

**THE DATASHEET OF
MT89L80AP1**

Features

Sept. 2006

- 3.3 volt supply
- 5 V tolerant inputs and TTL compatible outputs.
- 256 x 256 channel non-blocking switch
- Accepts serial streams at 2.048 Mb/s
- Per-channel three-state control
- Patented per channel message mode
- Non-multiplexed microprocessor interface
- Zarlink ST-BUS compatible
- Low power consumption: typical 15 mW
- Pin compatible with the MT8980DP

Applications

- Key telephone systems
- PBX systems
- Small and medium voice switching systems

Description

This VLSI CMOS device is designed for switching PCM-encoded voice or data, under microprocessor control, in a modern digital exchange, PBX or Central Office. It provides simultaneous connections for up to 256 64 kbit/s channels. Each of the eight serial inputs and outputs consist of 32 64 kbit/s channels multiplexed to form a 2048 kbit/s ST-BUS stream. In addition, the MT89L80 provides microprocessor read and write access to individual ST-BUS channels.

Figure 1 - Functional Block Diagram

Figure 2 - Pin Connections

Pin Description

Pin #		Name	Description
44 PLCC	48 SSOP		
2	2	DTA	Data Acknowledgment (5 V Tolerant Three-state Output). This active low output indicates that a data bus transfer is complete. A pull-up resistor is required at this output.
3-5	3-5	STi0-2	ST-BUS Inputs 0 to 2 (5 V-tolerant Inputs). Serial data input streams. These streams have data rates of 2.048 Mbit/s with 32 channels.
7-11	7-11	STi3-7	ST-BUS Inputs 3 to 7 (5 V-tolerant Inputs). Serial data input streams. These streams may have data rates of 2.048 Mbit/s with 32channels.
12	12,36	V_{DD}	+3.3 Volt Power Supply.
	13	RESET	Device Reset (5 V-tolerant input). This pin is only available for the 48-pin SSOP package.This active low input puts the device in its reset state. It clears the internal counters and registers. All ST-BUS outputs are set to the high impedance state. In normal operation. The RESET pin must be held low for a minimum of 100nsec to reset the device. Internal pull-up.
13	14	FOi	Frame Pulse (5 V-tolerant Input). This is the input for the frame synchronization pulse for the 2048 kbit/s ST-BUS streams. A low on this input causes the internal counter to reset on the next negative transition of C4i.

Pin Description (continued)

Pin #		Name	Description
44 PLCC	48 SSOP		
14	15	$\overline{\text{C4i}}$	4.096 MHz Clock (5 V-tolerant Input). ST-BUS bit cell boundaries lie on the alternate falling edges of this clock.
15-17	16-18	A0-2	Address 0-2 / Input Streams 8-10 (5 V-tolerant Input). These are the inputs for the address lines on the microprocessor interface.
19-21	20-22	A3-5	Address 3-5 / Input Streams 11-13 (5 V-tolerant Input). These are the inputs for the address lines on the microprocessor interface.
22	23	DS	Data Strobe (5 V-tolerant Input). This is the input for the active high data strobe on the microprocessor interface.
23	24	$\overline{\text{R/W}}$	Read/Write (5 V-tolerant Input). This is the input for the read/write signal on the microprocessor interface - high for read, low for write.
24	26	$\overline{\text{CS}}$	Chip Select (5 V-tolerant Input). This is the input for the active low chip select on the microprocessor interface
25-27	27-29	D7-D5	Data Bus (5 V-tolerant I/O): These are the bidirectional data pins on the microprocessor interface.
29-33	31-35	D4-D0	Data Bus (5 V-tolerant I/O): These are the bidirectional data pins on the microprocessor interface.
34	1, 25,37	V_{SS}	Ground.
35-39	38-42	STo7-3	ST-BUS Outputs 7 to 3 (5 V-Tolerant Three-state Outputs). These are the pins for the eight 2048 kbit/s ST-BUS output streams.
41-43	44-46	STo2-0	ST-BUS Outputs 2to 0 (5 V-Tolerant Three-state Outputs). These are the pins for the eight 2048kbit/s ST-BUS output streams.
44	47	ODE	Output Drive Enable (5 V-tolerant Input). If this input is held high, the STo0-STo7 output drivers function normally. If this input is low, the STo0-STo7 output drivers go into their high impedance state. NB: Even when ODE is high, channels on the STo0-STo7 outputs can go high impedance under software control.
1	48	CSTo	Control ST-BUS Output (5 V-Tolerant Output). Each frame of 256 bits on this ST-BUS output contains the values of bit 1 in the 256 locations of the Connection Memory High.
6, 18, 28, 40	6, 19, 30, 43	NC	No Connection.

Functional Description

In recent years, there has been a trend in telephony towards digital switching, particularly in association with software control. Simultaneously, there has been a trend in system architectures towards distributed processing or multi-processor systems.

In accordance with these trends, Zarlink has devised the ST-BUS (Serial Telecom Bus). This bus architecture can be used both in software-controlled digital voice and data switching, and for interprocessor communications. The uses in switching and in interprocessor communications are completely integrated to allow for a simple general purpose architecture appropriate for the systems of the future.

The serial streams of the ST-BUS operate continuously at 2048 kbit/s and are arranged in 125 μ s wide frames which contain 32 8-bit channels. Zarlink manufactures a number of devices which interface to the ST-BUS; a key device being the MT89L80 chip.

The MT89L80 can switch data from channels on ST-BUS inputs to channels on ST-BUS outputs, and simultaneously allows its controlling microprocessor to read channels on ST-BUS inputs or write to channels on ST-BUS outputs (Message Mode). To the microprocessor, the MT89L80 looks like a memory peripheral. The microprocessor can write to the MT89L80 to establish switched connections between input ST-BUS channels and output ST-BUS channels, or to transmit messages on output ST-BUS channels. By reading from the MT89L80, the microprocessor can receive messages from ST-BUS input channels or check which switched connections have already been established.

By integrating both switching and interprocessor communications, the MT89L80 allows systems to use distributed processing and to switch voice or data in an ST-BUS architecture.

Hardware Description

Serial data at 2048 kbit/s is received at the eight ST-BUS inputs (STi0 to STi7), and serial data is transmitted at the eight ST-BUS outputs (STo0 to STo7). Each serial input accepts 32 channels of digital data, each channel containing an 8-bit word which may represent a PCM-encoded analog/voice sample as provided by a codec (e.g., Zarlink's MT8964).

This serial input word is converted into parallel data and stored in the 256 X 8 Data Memory. Locations in the Data Memory are associated with particular channels on particular ST-BUS input streams. These locations can be read by the microprocessor which controls the chip.

Locations in the Connection Memory, which is split into high and low parts, are associated with particular ST-BUS output streams. When a channel is due to be transmitted on an ST-BUS output, the data for the channel can either be switched from an ST-BUS input or it can originate from the microprocessor. If the data is switched from an input, then the contents of the Connection Memory Low location associated with the output channel is used to address the Data Memory. This Data Memory address corresponds to the channel on the input ST-BUS stream on which the data for switching arrived. If the data for the output channel originates from the microprocessor (Message Mode), then the contents of the Connection Memory Low location associated with the output channel are output directly, and this data is output repetitively on the channel once every frame until the microprocessor intervenes.

The Connection Memory data is received, via the Control Interface, at D7 to D0. The Control Interface also receives address information at A5 to A0 and handles the microprocessor control signals \overline{CS} , \overline{DTA} , R/W and \overline{DS} . There are two parts to any address in the Data Memory or Connection Memory. The higher order bits come from the Control Register, which may be written to or read from via the Control Interface. The lower order bits come from the address lines directly.

The Control Register also allows the chip to broadcast messages on all ST-BUS outputs (i.e., to put every channel into Message Mode), or to split the memory so that reads are from the Data Memory and writes are to the Connection Memory Low. The Connection Memory High determines whether individual output channels are in Message Mode, and allows individual output channels to go into a high-impedance state, which enables arrays of MT89L80s to be constructed. It also controls the CSTo pin.

All ST-BUS timing is derived from the two signals $\overline{C4i}$ and $\overline{F0i}$.

A5	A4	A3	A2	A1	A0	Hex Address	Location
0	0	0	0	0	0	00 - 1F	Control Register *
1	0	0	0	0	0	20	Channel 0†
1	0	0	0	0	1	21	Channel 1†

•	•	•	•	•	•	•	•
•	•	•	•	•	•	•	•
1	1	1	1	1	1	3F	Channel 31†

* Writing to the Control Register is the only fast transaction.
 † Memory and stream are specified by the contents of the Control Register.

Figure 3 - Address Memory Map

Software Control

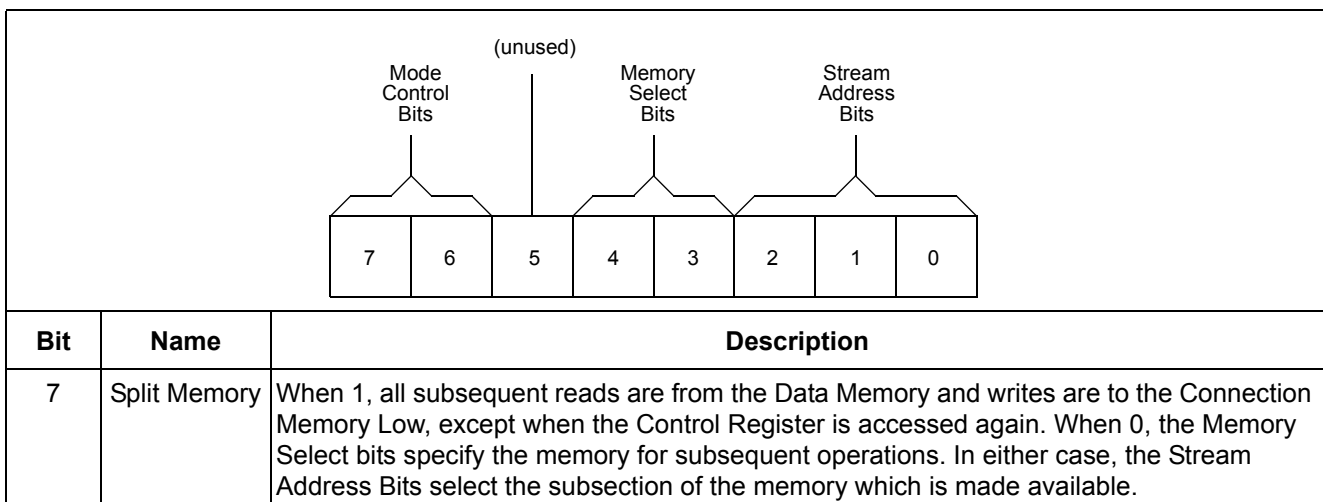

The address lines on the Control Interface give access to the Control Register directly or, depending on the contents of the Control Register, to the High or Low sections of the Connection Memory or to the Data Memory.

If address line A5 is low, then the Control Register is addressed regardless of the other address lines (see Fig. 3). If A5 is high, then the address lines A4-A0 select the memory location corresponding to channel 0-31 for the memory and stream selected in the Control Register.

The data in the Control Register consists of mode control bits, memory select bits, and stream address bits (see Fig. 4). The memory select bits allow the Connection Memory High or Low or the Data Memory to be chosen, and the stream address bits define one of the ST-BUS input or output streams.

Bit 7 of the Control Register allows split memory operation - reads are from the Data Memory and writes are to the Connection Memory Low.

The other mode control bit, bit 6, puts every output channel on every output stream into active Message Mode; i.e., the contents of the Connection Memory Low are output on the ST-BUS output streams once every frame unless the ODE pin is low. In this mode the chip behaves as if bits 2 and 0 of every Connection Memory High location were 1, regardless of the actual values.

Bit	Name	Description
6	Message Mode	When 1, the contents of the Connection Memory Low are output on the Serial Output streams except when the ODE pin is low. When 0, the Connection Memory bits for each channel determine what is output.
5	(unused)	
4-3	Memory Select Bits	0-0 - Not to be used 0-1 - Data Memory (read only from the microprocessor port) 1-0 - Connection Memory Low 1-1 - Connection Memory High
2-0	Stream Address Bits	The number expressed in binary notation on these bits refers to the input or output ST-BUS stream which corresponds to the subsection of memory made accessible for subsequent operations.

Figure 4 - Control Register Bits

Bit	Name	Description
2	Message Channel	When 1, the contents of the corresponding location in Connection Memory Low are output on the location's channel and stream. When 0, the contents of the corresponding location in Connection Memory Low act as an address for the Data Memory and so determine the source of the connection to the location's channel and stream.
1	CSTo Bit	This bit is output on the CSTo pin one channel early. The CSTo bit for stream 0 is output first.
0	Output Enable	If the ODE pin is high and bit 6 of the Control Register is 0, then this bit enables the output driver for the location's channel and stream. This allows individual channels on individual streams to be made high-impedance, allowing switching matrices to be constructed. A 1 enables the driver and a 0 disables it.

Figure 5 - Connection Memory High Bits

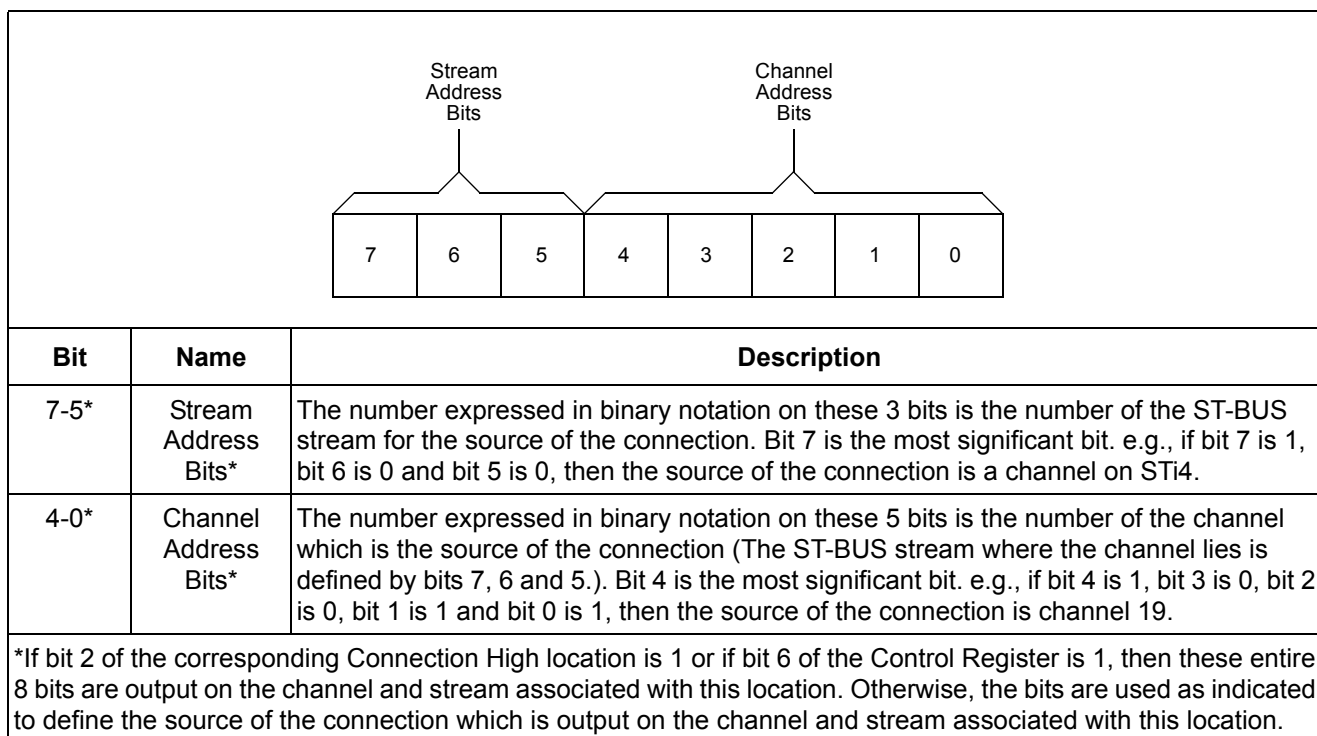

Figure 6 - Connection Memory Low Bits

If bit 6 of the Control Register is 0, then bits 2 and 0 of each Connection Memory High location function normally (see Fig. 5). If bit 2 is 1, the associated ST-BUS output channel is in Message Mode; i.e., the byte in the corresponding Connection Memory Low location is transmitted on the stream at that channel. Otherwise, one of the bytes received on the serial inputs is transmitted and the contents of the Connection Memory Low define the ST-BUS input stream and channel where the byte is to be found (see Fig. 6).

If the ODE pin is low, then all serial outputs are high-impedance. If it is high and bit 6 in the Control Register is 1, then all outputs are active. If the ODE pin is high and bit 6 in the Control Register is 0, then the bit 0 in the Connection Memory High location enables the output drivers for the corresponding individual ST-BUS output stream and channel. Bit 0=1 enables the driver and bit 0=0 disables it (see Fig. 5).

Bit 1 of each Connection Memory High location (see Fig. 5) is output on the CSto pin once every frame. To allow for delay in any external control circuitry the bit is output one channel before the corresponding channel on the ST-BUS streams, and the bit for stream 0 is output first in the channel; e.g., bit 1's for channel 9 of streams 0-7 are output synchronously with ST-BUS channel 8 bits 7-0.

Applications

Use in a Simple Digital Switching System

Figs. 7 and 8 show how MT89L80s can be used with MT8964s to form a simple digital switching system. Fig. 7 shows the interface between the MT89L80s and the filter/codecs. Fig. 8 shows the position of these components in an example architecture.

The MT8964 filter/codec in Fig. 7 receives and transmits digitized voice signals on the ST-BUS input D_R , and ST-BUS output D_X , respectively. These signals are routed to the ST-BUS inputs and outputs on the top MT89L80, which is used as a digital speech switch.

The MT8964 is controlled by the ST-BUS input D_C originating from the bottom MT89L80, which generates the appropriate signals from an output channel in Message Mode. This architecture optimizes the messaging capability

of the line circuit by building signalling logic, e.g., for on-off hook detection, which communicates on an ST-BUS output. This signalling ST-BUS output is monitored by a microprocessor (not shown) through an ST-BUS input on the bottom MT89L80.

Fig. 8 shows how a simple digital switching system may be designed using the ST-BUS architecture. This is a private telephone network with 256 extensions which uses a single MT89L80 as a speech switch and a second MT89L80 for communication with the line interface circuits.

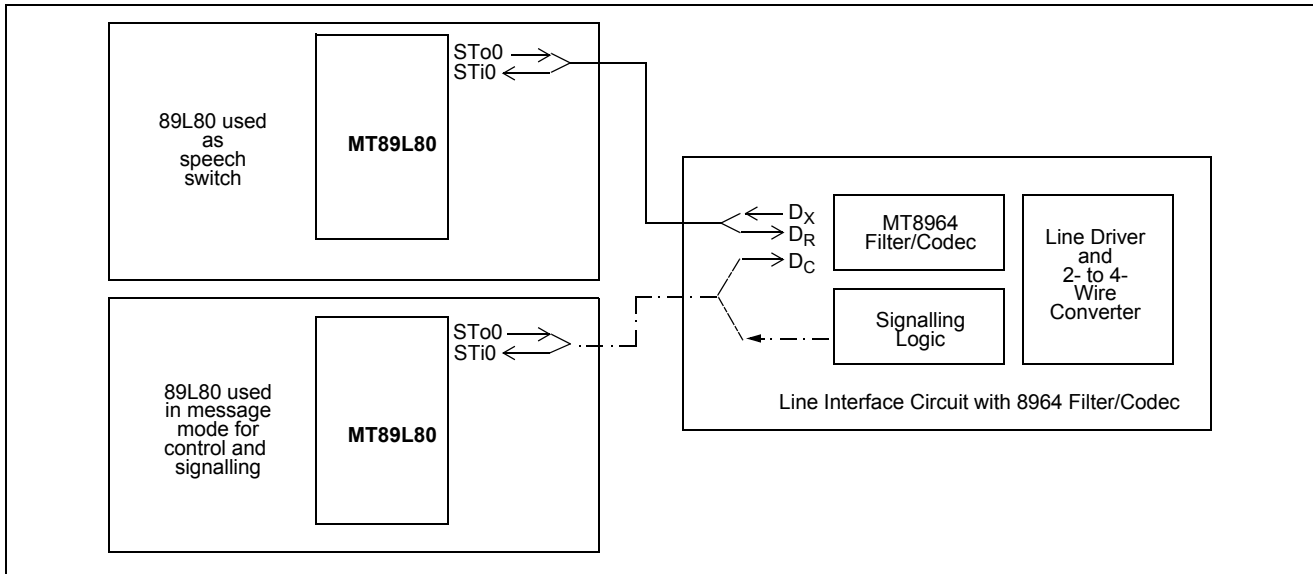

Figure 7 - Example of Typical Interface between 89L80s and 8964s for Simple Digital Switching System
