

## 4-Pin Reset Monitors

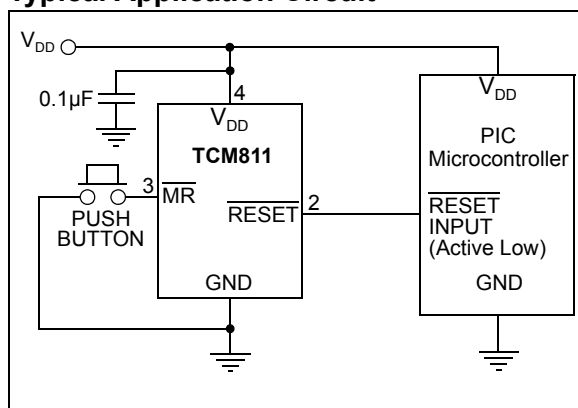

### Features

- Precision  $V_{DD}$  Monitor for 2.0V, 2.8V, 3.0V, 3.3V, 5.0V Nominal Supplies
- Manual Reset Input
- 140 ms Minimum RESET Output Duration
- $\overline{\text{RESET}}$  Output Valid to  $V_{DD} = 1.0\text{V}$  (TCM811)
- Low 6  $\mu\text{A}$  (typ.) Supply Current
- $V_{DD}$  Transient Immunity
- Small 4-Pin SOT-143 Package
- No External Components
- Replacement for MAX811/812 and Offers a Lower Threshold Voltage Option
- Push-Pull RESET Output
- Temperature Range:
  - Commercial (C)  $-40^{\circ}\text{C}$  to  $+85^{\circ}\text{C}$

### Applications

- Computers
- Embedded Systems
- Battery Powered Equipment
- Critical Microcontroller Power Supply Monitoring

### Typical Application Circuit

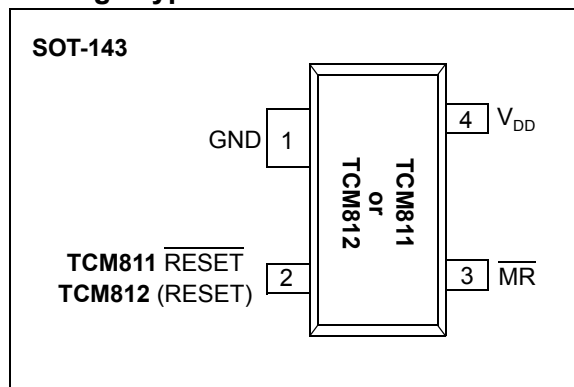

### General Description

The TCM811 and TCM812 are cost effective system supervisory circuits designed to monitor  $V_{DD}$  in digital systems and provide a reset signal to the host controller when necessary. A manual reset input is provided to override the reset monitor and is suitable for use as a push-button reset. No external components are required.

The reset output is driven active within 20  $\mu\text{s}$  (5  $\mu\text{s}$  for F version) of  $V_{DD}$  falling through the reset voltage threshold. RESET is maintained active for a minimum of 140 ms after  $V_{DD}$  rises above the reset threshold. The TCM812 has an active high  $\overline{\text{RESET}}$  output while the TCM811 has an active low  $\overline{\text{RESET}}$  output. The output of the TCM811 is valid down to  $V_{DD} = 1\text{V}$ . Both devices are available in a 4-Pin SOT-143 package, specified with a temperature range of  $-40^{\circ}\text{C}$  to  $+85^{\circ}\text{C}$ .

The TCM811/TCM812 are optimized to reject fast transient glitches on the  $V_{DD}$  line. A low supply current of 6  $\mu\text{A}$  ( $V_{DD} = 3.3\text{V}$ ) makes these devices ideal for battery powered applications.

## 3.0 PIN DESCRIPTIONS

The descriptions of the pins are listed in [Table 3-1](#).

**TABLE 3-1: PIN FUNCTION TABLE**

Pin No.	Symbol	Description
1	GND	Ground
2	$\overline{\text{RESET}}$ (TCM811)	$\overline{\text{RESET}}$ push-pull output remains low while $V_{DD}$ is below the reset voltage threshold, and for at least 140 ms (min.) after $V_{DD}$ rises above reset threshold
2	RESET (TCM812)	Reset push-pull output remains high while $V_{DD}$ is below the reset voltage threshold, and for at least 140 ms (min.) after $V_{DD}$ rises above reset threshold
3	$\overline{\text{MR}}$	Manual Reset input generates a Reset when $\overline{\text{MR}}$ is below $V_{IL}$
4	$V_{DD}$	Supply voltage

### 3.1 Ground Terminal (GND)

GND provides the negative reference for the analog input voltage. Typically, the circuit ground is used.

### 3.2 Reset Output ( $\overline{\text{RESET}}$ ) (TCM811)

$\overline{\text{RESET}}$  output remains low while  $V_{DD}$  is below the Reset voltage threshold ( $V_{TRIP}$ ). Once the device voltage ( $V_{DD}$ ) returns to a high level ( $V_{TRIP} + V_{HYS}$ ), the device will remain in Reset for the Reset delay timer ( $T_{RST}$ ). After that time expires, the  $\overline{\text{RESET}}$  pin will be driven to the high state.

### 3.3 Reset Output (RESET) (TCM812)

RESET output remains high while  $V_{DD}$  is below the Reset voltage threshold ( $V_{TRIP}$ ). Once the device voltage ( $V_{DD}$ ) returns to a high level ( $V_{TRIP} + V_{HYS}$ ), the device will remain in Reset for the Reset delay timer ( $T_{RST}$ ). After that time expires, the RESET pin will be driven to the low state.

### 3.4 Manual Reset ( $\overline{\text{MR}}$ )

The Manual Reset ( $\overline{\text{MR}}$ ) input pin allows a push button switch to easily be connected to the system. When the push button is depressed, it forces a system Reset. This pin has circuitry that filters noise that may be present on the MR signal.

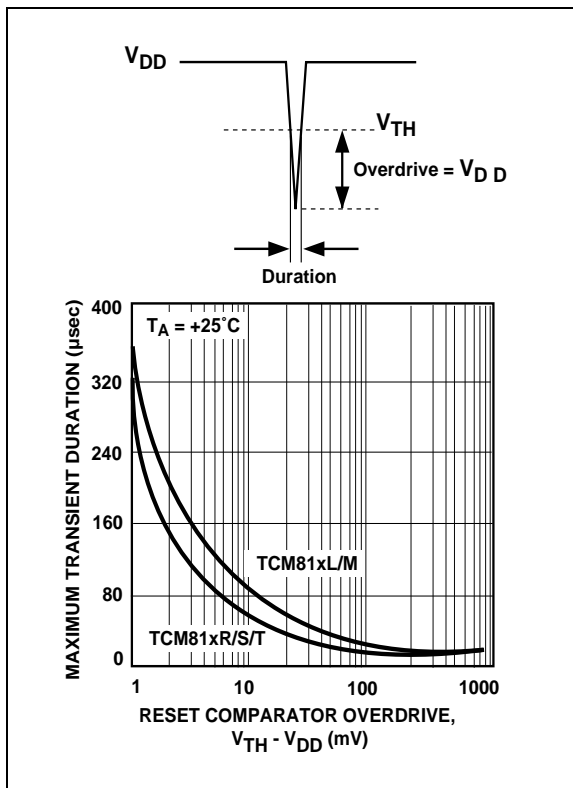

The  $\overline{\text{MR}}$  pin is active-low and has an internal pull-up resistor.

### 3.5 Supply Voltage ( $V_{DD}$ )

$V_{DD}$  can be used for power supply monitoring or a voltage level that requires monitoring.

## 4.0 APPLICATIONS INFORMATION

The TCM811/TCM812 provides accurate  $V_{DD}$  monitoring and reset timing during power-up, power-down, and brownout/sag conditions. These devices also reject negative-going transients (glitches) on the power supply line. Figure 4-1 shows the maximum transient duration vs. maximum negative excursion (overdrive) for glitch rejection. Any combination of duration and overdrive that is under the curve will not generate a reset signal. Combinations above the curve are detected as a brownout or power-down. Transient immunity can be improved by adding a 0.1  $\mu\text{F}$  capacitor in close proximity to the  $V_{DD}$  pin of the TCM811/TCM812.

**FIGURE 4-1:** Maximum Transient Duration vs. Overdrive for Glitch Rejection at  $+25^\circ\text{C}$ .

### 4.1 RESET Signal Integrity During Power-Down

The TCM811  $\overline{\text{RESET}}$  push-pull output is valid to  $V_{DD} = 1.0\text{V}$ . Below this voltage the output becomes an "open circuit" and does not sink current. This means CMOS logic inputs to the microcontroller will be floating at an undetermined voltage. Most digital systems are completely shutdown well above this voltage. However, in situations where  $\overline{\text{RESET}}$  must be maintained valid to  $V_{DD} = 0\text{V}$ , a pull-down resistor must be connected from  $\overline{\text{RESET}}$  to ground to discharge stray capacitances and hold the output low (Figure 4-2). This resistor value, though not critical, should be chosen

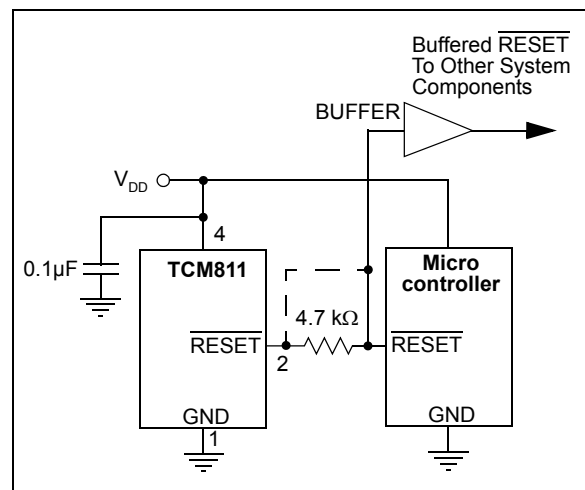

such that it does not appreciably load  $\overline{\text{RESET}}$  under normal operation (100  $\text{k}\Omega$  will be suitable for most applications). Similarly, a pull-up resistor to  $V_{DD}$  is required for the TCM812 to ensure a valid high  $\overline{\text{RESET}}$  for  $V_{DD}$  below 1.1V.

**FIGURE 4-2:** The addition of  $R_1$  at the  $\overline{\text{RESET}}$  output of the TCM811 ensures that the  $\overline{\text{RESET}}$  output is valid to  $V_{DD} = 0\text{V}$ .

### 4.2 Controllers and Processors With Bidirectional I/O Pins

Some microcontrollers have bidirectional reset pins. Depending on the current drive capability of the controller pin, an indeterminate logic level may result if there is a logic conflict. This can be avoided by adding a 4.7  $\text{k}\Omega$  resistor in series with the output of the TCM811/TCM812 (Figure 4-3). If there are other components in the system which require a reset signal, they should be buffered so as not to load the reset line. If the other components are required to follow the reset I/O of the microcontroller, the buffer should be connected as shown with the solid line.

**FIGURE 4-3:** Interfacing the TCM811 to a Bidirectional Reset I/O.
