence may be initiated by the following:

- A software command
- Expiration of the periodic/interval timer
- External trigger signal
- External gated signal (queue 1 only)

The software also specifies whether the QADC64E is to perform a single pass through the queue or is to scan continuously. When a single-scan mode is selected, the software selects the queue operating mode and sets the single-scan enable bit. When a continuous-scan mode is selected, the queue remains active in the selected queue operating mode after the QADC64E completes each queue scan sequence.

During queue execution, the QADC64E reads each CCW from the active queue and executes conversions in three stages:

- Initial sample
- Final sample
- Resolution

During initial sample, a buffered version of the selected input channel is connected to the sample capacitor at the input of the sample buffer amplifier.

During the final sample period, the sample buffer amplifier is bypassed, and the multiplexer input charges the sample capacitor directly. Each CCW specifies a final input sample time of two or 16 QCLK cycles. When an analog-to-digital conversion is complete, the result is written to the corresponding location in the result word table. The QADC64E continues to sequentially execute each CCW in the queue until the end of the queue is detected or a pause bit is found in a CCW.

When the pause bit is set in the current CCW, the QADC64E stops execution of the queue until a new trigger event occurs. The pause status flag bit is set, which may cause an interrupt to notify the software that the queue has reached the pause state. After the trigger event occurs, the paused state ends and the QADC64E continues to execute each CCW in the queue until another pause is encountered or the end of the queue is detected.

The following indicate the end-of-queue condition:

- The CCW channel field is programmed with 63 (0x3F) to specify the end of the queue
- The end-of-queue 1 is implied by the beginning of queue 2, which is specified in the BQ2 field in QACR2
- The physical end of the queue RAM space defines the end of either queue

When any of the end-of-queue conditions is recognized, a queue completion flag is set, and if enabled, an interrupt is issued to the software. The following situations prematurely terminate queue execution:

- Since queue 1 is higher in priority than queue 2, when a trigger event occurs on queue 1 during queue 2 execution, the execution of queue 2 is suspended by aborting the execution of the CCW in progress, and the queue 1 execution begins. When queue 1 execution is completed, queue 2

conversions restart with the first CCW entry in queue 2 or the first CCW of the queue 2 sub-queue being executed when queue 2 was suspended. Alternately, conversions can restart with the aborted queue 2 CCW entry. The RESUME bit in QACR2 allows the software to select where queue 2 begins after suspension. By choosing to re-execute all of the suspended queue 2 queue and sub-queue CCWs, all of the samples are guaranteed to have been taken during the same scan pass. However, a high trigger event rate for queue 1 can prohibit the completion of queue 2. If this occurs, the software may choose to begin execution of queue 2 with the aborted CCW entry.

- Software can change the queue operating mode to disabled mode. Any conversion in progress for that queue is aborted. Putting a queue into the disabled mode does not power down the converter.
- Software can change the queue operating mode to another valid mode. Any conversion in progress for that queue is aborted. The queue restarts at the beginning of the queue, once an appropriate trigger event occurs.
- For low power operation, software can set the stop mode bit to prepare the module for a loss of clocks. The QADC64E aborts any conversion in progress when the stop mode is entered.
- When the freeze enable bit is set by software and the IMB3 internal FREEZE line is asserted, the QADC64E freezes at the end of the conversion in progress. When internal FREEZE is negated, the QADC64E resumes queue execution beginning with the next CCW entry. Refer to [Section 14.4.7, “Configuration and Control Using the IMB3 Interface”](#) for more information.

| Bits | Name      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|------|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 8    | IST       | Input Sample Time. The IST field allows software to specify the length of the sample window. Provision is made to vary the input sample time, through software control, to offer flexibility in the source impedance of the circuitry providing the QADC64E analog channel inputs. Longer sample times permit more accurate A/D conversions of signals with higher source impedances. The programmable sample time can also be used to increase the time interval between conversions to adjust the queue execution time or the sampling rate.<br>0 QCLK period x 2<br>1 QCLK period x 8                                                                                                                                                                      |
| 9:15 | CHAN[6:0] | Channel Number. The CHAN field selects the input channel number. The software programs the channel field of the CCW with the channel number corresponding to the analog input signal to be sampled and converted. The analog input signal channel number assignments and the signal definitions vary depending on whether the multiplexed or non-multiplexed mode is used by the application. As far as the queue scanning operations are concerned, there is no distinction between an internally or externally multiplexed analog input. Refer to <a href="#">Section 14.2.5, “External Multiplexing”</a> for more information on external multiplexing.<br><a href="#">Table 14-20</a> and <a href="#">Table 14-21</a> show the channel number assignments |

**Table 14-20. QADC64E\_A Multiplexed Channel Assignments and Signal Designations**

| VRH/ALTREF <sup>1</sup>   | High Ref           | —                              | Input        | 0111101                          | 61        |
| —                         | —                  | (VRH – VRL)/2                  | —            | 0111110                          | 62        |
| —                         | —                  | End of Queue Code              | —            | 0111111                          | 63        |
| —                         | RESERVED           | —                              | —            | 1011000 to 1111111               | 64 to 127 |

<sup>1</sup> Whichever is selected in the CCW.

The channel field is programmed for channel 63 to indicate the end of the queue. Channels 60 to 62 are special internal channels. When one of the special channels is selected, the sampling amplifier is not used. The value of  $V_{RL}$ ,  $V_{RH}$ , or  $(V_{RH} - V_{RL})/2$  is placed directly onto the converter. Also for the internal special channels, programming any input sample time other than two has no benefit except to lengthen the overall conversion time.

### 14.3.10 Result Word Table

The result word table is a RAM, 64 words long and 10 bits wide. An entry is written by the QADC64E after completing an analog conversion specified by the corresponding CCW table entry. Software can read or write the result word table, but in normal operation, the software reads the result word table to obtain analog conversions from the QADC64E. Unimplemented bits are read as zeros, and write operations do not have any effect. See [Figure 14-15](#) for a diagram of the result word table

While there is only one result word table, the data can be accessed in three different data formats:

- Right justified in the 16-bit word, with zeros in the higher order unused bits
- Left justified, with the most significant bit inverted to form a sign bit, and zeros in the unused lower order bits
- Left justified, with zeros in the lower order unused bits

The left justified, signed format corresponds to a half-scale, offset binary, two's complement data format. The data is routed onto the IMB3 according to the selected format. The address used to access the table determines the data alignment format. All write operations to the result word table are right justified.

|        |                                                    |   |   |   |   |   |   |           |   |   |   |    |    |    |    |    |    |     |

**Figure 14-19. Left Justified, Unsigned Result Register (LJURR)**

The three result data formats are produced by routing the RAM bits onto the data bus. The software chooses among the three formats by reading the result at the memory address which produces the desired data alignment.

The result word table is read/write accessible by software. During normal operation, applications software only needs to read the result table. Write operations to the table may occur during test or debug breakpoint operation. When locations in the CCW table are not used by an application, software could use the corresponding locations in the result word table as scratch pad RAM, remembering that only 10 bits are implemented. The result alignment is only implemented for software read operations. Since write operations are not the normal use for the result registers, only one write data format is supported, which is right justified data.

### NOTE

Some write operations, like bit manipulation, may not operate as expected because the hardware cannot access a true 16-bit value.

### 14.3.10.1 Analog Subsystem

This section describes the QADC64E analog subsystem, which includes the front-end analog multiplexer and analog-to-digital converter.

### 14.3.11 Analog-to-Digital Converter Operation

The analog subsystem consists of the path from the input signals to the A/D converter block. Signals from the queue control logic are fed to the multiplexer and state machine. The end of convert (EOC) signal and the successive-approximation register (SAR) are the result of the conversion. Figure 14-20 shows a block diagram of the QADC64E analog subsystem.

Figure 14-20. QADC64E Analog Subsystem Block Diagram

#### 14.3.11.1 Conversion Cycle Times

Total conversion time is made up of initial sample time, final sample time, and resolution time. Initial sample time refers to the time during which the selected input channel is coupled through the buffer amplifier to the sample capacitor. This buffer is used to quickly reproduce its input signal on the sample capacitor and minimize charge sharing errors. During the final sampling period the amplifier is bypassed, and the multiplexer input charges the sample capacitor array directly for improved accuracy. During the resolution period, the voltage in the sample capacitor is converted to a digital value and stored in the SAR.

Initial sample time is fixed at two QCLK cycles. Final sample time can be two or eight QCLK cycles, depending on the value of the IST field in the CCW. Resolution time is ten QCLK cycles.

Therefore, conversion time requires a minimum of 14 QCLK clocks (seven  $\mu\text{s}$  with a 2.0-MHz QCLK). If the maximum final sample time period of 8 QCLKs is selected, the total conversion time is 20 QCLKs (10  $\mu\text{s}$  with a 2.0-MHz QCLK)

Figure 14-21 illustrates the timing for conversions.

Figure 14-21. Conversion Timing

### 14.3.12 Channel Decode and Multiplexer

The internal multiplexer selects one of the 16 analog input signals for conversion. The selected input is connected to the sample buffer amplifier. The multiplexer also includes positive and negative stress protection circuitry, which prevents deselected channels from affecting the selected channel when current is injected into the deselected channels. Refer to [Appendix F, “Electrical Characteristics,”](#) for specific current levels.

### 14.3.13 Sample Buffer Amplifier

The sample buffer is used to raise the effective input impedance of the A/D converter, so that external components (higher bandwidth or higher impedance) are less critical to accuracy. The input voltage is buffered onto the sample capacitor to reduce crosstalk between channels.

### 14.3.14 Digital to Analog Converter (DAC) Array

The digital to analog converter (DAC) array consists of binary-weighted capacitors and a resistor-divider chain. The reference voltages,  $V_{RH}$  and  $V_{RL}$ , are used by the DAC to perform ratiometric conversions. The DAC also converts the following three internal channels:

- $V_{RH}$  — Reference voltage high
- $V_{RL}$  — Reference voltage low
- $(V_{RH} - V_{RL})/2$  — Reference voltage

The DAC array serves to provide a mechanism for the successive approximation A/D conversion.

Resolution begins with the most significant bit (MSB) and works down to the least significant bit (LSB). The switching sequence is controlled by the comparator and successive-approximation register (SAR) logic.

- **Sample Capacitor** — The sample capacitor is employed to sample and hold the voltage to be converted.

### 14.3.15 Comparator

The comparator is used during the approximation process to sense whether the digitally selected arrangement of the DAC array produces a voltage level higher or lower than the sampled input. The comparator output feeds into the SAR which accumulates the A/D conversion result sequentially, beginning with the MSB.

### 14.3.16 Bias

The bias circuit is controlled by the STOP signal to power-up and power-down all the analog circuits.

### 14.3.17 Successive Approximation Register

The input of the successive approximation register (SAR) is connected to the comparator output. The SAR sequentially receives the conversion value one bit at a time, starting with the MSB. After accumulating the 10 bits of the conversion result, the SAR data is transferred to the appropriate result location, where it may be read from the IMB3 by user software.

### 14.3.18 State Machine

The state machine receives the QCLK, RST, STOP, IST, CHAN[6:0], and START CONV signals, from which it generates all timing to perform an A/D conversion. The start conversion signal (START CONV) indicates to the A/D converter that the desired channel has been sent to the multiplexor. IST indicates the desired sample time. The end of conversion (EOC) signal notifies the queue control logic that a result is available for storage in the result RAM.

## 14.4 Digital Subsystem

The digital control subsystem includes the control logic to sequence the conversion activity, the clock and periodic/interval timer, control and status registers, the conversion command word table RAM, and the result word table RAM.

The central element for control of the QADC64E conversions is the 64-entry CCW table. Each CCW specifies the conversion of one input channel. Depending on the application, one or two queues can be established in the CCW table. A queue is a scan sequence of one or more input channels. By using a pause mechanism, sub queues can be created in the two queues. Each queue can be operated using one of several different scan modes. The scan modes for queue 1 and queue 2 are programmed in QACR1 and QACR2 (control registers 1 and 2). Once a queue has been started by a trigger event (any of the ways to cause the QADC64E to begin executing the CCWs in a queue or sub-queue), the QADC64E performs a sequence of conversions and places the results in the result word table.

### 14.4.1 Queue Priority

Queue 1 has priority over queue 2 execution. The following cases show the conditions under which queue 1 asserts its priority:

- When a queue is not active, a trigger event for queue 1 or queue 2 causes the corresponding queue execution to begin.
- When queue 1 is active and a trigger event occurs for queue 2, queue 2 cannot begin execution until queue 1 reaches completion or the paused state. The status register records the trigger event by reporting the queue 2 status as trigger pending. Additional trigger events for queue 2, which occur before execution can begin, are captured as trigger overruns.
- When queue 2 is active and a trigger event occurs for queue 1, the current queue 2 conversion is aborted. The status register reports the queue 2 status as suspended. Any trigger events occurring for queue 2 while queue 2 is suspended are captured as trigger overruns. Once queue 1 reaches the completion or the paused state, queue 2 begins executing again. The programming of the RESUME bit in QACR2 determines which CCW is executed in queue 2. Refer to [Section 14.3.7, “Control Register 2”](#) for more information.
- When simultaneous trigger events occur for queue 1 and queue 2, queue 1 begins execution and the queue 2 status is changed to trigger pending.

### 14.4.2 Sub-Queues That are Paused

The pause feature can be used to divide queue 1 and/or queue 2 into multiple sub-queues. A sub-queue is defined by setting the pause bit in the last CCW of the sub-queue.

[Figure 14-22](#) shows the CCW format and an example of using pause to create sub-queues. Queue 1 is shown with four CCWs in each sub-queue and queue 2 has two CCWs in each sub-queue.

**Figure 14-22. QADC64E Queue Operation With Pause**

The queue operating mode selected for queue 1 determines what type of trigger event causes the execution of each of the sub-queues within queue 1. Similarly, the queue operating mode for queue 2 determines the type of trigger event required to execute each of the sub-queues within queue 2.

### NOTE

When the external trigger rising edge continuous-scan mode is selected for queue 1, and there are six sub-queues within queue 1, a separate rising edge is required on the external trigger signal after every pause to begin the execution of each sub-queue (refer to [Figure 14-22](#)). Refer to [Section 14.4.4, “Scan Modes”](#) for information on different scan modes.

The choice of single-scan or continuous-scan applies to the full queue, and is not applied to each sub-queue. Once a sub-queue is initiated, each CCW is executed sequentially until the last CCW in the sub-queue is executed and the pause state is entered. Execution can only continue with the next CCW, which is the beginning of the next sub-queue. A sub-queue cannot be executed a second time before the overall queue execution has been completed. Refer to [Section 14.3.7, “Control Register 2”](#) for more information.

Trigger events which occur during the execution of a sub-queue are ignored, except that the trigger overrun flag is set. When a continuous-scan mode is selected, a trigger event occurring after the completion of the last sub-queue (after the queue completion flag is set), causes the execution to continue with the first sub-queue, starting with the first CCW in the queue.

When the QADC64E encounters a CCW with the pause bit set, the queue enters the paused state after completing the conversion specified in the CCW with the pause bit. The pause flag is set and a pause software interrupt may optionally be issued. The status of the queue is shown to be paused, indicating completion of a sub-queue. The QADC64E then waits for another trigger event to again begin execution of the next sub-queue.

### 14.4.3 Boundary Conditions

The following are queue operation boundary conditions:

- The first CCW in a queue contains channel 63, the end-of-queue (EOQ) code. The queue becomes active and the first CCW is read. The end-of-queue is recognized, the completion flag is set, and the queue becomes idle. A conversion is not performed.
- BQ2 (beginning of queue 2) is set at the end of the CCW table (63) and a trigger event occurs on queue 2. Refer to [Section 14.3.7, “Control Register 2”](#) for more information on BQ2. The end-of-queue condition is recognized, a conversion is performed, the completion flag is set, and the queue becomes idle.
- BQ2 is set to CCW0 and a trigger event occurs on queue 1. After reading CCW0, the end-of-queue condition is recognized, the completion flag is set, and the queue becomes idle. A conversion is not performed.
- BQ2 is set beyond the end of the CCW table (64 – 127) and a trigger event occurs on queue 2. The end-of-queue condition is recognized immediately, the completion flag is set, and the queue becomes idle. A conversion is not performed.

#### NOTE

Multiple end-of-queue conditions may be recognized simultaneously, although there is no change in the QADC64E behavior. For example, if BQ2 is set to CCW0, CCW0 contains the EOQ code, and a trigger event occurs on queue 1, the QADC64E reads CCW0 and detects both end-of-queue conditions. The completion flag is set and queue 1 becomes idle.

Boundary conditions also exist for combinations of pause and end-of-queue. One case is when a pause bit is in one CCW and an end-of-queue condition is in the next CCW. The conversion specified by the CCW with the pause bit set completes normally. The pause flag is set. However, since the end-of-queue condition is recognized, the completion flag is also set and the queue status becomes idle, not paused. Examples of this situation include:

- The pause bit is set in CCW5 and the EOQ code is in CCW6
- The pause is set in CCW63
- During queue 1 operation, the pause bit is set in CCW20 and BQ2 points to CCW21

Another pause and end-of-queue boundary condition occurs when the pause and an end-of-queue condition occur in the same CCW. Both the pause and end-of-queue conditions are recognized simultaneously. The end-of-queue condition has precedence so a conversion is not performed for the CCW and the pause flag is not set. The QADC64E sets the completion flag and the queue status becomes idle. Examples of this situation are:

- The pause bit is set in CCW10 and EOQ is programmed into CCW10
- During queue 1 operation, the pause bit set in CCW32, which is also BQ2

## 14.4.4 Scan Modes

The QADC64E queuing mechanism allows the application to utilize different requirements for automatically scanning input channels.

In single-scan mode, a single pass through a sequence of conversions defined by a queue is performed. In continuous-scan mode, multiple passes through a sequence of conversions defined by a queue are executed. The possible modes are:

- Disabled and reserved mode
- Single-scan modes
  - Software initiated single-scan mode
  - External trigger single-scan mode
  - External gated single-scan mode
  - Periodic/Interval timer single-scan mode
- Continuous-scan modes
  - Software initiated continuous-scan mode
  - External trigger continuous-scan mode
  - External gated continuous-scan mode
  - Periodic/Interval timer continuous-scan mode

### 14.4.4.1 Disabled Mode

When the disabled mode is selected, the queue is not active. Trigger events cannot initiate queue execution. When both queue 1 and queue 2 are disabled, wait states are not encountered for IMB3 accesses of the RAM. When both queues are disabled, it is safe to change the QCLK prescaler values.

### 14.4.4.2 Reserved Mode

Reserved mode allows for future mode definitions. When the reserved mode is selected, the queue is not active. It functions the same as disabled mode.

#### WARNING

Do not use a reserved mode. Unspecified operations may result.

### 14.4.4.3 Single-Scan Modes

When the application software wants to execute a single pass through a sequence of conversions defined by a queue, a single-scan queue operating mode is selected. By programming the MQ field in QACR1 or QACR2, the following modes can be selected:

- Software initiated single-scan mode
- External trigger single-scan mode
- External gated single-scan mode
- Periodic/Interval timer single-scan mode

#### NOTE

Queue 2 cannot be programmed for external gated single-scan mode.

In all single-scan queue operating modes, the software must also enable the queue to begin execution by writing the single-scan enable bit to a one in the queue's control register. The single-scan enable bits, SSE1 and SSE2, are provided for queue 1 and queue 2 respectively.

Until the single-scan enable bit is set, any trigger events for that queue are ignored. The single-scan enable bit may be set to a one during the write cycle, which selects the single-scan queue operating mode. The single-scan enable bit is set through software, but will always read as a zero. Once set, writing the single-scan enable bit to zero has no effect. Only the QADC64E can clear the single-scan enable bit. The completion flag, completion interrupt, or queue status are used to determine when the queue has completed.

After the single-scan enable bit is set, a trigger event causes the QADC64E to begin execution with the first CCW in the queue. The single-scan enable bit remains set until the queue is completed. After the queue reaches completion, the QADC64E resets the single-scan enable bit to zero. If the single-scan enable bit is written to a one or a zero by the software before the queue scan is complete, the queue is not affected. However, if the software changes the queue operating mode, the new queue operating mode and the value of the single-scan enable bit are recognized immediately. The conversion in progress is aborted and the new queue operating mode takes effect.

In the software-initiated single-scan mode, the writing of a one to the single-scan enable bit causes the QADC64E to internally generate a trigger event and the queue execution begins immediately. In the other single-scan queue operating modes, once the single-scan enable bit is written, the selected trigger event must occur before the queue can start. The single-scan enable bit allows the entire queue to be scanned once. A trigger overrun is captured if a trigger event occurs during queue execution in an edge-sensitive external trigger mode or a periodic/interval timer mode.

In the periodic/interval timer single-scan mode, the next expiration of the timer is the trigger event for the queue. After the queue execution is complete, the queue status is shown as idle. The software can restart the queue by setting the single-scan enable bit to a one. Queue execution begins with the first CCW in the queue.

#### 14.4.4.3.1 Software Initiated Single-Scan Mode

Software can initiate the execution of a scan sequence for queue 1 or 2 by selecting the software initiated single-scan mode, and writing the single-scan enable bit in QACR1 or QACR2. A trigger event is

generated internally and the QADC64E immediately begins execution of the first CCW in the queue. If a pause occurs, another trigger event is generated internally, and then execution continues without pausing.

The QADC64E automatically performs the conversions in the queue until an end-of-queue condition is encountered. The queue remains idle until the software again sets the single-scan enable bit. While the time to internally generate and act on a trigger event is very short, software can momentarily read the status conditions, indicating that the queue is paused. The trigger overrun flag is never set while in the software initiated single-scan mode.

The software initiated single-scan mode is useful in the following applications:

- Allows software complete control of the queue execution
- Allows the software to easily alternate between several queue sequences.

#### 14.4.4.3.2 External Trigger Single-Scan Mode

The external trigger single-scan mode is available on both queue 1 and queue 2. The software programs the polarity of the external trigger edge that is to be detected, either a rising or a falling edge. The software must enable the scan to occur by setting the single-scan enable bit for the queue.

The first external trigger edge causes the queue to be executed one time. Each CCW is read and the indicated conversions are performed until an end-of-queue condition is encountered. After the queue is completed, the QADC64E clears the single-scan enable bit. Software may set the single-scan enable bit again to allow another scan of the queue to be initiated by the next external trigger edge.

The external trigger single-scan mode is useful when the input trigger rate can exceed the queue execution rate. Analog samples can be taken in sync with an external event, even though the software is not interested in data taken from every edge. The software can start the external trigger single-scan mode and get one set of data, and at a later time, start the queue again for the next set of samples.

When a pause bit is encountered during external trigger single-scan mode, another trigger event is required for queue execution to continue. Software involvement is not needed to enable queue execution to continue from the paused state.

#### 14.4.4.3.3 External Gated Single-Scan Mode

The QADC64E provides external gating for queue 1 only. When external gated single-scan mode is selected, the input level on the associated external trigger signal enables and disables queue execution. The polarity of the external gated signal is fixed so only a high level opens the gate and a low level closes the gate. Once the gate is open, each CCW is read and the indicated conversions are performed until the gate is closed. Software must enable the scan to occur by setting the single-scan enable bit for queue 1. If a pause in a CCW is encountered, the pause flag *will not set*, and execution continues without pausing.

While the gate is open, queue 1 executes one time. Each CCW is read and the indicated conversions are performed until an end-of-queue condition is encountered. When queue 1 completes, the QADC64E sets the completion flag (CF1) and clears the single-scan enable bit. Software may set the single-scan enable bit again to allow another scan of queue 1 to be initiated during the next open gate.

If the gate closes before queue 1 completes execution, the current CCW completes, execution of queue 1 stops, the single-scan enable bit is cleared, and the PF1 bit is set. Software can read the CWPQ1 to

determine the last valid conversion in the queue. Software must set the single-scan enable bit again and should clear the PF1 bit before another scan of queue 1 is initiated during the next open gate. The start of queue 1 is always the first CCW in the CCW table.

Since the condition of the gate is only sampled after each conversion during queue execution, closing the gate for a period less than a conversion time interval does not guarantee the closure will be captured.

#### 14.4.4.3.4 Periodic/Interval Timer Single-Scan Mode

Both queues can use the periodic/interval timer in a single-scan queue operating mode. The timer interval can range from 128- to 128-Kbyte QCLK cycles in binary multiples. When the periodic/ interval timer single-scan mode is selected and the software sets the single-scan enable bit in QACR1 or QACR2 , the timer begins counting. When the time interval elapses, an internal trigger event is created to start the queue and the QADC64E begins execution with the first CCW.

The QADC64E automatically performs the conversions in the queue until a pause or an end-of-queue condition is encountered. When a pause occurs, queue execution stops until the timer interval elapses again, and then queue execution continues. When the queue execution reaches an end-of-queue situation, the single-scan enable bit is cleared. Software may set the single-scan enable bit again, allowing another scan of the queue to be initiated by the periodic/interval timer.

The periodic/interval timer generates a trigger event whenever the time interval elapses. The trigger event may cause the queue execution to continue following a pause, or may be considered a trigger overrun. Once the queue execution is completed, the single-scan enable bit must be set again to enable the timer to count again.

Normally only one queue will be enabled for periodic/interval timer single-scan mode and the timer will reset at the end-of-queue. However, if both queues are enabled for either single-scan or continuous periodic/interval timer mode, the end-of-queue condition will not reset the timer while the other queue is active. In this case, the timer will reset when both queues have reached end-of-queue. See [Section 14.4.6, “Periodic/Interval Timer,”](#) for a definition of periodic/interval timer reset conditions.

The periodic/interval timer single-scan mode can be used in applications which need coherent results, for example:

- When it is necessary that all samples are guaranteed to be taken during the same scan of the analog signals
- When the interrupt rate in the periodic/interval timer continuous-scan mode would be too high
- In sensitive battery applications, where the single-scan mode uses less power than the software initiated continuous-scan mode

#### 14.4.4.4 Continuous-Scan Modes

When the application software wants to execute multiple passes through a sequence of conversions defined by a queue, a continuous-scan queue operating mode is selected. By programming the MQ1 field in QACR1 or the MQ2 field in QACR2, the following software initiated modes can be selected:

- Software initiated continuous-scan mode
- External trigger continuous-scan mode

- External gated continuous-scan mode
- Periodic/interval timer continuous-scan mode

When a queue is programmed for a continuous-scan mode, the single-scan enable bit in the queue control register does not have any meaning or effect. As soon as the queue operating mode is programmed, the selected trigger event can initiate queue execution.

In the case of the software-initiated continuous-scan mode, the trigger event is generated internally and queue execution begins immediately. In the other continuous-scan queue operating modes, the selected trigger event must occur before the queue can start. A trigger overrun is captured if a trigger event occurs during queue execution in the external trigger continuous-scan mode and the periodic/interval timer continuous-scan mode.

After the queue execution is complete, the queue status is shown as idle. Since the continuous-scan queue operating modes allow the entire queue to be scanned multiple times, software involvement is not needed to enable queue execution to continue from the idle state. The next trigger event causes queue execution to begin again, starting with the first CCW in the queue.

#### NOTE

Coherent samples are guaranteed. The time between consecutive conversions has been designed to be consistent. However, there is one exception. For queues that end with a CCW containing EOQ code (channel 63), the last queue conversion to the first queue conversion requires 1 additional CCW fetch cycle. Therefore continuous samples are not coherent at this boundary.

In addition, the time from trigger to first conversion cannot be guaranteed since it is a function of clock synchronization, programmable trigger events, queue priorities, and so on.

#### 14.4.4.4.1 Software Initiated Continuous-Scan Mode

When the software initiated continuous-scan mode is programmed, the trigger event is generated automatically by the QADC64E. Queue execution begins immediately. If a pause is encountered, another trigger event is generated internally, and then execution continues without pausing. When the end-of-queue is reached, another internal trigger event is generated, and queue execution begins again from the beginning of the queue.

While the time to internally generate and act on a trigger event is very short, software can momentarily read the status conditions, indicating that the queue is idle. The trigger overrun flag is never set while in the software-initiated continuous-scan mode.

The software initiated continuous-scan mode keeps the result registers updated more frequently than any of the other queue operating modes. The software can always read the result table to get the latest converted value for each channel. The channels scanned are kept up to date by the QADC64E without software involvement. Software can read a result value at any time.

The software initiated continuous-scan mode may be chosen for either queue, but is normally used only with queue 2. When the software initiated continuous-scan mode is chosen for queue 1, that queue operates

continuously and queue 2, being lower in priority, never gets executed. The short interval of time between a queue 1 completion and the subsequent trigger event is not sufficient to allow queue 2 execution to begin.

The software initiated continuous-scan mode is a useful choice with queue 2 for converting channels that do not need to be synchronized to anything, or for the slow-to-change analog channels. Interrupts are normally not used with the software initiated continuous-scan mode. Rather, the software reads the latest conversion result from the result table at any time. Once initiated, software action is not needed to sustain conversions of channel.

#### 14.4.4.4.2 External Trigger Continuous-Scan Mode

The QADC64E provides external trigger signals for both queues. When the external trigger software initiated continuous-scan mode is selected, a transition on the associated external trigger signal initiates queue execution. The polarity of the external trigger signal is programmable, so that the software can select a mode which begins queue execution on the rising or falling edge. Each CCW is read and the indicated conversions are performed until an end-of-queue condition is encountered. When the next external trigger edge is detected, the queue execution begins again automatically. Software initialization is not needed between trigger events.

When a pause bit is encountered in external trigger continuous-scan mode, another trigger event is required for queue execution to continue. Software involvement is not needed to enable queue execution to continue from the paused state.

Some applications need to synchronize the sampling of analog channels to external events. There are cases when it is not possible to use software initiation of the queue scan sequence, since interrupt response times vary.

#### 14.4.4.4.3 External Gated Continuous-Scan Mode

The QADC64E provides external gating for queue 1 only. When external gated continuous-scan mode is selected, the input level on the associated external trigger signal enables and disables queue execution. The polarity of the external gated signal is fixed so a high level opens the gate and a low level closes the gate. Once the gate is open, each CCW is read and the indicated conversions are performed until the gate is closed. When the gate opens again, the queue execution automatically begins again from the beginning of the queue. Software initialization is not needed between trigger events. If a pause in a CCW is encountered, the pause flag *will not set*, and execution continues without pausing.

The purpose of external gated continuous-scan mode is to continuously collect digitized samples while the gate is open and to have the most recent samples available. It is up to the programmer to ensure that the queue is large enough so that a maximum gate open time will not reach an end-of-queue. However it is useful to take advantage of a smaller queue in the manner described in the next paragraph.

In the event that the queue completes before the gate closes, a completion flag will be set and the queue will roll over to the beginning and continue conversions until the gate closes. If the gate remains open and the completion flag is not cleared, when the queue completes a second time the trigger overrun flag will be set and the queue will roll-over again. The queue will continue to execute until the gate closes or the mode is disabled.

If the gate closes before queue 1 completes execution, the current CCW completes execution of queue 1 stops and QADC64E sets the PF1 bit to indicate an incomplete queue. Software can read the CWPQ1 to determine the last valid conversion in the queue. In this mode, if the gate opens again, execution of queue 1 begins again. The start of queue 1 is always the first CCW in the CCW table.

Since the condition of the gate is only sampled after each conversion during queue execution, closing the gate for a period less than a conversion time interval does not guarantee the closure will be captured.

#### **14.4.4.4 Periodic/Interval Timer Continuous-Scan Mode**

The QADC64E includes a dedicated periodic/interval timer for initiating a scan sequence on queue 1 and/or queue 2. Software selects a programmable timer interval ranging from 128 to 128 Kbytes times the QCLK period in binary multiples. The QCLK period is prescaled down from the IMB3 MCU clock.

When a periodic/interval timer continuous-scan mode is selected for queue 1 and/or queue 2, the timer begins counting. After the programmed interval elapses, the timer generated trigger event starts the appropriate queue. Meanwhile, the QADC64E automatically performs the conversions in the queue until an end-of-queue condition or a pause is encountered. When a pause occurs, the QADC64E waits for the periodic interval to expire again, then continues with the queue. Once end-of-queue has been detected, the next trigger event causes queue execution to begin again with the first CCW in the queue.

The periodic/interval timer generates a trigger event whenever the time interval elapses. The trigger event may cause the queue execution to continue following a pause or queue completion, or may be considered a trigger overrun. As with all continuous-scan queue operating modes, software action is not needed between trigger events. Since both queues may be triggered by the periodic/interval timer, see [Section 14.4.6, “Periodic/Interval Timer”](#) for a summary of periodic/interval timer reset conditions.

Software enables the completion interrupt when using the periodic/interval timer continuous-scan mode. When the interrupt occurs, the software knows that the periodically collected analog results have just been taken. The software can use the periodic interrupt to obtain non-analog inputs as well, such as contact closures, as part of a periodic look at all inputs.

### **14.4.5 QADC64E Clock (QCLK) Generation**

[Figure 14-23](#) is a block diagram of the clock subsystem. The QCLK provides the timing for the A/D converter state machine which controls the timing of the conversion. The QCLK is also the input to a 17-stage binary divider which implements the periodic/interval timer. To retain the specified analog conversion accuracy, the QCLK frequency ( $F_{QCLK}$ ) must be within the tolerance specified in [Appendix F, “Electrical Characteristics.”](#)

Before using the QADC64E, the software must initialize the prescaler with values that put the QCLK within the specified range. Though most software applications initialize the prescaler once and do not change it, write operations to the prescaler fields are permitted.

### WARNING

A change in the prescaler value while a conversion is in progress is likely to corrupt the result from any conversion in progress. Therefore, any prescaler write operation should be done only when both queues are in the disabled modes.
