Bits 15:12 **IC2F**: Input capture 2 filter

Bits 11:10 **IC2PSC[1:0]**: Input capture 2 prescaler

Bits 9:8 **CC2S**: Capture/compare 2 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

00: CC2 channel is configured as output.

01: CC2 channel is configured as input, IC2 is mapped on TI2.

10: CC2 channel is configured as input, IC2 is mapped on TI1.

11: CC2 channel is configured as input, IC2 is mapped on TRC. This mode is working only if an internal trigger input is selected through TS bit (TIMx\_SMCR register)

*Note: CC2S bits are writable only when the channel is OFF (CC2E = 0 in TIMx\_CCER).*

Bits 7:4 **IC1F**: Input capture 1 filter

This bit-field defines the frequency used to sample TI1 input and the length of the digital filter applied to TI1. The digital filter is made of an event counter in which N consecutive events are needed to validate a transition on the output:

0000: No filter, sampling is done at  $f_{DTS}$

0001:  $f_{SAMPLING}=f_{CK\_INT}$ , N=2

0010:  $f_{SAMPLING}=f_{CK\_INT}$ , N=4

0011:  $f_{SAMPLING}=f_{CK\_INT}$ , N=8

0100:  $f_{SAMPLING}=f_{DTS}/2$ , N=6

0101:  $f_{SAMPLING}=f_{DTS}/2$ , N=8

0110:  $f_{SAMPLING}=f_{DTS}/4$ , N=6

0111:  $f_{SAMPLING}=f_{DTS}/4$ , N=8

1000:  $f_{SAMPLING}=f_{DTS}/8$ , N=6

1001:  $f_{SAMPLING}=f_{DTS}/8$ , N=8

1010:  $f_{SAMPLING}=f_{DTS}/16$ , N=5

1011:  $f_{SAMPLING}=f_{DTS}/16$ , N=6

1100:  $f_{SAMPLING}=f_{DTS}/16$ , N=8

1101:  $f_{SAMPLING}=f_{DTS}/32$ , N=5

1110:  $f_{SAMPLING}=f_{DTS}/32$ , N=6

1111:  $f_{SAMPLING}=f_{DTS}/32$ , N=8

Bits 3:2 **IC1PSC**: Input capture 1 prescaler

This bit-field defines the ratio of the prescaler acting on CC1 input (IC1). The prescaler is reset as soon as CC1E=0 (TIMx\_CCER register).

00: no prescaler, capture is done each time an edge is detected on the capture input

01: capture is done once every 2 events

10: capture is done once every 4 events

11: capture is done once every 8 events

Bits 1:0 **CC1S**: Capture/Compare 1 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

00: CC1 channel is configured as output

01: CC1 channel is configured as input, IC1 is mapped on TI1

10: CC1 channel is configured as input, IC1 is mapped on TI2

11: CC1 channel is configured as input, IC1 is mapped on TRC. This mode is working only if an internal trigger input is selected through TS bit (TIMx\_SMCR register)

*Note: CC1S bits are writable only when the channel is OFF (CC1E = 0 in TIMx\_CCER).*

## 23.4.8 TIMx capture/compare mode register 2 (TIMx\_CCMR2)(x = 2 to 5)

Address offset: 0x1C

Reset value: 0x0000

Refer to the above CCMR1 register description.

## Output compare mode

Bits 31:25 Reserved, always read as 0.

Bit 24 **OC4M[3]**: Output Compare 2 mode - bit 3

Bits 23:17 Reserved, always read as 0.

Bit 16 **OC3M[3]**: Output Compare 1 mode - bit 3

Bit 15 **OC4CE**: Output compare 4 clear enable

Bits 14:12 **OC4M**: Output compare 4 mode

Refer to OC1M description (bits 6:4 in TIMx\_CCMR1 register)

Bit 11 **OC4PE**: Output compare 4 preload enable

Bit 10 **OC4FE**: Output compare 4 fast enable

Bits 9:8 **CC4S**: Capture/Compare 4 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

00: CC4 channel is configured as output

01: CC4 channel is configured as input, IC4 is mapped on TI4

10: CC4 channel is configured as input, IC4 is mapped on TI3

11: CC4 channel is configured as input, IC4 is mapped on TRC. This mode is working only if an internal trigger input is selected through TS bit (TIMx\_SMCR register)

*Note: CC4S bits are writable only when the channel is OFF (CC4E = 0 in TIMx\_CCER).*

Bit 7 **OC3CE**: Output compare 3 clear enable

Bits 6:4 **OC3M**: Output compare 3 mode

Refer to OC1M description (bits 6:4 in TIMx\_CCMR1 register)

Bit 3 **OC3PE**: Output compare 3 preload enable

Bit 2 **OC3FE**: Output compare 3 fast enable

Bits 1:0 **CC3S**: Capture/Compare 3 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

00: CC3 channel is configured as output

01: CC3 channel is configured as input, IC3 is mapped on TI3

10: CC3 channel is configured as input, IC3 is mapped on TI4

11: CC3 channel is configured as input, IC3 is mapped on TRC. This mode is working only if an internal trigger input is selected through TS bit (TIMx\_SMCR register)

*Note: CC3S bits are writable only when the channel is OFF (CC3E = 0 in TIMx\_CCER).*

## Input capture mode

Bits 31:16 Reserved, always read as 0.

Bits 15:12 **IC4F**: Input capture 4 filter

Bits 11:10 **IC4PSC**: Input capture 4 prescaler

Bits 9:8 **CC4S**: Capture/Compare 4 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

00: CC4 channel is configured as output

01: CC4 channel is configured as input, IC4 is mapped on TI4

10: CC4 channel is configured as input, IC4 is mapped on TI3

11: CC4 channel is configured as input, IC4 is mapped on TRC. This mode is working only if an internal trigger input is selected through TS bit (TIMx\_SMCR register)

*Note: CC4S bits are writable only when the channel is OFF (CC4E = 0 in TIMx\_CCER).*

Bits 7:4 **IC3F**: Input capture 3 filter

Bits 3:2 **IC3PSC**: Input capture 3 prescaler

Bits 1:0 **CC3S**: Capture/Compare 3 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

00: CC3 channel is configured as output

01: CC3 channel is configured as input, IC3 is mapped on TI3

10: CC3 channel is configured as input, IC3 is mapped on TI4

11: CC3 channel is configured as input, IC3 is mapped on TRC. This mode is working only if an internal trigger input is selected through TS bit (TIMx\_SMCR register)

*Note: CC3S bits are writable only when the channel is OFF (CC3E = 0 in TIMx\_CCER).*

### 23.4.9 TIMx capture/compare enable register (TIMx\_CCER)(x = 2 to 5)

Address offset: 0x20

Reset value: 0x0000

| 15    | 14   | 13   | 12   | 11    | 10   | 9    | 8    | 7     | 6    | 5    | 4    | 3     | 2    | 1    | 0    |
|-------|------|------|------|-------|------|------|------|-------|------|------|------|-------|------|------|------|
| CC4NP | Res. | CC4P | CC4E | CC3NP | Res. | CC3P | CC3E | CC2NP | Res. | CC2P | CC2E | CC1NP | Res. | CC1P | CC1E |
| r/w   |      | r/w  | r/w  | r/w   |      | r/w  | r/w  | r/w   |      | r/w  | r/w  | r/w   |      | r/w  | r/w  |

Bit 15 **CC4NP**: Capture/Compare 4 output Polarity.

Refer to CC1NP description

Bit 14 Reserved, must be kept at reset value.

Bit 13 **CC4P**: Capture/Compare 4 output Polarity.

Refer to CC1P description

Bit 12 **CC4E**: Capture/Compare 4 output enable.

refer to CC1E description

Bit 11 **CC3NP**: Capture/Compare 3 output Polarity.

Refer to CC1NP description

Bit 10 Reserved, must be kept at reset value.

Bit 9 **CC3P**: Capture/Compare 3 output Polarity.

Refer to CC1P description

Bit 8 **CC3E**: Capture/Compare 3 output enable.

Refer to CC1E description

Bit 7 **CC2NP**: Capture/Compare 2 output Polarity.

Refer to CC1NP description

Bit 6 Reserved, must be kept at reset value.

Bit 5 **CC2P**: Capture/Compare 2 output Polarity.

refer to CC1P description

Bit 4 **CC2E**: Capture/Compare 2 output enable.

Refer to CC1E description

Bit 3 **CC1NP**: Capture/Compare 1 output Polarity.

**CC1 channel configured as output**: CC1NP must be kept cleared in this case.

**CC1 channel configured as input**: This bit is used in conjunction with CC1P to define TI1FP1/TI2FP1 polarity. refer to CC1P description.

Bit 2 Reserved, must be kept at reset value.

Bit 1 **CC1P**: Capture/Compare 1 output Polarity.

**CC1 channel configured as output:**

0: OC1 active high

1: OC1 active low

**CC1 channel configured as input:** CC1NP/CC1P bits select TI1FP1 and TI2FP1 polarity for trigger or capture operations.

00: noninverted/rising edge

Circuit is sensitive to TIxFP1 rising edge (capture, trigger in reset, external clock or trigger mode), TIxFP1 is not inverted (trigger in gated mode, encoder mode).

01: inverted/falling edge

Circuit is sensitive to TIxFP1 falling edge (capture, trigger in reset, external clock or trigger mode), TIxFP1 is inverted (trigger in gated mode, encoder mode).

10: reserved, do not use this configuration.

11: noninverted/both edges

Circuit is sensitive to both TIxFP1 rising and falling edges (capture, trigger in reset, external clock or trigger mode), TIxFP1 is not inverted (trigger in gated mode). This configuration must not be used for encoder mode.

Bit 0 **CC1E**: Capture/Compare 1 output enable.

CC1 channel configured as output:

0: Off - OC1 is not active

1: On - OC1 signal is output on the corresponding output pin

**CC1 channel configured as input:** This bit determines if a capture of the counter value can actually be done into the input capture/compare register 1 (TIMx\_CCR1) or not.

0: Capture disabled

1: Capture enabled

**Table 152. Output control bit for standard OCx channels**

| CCxE bit | OCx output state                  |
|----------|-----------------------------------|
| 0        | Output Disabled (OCx=0, OCx_EN=0) |
| 1        | OCx=OCxREF + Polarity, OCx_EN=1   |

*Note: The state of the external IO pins connected to the standard OCx channels depends on the OCx channel state and the GPIO and AFIO registers.*

### 23.4.10 TIMx counter (TIMx\_CNT)(x = 2 to 5)

Address offset: 0x24

Reset value: 0x0000 0000

|                         |            |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|-------------------------|------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31                      | 30         | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| CNT[31]<br>or<br>UIFCPY | CNT[30:16] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|                         | rW         | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW |
| 15                      | 14         | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| CNT[15:0]               |            |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rW                      | rW         | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW |

Bit 31 Value depends on UIFREMAP in TIMx\_CR1.

If UIFREMAP = 0

**CNT[31]:** Most significant bit of counter value (on TIM2 and TIM5)

Reserved on other timers

If UIFREMAP = 1

**UIFCPY:** UIF Copy

This bit is a read-only copy of the UIF bit of the TIMx\_ISR register

Bits 30:16 **CNT[30:16]:** Most significant part counter value (on TIM2 and TIM5)

Bits 15:0 **CNT[15:0]:** Least significant part of counter value

### 23.4.11 TIMx prescaler (TIMx\_PSC)(x = 2 to 5)

Address offset: 0x28

Reset value: 0x0000

|           |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|-----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 15        | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| PSC[15:0] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw        | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 15:0 **PSC[15:0]:** Prescaler value

The counter clock frequency CK\_CNT is equal to  $f_{CK\_PSC} / (PSC[15:0] + 1)$ .

PSC contains the value to be loaded in the active prescaler register at each update event (including when the counter is cleared through UG bit of TIMx\_EGR register or through trigger controller when configured in "reset mode").

### 23.4.12 TIMx auto-reload register (TIMx\_ARR)(x = 2 to 5)

Address offset: 0x2C

Reset value: 0xFFFF FFFF

|            |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31         | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| ARR[31:16] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw         | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |
| 15         | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| ARR[15:0]  |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw         | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 31:16 **ARR[31:16]:** High auto-reload value (on TIM2 and TIM5)

Bits 15:0 **ARR[15:0]:** Low Auto-reload value

ARR is the value to be loaded in the actual auto-reload register.

Refer to the [Section 23.3.1: Time-base unit on page 745](#) for more details about ARR update and behavior.

The counter is blocked while the auto-reload value is null.

**23.4.13 TIMx capture/compare register 1 (TIMx\_CCR1)(x = 2 to 5)**

Address offset: 0x34

Reset value: 0x0000 0000

|                                   |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
|-----------------------------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| 31                                | 30  | 29  | 28  | 27  | 26  | 25  | 24  | 23  | 22  | 21  | 20  | 19  | 18  | 17  | 16  |
| CCR1[31:16] (depending on timers) |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
| r/w                               | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w |
| 15                                | 14  | 13  | 12  | 11  | 10  | 9   | 8   | 7   | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
| CCR1[15:0]                        |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
| r/w                               | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w |

Bits 31:16 **CCR1[31:16]**: High Capture/Compare 1 value (on TIM2 and TIM5)Bits 15:0 **CCR1[15:0]**: Low Capture/Compare 1 value**If channel CC1 is configured as output:**

CCR1 is the value to be loaded in the actual capture/compare 1 register (preload value).

It is loaded permanently if the preload feature is not selected in the TIMx\_CCMR1 register (bit OC1PE). Else the preload value is copied in the active capture/compare 1 register when an update event occurs.

The active capture/compare register contains the value to be compared to the counter TIMx\_CNT and signaled on OC1 output.

**If channel CC1 is configured as input:**

CCR1 is the counter value transferred by the last input capture 1 event (IC1). The TIMx\_CCR1 register is read-only and cannot be programmed.

**23.4.14 TIMx capture/compare register 2 (TIMx\_CCR2)(x = 2 to 5)**

Address offset: 0x38

Reset value: 0x0000 0000

|                                   |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
|-----------------------------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|

Bits 31:16 **CCR2[31:16]**: High Capture/Compare 2 value (on TIM2 and TIM5)Bits 15:0 **CCR2[15:0]**: Low Capture/Compare 2 value**If channel CC2 is configured as output:**

CCR2 is the value to be loaded in the actual capture/compare 2 register (preload value).

It is loaded permanently if the preload feature is not selected in the TIMx\_CCMR1 register (bit OC2PE). Else the preload value is copied in the active capture/compare 2 register when an update event occurs.

The active capture/compare register contains the value to be compared to the counter TIMx\_CNT and signalled on OC2 output.

**If channel CC2 is configured as input:**

CCR2 is the counter value transferred by the last input capture 2 event (IC2). The TIMx\_CCR2 register is read-only and cannot be programmed.

### 23.4.15 TIMx capture/compare register 3 (TIMx\_CCR3)(x = 2 to 5)

Address offset: 0x3C

Reset value: 0x0000 0000

| rW                                | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW |

Bits 31:16 **CCR4[31:16]**: High Capture/Compare 4 value (on TIM2 and TIM5)

Bits 15:0 **CCR4[15:0]**: Low Capture/Compare value

1. if CC4 channel is configured as output (CC4S bits):

CCR4 is the value to be loaded in the actual capture/compare 4 register (preload value).

It is loaded permanently if the preload feature is not selected in the TIMx\_CCMR2 register (bit OC4PE). Else the preload value is copied in the active capture/compare 4 register when an update event occurs.

The active capture/compare register contains the value to be compared to the counter TIMx\_CNT and signalled on OC4 output.

2. if CC4 channel is configured as input (CC4S bits in TIMx\_CCMR4 register):

CCR4 is the counter value transferred by the last input capture 4 event (IC4). The TIMx\_CCR4 register is read-only and cannot be programmed.

**23.4.17 TIMx DMA control register (TIMx\_DCR)(x = 2 to 5)**

Address offset: 0x48

Reset value: 0x0000

| 15   | 14   | 13   | 12       | 11 | 10 | 9  | 8  | 7    | 6    | 5    | 4        | 3  | 2  | 1  | 0  |
|------|------|------|----------|----|----|----|----|------|------|------|----------|----|----|----|----|
| Res. | Res. | Res. | DBL[4:0] |    |    |    |    | Res. | Res. | Res. | DBA[4:0] |    |    |    |    |
|      |      |      | rw       | rw | rw | rw | rw |      |      |      | rw       | rw | rw | rw | rw |

Bits 15:13 Reserved, must be kept at reset value.

Bits 12:8 **DBL[4:0]**: DMA burst length

This 5-bit vector defines the number of DMA transfers (the timer recognizes a burst transfer when a read or a write access is done to the TIMx\_DMAR address).

00000: 1 transfer,

00001: 2 transfers,

00010: 3 transfers,

...

10001: 18 transfers.

Bits 7:5 Reserved, must be kept at reset value.

Bits 4:0 **DBA[4:0]**: DMA base address

This 5-bit vector defines the base-address for DMA transfers (when read/write access are done through the TIMx\_DMAR address). DBA is defined as an offset starting from the address of the TIMx\_CR1 register.

Example:

00000: TIMx\_CR1

00001: TIMx\_CR2

00010: TIMx\_SMCR

...

**Example:** Let us consider the following transfer: DBL = 7 transfers & DBA = TIMx\_CR1. In this case the transfer is done to/from 7 registers starting from the TIMx\_CR1 address.**23.4.18 TIMx DMA address for full transfer (TIMx\_DMAR)(x = 2 to 5)**

Address offset: 0x4C

Reset value: 0x0000

| 15         | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
|------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| DMAB[15:0] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw         | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 15:0 **DMAB[15:0]**: DMA register for burst accessesA read or write operation to the DMAR register accesses the register located at the address  
(TIMx\_CR1 address) + (DBA + DMA index) x 4

where TIMx\_CR1 address is the address of the control register 1, DBA is the DMA base address configured in TIMx\_DCR register, DMA index is automatically controlled by the DMA transfer, and ranges from 0 to DBL (DBL configured in TIMx\_DCR).

### 23.4.19 TIM2 option register (TIM2\_OR)

Address offset: 0x50

Reset value: 0x0000

| 15   | 14   | 13   | 12   | 11            | 10 | 9    | 8    | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0    |

## 24 General-purpose timers (TIM9/TIM10/TIM11/TIM12/TIM13/TIM14)

### 24.1 TIM9/TIM10/TIM11/TIM12/TIM13/TIM14 introduction

The TIM9/TIM10/TIM11/TIM12/TIM13/TIM14 general-purpose timers consist in a 16-bit auto-reload counter driven by a programmable prescaler.

They may be used for a variety of purposes, including measuring the pulse lengths of input signals (input capture) or generating output waveforms (output compare, PWM).

Pulse lengths and waveform periods can be modulated from a few microseconds to several milliseconds using the timer prescaler and the RCC clock controller prescalers.

The TIM9/TIM10/TIM11/TIM12/TIM13/TIM14 timers are completely independent, and do not share any resources. They can be synchronized together as described in [Section 24.3.16: Timer synchronization \(TIM9/TIM12\)](#).

### 24.2 TIM9/TIM10/TIM11/TIM12/TIM13/TIM14 main features

#### 24.2.1 TIM9/TIM12 main features

The features of the TIM9/TIM12 general-purpose timers include:

- 16-bit auto-reload upcounter
- 16-bit programmable prescaler used to divide the counter clock frequency by any factor between 1 and 65536 (can be changed “on the fly”)
- Up to 2 independent channels for:
  - Input capture
  - Output compare
  - PWM generation (edge-aligned mode)
  - One-pulse mode output
- Synchronization circuit to control the timer with external signals and to interconnect several timers together
- Interrupt generation on the following events:
  - Update: counter overflow, counter initialization (by software or internal trigger)
  - Trigger event (counter start, stop, initialization or count by internal trigger)
  - Input capture
  - Output compare

Figure 256. General-purpose timer block diagram (TIM9/TIM12)

## 24.2.2 TIM10/TIM11/TIM13/TIM14 main features

The features of general-purpose timers TIM10/TIM11/TIM13/TIM14 include:

- 16-bit auto-reload upcounter
- 16-bit programmable prescaler used to divide the counter clock frequency by any factor between 1 and 65536 (can be changed “on the fly”)
- independent channel for:
  - Input capture
  - Output compare
  - PWM generation (edge-aligned mode)
  - One-pulse mode output
- Interrupt generation on the following events:
  - Update: counter overflow, counter initialization (by software)
  - Input capture
  - Output compare

Figure 257. General-purpose timer block diagram (TIM10/TIM11/TIM13/TIM14)

## 24.3 TIM9/TIM10/TIM11/TIM12/TIM13/TIM14 functional description

### 24.3.1 Time-base unit

The main block of the timer is a 16-bit up-counter with its related auto-reload register. The counter clock can be divided by a prescaler.

The counter, the auto-reload register and the prescaler register can be written or read by software. This is true even when the counter is running.

The time-base unit includes:

- Counter register (TIMx\_CNT)
- Prescaler register (TIMx\_PSC)
- Auto-reload register (TIMx\_ARR)

The auto-reload register is preloaded. Writing to or reading from the auto-reload register accesses the preload register. The content of the preload register are transferred into the shadow register permanently or at each update event (UEV), depending on the auto-reload preload enable bit (ARPE) in TIMx\_CR1 register. The update event is sent when the counter reaches the overflow and if the UDIS bit equals 0 in the TIMx\_CR1 register. It can also be generated by software. The generation of the update event is described in details for each configuration.

The counter is clocked by the prescaler output CK\_CNT, which is enabled only when the counter enable bit (CEN) in TIMx\_CR1 register is set (refer also to the slave mode controller description to get more details on counter enabling).

Note that the counter starts counting 1 clock cycle after setting the CEN bit in the TIMx\_CR1 register.

#### Prescaler description

The prescaler can divide the counter clock frequency by any factor between 1 and 65536. It is based on a 16-bit counter controlled through a 16-bit register (in the TIMx\_PSC register). It can be changed on the fly as this control register is buffered. The new prescaler ratio is taken into account at the next update event.

[Figure 258](#) and [Figure 259](#) give some examples of the counter behavior when the prescaler ratio is changed on the fly.

Figure 258. Counter timing diagram with prescaler division change from 1 to 2

Figure 259. Counter timing diagram with prescaler division change from 1 to 4

## 24.3.2 Counter modes

### Upcounting mode

In upcounting mode, the counter counts from 0 to the auto-reload value (content of the TIMx\_ARR register), then restarts from 0 and generates a counter overflow event.

Setting the UG bit in the TIMx\_EGR register (by software or by using the slave mode controller on TIM9/TIM12) also generates an update event.

The UEV event can be disabled by software by setting the UDIS bit in the TIMx\_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until the UDIS bit has been written to 0. However, the counter restarts from 0, as well as the counter of the prescaler (but the prescale rate does not change). In addition, if the URS bit (update request selection) in TIMx\_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMx\_SR register) is set (depending on the URS bit):

- The auto-reload shadow register is updated with the preload value (TIMx\_ARR),
- The buffer of the prescaler is reloaded with the preload value (content of the TIMx\_PSC register).

The following figures show some examples of the counter behavior for different clock frequencies when TIMx\_ARR=0x36.

**Figure 260. Counter timing diagram, internal clock divided by 1**

Figure 261. Counter timing diagram, internal clock divided by 2

Figure 262. Counter timing diagram, internal clock divided by 4

Figure 263. Counter timing diagram, internal clock divided by N

Figure 264. Counter timing diagram, update event when ARPE=0 (TIMx\_ARR not preloaded)

**Figure 265. Counter timing diagram, update event when ARPE=1 (TIMx\_ARR preloaded)**

### 24.3.3 Clock selection

The counter clock can be provided by the following clock sources:

- Internal clock (CK\_INT)
- External clock mode1 (for TIM9/TIM12): external input pin (TIx)
- Internal trigger inputs (ITRx) (for TIM9/TIM12): connecting the trigger output from another timer. For instance, another timer can be configured as a prescaler for TIM12. Refer to [Section : Using one timer as prescaler for another timer](#) for more details.

#### Internal clock source (CK\_INT)

The internal clock source is the default clock source for TIM10/TIM11/TIM13/TIM14.

For TIM9/TIM12, the internal clock source is selected when the slave mode controller is disabled (SMS='000'). The CEN bit in the TIMx\_CR1 register and the UG bit in the TIMx\_EGR register are then used as control bits and can be changed only by software (except for UG which remains cleared). As soon as the CEN bit is programmed to 1, the prescaler is clocked by the internal clock CK\_INT.

[Figure 266](#) shows the behavior of the control circuit and the upcounter in normal mode, without prescaler.

Figure 266. Control circuit in normal mode, internal clock divided by 1

External clock source mode 1 (TIM9/TIM12)

This mode is selected when SMS='111' in the TIMx\_SMCR register. The counter can count at each rising or falling edge on a selected input.

Figure 267. TI2 external clock connection example

For example, to configure the upcounter to count in response to a rising edge on the TI2 input, use the following procedure:

1. Configure channel 2 to detect rising edges on the TI2 input by writing CC2S = '01' in the TIMx\_CCMR1 register.
2. Configure the input filter duration by writing the IC2F[3:0] bits in the TIMx\_CCMR1 register (if no filter is needed, keep IC2F='0000').
3. Select the rising edge polarity by writing CC2P='0' and CC2NP='0' in the TIMx\_CCER register.
4. Configure the timer in external clock mode 1 by writing SMS='111' in the TIMx\_SMCR register.
5. Select TI2 as the trigger input source by writing TS='110' in the TIMx\_SMCR register.
6. Enable the counter by writing CEN='1' in the TIMx\_CR1 register.

**Note:** The capture prescaler is not used for triggering, so you don't need to configure it.

When a rising edge occurs on TI2, the counter counts once and the TIF flag is set.

The delay between the rising edge on TI2 and the actual clock of the counter is due to the resynchronization circuit on TI2 input.

**Figure 268. Control circuit in external clock mode 1**

### 24.3.4 Capture/compare channels

Each Capture/Compare channel is built around a capture/compare register (including a shadow register), a input stage for capture (with digital filter, multiplexing and prescaler) and an output stage (with comparator and output control).

[Figure 269](#) to [Figure 271](#) give an overview of one capture/compare channel.

The input stage samples the corresponding TIx input to generate a filtered signal TIxF. Then, an edge detector with polarity selection generates a signal (TIxFPx) which can be used as trigger input by the slave mode controller or as the capture command. It is prescaled before the capture register (ICxPS).

**Figure 269. Capture/compare channel (example: channel 1 input stage)**

The output stage generates an intermediate waveform which is then used for reference: OCxRef (active high). The polarity acts at the end of the chain.

**Figure 270. Capture/compare channel 1 main circuit**

Figure 271. Output stage of capture/compare channel (channel 1)

The capture/compare block is made of one preload register and one shadow register. Write and read always access the preload register.

In capture mode, captures are actually done in the shadow register, which is copied into the preload register.

In compare mode, the content of the preload register is copied into the shadow register which is compared to the counter.

### 24.3.5 Input capture mode

In Input capture mode, the Capture/Compare Registers (TIMx\_CCRx) are used to latch the value of the counter after a transition detected by the corresponding ICx signal. When a capture occurs, the corresponding CCXIF flag (TIMx\_SR register) is set and an interrupt or a DMA request can be sent if they are enabled. If a capture occurs while the CCxIF flag was already high, then the over-capture flag CCxOF (TIMx\_SR register) is set. CCxIF can be cleared by software by writing it to '0' or by reading the captured data stored in the TIMx\_CCRx register. CCxOF is cleared when you write it to '0'.

The following example shows how to capture the counter value in TIMx\_CCR1 when TI1 input rises. To do this, use the following procedure:

1. Select the active input: TIMx\_CCR1 must be linked to the TI1 input, so write the CC1S bits to '01' in the TIMx\_CCMR1 register. As soon as CC1S becomes different from '00', the channel is configured in input mode and the TIMx\_CCR1 register becomes read-only.
2. Program the input filter duration you need with respect to the signal you connect to the timer (by programming the ICxF bits in the TIMx\_CCMRx register if the input is one of the TIx inputs). Let's imagine that, when toggling, the input signal is not stable during at most 5 internal clock cycles. We must program a filter duration longer than these 5 clock cycles. We can validate a transition on TI1 when 8 consecutive samples with the

new level have been detected (sampled at  $f_{DTS}$  frequency). Then write IC1F bits to '0011' in the TIMx\_CCMR1 register.

3. Select the edge of the active transition on the TI1 channel by programming CC1P and CC1NP bits to '00' in the TIMx\_CCER register (rising edge in this case).
4. Program the input prescaler. In our example, we wish the capture to be performed at each valid transition, so the prescaler is disabled (write IC1PS bits to '00' in the TIMx\_CCMR1 register).
5. Enable capture from the counter into the capture register by setting the CC1E bit in the TIMx\_CCER register.
6. If needed, enable the related interrupt request by setting the CC1IE bit in the TIMx\_DIER register.

When an input capture occurs:

- The TIMx\_CCR1 register gets the value of the counter on the active transition.
- CC1IF flag is set (interrupt flag). CC1OF is also set if at least two consecutive captures occurred whereas the flag was not cleared.
- An interrupt is generated depending on the CC1IE bit.

In order to handle the overcapture, it is recommended to read the data before the overcapture flag. This is to avoid missing an overcapture which could happen after reading the flag and before reading the data.

*Note:* IC interrupt requests can be generated by software by setting the corresponding CCxG bit in the TIMx\_EGR register.

### 24.3.6 PWM input mode (only for TIM9/TIM12)

This mode is a particular case of input capture mode. The procedure is the same except:

- Two ICx signals are mapped on the same TIx input.
- These 2 ICx signals are active on edges with opposite polarity.
- One of the two TIxFP signals is selected as trigger input and the slave mode controller is configured in reset mode.

For example, you can measure the period (in TIMx\_CCR1 register) and the duty cycle (in TIMx\_CCR2 register) of the PWM applied on TI1 using the following procedure (depending on CK\_INT frequency and prescaler value):

1. Select the active input for TIMx\_CCR1: write the CC1S bits to '01' in the TIMx\_CCMR1 register (TI1 selected).
2. Select the active polarity for TI1FP1 (used both for capture in TIMx\_CCR1 and counter clear): program the CC1P and CC1NP bits to '00' (active on rising edge).
3. Select the active input for TIMx\_CCR2: write the CC2S bits to '10' in the TIMx\_CCMR1 register (TI1 selected).
4. Select the active polarity for TI1FP2 (used for capture in TIMx\_CCR2): program the CC2P and CC2NP bits to '11' (active on falling edge).
5. Select the valid trigger input: write the TS bits to '101' in the TIMx\_SMCR register (TI1FP1 selected).
6. Configure the slave mode controller in reset mode: write the SMS bits to '100' in the TIMx\_SMCR register.
7. Enable the captures: write the CC1E and CC2E bits to '1' in the TIMx\_CCER register.

Figure 272. PWM input mode timing

1. The PWM input mode can be used only with the TIMx\_CH1/TIMx\_CH2 signals due to the fact that only TI1FP1 and TI2FP2 are connected to the slave mode controller.

### 24.3.7 Forced output mode

In output mode (CCxS bits = '00' in the TIMx\_CCMRx register), each output compare signal (OCxREF and then OCx) can be forced to active or inactive level directly by software, independently of any comparison between the output compare register and the counter.

To force an output compare signal (OCXREF/OCx) to its active level, you just need to write '0101' in the OCxM bits in the corresponding TIMx\_CCMRx register. Thus OCXREF is forced high (OCxREF is always active high) and OCx get opposite value to CCxP polarity bit.

For example: CCxP='0' (OCx active high) => OCx is forced to high level.

The OCxREF signal can be forced low by writing the OCxM bits to '0100' in the TIMx\_CCMRx register.

Anyway, the comparison between the TIMx\_CCRx shadow register and the counter is still performed and allows the flag to be set. Interrupt requests can be sent accordingly. This is described in the output compare mode section below.

### 24.3.8 Output compare mode

This function is used to control an output waveform or indicating when a period of time has elapsed.

When a match is found between the capture/compare register and the counter, the output compare function:

1. Assigns the corresponding output pin to a programmable value defined by the output compare mode (OCxM bits in the TIMx\_CCMRx register) and the output polarity (CCxP bit in the TIMx\_CCER register). The output pin can keep its level (OCxM='0000'), be set active (OCxM='0001'), be set inactive (OCxM='0010') or can toggle (OCxM='0011') on match.
2. Sets a flag in the interrupt status register (CCxIF bit in the TIMx\_SR register).
3. Generates an interrupt if the corresponding interrupt mask is set (CCXIE bit in the TIMx\_DIER register).

The TIMx\_CCRx registers can be programmed with or without preload registers using the OCxPE bit in the TIMx\_CCMRx register.

In output compare mode, the update event UEV has no effect on OCxREF and OCx output. The timing resolution is one count of the counter. Output compare mode can also be used to output a single pulse (in One-pulse mode).

Procedure:

1. Select the counter clock (internal, external, prescaler).
2. Write the desired data in the TIMx\_ARR and TIMx\_CCRx registers.
3. Set the CCxIE bit if an interrupt request is to be generated.
4. Select the output mode. For example:
  - Write OCxM = '0011' to toggle OCx output pin when CNT matches CCRx
  - Write OCxPE = '0' to disable preload register
  - Write CCxP = '0' to select active high polarity
  - Write CCxE = '1' to enable the output
5. Enable the counter by setting the CEN bit in the TIMx\_CR1 register.

The TIMx\_CCRx register can be updated at any time by software to control the output waveform, provided that the preload register is not enabled (OCxPE='0', else TIMx\_CCRx shadow register is updated only at the next update event UEV). An example is given in [Figure 273](#).

**Figure 273. Output compare mode, toggle on OC1.**

### 24.3.9 PWM mode

Pulse Width Modulation mode allows you to generate a signal with a frequency determined by the value of the TIMx\_ARR register and a duty cycle determined by the value of the TIMx\_CCRx register.

The PWM mode can be selected independently on each channel (one PWM per OCx output) by writing '0110' (PWM mode 1) or '0111' (PWM mode 2) in the OCxM bits in the

TIMx\_CCMRx register. You must enable the corresponding preload register by setting the OCxPE bit in the TIMx\_CCMRx register, and eventually the auto-reload preload register (in upcounting or center-aligned modes) by setting the ARPE bit in the TIMx\_CR1 register.

As the preload registers are transferred to the shadow registers only when an update event occurs, before starting the counter, you have to initialize all the registers by setting the UG bit in the TIMx\_EGR register.

The OCx polarity is software programmable using the CCxP bit in the TIMx\_CCER register. It can be programmed as active high or active low. The OCx output is enabled by the CCxE bit in the TIMx\_CCER register. Refer to the TIMx\_CCERx register description for more details.

In PWM mode (1 or 2), TIMx\_CNT and TIMx\_CCRx are always compared to determine whether  $TIMx\_CNT \leq TIMx\_CCRx$ .

The timer is able to generate PWM in edge-aligned mode only since the counter is upcounting.

In the following example, we consider PWM mode 1. The reference PWM signal OCxREF is high as long as  $TIMx\_CNT < TIMx\_CCRx$  else it becomes low. If the compare value in TIMx\_CCRx is greater than the auto-reload value (in TIMx\_ARR) then OCxREF is held at '1'. If the compare value is 0 then OCxRef is held at '0'. [Figure 274](#) shows some edge-aligned PWM waveforms in an example where TIMx\_ARR=8.

**Figure 274. Edge-aligned PWM waveforms (ARR=8)**

MS31093V1

### 24.3.10 Combined PWM mode (TIM9/TIM12 only)

Combined PWM mode allows two edge or center-aligned PWM signals to be generated with programmable delay and phase shift between respective pulses. While the frequency is determined by the value of the TIMx\_ARR register, the duty cycle and delay are determined

by the two TIMx\_CCRx registers. The resulting signals, OCxREFC, are made of an OR or AND logical combination of two reference PWMs:

- OC1REFC (or OC2REFC) is controlled by the TIMx\_CCR1 and TIMx\_CCR2 registers

Combined PWM mode can be selected independently on two channels (one OCx output per pair of CCR registers) by writing '1100' (Combined PWM mode 1) or '1101' (Combined PWM mode 2) in the OCxM bits in the TIMx\_CCMRx register.

When a given channel is used as a combined PWM channel, its complementary channel must be configured in the opposite PWM mode (for instance, one in Combined PWM mode 1 and the other in Combined PWM mode 2).

**Note:** The OCxM[3:0] bit field is split into two parts for compatibility reasons, the most significant bit is not contiguous with the 3 least significant ones.

Figure 275 represents an example of signals that can be generated using combined PWM mode, obtained with the following configuration:

- Channel 1 is configured in Combined PWM mode 2,
- Channel 2 is configured in PWM mode 1,

**Figure 275. Combined PWM mode on channel 1 and 2**

The OPM waveform is defined by writing the compare registers (taking into account the clock frequency and the counter prescaler).

- The  $t_{\text{DELAY}}$  is defined by the value written in the TIMx\_CCR1 register.
- The  $t_{\text{PULSE}}$  is defined by the difference between the auto-reload value and the compare value (TIMx\_ARR - TIMx\_CCR1).
- Let's say you want to build a waveform with a transition from '0' to '1' when a compare match occurs and a transition from '1' to '0' when the counter reaches the auto-reload value. To do this you enable PWM mode 2 by writing OC1M='0111' in the TIMx\_CCMR1 register. You can optionally enable the preload registers by writing OC1PE='1' in the TIMx\_CCMR1 register and ARPE in the TIMx\_CR1 register. In this case you have to write the compare value in the TIMx\_CCR1 register, the auto-reload value in the TIMx\_ARR register, generate an update by setting the UG bit and wait for external trigger event on TI2. CC1P is written to '0' in this example.

You only want 1 pulse (Single mode), so you write '1' in the OPM bit in the TIMx\_CR1 register to stop the counter at the next update event (when the counter rolls over from the auto-reload value back to 0). When OPM bit in the TIMx\_CR1 register is set to '0', so the Repetitive Mode is selected.

#### Particular case: OCx fast enable

In One-pulse mode, the edge detection on TIx input set the CEN bit which enables the counter. Then the comparison between the counter and the compare value makes the output toggle. But several clock cycles are needed for these operations and it limits the minimum delay  $t_{\text{DELAY}}$  min we can get.

If you want to output a waveform with the minimum delay, you can set the OCxFE bit in the TIMx\_CCMRx register. Then OCxRef (and OCx) are forced in response to the stimulus, without taking in account the comparison. Its new level is the same as if a compare match had occurred. OCxFE acts only if the channel is configured in PWM1 or PWM2 mode.

### 24.3.12 Retriggerable one pulse mode (OPM) (TIM12 only)

This mode allows the counter to be started in response to a stimulus and to generate a pulse with a programmable length, but with the following differences with non-retriggerable one pulse mode described in [Section 24.3.11: One-pulse mode](#):

- The pulse starts as soon as the trigger occurs (no programmable delay)
- The pulse is extended if a new trigger occurs before the previous one is completed

The timer must be in Slave mode, with the bits SMS[3:0] = '1000' (Combined Reset + trigger mode) in the TIMx\_SMCR register, and the OCxM[3:0] bits set to '1000' or '1001' for retriggerable OPM mode 1 or 2.

If the timer is configured in up-counting mode, the corresponding CCRx must be set to 0 (the ARR register sets the pulse length). If the timer is configured in down-counting mode, CCRx must be above or equal to ARR.

*Note:* The OCxM[3:0] and SMS[3:0] bit fields are split into two parts for compatibility reasons, the most significant bit are not contiguous with the 3 least significant ones.

*This mode must not be used with center-aligned PWM modes. It is mandatory to have CMS[1:0] = 00 in TIMx\_CR1.*

Figure 277. Retriggerable one pulse mode

### 24.3.13 UIF bit remapping

The IUFREMAP bit in the TIMx\_CR1 register forces a continuous copy of the Update Interrupt Flag UIF into bit 31 of the timer counter register (TIMxCNT[31]). This allows to atomically read both the counter value and a potential roll-over condition signaled by the UIFCPY flag. In particular cases, it can ease the calculations by avoiding race conditions caused for instance by a processing shared between a background task (counter reading) and an interrupt (Update Interrupt).

There is no latency between the assertions of the UIF and UIFCPY flags.

### 24.3.14 TIM9/TIM12 external trigger synchronization

The TIM9/TIM12 timers can be synchronized with an external trigger in several modes: Reset mode, Gated mode and Trigger mode.

#### Slave mode: Reset mode

The counter and its prescaler can be reinitialized in response to an event on a trigger input. Moreover, if the URS bit from the TIMx\_CR1 register is low, an update event UEV is generated. Then all the preloaded registers (TIMx\_ARR, TIMx\_CCRx) are updated.

In the following example, the upcounter is cleared in response to a rising edge on TI1 input:

1. Configure the channel 1 to detect rising edges on TI1. Configure the input filter duration (in this example, we don't need any filter, so we keep IC1F='0000'). The capture prescaler is not used for triggering, so you don't need to configure it. The CC1S bits select the input capture source only, CC1S = '01' in the TIMx\_CCMR1 register. Program CC1P and CC1NP to '00' in TIMx\_CCER register to validate the polarity (and detect rising edges only).
2. Configure the timer in reset mode by writing SMS='100' in TIMx\_SMCR register. Select TI1 as the input source by writing TS='101' in TIMx\_SMCR register.
3. Start the counter by writing CEN='1' in the TIMx\_CR1 register.

The counter starts counting on the internal clock, then behaves normally until TI1 rising edge. When TI1 rises, the counter is cleared and restarts from 0. In the meantime, the

trigger flag is set (TIF bit in the TIMx\_SR register) and an interrupt request can be sent if enabled (depending on the TIE bit in TIMx\_DIER register).

The following figure shows this behavior when the auto-reload register TIMx\_ARR=0x36. The delay between the rising edge on TI1 and the actual reset of the counter is due to the resynchronization circuit on TI1 input.

**Figure 278. Control circuit in reset mode**

MS31401V2

### Slave mode: Gated mode

The counter can be enabled depending on the level of a selected input.

In the following example, the upcounter counts only when TI1 input is low:

1. Configure the channel 1 to detect low levels on TI1. Configure the input filter duration (in this example, we don't need any filter, so we keep IC1F='0000'). The capture prescaler is not used for triggering, so you don't need to configure it. The CC1S bits select the input capture source only, CC1S='01' in TIMx\_CCMR1 register. Program CC1P='1' and CC1NP='0' in TIMx\_CCER register to validate the polarity (and detect low level only).
2. Configure the timer in gated mode by writing SMS='101' in TIMx\_SMCR register. Select TI1 as the input source by writing TS='101' in TIMx\_SMCR register.
3. Enable the counter by writing CEN='1' in the TIMx\_CR1 register (in gated mode, the counter doesn't start if CEN='0', whatever is the trigger input level).

The counter starts counting on the internal clock as long as TI1 is low and stops as soon as TI1 becomes high. The TIF flag in the TIMx\_SR register is set both when the counter starts or stops.

The delay between the rising edge on TI1 and the actual stop of the counter is due to the resynchronization circuit on TI1 input.

Figure 279. Control circuit in gated mode

### Slave mode: Trigger mode

The counter can start in response to an event on a selected input.

In the following example, the upcounter starts in response to a rising edge on TI2 input:

1. Configure the channel 2 to detect rising edges on TI2. Configure the input filter duration (in this example, we don't need any filter, so we keep IC2F='0000'). The capture prescaler is not used for triggering, so you don't need to configure it. The CC2S bits are configured to select the input capture source only, CC2S='01' in TIMx\_CCMR1 register. Program CC2P='1' and CC2NP='0' in TIMx\_CCER register to validate the polarity (and detect low level only).
2. Configure the timer in trigger mode by writing SMS='110' in TIMx\_SMCR register. Select TI2 as the input source by writing TS='110' in TIMx\_SMCR register.

When a rising edge occurs on TI2, the counter starts counting on the internal clock and the TIF flag is set.

The delay between the rising edge on TI2 and the actual start of the counter is due to the resynchronization circuit on TI2 input.

Figure 280. Control circuit in trigger mode

### 24.3.15 Slave mode – combined reset + trigger mode

In this case, a rising edge of the selected trigger input (TRGI) reinitializes the counter, generates an update of the registers, and starts the counter.

This mode is used for one-pulse mode.

### 24.3.16 Timer synchronization (TIM9/TIM12)

The TIM timers are linked together internally for timer synchronization or chaining. Refer to [Section 23.3.19: Timer synchronization](#) for details.

*Note:* The clock of the slave timer must be enabled prior to receive events from the master timer, and must not be changed on-the-fly while triggers are received from the master timer.

### 24.3.17 Debug mode

When the microcontroller enters debug mode (Cortex<sup>®</sup>-M7 core halted), the TIMx counter either continues to work normally or stops, depending on DBG\_TIMx\_STOP configuration bit in DBG module. For more details, refer to [Section 40.16.2: Debug support for timers, watchdog, bxCAN and I2C](#).

## 24.4 TIM9/TIM12 registers

Refer to [Section 1.2](#) for a list of abbreviations used in register descriptions.

The peripheral registers have to be written by half-words (16 bits) or words (32 bits). Read accesses can be done by bytes (8 bits), half-words (16 bits) or words (32 bits).

### 24.4.1 TIMx control register 1 (TIMx\_CR1)(x = 9, 12)

Address offset: 0x00

Reset value: 0x0000

| 15   | 14   | 13   | 12   | 11           | 10   | 9        | 8  | 7    | 6    | 5    | 4    | 3   | 2   | 1    | 0   |
|------|------|------|------|--------------|------|----------|----|------|------|------|------|-----|-----|------|-----|
| Res. | Res. | Res. | Res. | UIFRE<br>MAP | Res. | CKD[1:0] |    | ARPE | Res. | Res. | Res. | OPM | URS | UDIS | CEN |
|      |      |      |      | rw           |      | rw       | rw | rw   |      |      |      | rw  | rw  | rw   | rw  |

Bits 15:12 Reserved, must be kept at reset value.

Bit 11 **UIFREMAP**: UIF status bit remapping

0: No remapping. UIF status bit is not copied to TIMx\_CNT register bit 31.

1: Remapping enabled. UIF status bit is copied to TIMx\_CNT register bit 31.

Bit 10 Reserved, must be kept at reset value.

Bits 9:8 **CKD[1:0]**: Clock division

This bit-field indicates the division ratio between the timer clock (CK\_INT) frequency and sampling clock used by the digital filters (Tl<sub>x</sub>),

00:  $t_{DTS} = t_{CK\_INT}$

01:  $t_{DTS} = 2 \times t_{CK\_INT}$

10:  $t_{DTS} = 4 \times t_{CK\_INT}$

11: Reserved

Bit 7 **ARPE**: Auto-reload preload enable

0: TIMx\_ARR register is not buffered.

1: TIMx\_ARR register is buffered.

Bits 6:4 Reserved, must be kept at reset value.

Bit 3 **OPM**: One-pulse mode

- 0: Counter is not stopped on the update event
- 1: Counter stops counting on the next update event (clearing the CEN bit).

Bit 2 **URS**: Update request source

This bit is set and cleared by software to select the UEV event sources.

- 0: Any of the following events generates an update interrupt if enabled. These events can be:

- Counter overflow
- Setting the UG bit
- Update generation through the slave mode controller

- 1: Only counter overflow generates an update interrupt if enabled.

Bit 1 **UDIS**: Update disable

This bit is set and cleared by software to enable/disable update event (UEV) generation.

- 0: UEV enabled. An UEV is generated by one of the following events:

- Counter overflow
- Setting the UG bit

Buffered registers are then loaded with their preload values.

- 1: UEV disabled. No UEV is generated, shadow registers keep their value (ARR, PSC, CCRx). The counter and the prescaler are reinitialized if the UG bit is set.

Bit 0 **CEN**: Counter enable

- 0: Counter disabled
- 1: Counter enabled

CEN is cleared automatically in one-pulse mode, when an update event occurs.

*Note: External clock and gated mode can work only if the CEN bit has been previously set by software. However trigger mode can set the CEN bit automatically by hardware.*

#### 24.4.2 TIMx slave mode control register (TIMx\_SMCR)(x = 9, 12)

Address offset: 0x08

Reset value: 0x0000 0000

| 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6       | 5    | 4    | 3    | 2        | 1    | 0      |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | MSM  | TS[2:0] |      |      | Res. | SMS[2:0] |      |        |
|      |      |      |      |      |      |      |      | rw   | rw      | rw   | rw   |      | rw       | rw   | rw     |

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **SMS[3]**: Slave mode selection - bit 3

Refer to SMS description - bits 2:0

Bits 15:8 Reserved, must be kept at reset value.

Bit 7 **MSM**: Master/Slave mode

- 0: No action
- 1: The effect of an event on the trigger input (TRGI) is delayed to allow a perfect synchronization between the current timer and its slaves (through TRGO). It is useful in order to synchronize several timers on a single external event.

Bits 6:4 **TS[2:0]**: Trigger selection

This bitfield selects the trigger input to be used to synchronize the counter.

000: Internal Trigger 0 (ITR0)  
 001: Internal Trigger 1 (ITR1)  
 010: Internal Trigger 2 (ITR2)  
 011: Internal Trigger 3 (ITR3)  
 100: TI1 Edge Detector (TI1F\_ED)  
 101: Filtered Timer Input 1 (TI1FP1)  
 110: Filtered Timer Input 2 (TI2FP2)  
 111: Reserved.

See [Table 154: TIMx internal trigger connection on page 839](#) for more details on the meaning of ITRx for each timer.

*Note: These bits must be changed only when they are not used (e.g. when SMS='000') to avoid wrong edge detections at the transition.*

Bit 3 Reserved, must be kept at reset value.

Bits 16, 2, 1, 0 **SMS[3:0]**: Slave mode selection

When external signals are selected the active edge of the trigger signal (TRGI) is linked to the polarity selected on the external input (see Input Control register and Control Register description).

0000: Slave mode disabled - if CEN = '1' then the prescaler is clocked directly by the internal clock.  
 0001: Reserved  
 0010: Reserved  
 0011: Reserved  
 0100: Reset Mode - Rising edge of the selected trigger input (TRGI) reinitializes the counter and generates an update of the registers.  
 0101: Gated Mode - The counter clock is enabled when the trigger input (TRGI) is high. The counter stops (but is not reset) as soon as the trigger becomes low. Both start and stop of the counter are controlled.  
 0110: Trigger Mode - The counter starts at a rising edge of the trigger TRGI (but it is not reset). Only the start of the counter is controlled.  
 0111: External Clock Mode 1 - Rising edges of the selected trigger (TRGI) clock the counter.  
 1000: Combined reset + trigger mode - Rising edge of the selected trigger input (TRGI) reinitializes the counter, generates an update of the registers and starts the counter.  
 Other codes: reserved.

*Note: The gated mode must not be used if TI1F\_ED is selected as the trigger input (TS='100'). Indeed, TI1F\_ED outputs 1 pulse for each transition on TI1F, whereas the gated mode checks the level of the trigger signal.*

*Note: The clock of the slave timer must be enabled prior to receive events from the master timer, and must not be changed on-the-fly while triggers are received from the master timer.*

**Table 154. TIMx internal trigger connection**

| Slave TIM | ITR0 (TS = '000') | ITR1 (TS = '001') | ITR2 (TS = '010') | ITR3 (TS = '011') |

Bits 15:11 Reserved, must be kept at reset value.

Bit 10 **CC2OF**: Capture/compare 2 overcapture flag  
 refer to CC1OF description

Bit 9 **CC1OF**: Capture/Compare 1 overcapture flag  
 This flag is set by hardware only when the corresponding channel is configured in input capture mode. It is cleared by software by writing it to '0'.  
 0: No overcapture has been detected.  
 1: The counter value has been captured in TIMx\_CCR1 register while CC1IF flag was already set

Bits 8:7 Reserved, must be kept at reset value.

Bit 6 **TIF**: Trigger interrupt flag

This flag is set by hardware on trigger event (active edge detected on TRGI input when the slave mode controller is enabled in all modes but gated mode. It is set when the counter starts or stops when gated mode is selected. It is cleared by software.

0: No trigger event occurred.

1: Trigger interrupt pending.

Bits 5:3 Reserved, must be kept at reset value.

Bit 2 **CC2IF**: Capture/Compare 2 interrupt flag

refer to CC1IF description

Bit 1 **CC1IF**: Capture/compare 1 interrupt flag**If channel CC1 is configured as output:**

This flag is set by hardware when the counter matches the compare value. It is cleared by software.

0: No match.

1: The content of the counter TIMx\_CNT matches the content of the TIMx\_CCR1 register. When the contents of TIMx\_CCR1 are greater than the contents of TIMx\_ARR, the CC1IF bit goes high on the counter overflow.

**If channel CC1 is configured as input:**

This bit is set by hardware on a capture. It is cleared by software or by reading the TIMx\_CCR1 register.

0: No input capture occurred.

1: The counter value has been captured in TIMx\_CCR1 register (an edge has been detected on IC1 which matches the selected polarity).

Bit 0 **UIF**: Update interrupt flag

This bit is set by hardware on an update event. It is cleared by software.

0: No update occurred.

1: Update interrupt pending. This bit is set by hardware when the registers are updated:

- At overflow and if UDIS='0' in the TIMx\_CR1 register.
- When CNT is reinitialized by software using the UG bit in TIMx\_EGR register, if URS='0' and UDIS='0' in the TIMx\_CR1 register.
- When CNT is reinitialized by a trigger event (refer to the synchro control register description), if URS='0' and UDIS='0' in the TIMx\_CR1 register.

Bits 15:7 Reserved, must be kept at reset value.

Bit 6 **TG**: Trigger generation

This bit is set by software in order to generate an event, it is automatically cleared by hardware.

0: No action

1: The TIF flag is set in the TIMx\_SR register. Related interrupt can occur if enabled

Bits 5:3 Reserved, must be kept at reset value.

Bit 2 **CC2G**: Capture/compare 2 generation  
refer to CC1G description

Bit 1 **CC1G**: Capture/compare 1 generation

This bit is set by software to generate an event, it is automatically cleared by hardware.

0: No action

1: A capture/compare event is generated on channel 1:

**If channel CC1 is configured as output:**

the CC1IF flag is set, the corresponding interrupt is sent if enabled.

**If channel CC1 is configured as input:**

The current counter value is captured in the TIMx\_CCR1 register. The CC1IF flag is set, the corresponding interrupt is sent if enabled. The CC1OF flag is set if the CC1IF flag was already high.

Bit 0 **UG**: Update generation

This bit can be set by software, it is automatically cleared by hardware.

0: No action

1: Re-initializes the counter and generates an update of the registers. The prescaler counter is also cleared and the prescaler ratio is not affected. The counter is cleared.

#### 24.4.6 TIMx capture/compare mode register 1 (TIMx\_CCMR1)(x = 9, 12)

Address offset: 0x18

Reset value: 0x0000

The channels can be used in input (capture mode) or in output (compare mode). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits in this register have different functions in input and output modes. For a given bit, OCxx describes its function when the channel is configured in output mode, ICxx describes its function when the channel is configured in input mode. So you must take care that the same bit can have different meanings for the input stage and the output stage.

|           |           |      |      |             |       |           |             |           |           |      |             |       |       |           |             |

#### Output compare mode

Bits 31:25 Reserved, always read as 0

Bit 24 **OC2M[3]**: Output Compare 2 mode - bit 3

Refer to OC2M description on bits 14:12

Bits 23:17 Reserved, always read as 0

Bit 16 **OC1M[3]**: Output Compare 1 mode - bit 3

Refer to OC1M description on bits 6:4

Bit 15 Reserved, must be kept at reset value.

Bits 14:12 **OC2M[2:0]**: Output compare 2 mode

Refer to OC1M[3:0] for bit description.

Bit 11 **OC2PE**: Output compare 2 preload enable

Bit 10 **OC2FE**: Output compare 2 fast enable

Bits 9:8 **CC2S[1:0]**: Capture/Compare 2 selection

This bitfield defines the direction of the channel (input/output) as well as the used input.

00: CC2 channel is configured as output

01: CC2 channel is configured as input, IC2 is mapped on TI2

10: CC2 channel is configured as input, IC2 is mapped on TI1

11: CC2 channel is configured as input, IC2 is mapped on TRC. This mode works only if an internal trigger input is selected through the TS bit (TIMx\_SMCR register)

*Note: The CC2S bits are writable only when the channel is OFF (CC2E = 0 in TIMx\_CCER).*

Bit 7 Reserved, must be kept at reset value.

Bits 6:4 **OC1M[3:0]**: Output compare 1 mode (refer to bit 16 for OC1M[3])

These bits define the behavior of the output reference signal OC1REF from which OC1 is derived. OC1REF is active high whereas the active level of OC1 depends on the CC1P.

0000: Frozen - The comparison between the output compare register TIMx\_CCR1 and the counter TIMx\_CNT has no effect on the outputs.(this mode is used to generate a timing base).

0001: Set channel 1 to active level on match. The OC1REF signal is forced high when the TIMx\_CNT counter matches the capture/compare register 1 (TIMx\_CCR1).

0010: Set channel 1 to inactive level on match. The OC1REF signal is forced low when the TIMx\_CNT counter matches the capture/compare register 1 (TIMx\_CCR1).

0011: Toggle - OC1REF toggles when TIMx\_CNT=TIMx\_CCR1

0100: Force inactive level - OC1REF is forced low

0101: Force active level - OC1REF is forced high

0110: PWM mode 1 - channel 1 is active as long as TIMx\_CNT<TIMx\_CCR1 else it is inactive

0111: PWM mode 2 - channel 1 is inactive as long as TIMx\_CNT<TIMx\_CCR1 else it is active

1000: Retriggerable OPM mode 1 - The channel is active until a trigger event is detected (on TRGI signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes active again at the next update.

1001: Retriggerable OPM mode 2 - The channel is inactive until a trigger event is detected (on TRGI signal). Then, a comparison is performed as in PWM mode 2 and the channels becomes inactive again at the next update.

1010: Reserved,

1011: Reserved,

1100: Combined PWM mode 1 - OC1REF has the same behavior as in PWM mode 1. OC1REFC is the logical OR between OC1REF and OC2REF.

1101: Combined PWM mode 2 - OC1REF has the same behavior as in PWM mode 2. OC1REFC is the logical AND between OC1REF and OC2REF.

1110: Reserved,

1111: Reserved

*Note: In PWM mode 1 or 2, the OCREF level changes only when the result of the comparison changes or when the output compare mode switches from "frozen" mode to "PWM" mode.*

Bit 3 **OC1PE**: Output compare 1 preload enable

0: Preload register on TIMx\_CCR1 disabled. TIMx\_CCR1 can be written at anytime, the new value is taken into account immediately

1: Preload register on TIMx\_CCR1 enabled. Read/Write operations access the preload register. TIMx\_CCR1 preload value is loaded into the active register at each update event

*Note: The PWM mode can be used without validating the preload register only in one-pulse mode (OPM bit set in the TIMx\_CR1 register). Else the behavior is not guaranteed.*

Bit 2 **OC1FE**: Output compare 1 fast enable

This bit is used to accelerate the effect of an event on the trigger in input on the CC output.  
0: CC1 behaves normally depending on the counter and CCR1 values even when the trigger is ON. The minimum delay to activate the CC1 output when an edge occurs on the trigger input is 5 clock cycles

1: An active edge on the trigger input acts like a compare match on the CC1 output. Then, OC is set to the compare level independently of the result of the comparison. Delay to sample the trigger input and to activate CC1 output is reduced to 3 clock cycles. OC1FE acts only if the channel is configured in PWM1 or PWM2 mode.

Bits 1:0 **CC1S[1:0]**: Capture/Compare 1 selection

This bitfield defines the direction of the channel (input/output) as well as the used input.

00: CC1 channel is configured as output

01: CC1 channel is configured as input, IC1 is mapped on TI1

10: CC1 channel is configured as input, IC1 is mapped on TI2

11: CC1 channel is configured as input, IC1 is mapped on TRC. This mode works only if an internal trigger input is selected through the TS bit (TIMx\_SMCR register)

*Note: The CC1S bits are writable only when the channel is OFF (CC1E = 0 in TIMx\_CCER).*

## Input capture mode

Bits 15:12 **IC2F**: Input capture 2 filter

Bits 11:10 **IC2PSC[1:0]**: Input capture 2 prescaler

Bits 9:8 **CC2S**: Capture/compare 2 selection

This bitfield defines the direction of the channel (input/output) as well as the used input.

00: CC2 channel is configured as output

01: CC2 channel is configured as input, IC2 is mapped on TI2

10: CC2 channel is configured as input, IC2 is mapped on TI1

11: CC2 channel is configured as input, IC2 is mapped on TRC. This mode works only if an internal trigger input is selected through the TS bit (TIMx\_SMCR register)

*Note: The CC2S bits are writable only when the channel is OFF (CC2E = 0 in TIMx\_CCER).*

Bits 7:4 **IC1F**: Input capture 1 filter

This bitfield defines the frequency used to sample the TI1 input and the length of the digital filter applied to TI1. The digital filter is made of an event counter in which N consecutive events are needed to validate a transition on the output:

0000: No filter, sampling is done at  $f_{DTS}$

0001:  $f_{SAMPLING}=f_{CK\_INT}$ , N=2

0010:  $f_{SAMPLING}=f_{CK\_INT}$ , N=4

0011:  $f_{SAMPLING}=f_{CK\_INT}$ , N=8

0100:  $f_{SAMPLING}=f_{DTS}/2$ , N=6

0101:  $f_{SAMPLING}=f_{DTS}/2$ , N=8

0110:  $f_{SAMPLING}=f_{DTS}/4$ , N=6

0111:  $f_{SAMPLING}=f_{DTS}/4$ , N=8

1000:  $f_{SAMPLING}=f_{DTS}/8$ , N=6

1001:  $f_{SAMPLING}=f_{DTS}/8$ , N=8

1010:  $f_{SAMPLING}=f_{DTS}/16$ , N=5

1011:  $f_{SAMPLING}=f_{DTS}/16$ , N=6

1100:  $f_{SAMPLING}=f_{DTS}/16$ , N=8

1101:  $f_{SAMPLING}=f_{DTS}/32$ , N=5

1110:  $f_{SAMPLING}=f_{DTS}/32$ , N=6

1111:  $f_{SAMPLING}=f_{DTS}/32$ , N=8

Bits 3:2 **IC1PSC**: Input capture 1 prescaler

This bitfield defines the ratio of the prescaler acting on the CC1 input (IC1).

The prescaler is reset as soon as CC1E='0' (TIMx\_CCER register).

00: no prescaler, capture is done each time an edge is detected on the capture input

01: capture is done once every 2 events

10: capture is done once every 4 events

11: capture is done once every 8 events

Bits 1:0 **CC1S[1:0]**: Capture/Compare 1 selection

This bitfield defines the direction of the channel (input/output) as well as the used input.

00: CC1 channel is configured as output

01: CC1 channel is configured as input, IC1 is mapped on TI1

10: CC1 channel is configured as input, IC1 is mapped on TI2

11: CC1 channel is configured as input, IC1 is mapped on TRC. This mode is working only if an internal trigger input is selected through TS bit (TIMx\_SMCR register)

*Note: The CC1S bits are writable only when the channel is OFF (CC1E = 0 in TIMx\_CCER).*

**24.4.7 TIMx capture/compare enable register (TIMx\_CCER)(x = 9, 12)**

Address offset: 0x20

Reset value: 0x0000

| 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7     | 6    | 5    | 4    | 3     | 2    | 1    | 0    |
|------|------|------|------|------|------|------|------|-------|------|------|------|-------|------|------|------|
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | CC2NP | Res. | CC2P | CC2E | CC1NP | Res. | CC1P | CC1E |
|      |      |      |      |      |      |      |      | rw    |      | rw   | rw   | rw    |      | rw   | rw   |

Bits 15:8 Reserved, must be kept at reset value.

Bit 7 **CC2NP**: Capture/Compare 2 output Polarity

Refer to CC1NP description

Bit 6 Reserved, must be kept at reset value.

Bit 5 **CC2P**: Capture/Compare 2 output Polarity

Refer to CC1P description

Bit 4 **CC2E**: Capture/Compare 2 output enable

Refer to CC1E description

Bit 3 **CC1NP**: Capture/Compare 1 complementary output Polarity

CC1 channel configured as output: CC1NP must be kept cleared

CC1 channel configured as input: CC1NP is used in conjunction with CC1P to define TI1FP1/TI2FP1 polarity (refer to CC1P description).

Bit 2 Reserved, must be kept at reset value.

Bit 1 **CC1P**: Capture/Compare 1 output Polarity.**CC1 channel configured as output:**

0: OC1 active high.

1: OC1 active low.

**CC1 channel configured as input:**

The CC1P and CC1NP bits select TI1FP1 polarity for capture operations.

00: non-inverted/rising edge

Circuit is sensitive to TIxFP1 rising edge (capture, trigger in reset, external clock or trigger mode), TIxFP1 is not inverted (trigger in gated mode, encoder mode).

01: inverted/falling edge

Circuit is sensitive to TIxFP1 falling edge (capture, trigger in reset, external clock or trigger mode), TIxFP1 is inverted (trigger in gated mode, encoder mode).

10: reserved, do not use this configuration.

11: noninverted/both edges

Circuit is sensitive to both TIxFP1 rising and falling edges (capture, trigger in reset, external clock or trigger mode), TIxFP1 is not inverted (trigger in gated mode). This configuration must not be used for encoder mode.

Bit 0 **CC1E**: Capture/Compare 1 output enable.**CC1 channel configured as output:**

0: Off - OC1 is not active.

1: On - OC1 signal is output on the corresponding output pin.

**CC1 channel configured as input:**

This bit determines if a capture of the counter value can actually be done into the input capture/compare register 1 (TIMx\_CCR1) or not.

0: Capture disabled.

1: Capture enabled.

Table 155. Output control bit for standard OCx channels

| CCxE bit | OCx output state                      |
|----------|---------------------------------------|
| 0        | Output disabled (OCx='0', OCx_EN='0') |
| 1        | OCx=OCxREF + Polarity, OCx_EN='1'     |

*Note:* The states of the external I/O pins connected to the standard OCx channels depend on the state of the OCx channel and on the GPIO registers.

#### 24.4.8 TIMx counter (TIMx\_CNT)(x = 9, 12)

Address offset: 0x24

Reset value: 0x0000 0000

|            |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |

| rw         | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   |

Bit 31 **UIFCPY**: UIF Copy

This bit is a read-only copy of the UIF bit in the TIMx\_ISR register.

Bits 30:16 Reserved, must be kept at reset value.

Bits 15:0 **CNT[15:0]**: Counter value

#### 24.4.9 TIMx prescaler (TIMx\_PSC)(x = 9, 12)

Address offset: 0x28

Reset value: 0x0000

|           |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|-----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 15        | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| PSC[15:0] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw        | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 15:0 **PSC[15:0]**: Prescaler value

The counter clock frequency CK\_CNT is equal to  $f_{CK\_PSC} / (PSC[15:0] + 1)$ .

PSC contains the value to be loaded into the active prescaler register at each update event. (including when the counter is cleared through UG bit of TIMx\_EGR register or through trigger controller when configured in "reset mode").

**24.4.10 TIMx auto-reload register (TIMx\_ARR)(x = 9, 12)**

Address offset: 0x2C

Reset value: 0xFFFF

|           |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|-----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 15        | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| ARR[15:0] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rW        | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW |

Bits 15:0 **ARR[15:0]**: Auto-reload value

ARR is the value to be loaded into the actual auto-reload register.

Refer to the [Section 24.3.1: Time-base unit on page 816](#) for more details about ARR update and behavior.

The counter is blocked while the auto-reload value is null.

**24.4.11 TIMx capture/compare register 1 (TIMx\_CCR1)(x = 9, 12)**

Address offset: 0x34

Reset value: 0x0000

|            |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 15         | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| CCR1[15:0] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rW         | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW |

Bits 15:0 **CCR1[15:0]**: Capture/Compare 1 value**If channel CC1 is configured as output:**

CCR1 is the value to be loaded into the actual capture/compare 1 register (preload value). It is loaded permanently if the preload feature is not selected in the TIMx\_CCMR1 register (OC1PE bit). Else the preload value is copied into the active capture/compare 1 register when an update event occurs.

The active capture/compare register contains the value to be compared to the TIMx\_CNT counter and signaled on the OC1 output.

**If channel CC1 is configured as input:**

CCR1 is the counter value transferred by the last input capture 1 event (IC1).

**24.4.12 TIMx capture/compare register 2 (TIMx\_CCR2)(x = 9, 12)**

Address offset: 0x38

Reset value: 0x0000

|            |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 15         | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| CCR2[15:0] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rW         | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW |

Bits 15:0 **CCR2[15:0]**: Capture/Compare 2 value

**If channel CC2 is configured as output:**

CCR2 is the value to be loaded into the actual capture/compare 2 register (preload value). It is loaded permanently if the preload feature is not selected in the TIMx\_CCMR2 register (OC2PE bit). Else the preload value is copied into the active capture/compare 2 register when an update event occurs.

The active capture/compare register contains the value to be compared to the TIMx\_CNT counter and signalled on the OC2 output.

**If channel CC2 is configured as input:**

CCR2 is the counter value transferred by the last input capture 2 event (IC2).

## 24.4.13 TIM9/TIM12 register map

TIM9/TIM12 registers are mapped as 16-bit addressable registers as described below:

Table 156. TIM9/TIM12 register map and reset values

| Offset | Register name                  | 31       | 30   | 29   | 28   | 27   | 26   | 25   | 24      | 23   | 22   | 21   | 20   | 19   | 18   | 17   | 16      | 15        | 14         | 13   | 12            | 11         | 10    | 9          | 8         | 7    | 6       | 5             | 4          | 3    | 2        | 1     | 0          |      |
|--------|--------------------------------|----------|------|------|------|------|------|------|---------|------|------|------|------|------|------|------|---------|-----------|------------|------|---------------|------------|-------|------------|-----------|------|---------|---------------|------------|------|----------|-------|------------|------|

Refer to [Section 2.2.2 on page 69](#) for the register boundary addresses.

## 24.5 TIM10/TIM11/TIM13/TIM14 registers

The peripheral registers have to be written by half-words (16 bits) or words (32 bits). Read accesses can be done by bytes (8 bits), half-words (16 bits) or words (32 bits).

### 24.5.1 TIMx control register 1 (TIMx\_CR1)(x = 10, 11, 13, 14)

Address offset: 0x00

Reset value: 0x0000

|------|------|------|------|--------------|------|----------|----|------|------|------|------|-----|-----|------|-----|
| Res. | Res. | Res. | Res. | UIFRE<br>MAP | Res. | CKD[1:0] |    | ARPE | Res. | Res. | Res. | OPM | URS | UDIS | CEN |
|      |      |      |      | rw           |      | rw       | rw | rw   |      |      |      | rw  | rw  | rw   | rw  |

Bits 15:12 Reserved, must be kept at reset value.

Bit 11 **UIFREMAP**: UIF status bit remapping

0: No remapping. UIF status bit is not copied to TIMx\_CNT register bit 31.

1: Remapping enabled. UIF status bit is copied to TIMx\_CNT register bit 31.

Bit 10 Reserved, must be kept at reset value.

Bits 9:8 **CKD[1:0]**: Clock division

This bit-field indicates the division ratio between the timer clock (CK\_INT) frequency and sampling clock used by the digital filters (Tl<sub>x</sub>),

00:  $t_{DTS} = t_{CK\_INT}$

01:  $t_{DTS} = 2 \times t_{CK\_INT}$

10:  $t_{DTS} = 4 \times t_{CK\_INT}$

11: Reserved

Bit 7 **ARPE**: Auto-reload preload enable

0: TIMx\_ARR register is not buffered

1: TIMx\_ARR register is buffered

Bits 6:4 Reserved, must be kept at reset value.

Bit 3 **OPM**: One-pulse mode

0: Counter is not stopped on the update event

1: Counter stops counting on the next update event (clearing the CEN bit).

Bit 2 **URS**: Update request source

This bit is set and cleared by software to select the update interrupt (UEV) sources.

0: Any of the following events generate an UEV if enabled:

- Counter overflow
- Setting the UG bit

1: Only counter overflow generates an UEV if enabled.

Bit 1 **UDIS**: Update disable

This bit is set and cleared by software to enable/disable update interrupt (UEV) event generation.

0: UEV enabled. An UEV is generated by one of the following events:

- Counter overflow
- Setting the UG bit.

Buffered registers are then loaded with their preload values.

1: UEV disabled. No UEV is generated, shadow registers keep their value (ARR, PSC, CCRx). The counter and the prescaler are reinitialized if the UG bit is set.

Bit 0 **CEN**: Counter enable

0: Counter disabled

1: Counter enabled

*Note:* External clock and gated mode can work only if the CEN bit has been previously set by software. However trigger mode can set the CEN bit automatically by hardware.

## 24.5.2 TIMx Interrupt enable register (TIMx\_DIER)(x = 10, 11, 13, 14)

Address offset: 0x0C

Reset value: 0x0000

| 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5    | 4    | 3    | 2    | 1     | 0   |
|------|------|------|------|------|------|------|------|------|------|------|------|------|------|-------|-----|
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | CC1IE | UIE |
|      |      |      |      |      |      |      |      |      |      |      |      |      |      | rw    | rw  |

Bits 15:2 Reserved, must be kept at reset value.

Bit 1 **CC1IE**: Capture/Compare 1 interrupt enable

0: CC1 interrupt disabled

1: CC1 interrupt enabled

Bit 0 **UIE**: Update interrupt enable

0: Update interrupt disabled

1: Update interrupt enabled

## 24.5.3 TIMx status register (TIMx\_SR)(x = 10, 11, 13, 14)

Address offset: 0x10

Reset value: 0x0000

| 15   | 14   | 13   | 12   | 11   | 10   | 9     | 8    | 7    | 6    | 5    | 4    | 3    | 2    | 1     | 0     |
|------|------|------|------|------|------|-------|------|------|------|------|------|------|------|-------|-------|
| Res. | Res. | Res. | Res. | Res. | Res. | CC1OF | Res. | Res. | Res. | Res. | Res. | Res. | Res. | CC1IF | UIF   |
|      |      |      |      |      |      | rc_w0 |      |      |      |      |      |      |      | rc_w0 | rc_w0 |

Bits 15:10 Reserved, must be kept at reset value.

Bit 9 **CC1OF**: Capture/Compare 1 overcapture flag

This flag is set by hardware only when the corresponding channel is configured in input capture mode. It is cleared by software by writing it to '0'.

0: No overcapture has been detected.

1: The counter value has been captured in TIMx\_CCR1 register while CC1IF flag was already set

Bits 8:2 Reserved, must be kept at reset value.

Bit 1 **CC1IF**: Capture/compare 1 interrupt flag

**If channel CC1 is configured as output:**

This flag is set by hardware when the counter matches the compare value. It is cleared by software.

0: No match.

1: The content of the counter TIMx\_CNT matches the content of the TIMx\_CCR1 register. When the contents of TIMx\_CCR1 are greater than the contents of TIMx\_ARR, the CC1IF bit goes high on the counter overflow.

**If channel CC1 is configured as input:**

This bit is set by hardware on a capture. It is cleared by software or by reading the TIMx\_CCR1 register.

0: No input capture occurred.

1: The counter value has been captured in TIMx\_CCR1 register (an edge has been detected on IC1 which matches the selected polarity).

Bit 0 **UIF**: Update interrupt flag

This bit is set by hardware on an update event. It is cleared by software.

0: No update occurred.

1: Update interrupt pending. This bit is set by hardware when the registers are updated:

- At overflow and if UDIS='0' in the TIMx\_CR1 register.
- When CNT is reinitialized by software using the UG bit in TIMx\_EGR register, if URS='0' and UDIS='0' in the TIMx\_CR1 register.

#### 24.5.4 TIMx event generation register (TIMx\_EGR)(x = 10, 11, 13, 14)

Address offset: 0x14

Reset value: 0x0000

| 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0  |
|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|----|
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | CC1G | UG |
|      |      |      |      |      |      |      |      |      |      |      |      |      |      | w    | w  |

Bits 15:2 Reserved, must be kept at reset value.

Bit 1 **CC1G**: Capture/compare 1 generation

This bit is set by software in order to generate an event, it is automatically cleared by hardware.

0: No action

1: A capture/compare event is generated on channel 1:

**If channel CC1 is configured as output:**

CC1IF flag is set, Corresponding interrupt or is sent if enabled.

**If channel CC1 is configured as input:**

The current value of the counter is captured in TIMx\_CCR1 register. The CC1IF flag is set, the corresponding interrupt is sent if enabled. The CC1OF flag is set if the CC1IF flag was already high.

Bit 0 **UG**: Update generation

This bit can be set by software, it is automatically cleared by hardware.

0: No action

1: Re-initialize the counter and generates an update of the registers. Note that the prescaler counter is cleared too (anyway the prescaler ratio is not affected). The counter is cleared.

### 24.5.5 TIMx capture/compare mode register 1 (TIMx\_CCMR1)(x = 10, 11, 13, 14)

Address offset: 0x18

Reset value: 0x0000

The channels can be used in input (capture mode) or in output (compare mode). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function in input and in output mode. For a given bit, OCxx describes its function when the channel is configured in output, ICxx describes its function when the channel is configured in input. So you must take care that the same bit can have a different meaning for the input stage and for the output stage.

## Output compare mode

Bits 31:17 Reserved, always read as 0

Bit 16 **OC1M[3]**: Output Compare 1 mode - bit 3  
Refer to OC1M description on bits 6:4

Bits 15:7 Reserved, must be kept at reset value.

Bits 6:4 **OC1M[3:0]**: Output compare 1 mode (refer to bit 16 for OC1M[3])

These bits define the behavior of the output reference signal OC1REF from which OC1 is derived. OC1REF is active high whereas OC1 active level depends on CC1P bit.

0000: Frozen. The comparison between the output compare register TIMx\_CCR1 and the counter TIMx\_CNT has no effect on the outputs.

0001: Set channel 1 to active level on match. OC1REF signal is forced high when the counter TIMx\_CNT matches the capture/compare register 1 (TIMx\_CCR1).

0010: Set channel 1 to inactive level on match. OC1REF signal is forced low when the counter TIMx\_CNT matches the capture/compare register 1 (TIMx\_CCR1).

0011: Toggle - OC1REF toggles when TIMx\_CNT = TIMx\_CCR1.

0100: Force inactive level - OC1REF is forced low.

0101: Force active level - OC1REF is forced high.

0110: PWM mode 1 - Channel 1 is active as long as TIMx\_CNT < TIMx\_CCR1 else inactive.

0111: PWM mode 2 - Channel 1 is inactive as long as TIMx\_CNT < TIMx\_CCR1 else active

Others: Reserved

*Note: In PWM mode 1 or 2, the OCREF level changes when the result of the comparison changes or when the output compare mode switches from frozen to PWM mode.*

Bit 3 **OC1PE**: Output compare 1 preload enable

0: Preload register on TIMx\_CCR1 disabled. TIMx\_CCR1 can be written at anytime, the new value is taken in account immediately.

1: Preload register on TIMx\_CCR1 enabled. Read/Write operations access the preload register. TIMx\_CCR1 preload value is loaded in the active register at each update event.

*Note: The PWM mode can be used without validating the preload register only in one pulse mode (OPM bit set in TIMx\_CR1 register). Else the behavior is not guaranteed.*

Bit 2 **OC1FE**: Output compare 1 fast enable

This bit is used to accelerate the effect of an event on the trigger in input on the CC output.

0: CC1 behaves normally depending on counter and CCR1 values even when the trigger is ON. The minimum delay to activate CC1 output when an edge occurs on the trigger input is 5 clock cycles.

1: An active edge on the trigger input acts like a compare match on CC1 output. OC is then set to the compare level independently of the result of the comparison. Delay to sample the trigger input and to activate CC1 output is reduced to 3 clock cycles. OC1FE acts only if the channel is configured in PWM1 or PWM2 mode.

Bits 1:0 **CC1S[1:0]**: Capture/Compare 1 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

00: CC1 channel is configured as output.

01: CC1 channel is configured as input, IC1 is mapped on TI1.

10: CC1 channel is configured as input, IC1 is mapped on TI2.

11: CC1 channel is configured as input, IC1 is mapped on TRC. This mode is working only if an internal trigger input is selected through TS bit (TIMx\_SMCR register).

*Note: CC1S bits are writable only when the channel is OFF (CC1E = 0 in TIMx\_CCER).*

## Input capture mode

Bits 15:8 Reserved, must be kept at reset value.

Bits 7:4 **IC1F**: Input capture 1 filter

This bit-field defines the frequency used to sample TI1 input and the length of the digital filter applied to TI1. The digital filter is made of an event counter in which N consecutive events are needed to validate a transition on the output:

0000: No filter, sampling is done at  $f_{DTS}$  1000:  $f_{SAMPLING}=f_{DTS}/8$ , N=6  
 0001:  $f_{SAMPLING}=f_{CK\_INT}$ , N=2 1001:  $f_{SAMPLING}=f_{DTS}/8$ , N=8  
 0010:  $f_{SAMPLING}=f_{CK\_INT}$ , N=4 1010:  $f_{SAMPLING}=f_{DTS}/16$ , N=5  
 0011:  $f_{SAMPLING}=f_{CK\_INT}$ , N=8 1011:  $f_{SAMPLING}=f_{DTS}/16$ , N=6  
 0100:  $f_{SAMPLING}=f_{DTS}/2$ , N=6 1100:  $f_{SAMPLING}=f_{DTS}/16$ , N=8  
 0101:  $f_{SAMPLING}=f_{DTS}/2$ , N=8 1101:  $f_{SAMPLING}=f_{DTS}/32$ , N=5  
 0110:  $f_{SAMPLING}=f_{DTS}/4$ , N=6 1110:  $f_{SAMPLING}=f_{DTS}/32$ , N=6  
 0111:  $f_{SAMPLING}=f_{DTS}/4$ , N=8 1111:  $f_{SAMPLING}=f_{DTS}/32$ , N=8

Bits 3:2 **IC1PSC**: Input capture 1 prescaler

This bit-field defines the ratio of the prescaler acting on CC1 input (IC1).

The prescaler is reset as soon as CC1E='0' (TIMx\_CCER register).

00: no prescaler, capture is done each time an edge is detected on the capture input  
 01: capture is done once every 2 events  
 10: capture is done once every 4 events  
 11: capture is done once every 8 events

Bits 1:0 **CC1S[1:0]**: Capture/Compare 1 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

00: CC1 channel is configured as output  
 01: CC1 channel is configured as input, IC1 is mapped on TI1  
 10: Reserved  
 11: Reserved

*Note: CC1S bits are writable only when the channel is OFF (CC1E = 0 in TIMx\_CCER).*

## 24.5.6 TIMx capture/compare enable register (TIMx\_CCER)(x = 10, 11, 13, 14)

Address offset: 0x20

Reset value: 0x0000

| 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5    | 4    | 3     | 2    | 1    | 0    |
|------|------|------|------|------|------|------|------|------|------|------|------|-------|------|------|------|
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | CC1NP | Res. | CC1P | CC1E |
|      |      |      |      |      |      |      |      |      |      |      |      | rw    |      | rw   | rw   |

Bits 15:4 Reserved, must be kept at reset value.

Bit 3 **CC1NP**: Capture/Compare 1 complementary output Polarity.

CC1 channel configured as output: CC1NP must be kept cleared.

CC1 channel configured as input: CC1NP bit is used in conjunction with CC1P to define TI1FP1 polarity (refer to CC1P description).

Bit 2 Reserved, must be kept at reset value.

Bit 1 **CC1P**: Capture/Compare 1 output Polarity.

**CC1 channel configured as output:**

0: OC1 active high

1: OC1 active low

**CC1 channel configured as input:**

The CC1P and CC1NP bits select TI1FP1 polarity for capture operations.

00: noninverted/rising edge

Circuit is sensitive to TI1FP1 rising edge (capture mode), TI1FP1 is not inverted.

01: inverted/falling edge

Circuit is sensitive to TI1FP1 falling edge (capture mode), TI1FP1 is inverted.

10: reserved, do not use this configuration.

11: noninverted/both edges

Circuit is sensitive to both TI1FP1 rising and falling edges (capture mode), TI1FP1 is not inverted.

Bit 0 **CC1E**: Capture/Compare 1 output enable.

**CC1 channel configured as output:**

0: Off - OC1 is not active

1: On - OC1 signal is output on the corresponding output pin

**CC1 channel configured as input:**

This bit determines if a capture of the counter value can actually be done into the input capture/compare register 1 (TIMx\_CCR1) or not.

0: Capture disabled

1: Capture enabled

**Table 157. Output control bit for standard OCx channels**

| CCxE bit | OCx output state                      |
|----------|---------------------------------------|
| 0        | Output Disabled (OCx='0', OCx_EN='0') |
| 1        | OCx=OCxREF + Polarity, OCx_EN='1'     |

*Note:* The state of the external I/O pins connected to the standard OCx channels depends on the OCx channel state and the GPIO registers.

### 24.5.7 TIMx counter (TIMx\_CNT)(x = 10, 11, 13, 14)

Address offset: 0x24

Reset value: 0x0000 0000

|            |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |

| rw         | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   |

Bit 31 **UIFCPY**: UIF Copy

This bit is a read-only copy of the UIF bit in the TIMx\_ISR register.

Bits 30:16 Reserved, must be kept at reset value.

Bits 15:0 **CNT[15:0]**: Counter value

### 24.5.8 TIMx prescaler (TIMx\_PSC)(x = 10, 11, 13, 14)

Address offset: 0x28

Reset value: 0x0000

|           |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|-----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 15        | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| PSC[15:0] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw        | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 15:0 **PSC[15:0]**: Prescaler value

The counter clock frequency CK\_CNT is equal to  $f_{CK\_PSC} / (PSC[15:0] + 1)$ .

PSC contains the value to be loaded in the active prescaler register at each update event.

(including when the counter is cleared through UG bit of TIMx\_EGR register or through trigger controller when configured in “reset mode”).

### 24.5.9 TIMx auto-reload register (TIMx\_ARR)(x = 10, 11, 13, 14)

Address offset: 0x2C

Reset value: 0xFFFF

|           |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|-----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 15        | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| ARR[15:0] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw        | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 15:0 **ARR[15:0]**: Auto-reload value

ARR is the value to be loaded in the actual auto-reload register.

Refer to [Section 24.3.1: Time-base unit on page 816](#) for more details about ARR update and behavior.

The counter is blocked while the auto-reload value is null.

### 24.5.10 TIMx capture/compare register 1 (TIMx\_CCR1)(x = 10, 11, 13, 14)

Address offset: 0x34

Reset value: 0x0000

|            |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 15         | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| CCR1[15:0] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw         | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 15:0 **CCR1[15:0]**: Capture/Compare 1 value

**If channel CC1 is configured as output:**

CCR1 is the value to be loaded in the actual capture/compare 1 register (preload value).

It is loaded permanently if the preload feature is not selected in the TIMx\_CCMR1 register (bit OC1PE). Else the preload value is copied in the active capture/compare 1 register when an update event occurs.

The active capture/compare register contains the value to be compared to the counter TIMx\_CNT and signaled on OC1 output.

**If channel CC1 is configured as input:**

CCR1 is the counter value transferred by the last input capture 1 event (IC1).

## 24.5.11 TIM11 option register 1 (TIM11\_OR)

Address offset: 0x50

Reset value: 0x0000

| 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5    | 4    | 3    | 2    | 1              | 0 |

Bits 15:2 Reserved, must be kept at reset value.

Bits 1:0 **TIM11\_RMP[1:0]**: TIM11 Input 1 remapping capability

Set and cleared by software.

00: TIM11 Channel1 is connected to GPIO (refer to the Alternate function mapping)

01: SPDIFRX\_FRAME\_SYNC is connected to TIM11\_CH1 to measure the clock drift of received SPDIF frames.

10: HSE internal clock (1MHz for RTC) is connected to TIM11\_CH1 input for measurement purposes

11: MCO1 is connected to TIM11\_CH1 input

## 24.5.12 TIM10/TIM11/TIM13/TIM14 register map

TIMx registers are mapped as 16-bit addressable registers as described in the tables below:

**Table 158. TIM10/TIM11/TIM13/TIM14 register map and reset values**

| Offset       | Register name    | 31   | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21   | 20   | 19   | 18   | 17   | 16   | 15   | 14   | 13   | 12   | 11       | 10   | 9         | 8    | 7    | 6    | 5    | 4    | 3    | 2    | 1     | 0   |

Refer to [Section 2.2.2 on page 69](#) for the register boundary addresses.

## 25 Basic timers (TIM6/TIM7)

### 25.1 TIM6/TIM7 introduction

The basic timers TIM6 and TIM7 consist of a 16-bit auto-reload counter driven by a programmable prescaler.

They may be used as generic timers for time-base generation but they are also specifically used to drive the digital-to-analog converter (DAC). In fact, the timers are internally connected to the DAC and are able to drive it through their trigger outputs.

The timers are completely independent, and do not share any resources.

### 25.2 TIM6/TIM7 main features

Basic timer (TIM6/TIM7) features include:

- 16-bit auto-reload upcounter
- 16-bit programmable prescaler used to divide (also “on the fly”) the counter clock frequency by any factor between 1 and 65535
- Synchronization circuit to trigger the DAC
- Interrupt/DMA generation on the update event: counter overflow

**Figure 281. Basic timer block diagram**

## 25.3 TIM6/TIM7 functional description

### 25.3.1 Time-base unit

The main block of the programmable timer is a 16-bit upcounter with its related auto-reload register. The counter clock can be divided by a prescaler.

The counter, the auto-reload register and the prescaler register can be written or read by software. This is true even when the counter is running.

The time-base unit includes:

- Counter Register (TIMx\_CNT)
- Prescaler Register (TIMx\_PSC)
- Auto-Reload Register (TIMx\_ARR)

The auto-reload register is preloaded. The preload register is accessed each time an attempt is made to write or read the auto-reload register. The contents of the preload register are transferred into the shadow register permanently or at each update event UEV, depending on the auto-reload preload enable bit (ARPE) in the TIMx\_CR1 register. The update event is sent when the counter reaches the overflow value and if the UDIS bit equals 0 in the TIMx\_CR1 register. It can also be generated by software. The generation of the update event is described in detail for each configuration.

The counter is clocked by the prescaler output CK\_CNT, which is enabled only when the counter enable bit (CEN) in the TIMx\_CR1 register is set.

Note that the actual counter enable signal CNT\_EN is set 1 clock cycle after CEN.

#### Prescaler description

The prescaler can divide the counter clock frequency by any factor between 1 and 65536. It is based on a 16-bit counter controlled through a 16-bit register (in the TIMx\_PSC register). It can be changed on the fly as the TIMx\_PSC control register is buffered. The new prescaler ratio is taken into account at the next update event.

[Figure 282](#) and [Figure 283](#) give some examples of the counter behavior when the prescaler ratio is changed on the fly.

Figure 282. Counter timing diagram with prescaler division change from 1 to 2

Figure 283. Counter timing diagram with prescaler division change from 1 to 4

### 25.3.2 Counting mode

The counter counts from 0 to the auto-reload value (contents of the TIMx\_ARR register), then restarts from 0 and generates a counter overflow event.

An update event can be generated at each counter overflow or by setting the UG bit in the TIMx\_EGR register (by software or by using the slave mode controller).

The UEV event can be disabled by software by setting the UDIS bit in the TIMx\_CR1 register. This avoids updating the shadow registers while writing new values into the preload registers. In this way, no update event occurs until the UDIS bit has been written to 0, however, the counter and the prescaler counter both restart from 0 (but the prescale rate does not change). In addition, if the URS (update request selection) bit in the TIMx\_CR1 register is set, setting the UG bit generates an update event UEV, but the UIF flag is not set (so no interrupt or DMA request is sent).

When an update event occurs, all the registers are updated and the update flag (UIF bit in the TIMx\_SR register) is set (depending on the URS bit):

- The buffer of the prescaler is reloaded with the preload value (contents of the TIMx\_PSC register)
- The auto-reload shadow register is updated with the preload value (TIMx\_ARR)

The following figures show some examples of the counter behavior for different clock frequencies when TIMx\_ARR = 0x36.

**Figure 284. Counter timing diagram, internal clock divided by 1**

Figure 285. Counter timing diagram, internal clock divided by 2

Figure 286. Counter timing diagram, internal clock divided by 4

Figure 287. Counter timing diagram, internal clock divided by N

Figure 288. Counter timing diagram, update event when ARPE = 0 (TIMx\_ARR not preloaded)

**Figure 289. Counter timing diagram, update event when ARPE=1 (TIMx\_ARR preloaded)**

### 25.3.3 UIF bit remapping

The IUFREMAP bit in the TIMx\_CR1 register forces a continuous copy of the Update Interrupt Flag UIF into the timer counter register's bit 31 (TIMxCNT[31]). This allows to atomically read both the counter value and a potential roll-over condition signaled by the UIFCPY flag. In particular cases, it can ease the calculations by avoiding race conditions caused for instance by a processing shared between a background task (counter reading) and an interrupt (Update Interrupt).

There is no latency between the assertions of the UIF and UIFCPY flags.

### 25.3.4 Clock source

The counter clock is provided by the Internal clock (CK\_INT) source.

The CEN (in the TIMx\_CR1 register) and UG bits (in the TIMx\_EGR register) are actual control bits and can be changed only by software (except for UG that remains cleared automatically). As soon as the CEN bit is written to 1, the prescaler is clocked by the internal clock CK\_INT.

[Figure 290](#) shows the behavior of the control circuit and the upcounter in normal mode, without prescaler.

Figure 290. Control circuit in normal mode, internal clock divided by 1

### 25.3.5 Debug mode

When the microcontroller enters the debug mode (Cortex<sup>®</sup>-M7 core - halted), the TIMx counter either continues to work normally or stops, depending on the DBG\_TIMx\_STOP configuration bit in the DBG module. For more details, refer to [Section 40.16.2: Debug support for timers, watchdog, bxCAN and I2C](#).

## 25.4 TIM6/TIM7 registers

Refer to [Section 1.2 on page 62](#) for a list of abbreviations used in register descriptions.

The peripheral registers can be accessed by half-words (16-bit) or words (32-bit).

### 25.4.1 TIM6/TIM7 control register 1 (TIMx\_CR1)

Address offset: 0x00

Reset value: 0x0000

| 15   | 14   | 13   | 12   | 11           | 10   | 9    | 8    | 7    | 6    | 5    | 4    | 3   | 2   | 1    | 0   |
|------|------|------|------|--------------|------|------|------|------|------|------|------|-----|-----|------|-----|
| Res. | Res. | Res. | Res. | UIFRE<br>MAP | Res. | Res. | Res. | ARPE | Res. | Res. | Res. | OPM | URS | UDIS | CEN |
|      |      |      |      | rw           |      |      |      | rw   |      |      |      | rw  | rw  | rw   | rw  |

Bits 15:12 Reserved, must be kept at reset value.

Bit 11 **UIFREMAP**: UIF status bit remapping

0: No remapping. UIF status bit is not copied to TIMx\_CNT register bit 31.

1: Remapping enabled. UIF status bit is copied to TIMx\_CNT register bit 31.

Bits 10:8 Reserved, must be kept at reset value.

Bit 7 **ARPE**: Auto-reload preload enable

0: TIMx\_ARR register is not buffered.

1: TIMx\_ARR register is buffered.

Bits 6:4 Reserved, must be kept at reset value.

Bit 3 **OPM**: One-pulse mode

0: Counter is not stopped at update event

1: Counter stops counting at the next update event (clearing the CEN bit).

Bit 2 **URS**: Update request source

This bit is set and cleared by software to select the UEV event sources.

0: Any of the following events generates an update interrupt or DMA request if enabled.

These events can be:

- Counter overflow/underflow
- Setting the UG bit
- Update generation through the slave mode controller

1: Only counter overflow/underflow generates an update interrupt or DMA request if enabled.

Bit 1 **UDIS**: Update disable

This bit is set and cleared by software to enable/disable UEV event generation.

0: UEV enabled. The Update (UEV) event is generated by one of the following events:

- Counter overflow/underflow
- Setting the UG bit
- Update generation through the slave mode controller

Buffered registers are then loaded with their preload values.

1: UEV disabled. The Update event is not generated, shadow registers keep their value (ARR, PSC). However the counter and the prescaler are reinitialized if the UG bit is set or if a hardware reset is received from the slave mode controller.

Bit 0 **CEN**: Counter enable

0: Counter disabled

1: Counter enabled

*Note: Gated mode can work only if the CEN bit has been previously set by software.*

*However trigger mode can set the CEN bit automatically by hardware.*

CEN is cleared automatically in one-pulse mode, when an update event occurs.

## 25.4.2 TIM6/TIM7 control register 2 (TIMx\_CR2)

Address offset: 0x04

Reset value: 0x0000

| 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6        | 5  | 4  | 3    | 2    | 1    | 0    |
|------|------|------|------|------|------|------|------|------|----------|----|----|------|------|------|------|
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | MMS[2:0] |    |    | Res. | Res. | Res. | Res. |
|      |      |      |      |      |      |      |      |      | rw       | rw | rw |      |      |      |      |

Bits 15:7 Reserved, must be kept at reset value.

Bits 6:4 **MMS**: Master mode selection

These bits are used to select the information to be sent in master mode to slave timers for synchronization (TRGO). The combination is as follows:

000: **Reset** - the UG bit from the TIMx\_EGR register is used as a trigger output (TRGO). If reset is generated by the trigger input (slave mode controller configured in reset mode) then the signal on TRGO is delayed compared to the actual reset.

001: **Enable** - the Counter enable signal, CNT\_EN, is used as a trigger output (TRGO). It is useful to start several timers at the same time or to control a window in which a slave timer is enabled. The Counter Enable signal is generated by a logic OR between CEN control bit and the trigger input when configured in gated mode.

When the Counter Enable signal is controlled by the trigger input, there is a delay on TRGO, except if the master/slave mode is selected (see the MSM bit description in the TIMx\_SMCR register).

010: **Update** - The update event is selected as a trigger output (TRGO). For instance a master timer can then be used as a prescaler for a slave timer.

*Note: The clock of the slave timer or ADC must be enabled prior to receive events from the master timer, and must not be changed on-the-fly while triggers are received from the master timer.*

Bits 3:0 Reserved, must be kept at reset value.

## 25.4.3 TIM6/TIM7 DMA/Interrupt enable register (TIMx\_DIER)

Address offset: 0x0C

Reset value: 0x0000

| 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8   | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0   |
|------|------|------|------|------|------|------|-----|------|------|------|------|------|------|------|-----|
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | UDE | Res. | Res. | Res. | Res. | Res. | Res. | Res. | UIE |
|      |      |      |      |      |      |      | rw  |      |      |      |      |      |      |      | rw  |

Bits 15:9 Reserved, must be kept at reset value.

Bit 8 **UDE**: Update DMA request enable

0: Update DMA request disabled.

1: Update DMA request enabled.

Bits 7:1 Reserved, must be kept at reset value.

Bit 0 **UIE**: Update interrupt enable

0: Update interrupt disabled.

1: Update interrupt enabled.

### 25.4.4 TIM6/TIM7 status register (TIMx\_SR)

Address offset: 0x10

Reset value: 0x0000

| 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0     |
|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|-------|
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | UIF   |
|      |      |      |      |      |      |      |      |      |      |      |      |      |      |      | rc_w0 |

Bits 15:1 Reserved, must be kept at reset value.

Bit 0 **UIF**: Update interrupt flag

This bit is set by hardware on an update event. It is cleared by software.

0: No update occurred.

1: Update interrupt pending. This bit is set by hardware when the registers are updated:

- At overflow or underflow regarding the repetition counter value and if UDIS = 0 in the TIMx\_CR1 register.
- When CNT is reinitialized by software using the UG bit in the TIMx\_EGR register, if URS = 0 and UDIS = 0 in the TIMx\_CR1 register.

### 25.4.5 TIM6/TIM7 event generation register (TIMx\_EGR)

Address offset: 0x14

Reset value: 0x0000

| 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0  |
|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|----|
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | UG |
|      |      |      |      |      |      |      |      |      |      |      |      |      |      |      | w  |

Bits 15:1 Reserved, must be kept at reset value.

Bit 0 **UG**: Update generation

This bit can be set by software, it is automatically cleared by hardware.

0: No action.

1: Re-initializes the timer counter and generates an update of the registers. Note that the prescaler counter is cleared too (but the prescaler ratio is not affected).

### 25.4.6 TIM6/TIM7 counter (TIMx\_CNT)

Address offset: 0x24

Reset value: 0x0000 0000

| 31         | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21   | 20   | 19   | 18   | 17   | 16   |
|------------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|
| UIF<br>CPY | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. |
| r          |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
| 15         | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0    |
| CNT[15:0]  |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
| rW         | rW   | rW   | rW   | rW   | rW   | rW   | rW   | rW   | rW   | rW   | rW   | rW   | rW   | rW   | rW   |

Bit 31 **UIFCPY**: UIF Copy

This bit is a read-only copy of the UIF bit of the TIMx\_ISR register. If the UIFREMAP bit in TIMx\_CR1 is reset, bit 31 is reserved and read as 0.

Bits 30:16 Reserved, must be kept at reset value.

Bits 15:0 **CNT[15:0]**: Counter value

#### 25.4.7 TIM6/TIM7 prescaler (TIMx\_PSC)

Address offset: 0x28

Reset value: 0x0000

| 15        | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
|-----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| PSC[15:0] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw        | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 15:0 **PSC[15:0]**: Prescaler value

The counter clock frequency CK\_CNT is equal to  $f_{CK\_PSC} / (PSC[15:0] + 1)$ .

PSC contains the value to be loaded into the active prescaler register at each update event. (including when the counter is cleared through UG bit of TIMx\_EGR register or through trigger controller when configured in “reset mode”).

#### 25.4.8 TIM6/TIM7 auto-reload register (TIMx\_ARR)

Address offset: 0x2C

Reset value: 0xFFFF

| 15        | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
|-----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| ARR[15:0] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw        | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 15:0 **ARR[15:0]**: Prescaler value

ARR is the value to be loaded into the actual auto-reload register.

Refer to [Section 25.3.1: Time-base unit on page 863](#) for more details about ARR update and behavior.

The counter is blocked while the auto-reload value is null.

## 25.4.9 TIM6/TIM7 register map

TIMx registers are mapped as 16-bit addressable registers as described in the table below:

**Table 159. TIM6/TIM7 register map and reset values**

| Offset    | Register name | 31             | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21   | 20   | 19   | 18   | 17   | 16   | 15        | 14  | 13  | 12  | 11       | 10  | 9   | 8   | 7         | 6    | 5   | 4   | 3   | 2   | 1   | 0    |     |
|-----------|---------------|----------------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|-----------|-----|-----|-----|----------|-----|-----|-----|-----------|------|-----|-----|-----|-----|-----|------|-----|

Refer to [Section 2.2.2 on page 69](#) for the register boundary addresses.

## 26 Low-power timer (LPTIM)

### 26.1 Introduction

The LPTIM is a 16-bit timer that benefits from the ultimate developments in power consumption reduction. Thanks to its diversity of clock sources, the LPTIM is able to keep running in all power modes except for Standby mode. Given its capability to run even with no internal clock source, the LPTIM can be used as a “Pulse Counter” which can be useful in some applications. Also, the LPTIM capability to wake up the system from low-power modes, makes it suitable to realize “Timeout functions” with extremely low power consumption.

The LPTIM introduces a flexible clock scheme that provides the needed functionalities and performance, while minimizing the power consumption.

### 26.2 LPTIM main features

- 16 bit upcounter
- 3-bit prescaler with 8 possible dividing factors (1,2,4,8,16,32,64,128)
- Selectable clock
  - Internal clock sources: LSE, LSI, HSI or APB clock
  - External clock source over LPTIM input (working with no LP oscillator running, used by Pulse Counter application)
- 16 bit ARR autoreload register
- 16 bit compare register
- Continuous/One-shot mode
- Selectable software/hardware input trigger
- Programmable Digital Glitch filter
- Configurable output: Pulse, PWM
- Configurable I/O polarity
- Encoder mode

### 26.3 LPTIM implementation

[Table 160](#) describes LPTIM implementation on STM32F75xxx and STM32F74xxx devices: the full set of features is implemented in LPTIM1.

**Table 160. STM32F75xxx and STM32F74xxx LPTIM features**

| LPTIM modes/features <sup>(1)</sup> | LPTIM1 |
|-------------------------------------|--------|
| Encoder mode                        | X      |

1. X = supported.

## 26.4 LPTIM functional description

### 26.4.1 LPTIM block diagram

Figure 291. Low-power timer block diagram

### 26.4.2 LPTIM trigger mapping

The LPTIM external trigger connections are detailed hereafter:

Table 161. LPTIM1 external trigger connection

| TRIGSEL         | External trigger |
|-----------------|------------------|
| lptim_ext_trig0 | GPIO             |
| lptim_ext_trig1 | RTC_ALARMA       |
| lptim_ext_trig2 | RTC_ALARMB       |
| lptim_ext_trig3 | RTC_TAMP1_OUT    |
| lptim_ext_trig4 | RTC_TAMP2_OUT    |
| lptim_ext_trig5 | RTC_TAMP3_OUT    |

| lptim_ext_trig6 | Reserved         |
| lptim_ext_trig7 | Reserved         |

### 26.4.3 LPTIM reset and clocks

The LPTIM can be clocked using several clock sources. It can be clocked using an internal clock signal which can be chosen among APB, LSI, LSE or HSI sources through the Reset and Clock controller (RCC). Also, the LPTIM can be clocked using an external clock signal injected on its external Input1. When clocked with an external clock source, the LPTIM may run in one of these two possible configurations:

- The first configuration is when the LPTIM is clocked by an external signal but in the same time an internal clock signal is provided to the LPTIM either from APB or any other embedded oscillator including LSE, LSI and HSI.
- The second configuration is when the LPTIM is solely clocked by an external clock source through its external Input1. This configuration is the one used to realize Timeout function or Pulse counter function when all the embedded oscillators are turned off after entering a low-power mode.

Programming the CKSEL and COUNTMODE bits allows controlling whether the LPTIM will use an external clock source or an internal one.

When configured to use an external clock source, the CKPOL bits are used to select the external clock signal active edge. If both edges are configured to be active ones, an internal clock signal should also be provided (first configuration). In this case, the internal clock signal frequency should be at least four times higher than the external clock signal frequency.

### 26.4.4 Glitch filter

The LPTIM inputs, either external (mapped to microcontroller GPIOs) or internal (mapped on the chip-level to other embedded peripherals, such as embedded comparators), are protected with digital filters that prevent any glitches and noise perturbations to propagate inside the LPTIM. This is in order to prevent spurious counts or triggers.

Before activating the digital filters, an internal clock source should first be provided to the LPTIM. This is necessary to guarantee the proper operation of the filters.

The digital filters are divided into two groups:

- The first group of digital filters protects the LPTIM external inputs. The digital filters sensitivity is controlled by the CKFLT bits
- The second group of digital filters protects the LPTIM internal trigger inputs. The digital filters sensitivity is controlled by the TRGFLT bits.

*Note: The digital filters sensitivity is controlled by groups. It is not possible to configure each digital filter sensitivity separately inside the same group.*

The filter sensitivity acts on the number of consecutive equal samples that should be detected on one of the LPTIM inputs to consider a signal level change as a valid transition. [Figure 292](#) shows an example of glitch filter behavior in case of a 2 consecutive samples programmed.

Figure 292. Glitch filter timing diagram

**Note:** In case no internal clock signal is provided, the digital filter must be deactivated by setting the CKFLT and TRGFLT bits to '0'. In that case, an external analog filter may be used to protect the LPTIM external inputs against glitches.

### 26.4.5 Prescaler

The LPTIM 16-bit counter is preceded by a configurable power-of-2 prescaler. The prescaler division ratio is controlled by the PRESC[2:0] 3-bit field. The table below lists all the possible division ratios:

Table 162. Prescaler division ratios

| programming | dividing factor |
|-------------|-----------------|
| 000         | /1              |
| 001         | /2              |
| 010         | /4              |
| 011         | /8              |
| 100         | /16             |
| 101         | /32             |
| 110         | /64             |
| 111         | /128            |

### 26.4.6 Trigger multiplexer

The LPTIM counter may be started either by software or after the detection of an active edge on one of the 8 trigger inputs.

TRIGEN[1:0] is used to determine the LPTIM trigger source:

- When TRIGEN[1:0] equals '00', The LPTIM counter is started as soon as one of the CNTSTRT or the SNGSTRT bits is set by software. The three remaining possible values for the TRIGEN[1:0] are used to configure the active edge used by the trigger inputs. The LPTIM counter starts as soon as an active edge is detected.
- When TRIGEN[1:0] is different than '00', TRIGSEL[2:0] is used to select which of the 8 trigger inputs is used to start the counter.

The external triggers are considered asynchronous signals for the LPTIM. So after a trigger detection, a two-counter-clock period latency is needed before the timer starts running due to the synchronization.

If a new trigger event occurs when the timer is already started it will be ignored (unless timeout function is enabled).

**Note:** *The timer must be enabled before setting the SNGSTRT/CNTSTRT bits. Any write on these bits when the timer is disabled will be discarded by hardware.*

## 26.4.7 Operating mode

The LPTIM features two operating modes:

- The Continuous mode: the timer is free running, the timer is started from a trigger event and never stops until the timer is disabled
- One-shot mode: the timer is started from a trigger event and stops when reaching the ARR value.

### One-shot mode

To enable the one-shot counting, the SNGSTRT bit must be set.

A new trigger event will re-start the timer. Any trigger event occurring after the counter starts and before the counter reaches ARR will be discarded.

In case an external trigger is selected, each external trigger event arriving after the SNGSTRT bit is set, and after the counter register has stopped (contains zero value), will start the counter for a new one-shot counting cycle as shown in [Figure 293](#).

**Figure 293. LPTIM output waveform, single counting mode configuration**

- Set-once mode activated:

It should be noted that when the WAVE bit-field in the LPTIM\_CFGR register is set, the Set-once mode is activated. In this case, the counter is only started once following the first trigger, and any subsequent trigger event is discarded as shown in [Figure 294](#).

**Figure 294. LPTIM output waveform, Single counting mode configuration and Set-once mode activated (WAVE bit is set)**

In case of software start (TRIGEN[1:0] = '00'), the SNGSTRT setting will start the counter for one-shot counting.

### Continuous mode

To enable the continuous counting, the CNTSTRT bit must be set.

In case an external trigger is selected, an external trigger event arriving after CNTSTRT is set will start the counter for continuous counting. Any subsequent external trigger event will be discarded as shown in [Figure 295](#).

In case of software start (TRIGEN[1:0] = '00'), setting CNTSTRT will start the counter for continuous counting.

**Figure 295. LPTIM output waveform, Continuous counting mode configuration**

SNGSTRT and CNTSTRT bits can only be set when the timer is enabled (The ENABLE bit is set to '1'). It is possible to change "on the fly" from One-shot mode to Continuous mode.

If the Continuous mode was previously selected, setting SNGSTRT will switch the LPTIM to the One-shot mode. The counter (if active) will stop as soon as it reaches ARR.

If the One-shot mode was previously selected, setting CNTSTRT will switch the LPTIM to the Continuous mode. The counter (if active) will restart as soon as it reaches ARR.

### 26.4.8 Timeout function

The detection of an active edge on one selected trigger input can be used to reset the LPTIM counter. This feature is controlled through the TIMOUT bit.

The first trigger event will start the timer, any successive trigger event will reset the counter and the timer will restart.

The first trigger event will start the timer, any successive trigger event will reset the counter and the timer will restart.

A low-power timeout function can be realized. The timeout value corresponds to the compare value; if no trigger occurs within the expected time frame, the MCU is waked-up by the compare match event.

### 26.4.9 Waveform generation

Two 16-bit registers, the LPTIM\_ARR (autoreload register) and LPTIM\_CMP (compare register), are used to generate several different waveforms on LPTIM output

The timer can generate the following waveforms:

- The PWM mode: the LPTIM output is set as soon as the counter value in LPTIM\_CNT exceeds the compare value in LPTIM\_CMP. The LPTIM output is reset as soon as a match occurs between the LPTIM\_ARR and the LPTIM\_CNT registers.
- The One-pulse mode: the output waveform is similar to the one of the PWM mode for the first pulse, then the output is permanently reset
- The Set-once mode: the output waveform is similar to the One-pulse mode except that the output is kept to the last signal level (depends on the output configured polarity).

The above described modes require that the LPTIM\_ARR register value be strictly greater than the LPTIM\_CMP register value.

The LPTIM output waveform can be configured through the WAVE bit as follow:

- Resetting the WAVE bit to '0' forces the LPTIM to generate either a PWM waveform or a One pulse waveform depending on which bit is set: CNTSTRT or SNGSTRT.
- Setting the WAVE bit to '1' forces the LPTIM to generate a Set-once mode waveform.

The WAVPOL bit controls the LPTIM output polarity. The change takes effect immediately, so the output default value will change immediately after the polarity is re-configured, even before the timer is enabled.

Signals with frequencies up to the LPTIM clock frequency divided by 2 can be generated.

[Figure 296](#) below shows the three possible waveforms that can be generated on the LPTIM output. Also, it shows the effect of the polarity change using the WAVPOL bit.

Figure 296. Waveform generation

### 26.4.10 Register update

The LPTIM\_ARR register and LPTIM\_CMP register are updated immediately after the APB bus write operation, or at the end of the current period if the timer is already started.

The PRELOAD bit controls how the LPTIM\_ARR and the LPTIM\_CMP registers are updated:

- When the PRELOAD bit is reset to '0', the LPTIM\_ARR and the LPTIM\_CMP registers are immediately updated after any write access.
- When the PRELOAD bit is set to '1', the LPTIM\_ARR and the LPTIM\_CMP registers are updated at the end of the current period, if the timer has been already started.

The LPTIM APB interface and the LPTIM kernel logic use different clocks, so there is some latency between the APB write and the moment when these values are available to the counter comparator. Within this latency period, any additional write into these registers must be avoided.

The ARROK flag and the CMPOK flag in the LPTIM\_ISR register indicate when the write operation is completed to respectively the LPTIM\_ARR register and the LPTIM\_CMP register.

After a write to the LPTIM\_ARR register or the LPTIM\_CMP register, a new write operation to the same register can only be performed when the previous write operation is completed. Any successive write before respectively the ARROK flag or the CMPOK flag be set, will lead to unpredictable results.

### 26.4.11 Counter mode

The LPTIM counter can be used to count external events on the LPTIM Input1 or it can be used to count internal clock cycles. The CKSEL and COUNTMODE bits control which source will be used for updating the counter.

In case the LPTIM is configured to count external events on Input1, the counter can be updated following a rising edge, falling edge or both edges depending on the value written to the CKPOL[1:0] bits.

The count modes below can be selected, depending on CKSEL and COUNTMODE values:

- CKSEL = 0: the LPTIM is clocked by an internal clock source
  - COUNTMODE = 0  
The LPTIM is configured to be clocked by an internal clock source and the LPTIM counter is configured to be updated following each internal clock pulse.
  - COUNTMODE = 1  
The LPTIM external Input1 is sampled with the internal clock provided to the LPTIM.  
Consequently, in order not to miss any event, the frequency of the changes on the external Input1 signal should never exceed the frequency of the internal clock provided to the LPTIM. Also, the internal clock provided to the LPTIM must not be prescaled (PRESC[2:0] = 000).
- CKSEL = 1: the LPTIM is clocked by an external clock source  
COUNTMODE value is don't care.  
In this configuration, the LPTIM has no need for an internal clock source (except if the glitch filters are enabled). The signal injected on the LPTIM external Input1 is used as system clock for the LPTIM. This configuration is suitable for operation modes where no embedded oscillator is enabled.  
For this configuration, the LPTIM counter can be updated either on rising edges or falling edges of the input1 clock signal but not on both rising and falling edges.  
Since the signal injected on the LPTIM external Input1 is also used to clock the LPTIM kernel logic, there is some initial latency (after the LPTIM is enabled) before the counter is incremented. More precisely, the first five active edges on the LPTIM external Input1 (after LPTIM is enable) are lost.

### 26.4.12 Timer enable

The ENABLE bit located in the LPTIM\_CR register is used to enable/disable the LPTIM kernel logic. After setting the ENABLE bit, a delay of two counter clock is needed before the LPTIM is actually enabled.

The LPTIM\_CFGR and LPTIM\_IER registers must be modified only when the LPTIM is disabled.

### 26.4.13 Encoder mode

This mode allows handling signals from quadrature encoders used to detect angular position of rotary elements. Encoder interface mode acts simply as an external clock with direction selection. This means that the counter just counts continuously between 0 and the auto-reload value programmed into the LPTIM\_ARR register (0 up to ARR or ARR down to 0 depending on the direction). Therefore you must configure LPTIM\_ARR before starting. From the two external input signals, Input1 and Input2, a clock signal is generated to clock the LPTIM counter. The phase between those two signals determines the counting direction.

The Encoder mode is only available when the LPTIM is clocked by an internal clock source. The signals frequency on both Input1 and Input2 inputs must not exceed the LPTIM internal clock frequency divided by 4. This is mandatory in order to guarantee a proper operation of the LPTIM.

Direction change is signaled by the two Down and Up flags in the LPTIM\_ISR register. Also, an interrupt can be generated for both direction change events if enabled through the DOWNIE bit.

To activate the Encoder mode the ENC bit has to be set to '1'. The LPTIM must first be configured in Continuous mode.

When Encoder mode is active, the LPTIM counter is modified automatically following the speed and the direction of the incremental encoder. Therefore, its content always represents the encoder's position. The count direction, signaled by the Up and Down flags, correspond to the rotation direction of the encoder rotor.

According to the edge sensitivity configured using the CKPOL[1:0] bits, different counting scenarios are possible. The following table summarizes the possible combinations, assuming that Input1 and Input2 do not switch at the same time.

**Table 163. Encoder counting scenarios**

| Active edge  | Level on opposite signal (Input1 for Input2, Input2 for Input1) | Input1 signal |          | Input2 signal |          |
|--------------|-----------------------------------------------------------------|---------------|----------|---------------|----------|
|              |                                                                 | Rising        | Falling  | Rising        | Falling  |
| Rising Edge  | High                                                            | Down          | No count | Up            | No count |
|              | Low                                                             | Up            | No count | Down          | No count |
| Falling Edge | High                                                            | No count      | Up       | No count      | Down     |
|              | Low                                                             | No count      | Down     | No count      | Up       |
| Both Edges   | High                                                            | Down          | Up       | Up            | Down     |
|              | Low                                                             | Up            | Down     | Down          | Up       |

The following figure shows a counting sequence for Encoder mode where both-edge sensitivity is configured.

**Caution:** In this mode the LPTIM must be clocked by an internal clock source, so the CKSEL bit must be maintained to its reset value which is equal to '0'. Also, the prescaler division ratio must be equal to its reset value which is 1 (PRESC[2:0] bits must be '000').

Figure 297. Encoder mode counting sequence

#### 26.4.14 Debug mode

When the microcontroller enters debug mode (core halted), the LPTIM counter either continues to work normally or stops, depending on the DBG\_LPTIM\_STOP configuration bit in the DBG module.

### 26.5 LPTIM low-power modes

Table 164. Effect of low-power modes on the LPTIM

| Mode    | Description                                                                                                          |
|---------|----------------------------------------------------------------------------------------------------------------------|
| Sleep   | No effect. LPTIM interrupts cause the device to exit Sleep mode.                                                     |
| Stop    | The LPTIM peripheral is active when it is clocked by LSE or LSI. LPTIM interrupts cause the device to exit Stop mode |
| Standby | The LPTIM peripheral is powered down and must be reinitialized after exiting Standby mode.                           |

## 26.6 LPTIM interrupts

The following events generate an interrupt/wake-up event, if they are enabled through the LPTIM\_IER register:

- Compare match
- Auto-reload match (whatever the direction if encoder mode)
- External trigger event
- Autoreload register write completed
- Compare register write completed
- Direction change (encoder mode), programmable (up / down / both).

**Note:** *If any bit in the LPTIM\_IER register (Interrupt Enable Register) is set after that its corresponding flag in the LPTIM\_ISR register (Status Register) is set, the interrupt is not asserted.*

**Table 165. Interrupt events**

| Interrupt event                | Description                                                                                                                                                                                                                                      |
|--------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Compare match                  | Interrupt flag is raised when the content of the Counter register (LPTIM_CNT) matches the content of the compare register (LPTIM_CMP).                                                                                                           |
| Auto-reload match              | Interrupt flag is raised when the content of the Counter register (LPTIM_CNT) matches the content of the Auto-reload register (LPTIM_ARR).                                                                                                       |
| External trigger event         | Interrupt flag is raised when an external trigger event is detected                                                                                                                                                                              |
| Auto-reload register update OK | Interrupt flag is raised when the write operation to the LPTIM_ARR register is complete.                                                                                                                                                         |
| Compare register update OK     | Interrupt flag is raised when the write operation to the LPTIM_CMP register is complete.                                                                                                                                                         |
| Direction change               | Used in Encoder mode. Two interrupt flags are embedded to signal direction change: <ul style="list-style-type: none"> <li>– UP flag signals up-counting direction change</li> <li>– DOWN flag signals down-counting direction change.</li> </ul> |

## 26.7 LPTIM registers

### 26.7.1 LPTIM interrupt and status register (LPTIM\_ISR)

Address offset: 0x000

Reset value: 0x0000 0000

|      |      |      |      |      |      |      |      |      |      |      |           |           |             |      |      |
|------|------|------|------|------|------|------|------|------|------|------|-----------|-----------|-------------|------|------|
| 31   | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21   | 20        | 19        | 18          | 17   | 16   |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res.      | Res.      | Res.        | Res. | Res. |
|      |      |      |      |      |      |      |      |      |      |      |           |           |             |      |      |
| 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5    | 4         | 3         | 2           | 1    | 0    |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | DOWN | UP   | ARRO<br>K | CMP<br>OK | EXTTR<br>IG | ARRM | CMPM |
|      |      |      |      |      |      |      |      |      | r    | r    | r         | r         | r           | r    | r    |

Bits 31:22 Reserved, must be kept at reset value.

Bit 21 Reserved, must be kept at reset value.

Bit 20 Reserved, must be kept at reset value.

Bit 19 Reserved, must be kept at reset value.

Bits 18:16 Reserved, must be kept at reset value.

Bit 15 Reserved, must be kept at reset value.

Bit 14 Reserved, must be kept at reset value.

Bit 13 Reserved, must be kept at reset value.

Bit 12 Reserved, must be kept at reset value.

Bit 11 Reserved, must be kept at reset value.

Bit 10 Reserved, must be kept at reset value.

Bit 9 Reserved, must be kept at reset value.

Bits 8:7 Reserved, must be kept at reset value.

Bit 6 **DOWN**: Counter direction change up to down

In Encoder mode, DOWN bit is set by hardware to inform application that the counter direction has changed from up to down. DOWN flag can be cleared by writing 1 to the DOWNCF bit in the LPTIM\_ICR register.

Bit 5 **UP**: Counter direction change down to up

In Encoder mode, UP bit is set by hardware to inform application that the counter direction has changed from down to up. UP flag can be cleared by writing 1 to the UPCF bit in the LPTIM\_ICR register.

Bit 4 **ARROK**: Autoreload register update OK

ARROK is set by hardware to inform application that the APB bus write operation to the LPTIM\_ARR register has been successfully completed. ARROK flag can be cleared by writing 1 to the ARROKCF bit in the LPTIM\_ICR register.

Bit 3 **CMPOK**: Compare register update OK

CMPOK is set by hardware to inform application that the APB bus write operation to the LPTIM\_CMP register has been successfully completed.

Bit 2 **EXTTRIG**: External trigger edge event

EXTTRIG is set by hardware to inform application that a valid edge on the selected external trigger input has occurred. If the trigger is ignored because the timer has already started, then this flag is not set. EXTTRIG flag can be cleared by writing 1 to the EXTTRIGCF bit in the LPTIM\_ICR register.

Bit 1 **ARRM**: Autoreload match

ARRM is set by hardware to inform application that LPTIM\_CNT register's value reached the LPTIM\_ARR register's value. ARRM flag can be cleared by writing 1 to the ARRMCF bit in the LPTIM\_ICR register.

Bit 0 **CMPM**: Compare match

The CMPM bit is set by hardware to inform application that LPTIM\_CNT register value reached the LPTIM\_CMP register's value.

## 26.7.2 LPTIM interrupt clear register (LPTIM\_ICR)

Address offset: 0x004

Reset value: 0x0000 0000

|      |      |      |      |      |      |      |      |      |            |      |             |             |               |            |            |
|------|------|------|------|------|------|------|------|------|------------|------|-------------|-------------|---------------|------------|------------|

Bits 31:22 Reserved, must be kept at reset value.

Bit 21 Reserved, must be kept at reset value.

Bit 20 Reserved, must be kept at reset value.

Bit 19 Reserved, must be kept at reset value.

Bits 18:16 Reserved, must be kept at reset value.

Bit 15 Reserved, must be kept at reset value.

Bit 14 Reserved, must be kept at reset value.

Bit 13 Reserved, must be kept at reset value.

Bit 12 Reserved, must be kept at reset value.

Bit 11 Reserved, must be kept at reset value.

Bit 10 Reserved, must be kept at reset value.

Bit 9 Reserved, must be kept at reset value.

Bits 8:7 Reserved, must be kept at reset value.

Bit 6 **DOWNCF**: Direction change to down clear flag

Writing 1 to this bit clear the DOWN flag in the LPTIM\_ISR register.

Bit 5 **UPCF**: Direction change to UP clear flag

Writing 1 to this bit clear the UP flag in the LPTIM\_ISR register.

Bit 4 **ARROKCF**: Autoreload register update OK clear flag

Writing 1 to this bit clears the ARROK flag in the LPTIM\_ISR register

Bit 3 **CMPOKCF**: Compare register update OK clear flag

Writing 1 to this bit clears the CMPOK flag in the LPTIM\_ISR register

Bit 2 **EXTTRIGCF**: External trigger valid edge clear flag

Writing 1 to this bit clears the EXTTRIG flag in the LPTIM\_ISR register

Bit 1 **ARRMCF**: Autoreload match clear flag

Writing 1 to this bit clears the ARRM flag in the LPTIM\_ISR register

Bit 0 **CMPMCF**: Compare match clear flag

Writing 1 to this bit clears the CMP flag in the LPTIM\_ISR register

### 26.7.3 LPTIM interrupt enable register (LPTIM\_IER)

Address offset: 0x008

Reset value: 0x0000 0000

|      |      |      |      |      |      |      |      |      |            |      |             |             |               |            |            |

Bits 31:28 Reserved, must be kept at reset value.

Bit 27 Reserved, must be kept at reset value.

Bit 26 Reserved, must be kept at reset value.

Bit 25 Reserved, must be kept at reset value.

Bit 24 Reserved, must be kept at reset value.

Bit 23 Reserved, must be kept at reset value.

Bit 22 Reserved, must be kept at reset value.

Bit 21 Reserved, must be kept at reset value.

Bit 20 Reserved, must be kept at reset value.

Bit 19 Reserved, must be kept at reset value.

Bits 18:17 Reserved, must be kept at reset value.

Bit 16 Reserved, must be kept at reset value.

Bit 15 Reserved, must be kept at reset value.

Bit 14 Reserved, must be kept at reset value.

Bit 13 Reserved, must be kept at reset value.

Bit 12 Reserved, must be kept at reset value.

Bit 11 Reserved, must be kept at reset value.

Bit 10 Reserved, must be kept at reset value.

Bit 9 Reserved, must be kept at reset value.

Bits 8:7 Reserved, must be kept at reset value.

Bit 6 **DOWNIE**: Direction change to down Interrupt Enable

0: DOWN interrupt disabled

1: DOWN interrupt enabled

Bit 5 **UPIE**: Direction change to UP Interrupt Enable

0: UP interrupt disabled

1: UP interrupt enabled

Bit 4 **ARROKIE**: Autoreload register update OK Interrupt Enable

- 0: ARROK interrupt disabled
- 1: ARROK interrupt enabled

Bit 3 **CMPOKIE**: Compare register update OK Interrupt Enable

- 0: CMPOK interrupt disabled
- 1: CMPOK interrupt enabled

Bit 2 **EXTTRIGIE**: External trigger valid edge Interrupt Enable

- 0: EXTTRIG interrupt disabled
- 1: EXTTRIG interrupt enabled

Bit 1 **ARRMIE**: Autoreload match Interrupt Enable

- 0: ARRM interrupt disabled
- 1: ARRM interrupt enabled

Bit 0 **CMPMIE**: Compare match Interrupt Enable

- 0: CMPM interrupt disabled
- 1: CMPM interrupt enabled

**Caution:** The LPTIM\_IER register must only be modified when the LPTIM is disabled (ENABLE bit reset to '0')

## 26.7.4 LPTIM configuration register (LPTIM\_CFGR)

Address offset: 0x00C

Reset value: 0x0000 0000

| 31           | 30   | 29   | 28   | 27         | 26   | 25   | 24   | 23            | 22      | 21     | 20         | 19     | 18          | 17 | 16    |

Bits 31:30 Reserved, must be kept at reset value.

Bit 29 Reserved, must be kept at reset value.

Bits 28:25 Reserved, must be kept at reset value.

Bit 24 **ENC**: Encoder mode enable

The ENC bit controls the Encoder mode

- 0: Encoder mode disabled
- 1: Encoder mode enabled

Bit 23 **COUNTMODE**: counter mode enabled

The COUNTMODE bit selects which clock source is used by the LPTIM to clock the counter:

- 0: the counter is incremented following each internal clock pulse
- 1: the counter is incremented following each valid clock pulse on the LPTIM external Input1

- Bit 22 **PRELOAD**: Registers update mode  
The PRELOAD bit controls the LPTIM\_ARR and the LPTIM\_CMP registers update modality  
0: Registers are updated after each APB bus write access  
1: Registers are updated at the end of the current LPTIM period
- Bit 21 **WAVPOL**: Waveform shape polarity  
The WAVEPOL bit controls the output polarity  
0: The LPTIM output reflects the compare results between LPTIM\_ARR and LPTIM\_CMP registers  
1: The LPTIM output reflects the inverse of the compare results between LPTIM\_ARR and LPTIM\_CMP registers
- Bit 20 **WAVE**: Waveform shape  
The WAVE bit controls the output shape  
0: Deactivate Set-once mode, PWM / One Pulse waveform (depending on OPMODE bit)  
1: Activate the Set-once mode
- Bit 19 **TIMOUT**: Timeout enable  
The TIMOUT bit controls the Timeout feature  
0: a trigger event arriving when the timer is already started will be ignored  
1: A trigger event arriving when the timer is already started will reset and restart the counter  
1: A trigger event arriving when the timer is already started will reset and restart the counter
- Bits 18:17 **TRIGEN[1:0]**: Trigger enable and polarity  
The TRIGEN bits controls whether the LPTIM counter is started by an external trigger or not. If the external trigger option is selected, three configurations are possible for the trigger active edge:  
00: software trigger (counting start is initiated by software)  
01: rising edge is the active edge  
10: falling edge is the active edge  
11: both edges are active edges
- Bit 16 Reserved, must be kept at reset value.
- Bits 15:13 **TRIGSEL[2:0]**: Trigger selector  
The TRIGSEL bits select the trigger source that will serve as a trigger event for the LPTIM among the below 8 available sources:  
000: lptim\_ext\_trig0  
001: lptim\_ext\_trig1  
010: lptim\_ext\_trig2  
011: lptim\_ext\_trig3  
100: lptim\_ext\_trig4  
101: lptim\_ext\_trig5  
110: lptim\_ext\_trig6  
111: lptim\_ext\_trig7  
See [Section 26.4.2: LPTIM trigger mapping](#) for details.
- Bit 12 Reserved, must be kept at reset value.

Bits 11:9 **PRESC[2:0]**: Clock prescaler

The PRESC bits configure the prescaler division factor. It can be one among the following division factors:

000: /1  
001: /2  
010: /4  
011: /8  
100: /16  
101: /32  
110: /64  
111: /128

Bit 8 Reserved, must be kept at reset value.

Bits 7:6 **TRGFLT[1:0]**: Configurable digital filter for trigger

The TRGFLT value sets the number of consecutive equal samples that should be detected when a level change occurs on an internal trigger before it is considered as a valid level transition. An internal clock source must be present to use this feature

00: any trigger active level change is considered as a valid trigger

01: trigger active level change must be stable for at least 2 clock periods before it is considered as valid trigger.

10: trigger active level change must be stable for at least 4 clock periods before it is considered as valid trigger.

11: trigger active level change must be stable for at least 8 clock periods before it is considered as valid trigger.

Bit 5 Reserved, must be kept at reset value.

Bits 4:3 **CKFLT[1:0]**: Configurable digital filter for external clock

The CKFLT value sets the number of consecutive equal samples that should be detected when a level change occurs on an external clock signal before it is considered as a valid level transition. An internal clock source must be present to use this feature

00: any external clock signal level change is considered as a valid transition

01: external clock signal level change must be stable for at least 2 clock periods before it is considered as valid transition.

10: external clock signal level change must be stable for at least 4 clock periods before it is considered as valid transition.

11: external clock signal level change must be stable for at least 8 clock periods before it is considered as valid transition.

Bits 2:1 **CKPOL[1:0]**: Clock Polarity

If LPTIM is clocked by an external clock source:

When the LPTIM is clocked by an external clock source, CKPOL bits is used to configure the active edge or edges used by the counter:

00: the rising edge is the active edge used for counting

01: the falling edge is the active edge used for counting

10: both edges are active edges. When both external clock signal edges are considered active ones, the LPTIM must also be clocked by an internal clock source with a frequency equal to at least four time the external clock frequency.

11: not allowed

If the LPTIM is configured in Encoder mode (ENC bit is set):

00: the encoder sub-mode 1 is active

01: the encoder sub-mode 2 is active

10: the encoder sub-mode 3 is active

Refer to [Section 26.4.13: Encoder mode](#) for more details about Encoder mode sub-modes.

Bit 0 **CKSEL**: Clock selector

The CKSEL bit selects which clock source the LPTIM will use:

0: LPTIM is clocked by internal clock source (APB clock or any of the embedded oscillators)

1: LPTIM is clocked by an external clock source through the LPTIM external Input1

**Caution:** The LPTIM\_CFGR register must only be modified when the LPTIM is disabled (ENABLE bit reset to '0').

## 26.7.5 LPTIM control register (LPTIM\_CR)

Address offset: 0x010

Reset value: 0x0000 0000

|      |      |      |      |      |      |      |      |      |      |      |      |      |             |             |            |
|------|------|------|------|------|------|------|------|------|------|------|------|------|-------------|-------------|------------|
| 31   | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21   | 20   | 19   | 18          | 17          | 16         |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res.        | Res.        | Res.       |
|      |      |      |      |      |      |      |      |      |      |      |      |      |             |             |            |
| 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5    | 4    | 3    | 2           | 1           | 0          |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | CNT<br>STRT | SNG<br>STRT | ENA<br>BLE |
|      |      |      |      |      |      |      |      |      |      |      |      |      | rw          | rw          | rw         |

Bits 31:3 Reserved, must be kept at reset value.

Bit 2 **CNTSTRT**: Timer start in Continuous mode

This bit is set by software and cleared by hardware.

In case of software start (TRIGEN[1:0] = '00'), setting this bit starts the LPTIM in Continuous mode.

If the software start is disabled (TRIGEN[1:0] different than '00'), setting this bit starts the timer in Continuous mode as soon as an external trigger is detected.

If this bit is set when a single pulse mode counting is ongoing, then the timer will not stop at the next match between the LPTIM\_ARR and LPTIM\_CNT registers and the LPTIM counter keeps counting in Continuous mode.

This bit can be set only when the LPTIM is enabled. It will be automatically reset by hardware.

Bit 1 **SNGSTRT**: LPTIM start in Single mode

This bit is set by software and cleared by hardware.

In case of software start (TRIGEN[1:0] = '00'), setting this bit starts the LPTIM in single pulse mode.

If the software start is disabled (TRIGEN[1:0] different than '00'), setting this bit starts the LPTIM in single pulse mode as soon as an external trigger is detected.

If this bit is set when the LPTIM is in continuous counting mode, then the LPTIM will stop at the following match between LPTIM\_ARR and LPTIM\_CNT registers.

This bit can only be set when the LPTIM is enabled. It will be automatically reset by hardware.

Bit 0 **ENABLE**: LPTIM enable

The ENABLE bit is set and cleared by software.

0:LPTIM is disabled

1:LPTIM is enabled

## 26.7.6 LPTIM compare register (LPTIM\_CMP)

Address offset: 0x014

Reset value: 0x0000 0000

|           |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
|-----------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|
| 31        | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21   | 20   | 19   | 18   | 17   | 16   |
| Res.      | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. |
|           |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
| 15        | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0    |
| CMP[15:0] |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
| rw        | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   |

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **CMP[15:0]**: Compare value

CMP is the compare value used by the LPTIM.

**Caution:** The LPTIM\_CMP register must only be modified when the LPTIM is enabled (ENABLE bit set to '1').

### 26.7.7 LPTIM autoreload register (LPTIM\_ARR)

Address offset: 0x018

Reset value: 0x0000 0001

|           |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
|-----------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|
| 31        | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21   | 20   | 19   | 18   | 17   | 16   |
| Res.      | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. |
|           |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
| 15        | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0    |
| ARR[15:0] |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
| rw        | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   |

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **ARR[15:0]**: Auto reload value

ARR is the autoreload value for the LPTIM.

This value must be strictly greater than the CMP[15:0] value.

**Caution:** The LPTIM\_ARR register must only be modified when the LPTIM is enabled (ENABLE bit set to '1').

### 26.7.8 LPTIM counter register (LPTIM\_CNT)

Address offset: 0x01C

Reset value: 0x0000 0000

|           |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
|-----------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|
| 31        | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21   | 20   | 19   | 18   | 17   | 16   |
| Res.      | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. |
|           |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
| 15        | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0    |
| CNT[15:0] |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
| r         | r    | r    | r    | r    | r    | r    | r    | r    | r    | r    | r    | r    | r    | r    | r    |

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **CNT[15:0]**: Counter value

When the LPTIM is running with an asynchronous clock, reading the LPTIM\_CNT register may return unreliable values. So in this case it is necessary to perform two consecutive read accesses and verify that the two returned values are identical.

It should be noted that for a reliable LPTIM\_CNT register read access, two consecutive read accesses must be performed and compared. A read access can be considered reliable when the values of the two consecutive read accesses are equal.

## 26.7.9 LPTIM register map

The following table summarizes the LPTIM registers.

**Table 166. LPTIM register map and reset values**

| Offset | Register name | 31   | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23        | 22      | 21     | 20   | 19     | 18     | 17   | 16   | 15           | 14   | 13   | 12   | 11   | 10   | 9     | 8    | 7      | 6      | 5    | 4      | 3       | 2         | 1       | 0      |
|--------|---------------|------|------|------|------|------|------|------|------|-----------|---------|--------|------|--------|--------|------|------|--------------|------|------|------|------|------|-------|------|--------|--------|------|--------|---------|-----------|---------|--------|

Refer to [Section 2.2.2 on page 69](#) for the register boundary addresses.

## 27 Independent watchdog (IWDG)

### 27.1 Introduction

The devices feature an embedded watchdog peripheral that offers a combination of high safety level, timing accuracy and flexibility of use. The Independent watchdog peripheral detects and solves malfunctions due to software failure, and triggers system reset when the counter reaches a given timeout value.

The independent watchdog (IWDG) is clocked by its own dedicated low-speed clock (LSI) and thus stays active even if the main clock fails.

The IWDG is best suited for applications that require the watchdog to run as a totally independent process outside the main application, but have lower timing accuracy constraints. For further information on the window watchdog, refer to [Section 28 on page 906](#).

### 27.2 IWDG main features

- Free-running downcounter
- Clocked from an independent RC oscillator (can operate in Standby and Stop modes)
- Conditional Reset
  - Reset (if watchdog activated) when the downcounter value becomes lower than 0x000
  - Reset (if watchdog activated) if the downcounter is reloaded outside the window

### 27.3 IWDG functional description

#### 27.3.1 IWDG block diagram

[Figure 298](#) shows the functional blocks of the independent watchdog module.

**Figure 298. Independent watchdog block diagram**

1. The watchdog function is implemented in the  $V_{CORE}$  voltage domain that is still functional in Stop and Standby modes.

When the independent watchdog is started by writing the value 0x0000 CCCC in the [Key register \(IWDG\\_KR\)](#), the counter starts counting down from the reset value of 0xFFFF. When it reaches the end of count value (0x000) a reset signal is generated (IWDG reset).

Whenever the key value 0x0000 AAAA is written in the [Key register \(IWDG\\_KR\)](#), the IWDG\_RLR value is reloaded in the counter and the watchdog reset is prevented.

### 27.3.2 Window option

The IWDG can also work as a window watchdog by setting the appropriate window in the [Window register \(IWDG\\_WINR\)](#).

If the reload operation is performed while the counter is greater than the value stored in the [Window register \(IWDG\\_WINR\)](#), then a reset is provided.

The default value of the [Window register \(IWDG\\_WINR\)](#) is 0x0000 0FFF, so if it is not updated, the window option is disabled.

As soon as the window value is changed, a reload operation is performed in order to reset the downcounter to the [Reload register \(IWDG\\_RLR\)](#) value and ease the cycle number calculation to generate the next reload.

#### Configuring the IWDG when the window option is enabled

1. Enable the IWDG by writing 0x0000 CCCC in the [Key register \(IWDG\\_KR\)](#).
2. Enable register access by writing 0x0000 5555 in the [Key register \(IWDG\\_KR\)](#).
3. Write the IWDG prescaler by programming [Prescaler register \(IWDG\\_PR\)](#) from 0 to 7.
4. Write the [Reload register \(IWDG\\_RLR\)](#).
5. Wait for the registers to be updated (IWDG\_SR = 0x0000 0000).
6. Write to the [Window register \(IWDG\\_WINR\)](#). This automatically refreshes the counter value in the [Reload register \(IWDG\\_RLR\)](#).

*Note:* Writing the window value allows to refresh the Counter value by the RLR when [Status register \(IWDG\\_SR\)](#) is set to 0x0000 0000.

#### Configuring the IWDG when the window option is disabled

When the window option it is not used, the IWDG can be configured as follows:

1. Enable the IWDG by writing 0x0000 CCCC in the [Key register \(IWDG\\_KR\)](#).
2. Enable register access by writing 0x0000 5555 in the [Key register \(IWDG\\_KR\)](#).
3. Write the prescaler by programming the [Prescaler register \(IWDG\\_PR\)](#) from 0 to 7.
4. Write the [Reload register \(IWDG\\_RLR\)](#).
5. Wait for the registers to be updated (IWDG\_SR = 0x0000 0000).
6. Refresh the counter value with IWDG\_RLR (IWDG\_KR = 0x0000 AAAA).

### 27.3.3 Hardware watchdog

If the “Hardware watchdog” feature is enabled through the device option bits, the watchdog is automatically enabled at power-on, and generates a reset unless the [Key register \(IWDG\\_KR\)](#) is written by the software before the counter reaches end of count or if the downcounter is reloaded inside the window.

### 27.3.4 Low-power freeze

Depending on the IWDG\_STOP and IWDG\_STBY options configuration, the IWDG can continue counting or not during the Stop mode and the Standby mode respectively. If the IWDG is kept running during Stop or Standby modes, it can wake up the device from this mode. Refer to [Section : User and read protection option bytes](#)[Section : User and read protection option bytes](#) for more details.

### 27.3.5 Behavior in Stop and Standby modes

Once running, the IWDG cannot be stopped.

### 27.3.6 Register access protection

Write access to [Prescaler register \(IWDG\\_PR\)](#), [Reload register \(IWDG\\_RLR\)](#) and [Window register \(IWDG\\_WINR\)](#) is protected. To modify them, the user must first write the code 0x0000 5555 in the [Key register \(IWDG\\_KR\)](#). A write access to this register with a different value will break the sequence and register access will be protected again. This is the case of the reload operation (writing 0x0000 AAAA).

A status register is available to indicate that an update of the prescaler or the down-counter reload value or the window value is on going.

### 27.3.7 Debug mode

When the microcontroller enters Debug mode (core halted), the IWDG counter either continues to work normally or stops, depending on DBG\_IWDG\_STOP configuration bit in DBG module.

## 27.4 IWDG registers

Refer to [Section 1.2 on page 62](#) for a list of abbreviations used in register descriptions.

The peripheral registers can be accessed by half-words (16-bit) or words (32-bit).

### 27.4.1 Key register (IWDG\_KR)

Address offset: 0x00

Reset value: 0x0000 0000 (reset by Standby mode)

|           |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
|-----------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|
| 31        | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21   | 20   | 19   | 18   | 17   | 16   |
| Res.      | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. |
|           |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
| 15        | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0    |
| KEY[15:0] |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
| w         | w    | w    | w    | w    | w    | w    | w    | w    | w    | w    | w    | w    | w    | w    | w    |

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **KEY[15:0]**: Key value (write only, read 0x0000)

These bits must be written by software at regular intervals with the key value 0xAAAA, otherwise the watchdog generates a reset when the counter reaches 0.

Writing the key value 0x5555 to enable access to the IWDG\_PR, IWDG\_RLR and IWDG\_WINR registers (see [Section 27.3.6: Register access protection](#))

Writing the key value 0xCCCC starts the watchdog (except if the hardware watchdog option is selected)

## 27.4.2 Prescaler register (IWDG\_PR)

Address offset: 0x04

Reset value: 0x0000 0000

|      |      |      |      |      |      |      |      |      |      |      |      |      |         |      |      |
|------|------|------|------|------|------|------|------|------|------|------|------|------|---------|------|------|
| 31   | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21   | 20   | 19   | 18      | 17   | 16   |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res.    | Res. | Res. |
|      |      |      |      |      |      |      |      |      |      |      |      |      |         |      |      |
| 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5    | 4    | 3    | 2       | 1    | 0    |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | PR[2:0] |      |      |
|      |      |      |      |      |      |      |      |      |      |      |      |      | rw      | rw   | rw   |

Bits 31:3 Reserved, must be kept at reset value.

Bits 2:0 **PR[2:0]**: Prescaler divider

These bits are write access protected see [Section 27.3.6: Register access protection](#). They are written by software to select the prescaler divider feeding the counter clock. PVU bit of the [Status register \(IWDG\\_SR\)](#) must be reset in order to be able to change the prescaler divider.

000: divider /4  
 001: divider /8  
 010: divider /16  
 011: divider /32  
 100: divider /64  
 101: divider /128  
 110: divider /256  
 111: divider /256

*Note:* Reading this register returns the prescaler value from the  $V_{DD}$  voltage domain. This value may not be up to date/valid if a write operation to this register is ongoing. For this reason the value read from this register is valid only when the PVU bit in the [Status register \(IWDG\\_SR\)](#) is reset.

### 27.4.3 Reload register (IWDG\_RLR)

Address offset: 0x08

Reset value: 0x0000 0FFF (reset by Standby mode)

|      |      |      |      |          |      |      |      |      |      |      |      |      |      |      |      |
|------|------|------|------|----------|------|------|------|------|------|------|------|------|------|------|------|
| 31   | 30   | 29   | 28   | 27       | 26   | 25   | 24   | 23   | 22   | 21   | 20   | 19   | 18   | 17   | 16   |
| Res. | Res. | Res. | Res. | Res.     | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. |
|      |      |      |      |          |      |      |      |      |      |      |      |      |      |      |      |
| 15   | 14   | 13   | 12   | 11       | 10   | 9    | 8    | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0    |
| Res. | Res. | Res. | Res. | RL[11:0] |      |      |      |      |      |      |      |      |      |      |      |
|      |      |      |      | rW       | rW   | rW   | rW   | rW   | rW   | rW   | rW   | rW   | rW   | rW   | rW   |

Bits 31:12 Reserved, must be kept at reset value.

Bits 11:0 **RL[11:0]**: Watchdog counter reload value

These bits are write access protected see [Register access protection](#). They are written by software to define the value to be loaded in the watchdog counter each time the value 0xAAAA is written in the [Key register \(IWDG\\_KR\)](#). The watchdog counter counts down from this value. The timeout period is a function of this value and the clock prescaler. Refer to the datasheet for the timeout information.

The RVU bit in the [Status register \(IWDG\\_SR\)](#) must be reset to be able to change the reload value.

*Note:* Reading this register returns the reload value from the  $V_{DD}$  voltage domain. This value may not be up to date/valid if a write operation to this register is ongoing on it. For this reason the value read from this register is valid only when the RVU bit in the [Status register \(IWDG\\_SR\)](#) is reset.

## 27.4.4 Status register (IWDG\_SR)

Address offset: 0x0C

Reset value: 0x0000 0000 (not reset by Standby mode)

|      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|
| 31   | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21   | 20   | 19   | 18   | 17   | 16   |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. |
|      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
| 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0    |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | WVU  | RVU  | PVU  |
|      |      |      |      |      |      |      |      |      |      |      |      |      | r    | r    | r    |

Bits 31:3 Reserved, must be kept at reset value.

### Bit 2 **WVU**: Watchdog counter window value update

This bit is set by hardware to indicate that an update of the window value is ongoing. It is reset by hardware when the reload value update operation is completed in the  $V_{DD}$  voltage domain (takes up to five RC 40 kHz cycles).

Window value can be updated only when WVU bit is reset.

This bit is generated only if generic “window” = 1

### Bit 1 **RVU**: Watchdog counter reload value update

This bit is set by hardware to indicate that an update of the reload value is ongoing. It is reset by hardware when the reload value update operation is completed in the  $V_{DD}$  voltage domain (takes up to five RC 40 kHz cycles).

Reload value can be updated only when RVU bit is reset.

### Bit 0 **PVU**: Watchdog prescaler value update

This bit is set by hardware to indicate that an update of the prescaler value is ongoing. It is reset by hardware when the prescaler update operation is completed in the  $V_{DD}$  voltage domain (takes up to five RC 40 kHz cycles).

Prescaler value can be updated only when PVU bit is reset.

**Note:** *If several reload, prescaler, or window values are used by the application, it is mandatory to wait until RVU bit is reset before changing the reload value, to wait until PVU bit is reset before changing the prescaler value, and to wait until WVU bit is reset before changing the window value. However, after updating the prescaler and/or the reload/window value it is not necessary to wait until RVU or PVU or WVU is reset before continuing code execution except in case of low-power mode entry.*

27.4.5 Window register (IWDG\_WINR)

Address offset: 0x10

Reset value: 0x0000 0FFF (reset by Standby mode)

|      |      |      |      |           |      |      |      |      |      |      |      |      |      |      |      |
|------|------|------|------|-----------|------|------|------|------|------|------|------|------|------|------|------|
| 31   | 30   | 29   | 28   | 27        | 26   | 25   | 24   | 23   | 22   | 21   | 20   | 19   | 18   | 17   | 16   |
| Res. | Res. | Res. | Res. | Res.      | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. |
|      |      |      |      |           |      |      |      |      |      |      |      |      |      |      |      |
| 15   | 14   | 13   | 12   | 11        | 10   | 9    | 8    | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0    |
| Res. | Res. | Res. | Res. | WIN[11:0] |      |      |      |      |      |      |      |      |      |      |      |
|      |      |      |      | rw        | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   |

Bits 31:12 Reserved, must be kept at reset value.

Bits 11:0 **WIN[11:0]**: Watchdog counter window value

These bits are write access protected, see [Section 27.3.6](#), they contain the high limit of the window value to be compared with the downcounter.

To prevent a reset, the downcounter must be reloaded when its value is lower than the window register value and greater than 0x0

The WVU bit in the [Status register \(IWDG\\_SR\)](#) must be reset in order to be able to change the reload value.

*Note: Reading this register returns the reload value from the V<sub>DD</sub> voltage domain. This value may not be valid if a write operation to this register is ongoing. For this reason the value read from this register is valid only when the WVU bit in the [Status register \(IWDG\\_SR\)](#) is reset.*

## 27.4.6 IWDG register map

The following table gives the IWDG register map and reset values.

**Table 167. IWDG register map and reset values**

| Offset | Register name | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15        | 14 | 13 | 12 | 11 | 10        | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0       |     |     |  |  |  |
|--------|---------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|-----------|----|----|----|----|-----------|---|---|---|---|---|---|---|---|---|---------|-----|-----|--|--|--|

## 28 System window watchdog (WWDG)

### 28.1 Introduction

The system window watchdog (WWDG) is used to detect the occurrence of a software fault, usually generated by external interference or by unforeseen logical conditions, which causes the application program to abandon its normal sequence. The watchdog circuit generates an MCU reset on expiry of a programmed time period, unless the program refreshes the contents of the downcounter before the T6 bit becomes cleared. An MCU reset is also generated if the 7-bit downcounter value (in the control register) is refreshed before the downcounter has reached the window register value. This implies that the counter must be refreshed in a limited window.

The WWDG clock is prescaled from the APB clock and has a configurable time-window that can be programmed to detect abnormally late or early application behavior.

The WWDG is best suited for applications which require the watchdog to react within an accurate timing window.

### 28.2 WWDG main features

- Programmable free-running downcounter
- Conditional reset
  - Reset (if watchdog activated) when the downcounter value becomes lower than 0x40
  - Reset (if watchdog activated) if the downcounter is reloaded outside the window (see [Figure 300](#))
- Early wakeup interrupt (EWI): triggered (if enabled and the watchdog activated) when the downcounter is equal to 0x40.

### 28.3 WWDG functional description

If the watchdog is activated (the WDGA bit is set in the WWDG\_CR register) and when the 7-bit downcounter (T[6:0] bits) is decremented from 0x40 to 0x3F (T6 becomes cleared), it initiates a reset. If the software reloads the counter while the counter is greater than the value stored in the window register, then a reset is generated.

The application program must write in the WWDG\_CR register at regular intervals during normal operation to prevent an MCU reset. This operation must occur only when the counter value is lower than the window register value and higher than 0x3F. The value to be stored in the WWDG\_CR register must be between 0xFF and 0xC0.

Refer to [Figure 299](#) for the WWDG block diagram.

### 28.3.1 WWDG block diagram

Figure 299. Watchdog block diagram

### 28.3.2 Enabling the watchdog

When the user option WWDG\_SW selects “Software window watchdog”, the watchdog is always disabled after a reset. It is enabled by setting the WDGA bit in the WWDG\_CR register, then it cannot be disabled again except by a reset.

When the user option WWDG\_SW selects “Hardware window watchdog”, the watchdog is always enabled after a reset, it cannot be disabled.

### 28.3.3 Controlling the downcounter

This downcounter is free-running, counting down even if the watchdog is disabled. When the watchdog is enabled, the T6 bit must be set to prevent generating an immediate reset.

The T[5:0] bits contain the number of increments which represents the time delay before the watchdog produces a reset. The timing varies between a minimum and a maximum value due to the unknown status of the prescaler when writing to the WWDG\_CR register (see [Figure 300](#)). The Configuration register (WWDG\_CFR) contains the high limit of the window: To prevent a reset, the downcounter must be reloaded when its value is lower than the window register value and greater than 0x3F. [Figure 300](#) describes the window watchdog process.

**Note:** The T6 bit can be used to generate a software reset (the WDGA bit is set and the T6 bit is cleared).

### 28.3.4 Advanced watchdog interrupt feature

The early wakeup interrupt (EWI) can be used if specific safety operations or data logging must be performed before the actual reset is generated. The EWI interrupt is enabled by setting the EWI bit in the WWDG\_CFR register. When the downcounter reaches the value 0x40, an EWI interrupt is generated and the corresponding interrupt service routine (ISR)

can be used to trigger specific actions (such as communications or data logging), before resetting the device.

In some applications, the EWI interrupt can be used to manage a software system check and/or system recovery/graceful degradation, without generating a WWDG reset. In this case, the corresponding interrupt service routine (ISR) should reload the WWDG counter to avoid the WWDG reset, then trigger the required actions.

The EWI interrupt is cleared by writing '0' to the EWIF bit in the WWDG\_SR register.

**Note:** When the EWI interrupt cannot be served, e.g. due to a system lock in a higher priority task, the WWDG reset is eventually generated.

### 28.3.5 How to program the watchdog timeout

Use the formula in [Figure 300](#) to calculate the WWDG timeout.

---

**Warning:** When writing to the WWDG\_CR register, always write 1 in the T6 bit to avoid generating an immediate reset.

---

**Figure 300. Window watchdog timing diagram**

The formula to calculate the timeout value is given by:

$$t_{\text{WWDG}} = t_{\text{PCLK}} \times 4096 \times 2^{\text{WDGTB}[1:0]} \times (T[5:0] + 1) \quad (\text{ms})$$

where:

$t_{\text{WWDG}}$ : WWDG timeout

$t_{\text{PCLK}}$ : APB clock period measured in ms

4096: value corresponding to internal divider

As an example, let's assume APB frequency is equal to 48 MHz, WDGTB1:0] is set to 3 and T[5:0] is set to 63:

$$t_{\text{WWDG}} = (1 / 48000) \times 4096 \times 2^3 \times (63 + 1) = 43.69\text{ms}$$

Refer to the datasheet for the minimum and maximum values of the  $t_{\text{WWDG}}$ .

### 28.3.6 Debug mode

When the microcontroller enters debug mode (processor halted), the WWDG counter either continues to work normally or stops, depending on the configuration bit in DBG module. For more details refer to [Section 40.16.2: Debug support for timers, watchdog, bxCAN and I2C](#).

## 28.4 WWDG registers

Refer to [Section 1.2 on page 62](#) for a list of abbreviations used in register descriptions.

The peripheral registers can be accessed by half-words (16-bit) or words (32-bit).

### 28.4.1 Control register (WWDG\_CR)

Address offset: 0x000

Reset value: 0x0000 007F

|      |      |      |      |      |      |      |      |      |        |      |      |      |      |      |      |
|------|------|------|------|------|------|------|------|------|--------|------|------|------|------|------|------|
| 31   | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22     | 21   | 20   | 19   | 18   | 17   | 16   |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res.   | Res. | Res. | Res. | Res. | Res. | Res. |
|      |      |      |      |      |      |      |      |      |        |      |      |      |      |      |      |
| 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6      | 5    | 4    | 3    | 2    | 1    | 0    |

|      |      |      |      |      |      |      |      | rs   | rw     | rw   | rw   | rw   | rw   | rw   | rw   |

Bits 31:8 Reserved, must be kept at reset value.

Bit 7 **WDGA**: Activation bit

This bit is set by software and only cleared by hardware after a reset. When WDGA = 1, the watchdog can generate a reset.

0: Watchdog disabled

1: Watchdog enabled

Bits 6:0 **T[6:0]**: 7-bit counter (MSB to LSB)

These bits contain the value of the watchdog counter, decremented every  $(4096 \times 2^{WDGTB1:0})$  PCLK cycles. A reset is produced when it is decremented from 0x40 to 0x3F (T6 becomes cleared).

### 28.4.2 Configuration register (WWDG\_CFR)

Address offset: 0x004

Reset value: 0x0000 007F

|      |      |      |      |      |      |      |            |        |      |      |      |      |      |      |      |
|------|------|------|------|------|------|------|------------|--------|------|------|------|------|------|------|------|

| 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8          | 7      | 6    | 5    | 4    | 3    | 2    | 1    | 0    |
| Res. | Res. | Res. | Res. | Res. | Res. | EWI  | WDGTB[1:0] | W[6:0] |      |      |      |      |      |      |      |
|      |      |      |      |      |      | rs   | rw         | rw     | rw   | rw   | rw   | rw   | rw   | rw   | rw   |

Bits 31:10 Reserved, must be kept at reset value.

Bit 9 **EWI**: Early wakeup interrupt

When set, an interrupt occurs whenever the counter reaches the value 0x40. This interrupt is only cleared by hardware after a reset.

Bits 8:7 **WDGTB[1:0]**: Timer base

The time base of the prescaler can be modified as follows:

00: CK Counter Clock (PCLK div 4096) div 1

01: CK Counter Clock (PCLK div 4096) div 2

10: CK Counter Clock (PCLK div 4096) div 4

11: CK Counter Clock (PCLK div 4096) div 8

Bits 6:0 **W[6:0]**: 7-bit window value

These bits contain the window value to be compared with the downcounter.

### 28.4.3 Status register (WWDG\_SR)

Address offset: 0x008

Reset value: 0x0000 0000

|      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |       |
|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|-------|
| 31   | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21   | 20   | 19   | 18   | 17   | 16    |

|      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |       |
| 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0     |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | EWIF  |
|      |      |      |      |      |      |      |      |      |      |      |      |      |      |      | rc_w0 |

Bits 31:1 Reserved, must be kept at reset value.

Bit 0 **EWIF**: Early wakeup interrupt flag

This bit is set by hardware when the counter has reached the value 0x40. It must be cleared by software by writing '0'. Writing '1' has no effect. This bit is also set if the interrupt is not enabled.

## 28.4.4 WWDG register map

The following table gives the WWDG register map and reset values.

**Table 168. WWDG register map and reset values**

| Offset | Register    | 31   | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21   | 20   | 19   | 18   | 17   | 16   | 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8      | 7      | 6      | 5    | 4    | 3    | 2    | 1    | 0 |  |  |  |

Refer to [Section 2.2.2 on page 69](#) for the register boundary addresses.

## 29 Real-time clock (RTC)

### 29.1 Introduction

The RTC provides an automatic wakeup to manage all low-power modes.

The real-time clock (RTC) is an independent BCD timer/counter. The RTC provides a time-of-day clock/calendar with programmable alarm interrupts.

The RTC includes also a periodic programmable wakeup flag with interrupt capability.

Two 32-bit registers contain the seconds, minutes, hours (12- or 24-hour format), day (day of week), date (day of month), month, and year, expressed in binary coded decimal format (BCD). The sub-seconds value is also available in binary format.

Compensations for 28-, 29- (leap year), 30-, and 31-day months are performed automatically. Daylight saving time compensation can also be performed.

Additional 32-bit registers contain the programmable alarm subseconds, seconds, minutes, hours, day, and date.

A digital calibration feature is available to compensate for any deviation in crystal oscillator accuracy.

After Backup domain reset, all RTC registers are protected against possible parasitic write accesses.

As long as the supply voltage remains in the operating range, the RTC never stops, regardless of the device status (Run mode, low-power mode or under reset).

## 29.2 RTC main features

The RTC unit main features are the following (see [Figure 301: RTC block diagram](#)):

- Calendar with subseconds, seconds, minutes, hours (12 or 24 format), day (day of week), date (day of month), month, and year.
- Daylight saving compensation programmable by software.
- Programmable alarm with interrupt function. The alarm can be triggered by any combination of the calendar fields.
- Automatic wakeup unit generating a periodic flag that triggers an automatic wakeup interrupt.
- Reference clock detection: a more precise second source clock (50 or 60 Hz) can be used to enhance the calendar precision.
- Accurate synchronization with an external clock using the subsecond shift feature.
- Digital calibration circuit (periodic counter correction): 0.95 ppm accuracy, obtained in a calibration window of several seconds
- Time-stamp function for event saving
- Tamper detection event with configurable filter and internal pull-up
- Maskable interrupts/events:
  - Alarm A
  - Alarm B
  - Wakeup interrupt
  - Time-stamp
  - Tamper detection
- 32 backup registers.

## 29.3 RTC functional description

### 29.3.1 RTC block diagram

Figure 301. RTC block diagram

The RTC includes:

- Two alarms
- Three tamper events from I/Os
  - Tamper detection erases the backup registers.
- One timestamp event from I/O
- Tamper event detection can generate a timestamp event
- Timestamp can be generated when a switch to  $V_{BAT}$  occurs
- 32 x 32-bit backup registers
  - The backup registers (RTC\_BKPxR) are implemented in the RTC domain that remains powered-on by VBAT when the VDD power is switched off.
- Output functions: RTC\_OUT which selects one of the following two outputs:
  - RTC\_CALIB: 512 Hz or 1Hz clock output (with an LSE frequency of 32.768 kHz). This output is enabled by setting the COE bit in the RTC\_CR register.
  - RTC\_ALARM: This output is enabled by configuring the OSEL[1:0] bits in the RTC\_CR register which select the Alarm A, Alarm B or Wakeup outputs.
- Input functions:
  - RTC\_TS: timestamp event
  - RTC\_TAMP1: tamper1 event detection
  - RTC\_TAMP2: tamper2 event detection
  - RTC\_TAMP3: tamper3 event detection
  - RTC\_REFIN: 50 or 60 Hz reference clock input

### 29.3.2 GPIOs controlled by the RTC

RTC\_OUT, RTC\_TS and RTC\_TAMP1 are mapped on the same pin (PC13). PC13 pin configuration is controlled by the RTC, whatever the PC13 GPIO configuration, except for the RTC\_ALARM output open-drain mode. The RTC functions mapped on PC13 are available in all low-power modes and in VBAT mode.

The output mechanism follows the priority order shown in [Table 169](#).

**Table 169. RTC pin PC13 configuration<sup>(1)</sup>**

| PC13 Pin configuration and function | OSEL[1:0] bits (RTC_ALARM output enable) | COE bit (RTC_CALIB output enable) | RTC_ALARM_TYPE bit | TAMP1E bit (RTC_TAMP1 input enable) | TSE bit (RTC_TS input enable) | TSINSEL bits |
|-------------------------------------|------------------------------------------|-----------------------------------|--------------------|-------------------------------------|-------------------------------|--------------|
| RTC_ALARM output OD                 | 01 or 10 or 11                           | Don't care                        | 0                  | Don't care                          | Don't care                    | Don't care   |
| RTC_ALARM output PP                 | 01 or 10 or 11                           | Don't care                        | 1                  | Don't care                          | Don't care                    | Don't care   |
| RTC_CALIB output PP                 | 00                                       | 1                                 | Don't care         | Don't care                          | Don't care                    | Don't care   |

Table 169. RTC pin PC13 configuration<sup>(1)</sup> (continued)

| PC13 Pin configuration and function | OSEL[1:0] bits (RTC_ALARM output enable) | COE bit (RTC_CALIB output enable) | RTC_ALARM_TYPE bit | TAMP1E bit (RTC_TAMP1 input enable) | TSE bit (RTC_TS input enable) | TSINSEL bits |
|-------------------------------------|------------------------------------------|-----------------------------------|--------------------|-------------------------------------|-------------------------------|--------------|
| RTC_TAMP1 input floating            | 00                                       | 0                                 | Don't care         | 1                                   | 0                             | Don't care   |
|                                     | 00                                       | 1                                 |                    |                                     |                               |              |
|                                     | 01 or 10 or 11                           | 0                                 |                    |                                     |                               |              |
| RTC_TS and RTC_TAMP1 input floating | 00                                       | 0                                 | Don't care         | 1                                   | 1                             | 00           |
|                                     | 00                                       | 1                                 |                    |                                     |                               |              |
|                                     | 01 or 10 or 11                           | 0                                 |                    |                                     |                               |              |
| RTC_TS input floating               | 00                                       | 0                                 | Don't care         | 0                                   | 1                             | 00           |
|                                     | 00                                       | 1                                 |                    |                                     |                               |              |
|                                     | 01 or 10 or 11                           | 0                                 |                    |                                     |                               |              |
| Wakeup pin or Standard GPIO         | 00                                       | 0                                 | Don't care         | 0                                   | 0                             | Don't care   |

1. OD: open drain; PP: push-pull.

RTC\_TAMP2 and RTC\_TS are mapped on the same pin (PI8). PI8 configuration is controlled by the RTC, whatever the PI8 GPIO configuration. The RTC functions mapped on PI8 are available in all low-power modes and in VBAT mode.

The output mechanism follows the priority order shown in [Table 170](#).

Table 170. RTC pin PI8 configuration

| PI8 pin configuration and function  | TAMP2E bit (RTC_TAMP2 input enable) | TSE bit (RTC_TS input enable) | TSINSEL bit (Timestamp pin selection) |
|-------------------------------------|-------------------------------------|-------------------------------|---------------------------------------|
| RTC_TAMP2 input floating            | 1                                   | 0                             | Don't care                            |
| RTC_TS and RTC_TAMP2 input floating | 1                                   | 1                             | 01                                    |
| RTC_TS input floating               | 0                                   | 1                             | 01                                    |
| Wakeup pin or Standard GPIO         | 0                                   | 0                             | Don't care                            |

RTC\_TAMP3 and RTC\_TS are mapped on the same pin (PC1). PC1 configuration is controlled by the RTC, whatever the PC1 GPIO configuration. The RTC functions mapped on PC1 are available in all low-power modes, but are not available in VBAT mode.

Table 171. RTC pin PC2 configuration

| PC2 pin configuration and function  | TAMP2E bit<br>(RTC_TAMP3 input enable) | TSE bit<br>(RTC_TS input enable) | TSINSEL bit<br>(Timestamp pin selection) |
|-------------------------------------|----------------------------------------|----------------------------------|------------------------------------------|
| RTC_TAMP3 input floating            | 1                                      | 0                                | Don't care                               |
| RTC_TS and RTC_TAMP3 input floating | 1                                      | 1                                | 10 or 11                                 |
| RTC_TS input floating               | 0                                      | 1                                | 01                                       |
| Wakeup pin or Standard GPIO         | 0                                      | 0                                | Don't care                               |

RTC\_REFIN is mapped on PB15. PB15 must be configured in alternate function mode to allow RTC\_REFIN function. RTC\_REFIN is not available in VBAT and in Standby mode.

The table below summarizes the RTC pins and functions capabilities in all modes.

Table 172. RTC functions over modes

| Pin  | RTC functions                  | Functional in all low-power modes except Standby modes | Functional in Standby mode | Functional in VBAT mode |
|------|--------------------------------|--------------------------------------------------------|----------------------------|-------------------------|
| PC13 | RTC_TAMP1<br>RTC_TS<br>RTC_OUT | YES                                                    | YES                        | YES                     |
| PI8  | RTC_TAMP2<br>RTC_TS            | YES                                                    | YES                        | YES                     |
| PC1  | RTC_TAMP3<br>RTC_TS            | YES                                                    | YES                        | NO                      |
| PB15 | RTC_REFIN                      | YES                                                    | NO                         | NO                      |

### 29.3.3 Clock and prescalers

The RTC clock source (RTCCLK) is selected through the clock controller among the LSE clock, the LSI oscillator clock, and the HSE clock. For more information on the RTC clock source configuration, refer to [Section 5: Reset and clock control \(RCC\)](#).

A programmable prescaler stage generates a 1 Hz clock which is used to update the calendar. To minimize power consumption, the prescaler is split into 2 programmable prescalers (see [Figure 301: RTC block diagram](#)):

- A 7-bit asynchronous prescaler configured through the PREDIV\_A bits of the RTC\_PRER register.
- A 15-bit synchronous prescaler configured through the PREDIV\_S bits of the RTC\_PRER register.

**Note:** When both prescalers are used, it is recommended to configure the asynchronous prescaler to a high value to minimize consumption.

The asynchronous prescaler division factor is set to 128, and the synchronous division factor to 256, to obtain an internal clock frequency of 1 Hz (ck\_spre) with an LSE frequency of 32.768 kHz.

The minimum division factor is 1 and the maximum division factor is  $2^{22}$ .

This corresponds to a maximum input frequency of around 4 MHz.

$f_{ck\_apre}$  is given by the following formula:

$$f_{CK\_APRE} = \frac{f_{RTCCLK}}{PREDIV\_A + 1}$$

The ck\_apre clock is used to clock the binary RTC\_SSR subseconds downcounter. When it reaches 0, RTC\_SSR is reloaded with the content of PREDIV\_S.

$f_{ck\_spre}$  is given by the following formula:

$$f_{CK\_SPRE} = \frac{f_{RTCCLK}}{(PREDIV\_S + 1) \times (PREDIV\_A + 1)}$$

The ck\_spre clock can be used either to update the calendar or as timebase for the 16-bit wakeup auto-reload timer. To obtain short timeout periods, the 16-bit wakeup auto-reload timer can also run with the RTCCLK divided by the programmable 4-bit asynchronous prescaler (see [Section 29.3.6: Periodic auto-wakeup](#) for details).

### 29.3.4 Real-time clock and calendar

The RTC calendar time and date registers are accessed through shadow registers which are synchronized with PCLK (APB clock). They can also be accessed directly in order to avoid waiting for the synchronization duration.

- RTC\_SSR for the subseconds
- RTC\_TR for the time
- RTC\_DR for the date

Every RTCCLK period, the current calendar value is copied into the shadow registers, and the RSF bit of RTC\_ISR register is set (see [Section 29.6.4: RTC initialization and status register \(RTC\\_ISR\)](#)). The copy is not performed in Stop and Standby mode. When exiting these modes, the shadow registers are updated after up to 1 RTCCLK period.

When the application reads the calendar registers, it accesses the content of the shadow registers. It is possible to make a direct access to the calendar registers by setting the BYPSHAD control bit in the RTC\_CR register. By default, this bit is cleared, and the user accesses the shadow registers.

When reading the RTC\_SSR, RTC\_TR or RTC\_DR registers in BYPSHAD=0 mode, the frequency of the APB clock ( $f_{APB}$ ) must be at least 7 times the frequency of the RTC clock ( $f_{RTCCLK}$ ).

The shadow registers are reset by system reset.

### 29.3.5 Programmable alarms

The RTC unit provides programmable alarm: Alarm A and Alarm B. The description below is given for Alarm A, but can be translated in the same way for Alarm B.

The programmable alarm function is enabled through the ALRAE bit in the RTC\_CR register. The ALRAF is set to 1 if the calendar subseconds, seconds, minutes, hours, date or day match the values programmed in the alarm registers RTC\_ALRMASSR and RTC\_ALRMAR. Each calendar field can be independently selected through the MSKx bits of the RTC\_ALRMAR register, and through the MASKSSx bits of the RTC\_ALRMASSR register. The alarm interrupt is enabled through the ALRAIE bit in the RTC\_CR register.

**Caution:** If the seconds field is selected (MSK1 bit reset in RTC\_ALRMAR), the synchronous prescaler division factor set in the RTC\_PRER register must be at least 3 to ensure correct behavior.

Alarm A and Alarm B (if enabled by bits OSEL[1:0] in RTC\_CR register) can be routed to the RTC\_ALARM output. RTC\_ALARM output polarity can be configured through bit POL the RTC\_CR register.

### 29.3.6 Periodic auto-wakeup

The periodic wakeup flag is generated by a 16-bit programmable auto-reload down-counter. The wakeup timer range can be extended to 17 bits.

The wakeup function is enabled through the WUTE bit in the RTC\_CR register.

The wakeup timer clock input can be:

- RTC clock (RTCCLK) divided by 2, 4, 8, or 16.  
When RTCCLK is LSE(32.768kHz), this allows to configure the wakeup interrupt period from 122  $\mu$ s to 32 s, with a resolution down to 61  $\mu$ s.
- ck\_spre (usually 1 Hz internal clock)  
When ck\_spre frequency is 1Hz, this allows to achieve a wakeup time from 1 s to around 36 hours with one-second resolution. This large programmable time range is divided in 2 parts:
  - from 1s to 18 hours when WUCKSEL [2:1] = 10
  - and from around 18h to 36h when WUCKSEL[2:1] = 11. In this last case  $2^{16}$  is added to the 16-bit counter current value. When the initialization sequence is complete (see [Programming the wakeup timer on page 922](#)), the timer starts counting down. When the wakeup function is enabled, the down-counting remains active in low-power modes. In addition, when it reaches 0, the WUTF flag is set in the RTC\_ISR register, and the wakeup counter is automatically reloaded with its reload value (RTC\_WUTR register value).

The WUTF flag must then be cleared by software.

When the periodic wakeup interrupt is enabled by setting the WUTIE bit in the RTC\_CR register, it can exit the device from low-power modes.

The periodic wakeup flag can be routed to the RTC\_ALARM output provided it has been enabled through bits OSEL[1:0] of RTC\_CR register. RTC\_ALARM output polarity can be configured through the POL bit in the RTC\_CR register.

System reset, as well as low-power modes (Sleep, Stop and Standby) have no influence on the wakeup timer.

## 29.3.7 RTC initialization and configuration

### RTC register access

The RTC registers are 32-bit registers. The APB interface introduces 2 wait-states in RTC register accesses except on read accesses to calendar shadow registers when BYPSHAD=0.

### RTC register write protection

After system reset, the RTC registers are protected against parasitic write access by clearing the DBP bit in the PWR\_CR1 register (refer to the power control section). DBP bit must be set in order to enable RTC registers write access.

After Backup domain reset, all the RTC registers are write-protected. Writing to the RTC registers is enabled by writing a key into the Write Protection register, RTC\_WPR.

The following steps are required to unlock the write protection on all the RTC registers except for RTC\_TAMPCR, RTC\_BKPxR, RTC\_OR and RTC\_ISR[13:8].

1. Write '0xCA' into the RTC\_WPR register.
2. Write '0x53' into the RTC\_WPR register.

Writing a wrong key reactivates the write protection.

The protection mechanism is not affected by system reset.

### Calendar initialization and configuration

To program the initial time and date calendar values, including the time format and the prescaler configuration, the following sequence is required:

1. Set INIT bit to 1 in the RTC\_ISR register to enter initialization mode. In this mode, the calendar counter is stopped and its value can be updated.
2. Poll INITF bit of in the RTC\_ISR register. The initialization phase mode is entered when INITF is set to 1. It takes around 2 RTCCLK clock cycles (due to clock synchronization).
3. To generate a 1 Hz clock for the calendar counter, program both the prescaler factors in RTC\_PRER register.
4. Load the initial time and date values in the shadow registers (RTC\_TR and RTC\_DR), and configure the time format (12 or 24 hours) through the FMT bit in the RTC\_CR register.
5. Exit the initialization mode by clearing the INIT bit. The actual calendar counter value is then automatically loaded and the counting restarts after 4 RTCCLK clock cycles.

When the initialization sequence is complete, the calendar starts counting.

*Note:*

*After a system reset, the application can read the INITS flag in the RTC\_ISR register to check if the calendar has been initialized or not. If this flag equals 0, the calendar has not been initialized since the year field is set at its Backup domain reset default value (0x00).*

*To read the calendar after initialization, the software must first check that the RSF flag is set in the RTC\_ISR register.*

### Daylight saving time

The daylight saving time management is performed through bits SUB1H, ADD1H, and BKP of the RTC\_CR register.

Using SUB1H or ADD1H, the software can subtract or add one hour to the calendar in one single operation without going through the initialization procedure.

In addition, the software can use the BKP bit to memorize this operation.

### Programming the alarm

A similar procedure must be followed to program or update the programmable alarms. The procedure below is given for Alarm A but can be translated in the same way for Alarm B.

1. Clear ALRAE in RTC\_CR to disable Alarm A.
2. Program the Alarm A registers (RTC\_ALRMASSR/RTC\_ALRMAR).
3. Set ALRAE in the RTC\_CR register to enable Alarm A again.

*Note:* Each change of the RTC\_CR register is taken into account after around 2 RTCCLK clock cycles due to clock synchronization.

### Programming the wakeup timer

The following sequence is required to configure or change the wakeup timer auto-reload value (WUT[15:0] in RTC\_WUTR):

1. Clear WUTE in RTC\_CR to disable the wakeup timer.
2. Poll WUTWF until it is set in RTC\_ISR to make sure the access to wakeup auto-reload counter and to WUCKSEL[2:0] bits is allowed. It takes around 2 RTCCLK clock cycles (due to clock synchronization).
3. Program the wakeup auto-reload value WUT[15:0], and the wakeup clock selection (WUCKSEL[2:0] bits in RTC\_CR). Set WUTE in RTC\_CR to enable the timer again. The wakeup timer restarts down-counting. The WUTWF bit is cleared up to 2 RTCCLK clock cycles after WUTE is cleared, due to clock synchronization.

## 29.3.8 Reading the calendar

### When BYPSHAD control bit is cleared in the RTC\_CR register

To read the RTC calendar registers (RTC\_SSR, RTC\_TR and RTC\_DR) properly, the APB clock frequency ( $f_{PCLK}$ ) must be equal to or greater than seven times the RTC clock frequency ( $f_{RTCCLK}$ ). This ensures a secure behavior of the synchronization mechanism.

If the APB clock frequency is less than seven times the RTC clock frequency, the software must read the calendar time and date registers twice. If the second read of the RTC\_TR gives the same result as the first read, this ensures that the data is correct. Otherwise a third read access must be done. In any case the APB clock frequency must never be lower than the RTC clock frequency.

The RSF bit is set in RTC\_ISR register each time the calendar registers are copied into the RTC\_SSR, RTC\_TR and RTC\_DR shadow registers. The copy is performed every RTCCLK cycles. To ensure consistency between the 3 values, reading either RTC\_SSR or RTC\_TR locks the values in the higher-order calendar shadow registers until RTC\_DR is read. In case the software makes read accesses to the calendar in a time interval smaller than 2 RTCCLK periods: RSF must be cleared by software after the first calendar read, and

then the software must wait until RSF is set before reading again the RTC\_SSR, RTC\_TR and RTC\_DR registers.

After waking up from low-power mode (Stop or Standby), RSF must be cleared by software. The software must then wait until it is set again before reading the RTC\_SSR, RTC\_TR and RTC\_DR registers.

The RSF bit must be cleared after wakeup and not before entering low-power mode.

After a system reset, the software must wait until RSF is set before reading the RTC\_SSR, RTC\_TR and RTC\_DR registers. Indeed, a system reset resets the shadow registers to their default values.

After an initialization (refer to [Calendar initialization and configuration on page 921](#)): the software must wait until RSF is set before reading the RTC\_SSR, RTC\_TR and RTC\_DR registers.

After synchronization (refer to [Section 29.3.10: RTC synchronization](#)): the software must wait until RSF is set before reading the RTC\_SSR, RTC\_TR and RTC\_DR registers.

### When the BYPSHAD control bit is set in the RTC\_CR register (bypass shadow registers)

Reading the calendar registers gives the values from the calendar counters directly, thus eliminating the need to wait for the RSF bit to be set. This is especially useful after exiting from low-power modes (STOP or Standby), since the shadow registers are not updated during these modes.

When the BYPSHAD bit is set to 1, the results of the different registers might not be coherent with each other if an RTCCLK edge occurs between two read accesses to the registers. Additionally, the value of one of the registers may be incorrect if an RTCCLK edge occurs during the read operation. The software must read all the registers twice, and then compare the results to confirm that the data is coherent and correct. Alternatively, the software can just compare the two results of the least-significant calendar register.

*Note:* While BYPSHAD=1, instructions which read the calendar registers require one extra APB cycle to complete.

## 29.3.9 Resetting the RTC

The calendar shadow registers (RTC\_SSR, RTC\_TR and RTC\_DR) and some bits of the RTC status register (RTC\_ISR) are reset to their default values by all available system reset sources.

On the contrary, the following registers are reset to their default values by a Backup domain reset and are not affected by a system reset: the RTC current calendar registers, the RTC control register (RTC\_CR), the prescaler register (RTC\_PRER), the RTC calibration register (RTC\_CALR), the RTC shift register (RTC\_SHIFTR), the RTC timestamp registers (RTC\_TSSSR, RTC\_TSTR and RTC\_TSDR), the RTC tamper configuration register (RTC\_TAMPCR), the RTC backup registers (RTC\_BKPxR), the wakeup timer register (RTC\_WUTR), the Alarm A and Alarm B registers (RTC\_ALRMASSR/RTC\_ALRMAR and RTC\_ALRMBSSR/RTC\_ALRMBR), and the Option register (RTC\_OR).

In addition, when it is clocked by the LSE, the RTC keeps on running under system reset if the reset source is different from the Backup domain reset one (refer to the RTC clock section of the Reset and clock controller for details on the list of RTC clock sources not

affected by system reset). When a Backup domain reset occurs, the RTC is stopped and all the RTC registers are set to their reset values.

### 29.3.10 RTC synchronization

The RTC can be synchronized to a remote clock with a high degree of precision. After reading the sub-second field (RTC\_SSR or RTC\_TSSSR), a calculation can be made of the precise offset between the times being maintained by the remote clock and the RTC. The RTC can then be adjusted to eliminate this offset by “shifting” its clock by a fraction of a second using RTC\_SHIFTR.

RTC\_SSR contains the value of the synchronous prescaler counter. This allows one to calculate the exact time being maintained by the RTC down to a resolution of  $1 / (\text{PREDIV\_S} + 1)$  seconds. As a consequence, the resolution can be improved by increasing the synchronous prescaler value (PREDIV\_S[14:0]). The maximum resolution allowed (30.52  $\mu$ s with a 32768 Hz clock) is obtained with PREDIV\_S set to 0x7FFF.

However, increasing PREDIV\_S means that PREDIV\_A must be decreased in order to maintain the synchronous prescaler output at 1 Hz. In this way, the frequency of the asynchronous prescaler output increases, which may increase the RTC dynamic consumption.

The RTC can be finely adjusted using the RTC shift control register (RTC\_SHIFTR). Writing to RTC\_SHIFTR can shift (either delay or advance) the clock by up to a second with a resolution of  $1 / (\text{PREDIV\_S} + 1)$  seconds. The shift operation consists of adding the SUBFS[14:0] value to the synchronous prescaler counter SS[15:0]: this will delay the clock. If at the same time the ADD1S bit is set, this results in adding one second and at the same time subtracting a fraction of second, so this will advance the clock.

**Caution:** Before initiating a shift operation, the user must check that SS[15] = 0 in order to ensure that no overflow will occur.

As soon as a shift operation is initiated by a write to the RTC\_SHIFTR register, the SHPF flag is set by hardware to indicate that a shift operation is pending. This bit is cleared by hardware as soon as the shift operation has completed.

**Caution:** This synchronization feature is not compatible with the reference clock detection feature: firmware must not write to RTC\_SHIFTR when REFCKON=1.

### 29.3.11 RTC reference clock detection

The update of the RTC calendar can be synchronized to a reference clock, RTC\_REFIN, which is usually the mains frequency (50 or 60 Hz). The precision of the RTC\_REFIN reference clock should be higher than the 32.768 kHz LSE clock. When the RTC\_REFIN detection is enabled (REFCKON bit of RTC\_CR set to 1), the calendar is still clocked by the LSE, and RTC\_REFIN is used to compensate for the imprecision of the calendar update frequency (1 Hz).

Each 1 Hz clock edge is compared to the nearest RTC\_REFIN clock edge (if one is found within a given time window). In most cases, the two clock edges are properly aligned. When the 1 Hz clock becomes misaligned due to the imprecision of the LSE clock, the RTC shifts the 1 Hz clock a bit so that future 1 Hz clock edges are aligned. Thanks to this mechanism, the calendar becomes as precise as the reference clock.

The RTC detects if the reference clock source is present by using the 256 Hz clock (ck\_apre) generated from the 32.768 kHz quartz. The detection is performed during a time

window around each of the calendar updates (every 1 s). The window equals 7 ck\_apre periods when detecting the first reference clock edge. A smaller window of 3 ck\_apre periods is used for subsequent calendar updates.

Each time the reference clock is detected in the window, the synchronous prescaler which outputs the ck\_spre clock is forced to reload. This has no effect when the reference clock and the 1 Hz clock are aligned because the prescaler is being reloaded at the same moment. When the clocks are not aligned, the reload shifts future 1 Hz clock edges a little for them to be aligned with the reference clock.

If the reference clock halts (no reference clock edge occurred during the 3 ck\_apre window), the calendar is updated continuously based solely on the LSE clock. The RTC then waits for the reference clock using a large 7 ck\_apre period detection window centered on the ck\_spre edge.

When the RTC\_REFIN detection is enabled, PREDIV\_A and PREDIV\_S must be set to their default values:

- PREDIV\_A = 0x007F
- PREDIV\_S = 0x00FF

*Note:* RTC\_REFIN clock detection is not available in Standby mode.

### 29.3.12 RTC smooth digital calibration

The RTC frequency can be digitally calibrated with a resolution of about 0.954 ppm with a range from -487.1 ppm to +488.5 ppm. The correction of the frequency is performed using series of small adjustments (adding and/or subtracting individual RTCCLK pulses). These adjustments are fairly well distributed so that the RTC is well calibrated even when observed over short durations of time.

The smooth digital calibration is performed during a cycle of about  $2^{20}$  RTCCLK pulses, or 32 seconds when the input frequency is 32768 Hz. This cycle is maintained by a 20-bit counter, cal\_cnt[19:0], clocked by RTCCLK.

The smooth calibration register (RTC\_CALR) specifies the number of RTCCLK clock cycles to be masked during the 32-second cycle:

- Setting the bit CALM[0] to 1 causes exactly one pulse to be masked during the 32-second cycle.
- Setting CALM[1] to 1 causes two additional cycles to be masked
- Setting CALM[2] to 1 causes four additional cycles to be masked
- and so on up to CALM[8] set to 1 which causes 256 clocks to be masked.

*Note:* CALM[8:0] (RTC\_CALR) specifies the number of RTCCLK pulses to be masked during the 32-second cycle. Setting the bit CALM[0] to '1' causes exactly one pulse to be masked during the 32-second cycle at the moment when cal\_cnt[19:0] is 0x80000; CALM[1]=1 causes two other cycles to be masked (when cal\_cnt is 0x40000 and 0xC0000); CALM[2]=1 causes four other cycles to be masked (cal\_cnt = 0x20000/0x60000/0xA0000/ 0xE0000); and so on up to CALM[8]=1 which causes 256 clocks to be masked (cal\_cnt = 0xFFFF0).

While CALM allows the RTC frequency to be reduced by up to 487.1 ppm with fine resolution, the bit CALP can be used to increase the frequency by 488.5 ppm. Setting CALP to '1' effectively inserts an extra RTCCLK pulse every  $2^{11}$  RTCCLK cycles, which means that 512 clocks are added during every 32-second cycle.

Using CALM together with CALP, an offset ranging from -511 to +512 RTCCLK cycles can be added during the 32-second cycle, which translates to a calibration range of -487.1 ppm to +488.5 ppm with a resolution of about 0.954 ppm.

The formula to calculate the effective calibrated frequency ( $F_{CAL}$ ) given the input frequency ( $F_{RTCCLK}$ ) is as follows:

$$F_{CAL} = F_{RTCCLK} \times [1 + (CALP \times 512 - CALM) / (2^{20} + CALM - CALP \times 512)]$$

### Calibration when $PREDIV\_A < 3$

The CALP bit can not be set to 1 when the asynchronous prescaler value ( $PREDIV\_A$  bits in  $RTC\_PRER$  register) is less than 3. If CALP was already set to 1 and  $PREDIV\_A$  bits are set to a value less than 3, CALP is ignored and the calibration operates as if CALP was equal to 0.

To perform a calibration with  $PREDIV\_A$  less than 3, the synchronous prescaler value ( $PREDIV\_S$ ) should be reduced so that each second is accelerated by 8 RTCCLK clock cycles, which is equivalent to adding 256 clock cycles every 32 seconds. As a result, between 255 and 256 clock pulses (corresponding to a calibration range from 243.3 to 244.1 ppm) can effectively be added during each 32-second cycle using only the CALM bits.

With a nominal RTCCLK frequency of 32768 Hz, when  $PREDIV\_A$  equals 1 (division factor of 2),  $PREDIV\_S$  should be set to 16379 rather than 16383 (4 less). The only other interesting case is when  $PREDIV\_A$  equals 0,  $PREDIV\_S$  should be set to 32759 rather than 32767 (8 less).

If  $PREDIV\_S$  is reduced in this way, the formula given the effective frequency of the calibrated input clock is as follows:

$$F_{CAL} = F_{RTCCLK} \times [1 + (256 - CALM) / (2^{20} + CALM - 256)]$$

In this case,  $CALM[7:0]$  equals 0x100 (the midpoint of the CALM range) is the correct setting if RTCCLK is exactly 32768.00 Hz.

### Verifying the RTC calibration

RTC precision is ensured by measuring the precise frequency of RTCCLK and calculating the correct CALM value and CALP values. An optional 1 Hz output is provided to allow applications to measure and verify the RTC precision.

Measuring the precise frequency of the RTC over a limited interval can result in a measurement error of up to 2 RTCCLK clock cycles over the measurement period, depending on how the digital calibration cycle is aligned with the measurement period.

However, this measurement error can be eliminated if the measurement period is the same length as the calibration cycle period. In this case, the only error observed is the error due to the resolution of the digital calibration.

- By default, the calibration cycle period is 32 seconds.

Using this mode and measuring the accuracy of the 1 Hz output over exactly 32 seconds guarantees that the measure is within 0.477 ppm (0.5 RTCCLK cycles over 32 seconds, due to the limitation of the calibration resolution).

- $CALW16$  bit of the  $RTC\_CALR$  register can be set to 1 to force a 16- second calibration cycle period.

In this case, the RTC precision can be measured during 16 seconds with a maximum error of 0.954 ppm (0.5 RTCCLK cycles over 16 seconds). However, since the calibration

resolution is reduced, the long term RTC precision is also reduced to 0.954 ppm: CALM[0] bit is stuck at 0 when CALW16 is set to 1.

- CALW8 bit of the RTC\_CALR register can be set to 1 to force a 8- second calibration cycle period.

In this case, the RTC precision can be measured during 8 seconds with a maximum error of 1.907 ppm (0.5 RTCCLK cycles over 8s). The long term RTC precision is also reduced to 1.907 ppm: CALM[1:0] bits are stuck at 00 when CALW8 is set to 1.

### Re-calibration on-the-fly

The calibration register (RTC\_CALR) can be updated on-the-fly while RTC\_ISR/INITF=0, by using the follow process:

1. Poll the RTC\_ISR/RECALPF (re-calibration pending flag).
2. If it is set to 0, write a new value to RTC\_CALR, if necessary. RECALPF is then automatically set to 1
3. Within three ck\_apre cycles after the write operation to RTC\_CALR, the new calibration settings take effect.

## 29.3.13 Time-stamp function

Time-stamp is enabled by setting the TSE or ITSE bits of RTC\_CR register to 1.

When TSE is set:

The calendar is saved in the time-stamp registers (RTC\_TSSSR, RTC\_TSTR, RTC\_TSDR) when a time-stamp event is detected on the RTC\_TS pin.

When ITSE is set:

The calendar is saved in the time-stamp registers (RTC\_TSSSR, RTC\_TSTR, RTC\_TSDR) when an internal time-stamp event is detected. The internal timestamp event is generated by the switch to the VBAT supply.

When a time-stamp event occurs, due to internal or external event, the time-stamp flag bit (TSF) in RTC\_ISR register is set. In case the event is internal, the ITSF flag is also set in RTC\_ISR register.

By setting the TSIE bit in the RTC\_CR register, an interrupt is generated when a time-stamp event occurs.

If a new time-stamp event is detected while the time-stamp flag (TSF) is already set, the time-stamp overflow flag (TSOVF) flag is set and the time-stamp registers (RTC\_TSTR and RTC\_TSDR) maintain the results of the previous event.

**Note:** *TSF is set 2 ck\_apre cycles after the time-stamp event occurs due to synchronization process.*

*There is no delay in the setting of TSOVF. This means that if two time-stamp events are close together, TSOVF can be seen as '1' while TSF is still '0'. As a consequence, it is recommended to poll TSOVF only after TSF has been set.*

**Caution:** If a time-stamp event occurs immediately after the TSF bit is supposed to be cleared, then both TSF and TSOVF bits are set. To avoid masking a time-stamp event occurring at the same moment, the application must not write '0' into TSF bit unless it has already read it to '1'.

Optionally, a tamper event can cause a time-stamp to be recorded. See the description of the TAMPTS control bit in [Section 29.6.16: RTC tamper configuration register \(RTC\\_TAMPCR\)](#).

### 29.3.14 Tamper detection

The RTC\_TAMPx input events can be configured either for edge detection, or for level detection with filtering.

The tamper detection can be configured for the following purposes:

- erase the RTC backup registers (default configuration)
- generate an interrupt, capable to wakeup from Stop and Standby modes
- generate a hardware trigger for the low-power timers

#### RTC backup registers

The backup registers (RTC\_BKPxR) are not reset by system reset or when the device wakes up from Standby mode.

The backup registers are reset when a tamper detection event occurs (see [Section 29.6.20: RTC backup registers \(RTC\\_BKPxR\)](#) and [Tamper detection initialization on page 928](#)) except if the TAMPxNOERASE bit is set, or if TAMPxMF is set in the RTC\_TAMPCR register.

#### Tamper detection initialization

Each input can be enabled by setting the corresponding TAMPxE bits to 1 in the RTC\_TAMPCR register.

Each RTC\_TAMPx tamper detection input is associated with a flag TAMPxF in the RTC\_ISR register.

When TAMPxMF is cleared:

The TAMPxF flag is asserted after the tamper event on the pin, with the latency provided below:

- 3 ck\_apre cycles when TAMPFLT differs from 0x0 (Level detection with filtering)
- 3 ck\_apre cycles when TAMPTS=1 (Timestamp on tamper event)
- No latency when TAMPFLT=0x0 (Edge detection) and TAMPTS=0

A new tamper occurring on the same pin during this period and as long as TAMPxF is set cannot be detected.

When TAMPxMF is set:

A new tamper occurring on the same pin cannot be detected during the latency described above and 2.5 ck\_rtc additional cycles.

By setting the TAMPIE bit in the RTC\_TAMPCR register, an interrupt is generated when a tamper detection event occurs (when TAMPxF is set). Setting TAMPIE is not allowed when one or more TAMPxMF is set.

When TAMPIE is cleared, each tamper pin event interrupt can be individually enabled by setting the corresponding TAMPxIE bit in the RTC\_TAMPCR register. Setting TAMPxIE is not allowed when the corresponding TAMPxMF is set.

### Trigger output generation on tamper event

The tamper event detection can be used as trigger input by the low-power timers.

When TAMPxMF bit is cleared in RTC\_TAMPCR register, the TAMPxF flag must be cleared by software in order to allow a new tamper detection on the same pin.

When TAMPxMF bit is set, the TAMPxF flag is masked, and kept cleared in RTC\_ISR register. This configuration allows to trigger automatically the low-power timers in Stop mode, without requiring the system wakeup to perform the TAMPxF clearing. In this case, the backup registers are not cleared.

### Timestamp on tamper event

With TAMPTS set to '1', any tamper event causes a timestamp to occur. In this case, either the TSF bit or the TSOVF bit are set in RTC\_ISR, in the same manner as if a normal timestamp event occurs. The affected tamper flag register TAMPxF is set at the same time that TSF or TSOVF is set.

### Edge detection on tamper inputs

If the TAMPFLT bits are "00", the RTC\_TAMPx pins generate tamper detection events when either a rising edge or a falling edge is observed depending on the corresponding TAMPxTRG bit. The internal pull-up resistors on the RTC\_TAMPx inputs are deactivated when edge detection is selected.

**Caution:** When using the edge detection, it is recommended to check by software the tamper pin level just after enabling the tamper detection (by reading the GPIO registers), and before writing sensitive values in the backup registers, to ensure that an active edge did not occur before enabling the tamper event detection.  
When TAMPFLT="00" and TAMPxTRG = 0 (rising edge detection), a tamper event may be detected by hardware if the tamper input is already at high level before enabling the tamper detection.

After a tamper event has been detected and cleared, the RTC\_TAMPx should be disabled and then re-enabled (TAMPxE set to 1) before re-programming the backup registers (RTC\_BKPxR). This prevents the application from writing to the backup registers while the RTC\_TAMPx input value still indicates a tamper detection. This is equivalent to a level detection on the RTC\_TAMPx input.

**Note:** *Tamper detection is still active when  $V_{DD}$  power is switched off. To avoid unwanted resetting of the backup registers, the pin to which the RTC\_TAMPx is mapped should be externally tied to the correct level.*

### Level detection with filtering on RTC\_TAMPx inputs

Level detection with filtering is performed by setting TAMPFLT to a non-zero value. A tamper detection event is generated when either 2, 4, or 8 (depending on TAMPFLT) consecutive samples are observed at the level designated by the TAMPxTRG bits.

The RTC\_TAMPx inputs are precharged through the I/O internal pull-up resistance before its state is sampled, unless disabled by setting TAMPPUDIS to 1. The duration of the precharge is determined by the TAMPPRCH bits, allowing for larger capacitances on the RTC\_TAMPx inputs.

The trade-off between tamper detection latency and power consumption through the pull-up can be optimized by using TAMPFREQ to determine the frequency of the sampling for level detection.

*Note:* Refer to the datasheets for the electrical characteristics of the pull-up resistors.

### 29.3.15 Calibration clock output

When the COE bit is set to 1 in the RTC\_CR register, a reference clock is provided on the RTC\_CALIB device output.

If the COSEL bit in the RTC\_CR register is reset and PREDIV\_A = 0x7F, the RTC\_CALIB frequency is  $f_{\text{RTCCLK}}/64$ . This corresponds to a calibration output at 512 Hz for an RTCCLK frequency at 32.768 kHz. The RTC\_CALIB duty cycle is irregular: there is a light jitter on falling edges. It is therefore recommended to use rising edges.

When COSEL is set and “PREDIV\_S+1” is a non-zero multiple of 256 (i.e: PREDIV\_S[7:0] = 0xFF), the RTC\_CALIB frequency is  $f_{\text{RTCCLK}}/(256 * (\text{PREDIV\_A}+1))$ . This corresponds to a calibration output at 1 Hz for prescaler default values (PREDIV\_A = 0x7F, PREDIV\_S = 0xFF), with an RTCCLK frequency at 32.768 kHz. The 1 Hz output is affected when a shift operation is on going and may toggle during the shift operation (SHPF=1).

*Note:* When the RTC\_CALIB or RTC\_ALARM output is selected, the RTC\_OUT pin is automatically configured as output.

*When COSEL bit is cleared, the RTC\_CALIB output is the output of the 6th stage of the asynchronous prescaler.*

*When COSEL bit is set, the RTC\_CALIB output is the output of the 8th stage of the synchronous prescaler.*

### 29.3.16 Alarm output

The OSEL[1:0] control bits in the RTC\_CR register are used to activate the alarm output RTC\_ALARM, and to select the function which is output. These functions reflect the contents of the corresponding flags in the RTC\_ISR register.

The polarity of the output is determined by the POL control bit in RTC\_CR so that the opposite of the selected flag bit is output when POL is set to 1.

#### Alarm output

The RTC\_ALARM pin can be configured in output open drain or output push-pull using the control bit RTC\_ALARM\_TYPE in the RTC\_OR register.

*Note:* Once the RTC\_ALARM output is enabled, it has priority over RTC\_CALIB (COE bit is don't care and must be kept cleared).

*When the RTC\_CALIB or RTC\_ALARM output is selected, the RTC\_OUT pin is automatically configured as output.*

## 29.4 RTC low-power modes

**Table 173. Effect of low-power modes on RTC**

| Mode    | Description                                                                                                                                                                 |
|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Sleep   | No effect<br>RTC interrupts cause the device to exit the Sleep mode.                                                                                                        |
| Stop    | The RTC remains active when the RTC clock source is LSE or LSI. RTC alarm, RTC tamper event, RTC timestamp event, and RTC Wakeup cause the device to exit the Stop mode.    |
| Standby | The RTC remains active when the RTC clock source is LSE or LSI. RTC alarm, RTC tamper event, RTC timestamp event, and RTC Wakeup cause the device to exit the Standby mode. |

## 29.5 RTC interrupts

All RTC interrupts are connected to the EXTI controller. Refer to [Section 11: Extended interrupts and events controller \(EXTI\)](#).

To enable the RTC Alarm interrupt, the following sequence is required:

1. Configure and enable the EXTI line corresponding to the RTC Alarm event in interrupt mode and select the rising edge sensitivity.
2. Configure and enable the RTC\_ALARM IRQ channel in the NVIC.
3. Configure the RTC to generate RTC alarms.

To enable the RTC Tamper interrupt, the following sequence is required:

1. Configure and enable the EXTI line corresponding to the RTC Tamper event in interrupt mode and select the rising edge sensitivity.
2. Configure and Enable the RTC\_TAMP\_STAMP IRQ channel in the NVIC.
3. Configure the RTC to detect the RTC tamper event.

To enable the RTC TimeStamp interrupt, the following sequence is required:

1. Configure and enable the EXTI line corresponding to the RTC TimeStamp event in interrupt mode and select the rising edge sensitivity.
2. Configure and Enable the RTC\_TAMP\_STAMP IRQ channel in the NVIC.
3. Configure the RTC to detect the RTC time-stamp event.

To enable the Wakeup timer interrupt, the following sequence is required:

1. Configure and enable the EXTI line corresponding to the Wakeup timer even in interrupt mode and select the rising edge sensitivity.
2. Configure and Enable the RTC\_WKUP IRQ channel in the NVIC.
3. Configure the RTC to detect the RTC Wakeup timer event.

Table 174. Interrupt control bits

| Interrupt event           | Event flag | Enable control bit | Exit from Sleep mode | Exit from Stop mode | Exit from Standby mode |
|---------------------------|------------|--------------------|----------------------|---------------------|------------------------|
| Alarm A                   | ALRAF      | ALRAIE             | yes                  | yes <sup>(1)</sup>  | yes <sup>(1)</sup>     |
| Alarm B                   | ALRBF      | ALRBIE             | yes                  | yes <sup>(1)</sup>  | yes <sup>(1)</sup>     |
| RTC_TS input (timestamp)  | TSF        | TSIE               | yes                  | yes <sup>(1)</sup>  | yes <sup>(1)</sup>     |
| RTC_TAMP1 input detection | TAMP1F     | TAMPIE             | yes                  | yes <sup>(1)</sup>  | yes <sup>(1)</sup>     |
| RTC_TAMP2 input detection | TAMP2F     | TAMPIE             | yes                  | yes <sup>(1)</sup>  | yes <sup>(1)</sup>     |
| RTC_TAMP3 input detection | TAMP3F     | TAMPIE             | yes                  | yes <sup>(1)</sup>  | yes <sup>(1)</sup>     |
| Wakeup timer interrupt    | WUTF       | WUTIE              | yes                  | yes <sup>(1)</sup>  | yes <sup>(1)</sup>     |

1. Wakeup from STOP and Standby modes is possible only when the RTC clock source is LSE or LSI.

## 29.6 RTC registers

Refer to [Section 1.2 on page 62](#) of the reference manual for a list of abbreviations used in register descriptions.

The peripheral registers can be accessed by words (32-bit).

### 29.6.1 RTC time register (RTC\_TR)

The RTC\_TR is the calendar time shadow register. This register must be written in initialization mode only. Refer to [Calendar initialization and configuration on page 921](#) and [Reading the calendar on page 922](#).

This register is write protected. The write access procedure is described in [RTC register write protection on page 921](#).

Address offset: 0x00

Backup domain reset value: 0x0000 0000

System reset: 0x0000 0000 when BYPSHAD = 0. Not affected when BYPSHAD = 1.

|      |          |      |      |          |      |      |      |      |         |         |    |         |    |    |    |

Bits 31-23 Reserved, must be kept at reset value

Bit 22 **PM**: AM/PM notation

0: AM or 24-hour format

1: PM

Bits 21:20 **HT[1:0]**: Hour tens in BCD format

- Bits 19:16 **HU[3:0]**: Hour units in BCD format  
 Bit 15 Reserved, must be kept at reset value.  
 Bits 14:12 **MNT[2:0]**: Minute tens in BCD format  
 Bits 11:8 **MNU[3:0]**: Minute units in BCD format  
 Bit 7 Reserved, must be kept at reset value.  
 Bits 6:4 **ST[2:0]**: Second tens in BCD format  
 Bits 3:0 **SU[3:0]**: Second units in BCD format

## 29.6.2 RTC date register (RTC\_DR)

The RTC\_DR is the calendar date shadow register. This register must be written in initialization mode only. Refer to [Calendar initialization and configuration on page 921](#) and [Reading the calendar on page 922](#).

This register is write protected. The write access procedure is described in [RTC register write protection on page 921](#).

Address offset: 0x04

Backup domain reset value: 0x0000 2101

System reset: 0x0000 2101 when BYPSHAD = 0. Not affected when BYPSHAD = 1.

| r/w  | r/w   | r/w    | r/w    | r/w  | r/w  | r/w   | r/w   |      | r/w       | r/w     | r/w     | r/w    | r/w          | r/w   | r/w   |

Bits 31:25 Reserved, must be kept at reset value.

Bit 24 **ITSE**: timestamp on internal event enable

0: internal event timestamp disabled

1: internal event timestamp enabled

Bit 23 **COE**: Calibration output enable

This bit enables the RTC\_CALIB output

0: Calibration output disabled

1: Calibration output enabled

Bits 22:21 **OSEL[1:0]**: Output selection

These bits are used to select the flag to be routed to RTC\_ALARM output

00: Output disabled

01: Alarm A output enabled

10: Alarm B output enabled

11: Wakeup output enabled

Bit 20 **POL**: Output polarity

This bit is used to configure the polarity of RTC\_ALARM output

0: The pin is high when ALRAF/ALRBF/WUTF is asserted (depending on OSEL[1:0])

1: The pin is low when ALRAF/ALRBF/WUTF is asserted (depending on OSEL[1:0]).

Bit 19 **COSEL**: Calibration output selection

When COE=1, this bit selects which signal is output on RTC\_CALIB.

0: Calibration output is 512 Hz (with default prescaler setting)

1: Calibration output is 1 Hz (with default prescaler setting)

These frequencies are valid for RTCCLK at 32.768 kHz and prescalers at their default values (PREDIV\_A=127 and PREDIV\_S=255). Refer to [Section 29.3.15: Calibration clock output](#)

Bit 18 **BKP**: Backup

This bit can be written by the user to memorize whether the daylight saving time change has been performed or not.

- Bit 17 **SUB1H**: Subtract 1 hour (winter time change)  
When this bit is set, 1 hour is subtracted to the calendar time if the current hour is not 0. This bit is always read as 0.  
Setting this bit has no effect when current hour is 0.  
0: No effect  
1: Subtracts 1 hour to the current time. This can be used for winter time change outside initialization mode.
- Bit 16 **ADD1H**: Add 1 hour (summer time change)  
When this bit is set, 1 hour is added to the calendar time. This bit is always read as 0.  
0: No effect  
1: Adds 1 hour to the current time. This can be used for summer time change outside initialization mode.
- Bit 15 **TSIE**: Time-stamp interrupt enable  
0: Time-stamp Interrupt disable  
1: Time-stamp Interrupt enable
- Bit 14 **WUTIE**: Wakeup timer interrupt enable  
0: Wakeup timer interrupt disabled  
1: Wakeup timer interrupt enabled
- Bit 13 **ALRBIE**: *Alarm B interrupt enable*  
0: Alarm B Interrupt disable  
1: Alarm B Interrupt enable
- Bit 12 **ALRAIE**: Alarm A interrupt enable  
0: Alarm A interrupt disabled  
1: Alarm A interrupt enabled
- Bit 11 **TSE**: timestamp enable  
0: timestamp disable  
1: timestamp enable
- Bit 10 **WUTE**: Wakeup timer enable  
0: Wakeup timer disabled  
1: Wakeup timer enabled  
*Note: When the wakeup timer is disabled, wait for WUTWF=1 before enabling it again.*
- Bit 9 **ALRBE**: *Alarm B enable*  
0: Alarm B disabled  
1: Alarm B enabled
- Bit 8 **ALRAE**: Alarm A enable  
0: Alarm A disabled  
1: Alarm A enabled
- Bit 7 Reserved, must be kept at reset value.
- Bit 6 **FMT**: Hour format  
0: 24 hour/day format  
1: AM/PM hour format

Bit 5 **BYPSHAD**: Bypass the shadow registers

0: Calendar values (when reading from RTC\_SSR, RTC\_TR, and RTC\_DR) are taken from the shadow registers, which are updated once every two RTCCLK cycles.

1: Calendar values (when reading from RTC\_SSR, RTC\_TR, and RTC\_DR) are taken directly from the calendar counters.

*Note: If the frequency of the APB clock is less than seven times the frequency of RTCCLK, BYPSHAD must be set to '1'.*

Bit 4 **REFCKON**: RTC\_REFIN reference clock detection enable (50 or 60 Hz)

0: RTC\_REFIN detection disabled

1: RTC\_REFIN detection enabled

*Note: PREDIV\_S must be 0x00FF.*

Bit 3 **TSEDGE**: Time-stamp event active edge

0: RTC\_TS input rising edge generates a time-stamp event

1: RTC\_TS input falling edge generates a time-stamp event

TSE must be reset when TSEDGE is changed to avoid unwanted TSF setting.

Bits 2:0 **WUCKSEL[2:0]**: Wakeup clock selection

000: RTC/16 clock is selected

001: RTC/8 clock is selected

010: RTC/4 clock is selected

011: RTC/2 clock is selected

10x: ck\_spre (usually 1 Hz) clock is selected

11x: ck\_spre (usually 1 Hz) clock is selected and  $2^{16}$  is added to the WUT counter value (see note below)

*Note: Bits 7, 6 and 4 of this register can be written in initialization mode only (RTC\_ISR/INITF = 1).*

*WUT = Wakeup unit counter value.  $WUT = (0x0000 \text{ to } 0xFFFF) + 0x10000$  added when  $WUCKSEL[2:1] = 11$ .*

*Bits 2 to 0 of this register can be written only when RTC\_CR WUTE bit = 0 and RTC\_ISR WUTWF bit = 1.*

*It is recommended not to change the hour during the calendar hour increment as it could mask the incrementation of the calendar hour.*

*ADD1H and SUB1H changes are effective in the next second.*

*This register is write protected. The write access procedure is described in [RTC register write protection on page 921](#).*

**Caution:** TSE must be reset when TSEDGE is changed to avoid spuriously setting of TSF.

## 29.6.4 RTC initialization and status register (RTC\_ISR)

This register is write protected (except for RTC\_ISR[13:8] bits). The write access procedure is described in [RTC register write protection on page 921](#).

Address offset: 0x0C

Backup domain reset value: 0x0000 0007

System reset: not affected except INIT, INITF, and RSF bits which are cleared to '0'

|        |        |        |       |       |       |       |       |      |       |       |       |      |       |            |         |

Bits 31:18 Reserved, must be kept at reset value

Bit 17 **ITSF**: Internal tTime-stamp flag

This flag is set by hardware when a time-stamp on the internal event occurs.

This flag is cleared by software by writing 0, and must be cleared together with TSF bit by writing 0 in both bits.

Bit 16 **RECALPF**: Recalibration pending Flag

The RECALPF status flag is automatically set to '1' when software writes to the RTC\_CALR register, indicating that the RTC\_CALR register is blocked. When the new calibration settings are taken into account, this bit returns to '0'. Refer to [Re-calibration on-the-fly](#).

Bit 15 **TAMP3F**: RTC\_TAMP3 detection flag

This flag is set by hardware when a tamper detection event is detected on the RTC\_TAMP3 input.

It is cleared by software writing 0

Bit 14 **TAMP2F**: RTC\_TAMP2 detection flag

This flag is set by hardware when a tamper detection event is detected on the RTC\_TAMP2 input.

It is cleared by software writing 0

Bit 13 **TAMP1F**: RTC\_TAMP1 detection flag

This flag is set by hardware when a tamper detection event is detected on the RTC\_TAMP1 input.

It is cleared by software writing 0

Bit 12 **TSOVF**: Time-stamp overflow flag

This flag is set by hardware when a time-stamp event occurs while TSF is already set.

This flag is cleared by software by writing 0. It is recommended to check and then clear TSOVF only after clearing the TSF bit. Otherwise, an overflow might not be noticed if a time-stamp event occurs immediately before the TSF bit is cleared.

Bit 11 **TSF**: Time-stamp flag

This flag is set by hardware when a time-stamp event occurs.

This flag is cleared by software by writing 0. If ITSF flag is set, TSF must be cleared together with ITSF by writing 0 in both bits.

- Bit 10 **WUTF**: Wakeup timer flag  
This flag is set by hardware when the wakeup auto-reload counter reaches 0.  
This flag is cleared by software by writing 0.  
This flag must be cleared by software at least 1.5 RTCCLK periods before WUTF is set to 1 again.
- Bit 9 **ALRBF**: Alarm B flag  
This flag is set by hardware when the time/date registers (RTC\_TR and RTC\_DR) match the Alarm B register (RTC\_ALRMBR).  
This flag is cleared by software by writing 0.
- Bit 8 **ALRAF**: Alarm A flag  
This flag is set by hardware when the time/date registers (RTC\_TR and RTC\_DR) match the Alarm A register (RTC\_ALRMAR).  
This flag is cleared by software by writing 0.
- Bit 7 **INIT**: Initialization mode  
0: Free running mode  
1: Initialization mode used to program time and date register (RTC\_TR and RTC\_DR), and prescaler register (RTC\_PRER). Counters are stopped and start counting from the new value when INIT is reset.
- Bit 6 **INITF**: Initialization flag  
When this bit is set to 1, the RTC is in initialization state, and the time, date and prescaler registers can be updated.  
0: Calendar registers update is not allowed  
1: Calendar registers update is allowed
- Bit 5 **RSF**: Registers synchronization flag  
This bit is set by hardware each time the calendar registers are copied into the shadow registers (RTC\_SSRx, RTC\_TRx and RTC\_DRx). This bit is cleared by hardware in initialization mode, while a shift operation is pending (SHPF=1), or when in bypass shadow register mode (BYPSHAD=1). This bit can also be cleared by software.  
It is cleared either by software or by hardware in initialization mode.  
0: Calendar shadow registers not yet synchronized  
1: Calendar shadow registers synchronized
- Bit 4 **INITS**: Initialization status flag  
This bit is set by hardware when the calendar year field is different from 0 (Backup domain reset state).  
0: Calendar has not been initialized  
1: Calendar has been initialized
- Bit 3 **SHPF**: Shift operation pending  
0: No shift operation is pending  
1: A shift operation is pending  
This flag is set by hardware as soon as a shift operation is initiated by a write to the RTC\_SHIFTR register. It is cleared by hardware when the corresponding shift operation has been executed. Writing to the SHPF bit has no effect.

**Bit 2 WUTWF:** Wakeup timer write flag

This bit is set by hardware up to 2 RTCCLK cycles after the WUTE bit has been set to 0 in RTC\_CR, and is cleared up to 2 RTCCLK cycles after the WUTE bit has been set to 1. The wakeup timer values can be changed when WUTE bit is cleared and WUTWF is set.

0: Wakeup timer configuration update not allowed

1: Wakeup timer configuration update allowed

**Bit 1 ALRBWF:** Alarm B write flag

This bit is set by hardware when Alarm B values can be changed, after the ALRBE bit has been set to 0 in RTC\_CR.

It is cleared by hardware in initialization mode.

0: Alarm B update not allowed

1: Alarm B update allowed

**Bit 0 ALRAWF:** Alarm A write flag

This bit is set by hardware when Alarm A values can be changed, after the ALRAE bit has been set to 0 in RTC\_CR.

It is cleared by hardware in initialization mode.

0: Alarm A update not allowed

1: Alarm A update allowed

**Note:** *The bits ALRAF, ALRBF, WUTF and TSF are cleared 2 APB clock cycles after programming them to 0.*

## 29.6.5 RTC prescaler register (RTC\_PRER)

This register must be written in initialization mode only. The initialization must be performed in two separate write accesses. Refer to [Calendar initialization and configuration on page 921](#).

This register is write protected. The write access procedure is described in [RTC register write protection on page 921](#).

Address offset: 0x10

Backup domain reset value: 0x007F 00FF

System reset: not affected

|      |                |      |      |      |      |      |      |      |               |    |    |    |    |    |    |

Bits 31:23 Reserved, must be kept at reset value

Bits 22:16 **PREDIV\_A[6:0]**: Asynchronous prescaler factor

This is the asynchronous division factor:

$ck\_apre\ frequency = RTCCLK\ frequency / (PREDIV\_A + 1)$

Bit 15 Reserved, must be kept at reset value.

Bits 14:0 **PREDIV\_S[14:0]**: Synchronous prescaler factor

This is the synchronous division factor:

$ck\_spre\ frequency = ck\_apre\ frequency / (PREDIV\_S + 1)$

## 29.6.6 RTC wakeup timer register (RTC\_WUTR)

This register can be written only when WUTWF is set to 1 in RTC\_ISR.

This register is write protected. The write access procedure is described in [RTC register write protection on page 921](#).

Address offset: 0x14

Backup domain reset value: 0x0000 FFFF

System reset: not affected

| 15        | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0    |
| WUT[15:0] |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
| rw        | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   |

Bits 31:16 Reserved, must be kept at reset value

Bits 15:0 **WUT[15:0]**: Wakeup auto-reload value bits

When the wakeup timer is enabled (WUTE set to 1), the WUTF flag is set every (WUT[15:0] + 1) ck\_wut cycles. The ck\_wut period is selected through WUCKSEL[2:0] bits of the RTC\_CR register

When WUCKSEL[2] = 1, the wakeup timer becomes 17-bits and WUCKSEL[1] effectively becomes WUT[16] the most-significant bit to be reloaded into the timer.

The first assertion of WUTF occurs (WUT+1) ck\_wut cycles after WUTE is set. Setting WUT[15:0] to 0x0000 with WUCKSEL[2:0] = 011 (RTCCLK/2) is forbidden.

## 29.6.7 RTC alarm A register (RTC\_ALRMAR)

This register can be written only when ALRAWF is set to 1 in RTC\_ISR, or in initialization mode.

This register is write protected. The write access procedure is described in [RTC register write protection on page 921](#).

Address offset: 0x1C

Backup domain reset value: 0x0000 0000

System reset: not affected

|      |          |         |    |          |    |    |    |      |         |         |    |         |    |    |    |

Bit 31 **MSK4**: Alarm A date mask

- 0: Alarm A set if the date/day match
- 1: Date/day don't care in Alarm A comparison

Bit 30 **WDSEL**: Week day selection

- 0: DU[3:0] represents the date units
- 1: DU[3:0] represents the week day. DT[1:0] is don't care.

Bits 29:28 **DT[1:0]**: Date tens in BCD format.

Bits 27:24 **DU[3:0]**: Date units or day in BCD format.

Bit 23 **MSK3**: Alarm A hours mask

- 0: Alarm A set if the hours match
- 1: Hours don't care in Alarm A comparison

Bit 22 **PM**: AM/PM notation

- 0: AM or 24-hour format
- 1: PM

Bits 21:20 **HT[1:0]**: Hour tens in BCD format.

Bits 19:16 **HU[3:0]**: Hour units in BCD format.

Bit 15 **MSK2**: Alarm A minutes mask

- 0: Alarm A set if the minutes match
- 1: Minutes don't care in Alarm A comparison

Bits 14:12 **MNT[2:0]**: Minute tens in BCD format.

Bits 11:8 **MNU[3:0]**: Minute units in BCD format.

Bit 7 **MSK1**: Alarm A seconds mask

- 0: Alarm A set if the seconds match
- 1: Seconds don't care in Alarm A comparison

Bits 6:4 **ST[2:0]**: Second tens in BCD format.

Bits 3:0 **SU[3:0]**: Second units in BCD format.

## 29.6.8 RTC alarm B register (RTC\_ALRMBR)

This register can be written only when ALRBWF is set to 1 in RTC\_ISR, or in initialization mode.

This register is write protected. The write access procedure is described in [RTC register write protection on page 921](#).

Address offset: 0x20

Backup domain reset value: 0x0000 0000

System reset: not affected

|      |          |         |    |          |    |    |    |      |         |         |    |         |    |    |    |

Bit 31 **MSK4**: Alarm B date mask

0: Alarm B set if the date and day match

1: Date and day don't care in Alarm B comparison

Bit 30 **WDSEL**: Week day selection

0: DU[3:0] represents the date units

1: DU[3:0] represents the week day. DT[1:0] is don't care.

Bits 29:28 **DT[1:0]**: Date tens in BCD format

Bits 27:24 **DU[3:0]**: Date units or day in BCD format

Bit 23 **MSK3**: Alarm B hours mask

0: Alarm B set if the hours match

1: Hours don't care in Alarm B comparison

Bit 22 **PM**: AM/PM notation

0: AM or 24-hour format

1: PM

Bits 21:20 **HT[1:0]**: Hour tens in BCD format

Bits 19:16 **HU[3:0]**: Hour units in BCD format

Bit 15 **MSK2**: Alarm B minutes mask

0: Alarm B set if the minutes match

1: Minutes don't care in Alarm B comparison

Bits 14:12 **MNT[2:0]**: Minute tens in BCD format

Bits 11:8 **MNU[3:0]**: Minute units in BCD format

Bit 7 **MSK1**: Alarm B seconds mask

0: Alarm B set if the seconds match

1: Seconds don't care in Alarm B comparison

Bits 6:4 **ST[2:0]**: Second tens in BCD format

Bits 3:0 **SU[3:0]**: Second units in BCD format

## 29.6.9 RTC write protection register (RTC\_WPR)

Address offset: 0x24

Reset value: 0x0000 0000

|      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|
| 31   | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21   | 20   | 19   | 18   | 17   | 16   |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. |
|      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
| 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0    |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | KEY  |      |      |      |      |      |      |      |

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **KEY**: Write protection key

This byte is written by software.

Reading this byte always returns 0x00.

Refer to [RTC register write protection](#) for a description of how to unlock RTC register write protection.

## 29.6.10 RTC sub second register (RTC\_SSR)

Address offset: 0x28

Backup domain reset value: 0x0000 0000

System reset: 0x0000 0000 when BYPSHAD = 0. Not affected when BYPSHAD = 1.

|          |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
|----------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|
| 31       | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21   | 20   | 19   | 18   | 17   | 16   |
| Res.     | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. |
|          |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
| 15       | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0    |
| SS[15:0] |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
| r        | r    | r    | r    | r    | r    | r    | r    | r    | r    | r    | r    | r    | r    | r    | r    |

Bits31:16 Reserved, must be kept at reset value

Bits 15:0 **SS**: Sub second value

SS[15:0] is the value in the synchronous prescaler counter. The fraction of a second is given by the formula below:

$$\text{Second fraction} = (\text{PREDIV\_S} - \text{SS}) / (\text{PREDIV\_S} + 1)$$

*Note: SS can be larger than PREDIV\_S only after a shift operation. In that case, the correct time/date is one second less than as indicated by RTC\_TR/RTC\_DR.*

### 29.6.11 RTC shift control register (RTC\_SHIFTR)

This register is write protected. The write access procedure is described in [RTC register write protection on page 921](#).

Address offset: 0x2C

Backup domain reset value: 0x0000 0000

System reset: not affected

|       |             |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
|-------|-------------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|
| 31    | 30          | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21   | 20   | 19   | 18   | 17   | 16   |
| ADD1S | Res.        | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. |
| w     |             |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
| 15    | 14          | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0    |
| Res.  | SUBFS[14:0] |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
|       | w           | w    | w    | w    | w    | w    | w    | w    | w    | w    | w    | w    | w    | w    | w    |

Bit 31 **ADD1S**: Add one second

0: No effect

1: Add one second to the clock/calendar

This bit is write only and is always read as zero. Writing to this bit has no effect when a shift operation is pending (when SHPF=1, in RTC\_ISR).

This function is intended to be used with SUBFS (see description below) in order to effectively add a fraction of a second to the clock in an atomic operation.

Bits 30:15 Reserved, must be kept at reset value

Bits 14:0 **SUBFS**: Subtract a fraction of a second

These bits are write only and is always read as zero. Writing to this bit has no effect when a shift operation is pending (when SHPF=1, in RTC\_ISR).

The value which is written to SUBFS is added to the synchronous prescaler counter. Since this counter counts down, this operation effectively subtracts from (delays) the clock by:

Delay (seconds) = SUBFS / (PREDIV\_S + 1)

A fraction of a second can effectively be added to the clock (advancing the clock) when the ADD1S function is used in conjunction with SUBFS, effectively advancing the clock by:

Advance (seconds) = (1 - (SUBFS / (PREDIV\_S + 1))).

*Note: Writing to SUBFS causes RSF to be cleared. Software can then wait until RSF=1 to be sure that the shadow registers have been updated with the shifted time.*

### 29.6.12 RTC timestamp time register (RTC\_TSTR)

The content of this register is valid only when TSF is set to 1 in RTC\_ISR. It is cleared when TSF bit is reset.

Address offset: 0x30

Backup domain reset value: 0x0000 0000

System reset: not affected

|      |          |      |      |          |      |      |      |      |         |         |    |         |    |    |    |
|------|----------|------|------|----------|------|------|------|------|---------|---------|----|---------|----|----|----|
| 31   | 30       | 29   | 28   | 27       | 26   | 25   | 24   | 23   | 22      | 21      | 20 | 19      | 18 | 17 | 16 |

| Res. | MNT[2:0] |      |      | MNU[3:0] |      |      |      | Res. | ST[2:0] |         |    | SU[3:0] |    |    |    |
|      | r        | r    | r    | r        | r    | r    | r    |      | r       | r       | r  | r       | r  | r  | r  |

Bits 31:23 Reserved, must be kept at reset value

Bit 22 **PM**: AM/PM notation

0: AM or 24-hour format

1: PM

Bits 21:20 **HT[1:0]**: Hour tens in BCD format.

Bits 19:16 **HU[3:0]**: Hour units in BCD format.

Bit 15 Reserved, must be kept at reset value

Bits 14:12 **MNT[2:0]**: Minute tens in BCD format.

Bits 11:8 **MNU[3:0]**: Minute units in BCD format.

Bit 7 Reserved, must be kept at reset value

Bits 6:4 **ST[2:0]**: Second tens in BCD format.

Bits 3:0 **SU[3:0]**: Second units in BCD format.

### 29.6.13 RTC timestamp date register (RTC\_TSDR)

The content of this register is valid only when TSF is set to 1 in RTC\_ISR. It is cleared when TSF bit is reset.

Address offset: 0x34

Backup domain reset value: 0x0000 0000

System reset: not affected

|          |      |      |      |         |      |      |      |      |      |         |      |         |      |      |      |

Bits 31:16 Reserved, must be kept at reset value

Bits 15:13 **WDU[1:0]**: Week day units

Bit 12 **MT**: Month tens in BCD format

Bits 11:8 **MU[3:0]**: Month units in BCD format

Bits 7:6 Reserved, must be kept at reset value

Bits 5:4 **DT[1:0]**: Date tens in BCD format

Bits 3:0 **DU[3:0]**: Date units in BCD format

29.6.14 RTC time-stamp sub second register (RTC\_TSSSR)

The content of this register is valid only when RTC\_ISR/TSF is set. It is cleared when the RTC\_ISR/TSF bit is reset.

Address offset: 0x38

Backup domain reset value: 0x0000 0000

System reset: not affected

|          |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
|----------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|
| 31       | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21   | 20   | 19   | 18   | 17   | 16   |
| Res.     | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. |

| SS[15:0] |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
| r        | r    | r    | r    | r    | r    | r    | r    | r    | r    | r    | r    | r    | r    | r    | r    |

Bits 31:16 Reserved, must be kept at reset value

Bits 15:0 **SS**: Sub second value

SS[15:0] is the value of the synchronous prescaler counter when the timestamp event occurred.

### 29.6.15 RTC calibration register (RTC\_CALR)

This register is write protected. The write access procedure is described in [RTC register write protection on page 921](#).

Address offset: 0x3C

Backup domain reset value: 0x0000 0000

System reset: not affected

|      |       |        |      |      |      |      |           |      |      |      |      |      |      |      |      |
|------|-------|--------|------|------|------|------|-----------|------|------|------|------|------|------|------|------|
| 31   | 30    | 29     | 28   | 27   | 26   | 25   | 24        | 23   | 22   | 21   | 20   | 19   | 18   | 17   | 16   |
| Res. | Res.  | Res.   | Res. | Res. | Res. | Res. | Res.      | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. |
|      |       |        |      |      |      |      |           |      |      |      |      |      |      |      |      |
| 15   | 14    | 13     | 12   | 11   | 10   | 9    | 8         | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0    |
| CALP | CALW8 | CALW16 | Res. | Res. | Res. | Res. | CALM[8:0] |      |      |      |      |      |      |      |      |
| rw   | rw    | rw     |      |      |      |      | rw        | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   |

Bits 31:16 Reserved, must be kept at reset value

Bit 15 **CALP**: Increase frequency of RTC by 488.5 ppm

0: No RTCCLK pulses are added.

1: One RTCCLK pulse is effectively inserted every  $2^{11}$  pulses (frequency increased by 488.5 ppm).

This feature is intended to be used in conjunction with CALM, which lowers the frequency of the calendar with a fine resolution. If the input frequency is 32768 Hz, the number of RTCCLK pulses added during a 32-second window is calculated as follows:  $(512 * CALP) - CALM$ .

Refer to [Section 29.3.12: RTC smooth digital calibration](#).

Bit 14 **CALW8**: Use an 8-second calibration cycle period

When CALW8 is set to '1', the 8-second calibration cycle period is selected.

*Note: CALM[1:0] are stuck at "00" when CALW8='1'. Refer to [Section 29.3.12: RTC smooth digital calibration](#).*

Bit 13 **CALW16**: Use a 16-second calibration cycle period

When CALW16 is set to '1', the 16-second calibration cycle period is selected. This bit must not be set to '1' if CALW8=1.

*Note: CALM[0] is stuck at '0' when CALW16='1'. Refer to [Section 29.3.12: RTC smooth digital calibration](#).*

Bits 12:9 Reserved, must be kept at reset value

Bits 8:0 **CALM[8:0]**: Calibration minus

The frequency of the calendar is reduced by masking CALM out of  $2^{20}$  RTCCLK pulses (32 seconds if the input frequency is 32768 Hz). This decreases the frequency of the calendar with a resolution of 0.9537 ppm.

To increase the frequency of the calendar, this feature should be used in conjunction with CALP. See [Section 29.3.12: RTC smooth digital calibration on page 925](#).

## 29.6.16 RTC tamper configuration register (RTC\_TAMPCR)

Address offset: 0x40

Backup domain reset value: 0x0000 0000

System reset: not affected

|            |                |      |              |      |               |      |          |                |           |          |                |          |          |                |          |

| rw         | rw             | rw   | rw           | rw   | rw            | rw   | rw       | rw             | rw        | rw       | rw             | rw       | rw       | rw             | rw       |

Bits 31:25 Reserved, must be kept at reset value.

Bit 24 **TAMP3MF**: Tamper 3 mask flag

0: Tamper 3 event generates a trigger event and TAMP3F must be cleared by software to allow next tamper event detection.

1: Tamper 3 event generates a trigger event. TAMP3F is masked and internally cleared by hardware. The backup registers are not erased.

*Note: The Tamper 3 interrupt must not be enabled when TAMP3MF is set.*

Bit 23 **TAMP3NOERASE**: Tamper 3 no erase

0: Tamper 3 event erases the backup registers.

1: Tamper 3 event does not erase the backup registers.

Bit 22 **TAMP3IE**: Tamper 3 interrupt enable

0: Tamper 3 interrupt is disabled if TAMPIE = 0.

1: Tamper 3 interrupt enabled.

Bit 21 **TAMP2MF**: Tamper 2 mask flag

0: Tamper 2 event generates a trigger event and TAMP2F must be cleared by software to allow next tamper event detection.

1: Tamper 2 event generates a trigger event. TAMP2F is masked and internally cleared by hardware. The backup registers are not erased.

*Note: The Tamper 2 interrupt must not be enabled when TAMP2MF is set.*

Bit 20 **TAMP2NOERASE**: Tamper 2 no erase

0: Tamper 2 event erases the backup registers.

1: Tamper 2 event does not erase the backup registers.

Bit 19 **TAMP2IE**: Tamper 2 interrupt enable

0: Tamper 2 interrupt is disabled if TAMPIE = 0.

1: Tamper 2 interrupt enabled.

Bit 18 **TAMP1MF**: Tamper 1 mask flag

0: Tamper 1 event generates a trigger event and TAMP1F must be cleared by software to allow next tamper event detection.

1: Tamper 1 event generates a trigger event. TAMP1F is masked and internally cleared by hardware. The backup registers are not erased.

*Note: The Tamper 1 interrupt must not be enabled when TAMP1MF is set.*

- Bit 17 **TAMP1NOERASE**: Tamper 1 no erase  
 0: Tamper 1 event erases the backup registers.  
 1: Tamper 1 event does not erase the backup registers.
- Bit 16 **TAMP1IE**: Tamper 1 interrupt enable  
 0: Tamper 1 interrupt is disabled if TAMPIE = 0.  
 1: Tamper 1 interrupt enabled.
- Bit 15 **TAMPPUDIS**: RTC\_TAMPx pull-up disable  
 This bit determines if each of the RTC\_TAMPx pins are precharged before each sample.  
 0: Precharge RTC\_TAMPx pins before sampling (enable internal pull-up)  
 1: Disable precharge of RTC\_TAMPx pins.
- Bits 14:13 **TAMPPRCH[1:0]**: RTC\_TAMPx precharge duration  
 These bit determines the duration of time during which the pull-up/is activated before each sample. TAMPPRCH is valid for each of the RTC\_TAMPx inputs.  
 0x0: 1 RTCCLK cycle  
 0x1: 2 RTCCLK cycles  
 0x2: 4 RTCCLK cycles  
 0x3: 8 RTCCLK cycles
- Bits 12:11 **TAMPFLT[1:0]**: RTC\_TAMPx filter count  
 These bits determines the number of consecutive samples at the specified level (TAMP\*TRG) needed to activate a Tamper event. TAMPFLT is valid for each of the RTC\_TAMPx inputs.  
 0x0: Tamper event is activated on edge of RTC\_TAMPx input transitions to the active level (no internal pull-up on RTC\_TAMPx input).  
 0x1: Tamper event is activated after 2 consecutive samples at the active level.  
 0x2: Tamper event is activated after 4 consecutive samples at the active level.  
 0x3: Tamper event is activated after 8 consecutive samples at the active level.
- Bits 10:8 **TAMPFREQ[2:0]**: Tamper sampling frequency  
 Determines the frequency at which each of the RTC\_TAMPx inputs are sampled.  
 0x0: RTCCLK / 32768 (1 Hz when RTCCLK = 32768 Hz)  
 0x1: RTCCLK / 16384 (2 Hz when RTCCLK = 32768 Hz)  
 0x2: RTCCLK / 8192 (4 Hz when RTCCLK = 32768 Hz)  
 0x3: RTCCLK / 4096 (8 Hz when RTCCLK = 32768 Hz)  
 0x4: RTCCLK / 2048 (16 Hz when RTCCLK = 32768 Hz)  
 0x5: RTCCLK / 1024 (32 Hz when RTCCLK = 32768 Hz)  
 0x6: RTCCLK / 512 (64 Hz when RTCCLK = 32768 Hz)  
 0x7: RTCCLK / 256 (128 Hz when RTCCLK = 32768 Hz)
- Bit 7 **TAMPTS**: Activate timestamp on tamper detection event  
 0: Tamper detection event does not cause a timestamp to be saved  
 1: Save timestamp on tamper detection event  
 TAMPTS is valid even if TSE=0 in the RTC\_CR register.
- Bit 6 **TAMP3TRG**: Active level for RTC\_TAMP3 input  
 if TAMPFLT ≠ 00:  
 0: RTC\_TAMP3 input staying low triggers a tamper detection event.  
 1: RTC\_TAMP3 input staying high triggers a tamper detection event.  
 if TAMPFLT = 00:  
 0: RTC\_TAMP3 input rising edge triggers a tamper detection event.  
 1: RTC\_TAMP3 input falling edge triggers a tamper detection event.

*Note: The Tamper 3 falling edge detection is not allowed when switch to VBAT is used, otherwise a detection would always occurs when entering in Vbat mode.*

Bit 5 **TAMP3E**: RTC\_TAMP3 detection enable

- 0: RTC\_TAMP3 input detection disabled
- 1: RTC\_TAMP3 input detection enabled

Bit 4 **TAMP2TRG**: Active level for RTC\_TAMP2 input

- if TAMPFLT != 00:
  - 0: RTC\_TAMP2 input staying low triggers a tamper detection event.
  - 1: RTC\_TAMP2 input staying high triggers a tamper detection event.
- if TAMPFLT = 00:
  - 0: RTC\_TAMP2 input rising edge triggers a tamper detection event.
  - 1: RTC\_TAMP2 input falling edge triggers a tamper detection event.

Bit 3 **TAMP2E**: RTC\_TAMP2 input detection enable

- 0: RTC\_TAMP2 detection disabled
- 1: RTC\_TAMP2 detection enabled

Bit 2 **TAMPIE**: Tamper interrupt enable

- 0: Tamper interrupt disabled
- 1: Tamper interrupt enabled.

*Note: This bit enables the interrupt for all tamper pins events, whatever TAMPxIE level. If this bit is cleared, each tamper event interrupt can be individually enabled by setting TAMPxIE.*

Bit 1 **TAMP1TRG**: Active level for RTC\_TAMP1 input

- If TAMPFLT != 00
  - 0: RTC\_TAMP1 input staying low triggers a tamper detection event.
  - 1: RTC\_TAMP1 input staying high triggers a tamper detection event.
- if TAMPFLT = 00:
  - 0: RTC\_TAMP1 input rising edge triggers a tamper detection event.
  - 1: RTC\_TAMP1 input falling edge triggers a tamper detection event.

Bit 0 **TAMP1E**: RTC\_TAMP1 input detection enable

- 0: RTC\_TAMP1 detection disabled
- 1: RTC\_TAMP1 detection enabled

**Caution:** When TAMPFLT = 0, TAMPxE must be reset when TAMPxTRG is changed to avoid spuriously setting TAMPxF.

## 29.6.17 RTC alarm A sub second register (RTC\_ALRMASSR)

This register can be written only when ALRAE is reset in RTC\_CR register, or in initialization mode.

This register is write protected. The write access procedure is described in [RTC register write protection on page 921](#)

Address offset: 0x44

Backup domain reset value: 0x0000 0000

System reset: not affected

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:24 MASKSS[3:0]: Mask the most-significant bits starting at this bit

0: No comparison on sub seconds for Alarm A. The alarm is set when the seconds unit is incremented (assuming that the rest of the fields match).

1: SS[14:1] are don't care in Alarm A comparison. Only SS[0] is compared.

2: SS[14:2] are don't care in Alarm A comparison. Only SS[1:0] are compared.

3: SS[14:3] are don't care in Alarm A comparison. Only SS[2:0] are compared.

...

12: SS[14:12] are don't care in Alarm A comparison. SS[11:0] are compared.

13: SS[14:13] are don't care in Alarm A comparison. SS[12:0] are compared.

14: SS[14] is don't care in Alarm A comparison. SS[13:0] are compared.

15: All 15 SS bits are compared and must match to activate alarm.

The overflow bits of the synchronous counter (bits 15) is never compared. This bit can be different from 0 only after a shift operation.

Bits 23:15 Reserved, must be kept at reset value.

Bits 14:0 SS[14:0]: Sub seconds value

This value is compared with the contents of the synchronous prescaler counter to determine if Alarm A is to be activated. Only bits 0 up MASKSS-1 are compared.

## 29.6.18 RTC alarm B sub second register (RTC\_ALRMBSSR)

This register can be written only when ALRBE is reset in RTC\_CR register, or in initialization mode.

This register is write protected. The write access procedure is described in [Section : RTC register write protection](#).

Address offset: 0x48

Backup domain reset value: 0x0000 0000

System reset: not affected

Bits 31:4 Reserved, must be kept at reset value.

Bit 3 **RTC\_ALARM\_TYPE**: RTC\_ALARM on PC13 output type

0: RTC\_ALARM, when mapped on PC13, is open-drain output

1: RTC\_ALARM, when mapped on PC13, is push-pull output

Bits 2:1 **TSINSEL[1:0]**: TIMESTAMP mapping

00: TIMESTAMP is mapped on PC13

01: TIMESTAMP is mapped on PI8

10: TIMESTAMP is mapped on PC1

11: TIMESTAMP is mapped on PC1

Bit 0 Reserved, must be kept at reset value.

### 29.6.20 RTC backup registers (RTC\_BKPxR)

Address offset: 0x50 to 0xCC

Backup domain reset value: 0x0000 0000

System reset: not affected

|            |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

| rw         | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | w  | rw | rw |

Bits 31:0 BKP[31:0]

The application can write or read data to and from these registers.

They are powered-on by  $V_{BAT}$  when  $V_{DD}$  is switched off, so that they are not reset by

System reset, and their contents remain valid when the device operates in low-power mode.

This register is reset on a tamper detection event, as long as  $TAMPx F=1$ .

## 29.6.21 RTC register map

Table 175. RTC register map and reset values

| Offset | Register name | 31    | 30    | 29      | 28   | 27      | 26   | 25   | 24   | 23      | 22            | 21      | 20      | 19      | 18   | 17       | 16             | 15        | 14          | 13       | 12       | 11   | 10   | 9       | 8       | 7    | 6       | 5       | 4       | 3      | 2            | 1     | 0      |  |  |  |  |  |  |

Refer to [Section 2.2.2 on page 69](#) for the register boundary addresses.

## 30 Inter-integrated circuit (I2C) interface

### 30.1 Introduction

The I<sup>2</sup>C (inter-integrated circuit) bus interface handles communications between the microcontroller and the serial I<sup>2</sup>C bus. It provides multimaster capability, and controls all I<sup>2</sup>C bus-specific sequencing, protocol, arbitration and timing. It supports Standard-mode (Sm), Fast-mode (Fm) and Fast-mode Plus (Fm+).

It is also SMBus (system management bus) and PMBus (power management bus) compatible.

DMA can be used to reduce CPU overload.

### 30.2 I2C main features

- I<sup>2</sup>C bus specification rev03 compatibility:
  - Slave and master modes
  - Multimaster capability
  - Standard-mode (up to 100 kHz)
  - Fast-mode (up to 400 kHz)
  - Fast-mode Plus (up to 1 MHz)
  - 7-bit and 10-bit addressing mode
  - Multiple 7-bit slave addresses (2 addresses, 1 with configurable mask)
  - All 7-bit addresses acknowledge mode
  - General call
  - Programmable setup and hold times
  - Easy to use event management
  - Optional clock stretching
  - Software reset
- 1-byte buffer with DMA capability
- Programmable analog and digital noise filters

The following additional features are also available depending on the product implementation (see [Section 30.3: I2C implementation](#)):

- SMBus specification rev 3.0 compatibility:
  - Hardware PEC (Packet Error Checking) generation and verification with ACK control
  - Command and data acknowledge control
  - Address resolution protocol (ARP) support
  - Host and Device support
  - SMBus alert
  - Timeouts and idle condition detection
- PMBus rev 1.3 standard compatibility
- Independent clock: a choice of independent clock sources allowing the I2C communication speed to be independent from the PCLK reprogramming

### 30.3 I2C implementation

This manual describes the full set of features implemented in I2C1, I2C2, I2C3 and I2C4. In the STM32F75xxx and STM32F74xxx devices I2C1, I2C2, I2C3 and I2C4 are identical and implement the full set of features as shown in the following table.

**Table 176. STM32F75xxx and STM32F74xxx I2C implementation**

| I2C features <sup>(1)</sup>                                 | I2C1 | I2C2 | I2C3 | I2C4 |
|-------------------------------------------------------------|------|------|------|------|

### 30.4 I2C functional description

In addition to receiving and transmitting data, this interface converts it from serial to parallel format and vice versa. The interrupts are enabled or disabled by software. The interface is connected to the I<sup>2</sup>C bus by a data pin (SDA) and by a clock pin (SCL). It can be connected with a standard (up to 100 kHz), Fast-mode (up to 400 kHz) or Fast-mode Plus (up to 1 MHz) I<sup>2</sup>C bus.

This interface can also be connected to a SMBus with the data pin (SDA) and clock pin (SCL).

If SMBus feature is supported: the additional optional SMBus Alert pin (SMBA) is also available.

### 30.4.1 I2C block diagram

The block diagram of the I2C interface is shown in [Figure 302](#).

**Figure 302. I2C block diagram**

The I2C is clocked by an independent clock source which allows to the I2C to operate independently from the PCLK frequency.

For I2C I/Os supporting 20 mA output current drive for Fast-mode Plus operation, the driving capability is enabled through control bits in the system configuration controller (SYSCFG). Refer to [Section 30.3: I2C implementation](#).

### 30.4.2 I2C clock requirements

The I2C kernel is clocked by I2CCLK.

The I2CCLK period  $t_{I2CCLK}$  must respect the following conditions:

$$t_{I2CCLK} < (t_{LOW} - t_{filters}) / 4 \text{ and } t_{I2CCLK} < t_{HIGH}$$

with:

$t_{LOW}$ : SCL low time and  $t_{HIGH}$ : SCL high time

$t_{filters}$ : when enabled, sum of the delays brought by the analog filter and by the digital filter.

Analog filter delay is maximum 260 ns. Digital filter delay is  $DNF \times t_{I2CCLK}$ .

The PCLK clock period  $t_{PCLK}$  must respect the following condition:

$$t_{PCLK} < 4/3 t_{SCL}$$

with  $t_{SCL}$ : SCL period

**Caution:** When the I2C kernel is clocked by PCLK, this clock must respect the conditions for  $t_{I2CCLK}$ .

### 30.4.3 Mode selection

The interface can operate in one of the four following modes:

- Slave transmitter
- Slave receiver
- Master transmitter
- Master receiver

By default, it operates in slave mode. The interface automatically switches from slave to master when it generates a START condition, and from master to slave if an arbitration loss or a STOP generation occurs, allowing multimaster capability.

#### Communication flow

In Master mode, the I2C interface initiates a data transfer and generates the clock signal. A serial data transfer always begins with a START condition and ends with a STOP condition. Both START and STOP conditions are generated in master mode by software.

In Slave mode, the interface is capable of recognizing its own addresses (7 or 10-bit), and the General Call address. The General Call address detection can be enabled or disabled by software. The reserved SMBus addresses can also be enabled by software.

Data and addresses are transferred as 8-bit bytes, MSB first. The first byte(s) following the START condition contain the address (one in 7-bit mode, two in 10-bit mode). The address is always transmitted in Master mode.

A 9th clock pulse follows the 8 clock cycles of a byte transfer, during which the receiver must send an acknowledge bit to the transmitter. Refer to the following figure.

Figure 303. I<sup>2</sup>C bus protocol

Acknowledge can be enabled or disabled by software. The I2C interface addresses can be selected by software.

30.4.4 I2C initialization

Enabling and disabling the peripheral

The I2C peripheral clock must be configured and enabled in the clock controller.

Then the I2C can be enabled by setting the PE bit in the I2C\_CR1 register.

When the I2C is disabled (PE=0), the I<sup>2</sup>C performs a software reset. Refer to [Section 30.4.5: Software reset](#) for more details.

Noise filters

Before enabling the I2C peripheral by setting the PE bit in I2C\_CR1 register, the user must configure the noise filters, if needed. By default, an analog noise filter is present on the SDA and SCL inputs. This analog filter is compliant with the I<sup>2</sup>C specification which requires the suppression of spikes with a pulse width up to 50 ns in Fast-mode and Fast-mode Plus. The user can disable this analog filter by setting the ANFOFF bit, and/or select a digital filter by configuring the DNF[3:0] bit in the I2C\_CR1 register.

When the digital filter is enabled, the level of the SCL or the SDA line is internally changed only if it remains stable for more than DNF x I2CCLK periods. This allows to suppress spikes with a programmable length of 1 to 15 I2CCLK periods.

Table 177. Comparison of analog vs. digital filters

| -                                | Analog filter | Digital filter                                         |
|----------------------------------|---------------|--------------------------------------------------------|
| Pulse width of suppressed spikes | ≥ 50 ns       | Programmable length from 1 to 15 I2C peripheral clocks |

**Caution:** Changing the filter configuration is not allowed when the I2C is enabled.

## I2C timings

The timings must be configured in order to guarantee a correct data hold and setup time, used in master and slave modes. This is done by programming the PRESC[3:0], SCLDEL[3:0] and SDADEL[3:0] bits in the I2C\_TIMINGR register.

The STM32CubeMX tool calculates and provides the I2C\_TIMINGR content in the I2C configuration window

**Figure 304. Setup and hold timings**

- When the SCL falling edge is internally detected, a delay is inserted before sending SDA output. This delay is  $t_{SDADEL} = SDADEL \times t_{PRESC} + t_{I2CCLK}$  where  $t_{PRESC} = (PRESC+1) \times t_{I2CCLK}$ .  
 $t_{SDADEL}$  impacts the hold time  $t_{HD;DAT}$ .

The total SDA output delay is:

$$t_{SYNC1} + \{[SDADEL \times (PRESC+1) + 1] \times t_{I2CCLK}\}$$

$t_{SYNC1}$  duration depends on these parameters:

- SCL falling slope
- When enabled, input delay brought by the analog filter:  $t_{AF(min)} < t_{AF} < t_{AF(max)}$  ns.
- When enabled, input delay brought by the digital filter:  $t_{DNF} = DNF \times t_{I2CCLK}$
- Delay due to SCL synchronization to I2CCLK clock (2 to 3 I2CCLK periods)

In order to bridge the undefined region of the SCL falling edge, the user must program SDADEL in such a way that:

$$\{t_f(max) + t_{HD;DAT(min)} - t_{AF(min)} - [(DNF+3) \times t_{I2CCLK}]\} / \{(PRESC+1) \times t_{I2CCLK}\} \leq SDADEL$$

$$SDADEL \leq \{t_{HD;DAT(max)} - t_{AF(max)} - [(DNF+4) \times t_{I2CCLK}]\} / \{(PRESC+1) \times t_{I2CCLK}\}$$

*Note:*  $t_{AF(min)} / t_{AF(max)}$  are part of the equation only when the analog filter is enabled. Refer to device datasheet for  $t_{AF}$  values.

The maximum  $t_{HD;DAT}$  can be 3.45  $\mu$ s, 0.9  $\mu$ s and 0.45  $\mu$ s for Standard-mode, Fast-mode and Fast-mode Plus, but must be less than the maximum of  $t_{VD;DAT}$  by a transition time. This maximum must only be met if the device does not stretch the LOW period ( $t_{LOW}$ ) of the SCL signal. If the clock stretches the SCL, the data must be valid by the set-up time before it releases the clock.

The SDA rising edge is usually the worst case, so in this case the previous equation becomes:

$$SDADEL \leq \{t_{VD;DAT(max)} - t_r(max) - 260\text{ ns} - [(DNF+4) \times t_{I2CCLK}]\} / \{(PRESC+1) \times t_{I2CCLK}\}.$$

*Note:* This condition can be violated when NOSTRETCH=0, because the device stretches SCL low to guarantee the set-up time, according to the SCLDEL value.

Refer to [Table 178: I2C-SMBUS specification data setup and hold times](#) for  $t_f$ ,  $t_r$ ,  $t_{HD;DAT}$  and  $t_{VD;DAT}$  standard values.

- After  $t_{SDADEL}$  delay, or after sending SDA output in case the slave had to stretch the clock because the data was not yet written in I2C\_TXDR register, SCL line is kept at low level during the setup time. This setup time is  $t_{SCLDEL} = (SCLDEL+1) \times t_{PRESC}$  where  $t_{PRESC} = (PRESC+1) \times t_{I2CCLK}$ .  
 $t_{SCLDEL}$  impacts the setup time  $t_{SU;DAT}$ .

In order to bridge the undefined region of the SDA transition (rising edge usually worst case), the user must program SCLDEL in such a way that:

$$\{[t_r(max) + t_{SU;DAT(min)}] / [(PRESC+1) \times t_{I2CCLK}]\} - 1 \leq SCLDEL$$

Refer to [Table 178: I2C-SMBUS specification data setup and hold times](#) for  $t_r$  and  $t_{SU;DAT}$  standard values.

The SDA and SCL transition time values to be used are the ones in the application. Using the maximum values from the standard increases the constraints for the SDADEL and SCLDEL calculation, but ensures the feature whatever the application.

**Note:** At every clock pulse, after SCL falling edge detection, the I2C master or slave stretches SCL low during at least  $[(SDADEL+SCLDEL+1) \times (PRESC+1) + 1] \times t_{I2CCCLK}$ , in both transmission and reception modes. In transmission mode, in case the data is not yet written in I2C\_TXDR when SDADEL counter is finished, the I2C keeps on stretching SCL low until the next data is written. Then new data MSB is sent on SDA output, and SCLDEL counter starts, continuing stretching SCL low to guarantee the data setup time.

If NOSTRETCH=1 in slave mode, the SCL is not stretched. Consequently the SDADEL must be programmed in such a way to guarantee also a sufficient setup time.

**Table 178. I<sup>2</sup>C-SMBUS specification data setup and hold times**

| Symbol       | Parameter                             | Standard-mode (Sm) |      | Fast-mode (Fm) |     | Fast-mode Plus (Fm+) |      | SMBUS |      | Unit    |
|--------------|---------------------------------------|--------------------|------|----------------|-----|----------------------|------|-------|------|---------|
|              |                                       | Min.               | Max  | Min.           | Max | Min.                 | Max  | Min.  | Max  |         |
| $t_{HD;DAT}$ | Data hold time                        | 0                  | -    | 0              | -   | 0                    | -    | 0.3   | -    | $\mu s$ |
| $t_{VD;DAT}$ | Data valid time                       | -                  | 3.45 | -              | 0.9 | -                    | 0.45 | -     | -    |         |
| $t_{SU;DAT}$ | Data setup time                       | 250                | -    | 100            | -   | 50                   | -    | 250   | -    | ns      |
| $t_r$        | Rise time of both SDA and SCL signals | -                  | 1000 | -              | 300 | -                    | 120  | -     | 1000 |         |
| $t_f$        | Fall time of both SDA and SCL signals | -                  | 300  | -              | 300 | -                    | 120  | -     | 300  |         |

Additionally, in master mode, the SCL clock high and low levels must be configured by programming the PRESC[3:0], SCLH[7:0] and SCLL[7:0] bits in the I2C\_TIMINGR register.

- When the SCL falling edge is internally detected, a delay is inserted before releasing the SCL output. This delay is  $t_{SCLL} = (SCLL+1) \times t_{PRESC}$  where  $t_{PRESC} = (PRESC+1) \times t_{I2CCCLK}$ .  $t_{SCLL}$  impacts the SCL low time  $t_{LOW}$ .
- When the SCL rising edge is internally detected, a delay is inserted before forcing the SCL output to low level. This delay is  $t_{SCLH} = (SCLH+1) \times t_{PRESC}$  where  $t_{PRESC} = (PRESC+1) \times t_{I2CCCLK}$ .  $t_{SCLH}$  impacts the SCL high time  $t_{HIGH}$ .

Refer to [I2C master initialization](#) for more details.

**Caution:** Changing the timing configuration is not allowed when the I2C is enabled.

The I2C slave NOSTRETCH mode must also be configured before enabling the peripheral. Refer to [I2C slave initialization](#) for more details.

**Caution:** Changing the NOSTRETCH configuration is not allowed when the I2C is enabled.

Figure 305. I2C initialization flowchart

### 30.4.5 Software reset

A software reset can be performed by clearing the PE bit in the I2C\_CR1 register. In that case I2C lines SCL and SDA are released. Internal states machines are reset and communication control bits, as well as status bits come back to their reset value. The configuration registers are not impacted.

Here is the list of impacted register bits:

1. I2C\_CR2 register: START, STOP, NACK
2. I2C\_ISR register: BUSY, TXE, TXIS, RXNE, ADDR, NACKF, TCR, TC, STOPF, BERR, ARLO, OVR

and in addition when the SMBus feature is supported:

1. I2C\_CR2 register: PECBYTE
2. I2C\_ISR register: PECERR, TIMEOUT, ALERT

PE must be kept low during at least 3 APB clock cycles in order to perform the software reset. This is ensured by writing the following software sequence: - Write PE=0 - Check PE=0 - Write PE=1.

### 30.4.6 Data transfer

The data transfer is managed through transmit and receive data registers and a shift register.

#### Reception

The SDA input fills the shift register. After the 8th SCL pulse (when the complete data byte is received), the shift register is copied into I2C\_RXDR register if it is empty (RXNE=0). If RXNE=1, meaning that the previous received data byte has not yet been read, the SCL line is stretched low until I2C\_RXDR is read. The stretch is inserted between the 8th and 9th SCL pulse (before the Acknowledge pulse).

**Figure 306. Data reception**

## Transmission

If the I2C\_TXDR register is not empty (TXE=0), its content is copied into the shift register after the 9th SCL pulse (the Acknowledge pulse). Then the shift register content is shifted out on SDA line. If TXE=1, meaning that no data is written yet in I2C\_TXDR, SCL line is stretched low until I2C\_TXDR is written. The stretch is done after the 9th SCL pulse.

**Figure 307. Data transmission**

## Hardware transfer management

The I2C has a byte counter embedded in hardware in order to manage byte transfer and to close the communication in various modes such as:

- NACK, STOP and ReSTART generation in master mode
- ACK control in slave receiver mode
- PEC generation/checking when SMBus feature is supported

The byte counter is always used in master mode. By default it is disabled in slave mode, but it can be enabled by software by setting the SBC (Slave Byte Control) bit in the I2C\_CR2 register.

The number of bytes to be transferred is programmed in the NBYTES[7:0] bit field in the I2C\_CR2 register. If the number of bytes to be transferred (NBYTES) is greater than 255, or if a receiver wants to control the acknowledge value of a received data byte, the reload mode must be selected by setting the RELOAD bit in the I2C\_CR2 register. In this mode, TCR flag is set when the number of bytes programmed in NBYTES has been transferred, and an interrupt is generated if TCIE is set. SCL is stretched as long as TCR flag is set. TCR is cleared by software when NBYTES is written to a non-zero value.

When the NBYTES counter is reloaded with the last number of bytes, RELOAD bit must be cleared.

When RELOAD=0 in master mode, the counter can be used in 2 modes:

- **Automatic end mode** (AUTOEND = '1' in the I2C\_CR2 register). In this mode, the master automatically sends a STOP condition once the number of bytes programmed in the NBYTES[7:0] bit field has been transferred.
- **Software end mode** (AUTOEND = '0' in the I2C\_CR2 register). In this mode, software action is expected once the number of bytes programmed in the NBYTES[7:0] bit field has been transferred; the TC flag is set and an interrupt is generated if the TCIE bit is set. The SCL signal is stretched as long as the TC flag is set. The TC flag is cleared by software when the START or STOP bit is set in the I2C\_CR2 register. This mode must be used when the master wants to send a RESTART condition.

**Caution:** The AUTOEND bit has no effect when the RELOAD bit is set.

**Table 179. I2C configuration**

| Function                                | SBC bit | RELOAD bit | AUTOEND bit |
|-----------------------------------------|---------|------------|-------------|
| Master Tx/Rx NBYTES + STOP              | x       | 0          | 1           |
| Master Tx/Rx + NBYTES + RESTART         | x       | 0          | 0           |
| Slave Tx/Rx<br>all received bytes ACKed | 0       | x          | x           |
| Slave Rx with ACK control               | 1       | 1          | x           |

### 30.4.7 I2C slave mode

#### I2C slave initialization

In order to work in slave mode, the user must enable at least one slave address. Two registers I2C\_OAR1 and I2C\_OAR2 are available in order to program the slave own addresses OA1 and OA2.

- OA1 can be configured either in 7-bit mode (by default) or in 10-bit addressing mode by setting the OA1MODE bit in the I2C\_OAR1 register.  
OA1 is enabled by setting the OA1EN bit in the I2C\_OAR1 register.
- If additional slave addresses are required, the 2nd slave address OA2 can be configured. Up to 7 OA2 LSB can be masked by configuring the OA2MSK[2:0] bits in the I2C\_OAR2 register. Therefore for OA2MSK configured from 1 to 6, only OA2[7:2], OA2[7:3], OA2[7:4], OA2[7:5], OA2[7:6] or OA2[7] are compared with the received address. As soon as OA2MSK is not equal to 0, the address comparator for OA2 excludes the I2C reserved addresses (0000 XXX and 1111 XXX), which are not acknowledged. If OA2MSK=7, all received 7-bit addresses are acknowledged (except reserved addresses). OA2 is always a 7-bit address.  
These reserved addresses can be acknowledged if they are enabled by the specific enable bit, if they are programmed in the I2C\_OAR1 or I2C\_OAR2 register with OA2MSK=0.  
OA2 is enabled by setting the OA2EN bit in the I2C\_OAR2 register.
- The General Call address is enabled by setting the GCEN bit in the I2C\_CR1 register.

When the I2C is selected by one of its enabled addresses, the ADDR interrupt status flag is set, and an interrupt is generated if the ADDRIE bit is set.

By default, the slave uses its clock stretching capability, which means that it stretches the SCL signal at low level when needed, in order to perform software actions. If the master does not support clock stretching, the I2C must be configured with NOSTRETCH=1 in the I2C\_CR1 register.

After receiving an ADDR interrupt, if several addresses are enabled the user must read the ADDCODE[6:0] bits in the I2C\_ISR register in order to check which address matched. DIR flag must also be checked in order to know the transfer direction.

### Slave clock stretching (NOSTRETCH = 0)

In default mode, the I2C slave stretches the SCL clock in the following situations:

- When the ADDR flag is set: the received address matches with one of the enabled slave addresses. This stretch is released when the ADDR flag is cleared by software setting the ADDRCONF bit.
- In transmission, if the previous data transmission is completed and no new data is written in I2C\_TXDR register, or if the first data byte is not written when the ADDR flag is cleared (TXE=1). This stretch is released when the data is written to the I2C\_TXDR register.
- In reception when the I2C\_RXDR register is not read yet and a new data reception is completed. This stretch is released when I2C\_RXDR is read.
- When TCR = 1 in Slave Byte Control mode, reload mode (SBC=1 and RELOAD=1), meaning that the last data byte has been transferred. This stretch is released when then TCR is cleared by writing a non-zero value in the NBYTES[7:0] field.
- After SCL falling edge detection, the I2C stretches SCL low during  $[(SDADEL+SCLDEL+1) \times (PRESC+1) + 1] \times t_{I2CCLK}$ .

### Slave without clock stretching (NOSTRETCH = 1)

When NOSTRETCH = 1 in the I2C\_CR1 register, the I2C slave does not stretch the SCL signal.

- The SCL clock is not stretched while the ADDR flag is set.
- In transmission, the data must be written in the I2C\_TXDR register before the first SCL pulse corresponding to its transfer occurs. If not, an underrun occurs, the OVR flag is set in the I2C\_ISR register and an interrupt is generated if the ERRIE bit is set in the I2C\_CR1 register. The OVR flag is also set when the first data transmission starts and the STOPF bit is still set (has not been cleared). Therefore, if the user clears the STOPF flag of the previous transfer only after writing the first data to be transmitted in the next transfer, he ensures that the OVR status is provided, even for the first data to be transmitted.
- In reception, the data must be read from the I2C\_RXDR register before the 9th SCL pulse (ACK pulse) of the next data byte occurs. If not an overrun occurs, the OVR flag is set in the I2C\_ISR register and an interrupt is generated if the ERRIE bit is set in the I2C\_CR1 register.

### Slave Byte Control mode

In order to allow byte ACK control in slave reception mode, Slave Byte Control mode must be enabled by setting the SBC bit in the I2C\_CR1 register. This is required to be compliant with SMBus standards.

Reload mode must be selected in order to allow byte ACK control in slave reception mode (RELOAD=1). To get control of each byte, NBYTES must be initialized to 0x1 in the ADDR interrupt subroutine, and reloaded to 0x1 after each received byte. When the byte is received, the TCR bit is set, stretching the SCL signal low between the 8th and 9th SCL pulses. The user can read the data from the I2C\_RXDR register, and then decide to acknowledge it or not by configuring the ACK bit in the I2C\_CR2 register. The SCL stretch is released by programming NBYTES to a non-zero value: the acknowledge or not-acknowledge is sent and next byte can be received.

NBYTES can be loaded with a value greater than 0x1, and in this case, the reception flow is continuous during NBYTES data reception.

**Note:** The SBC bit must be configured when the I2C is disabled, or when the slave is not addressed, or when ADDR=1.

The RELOAD bit value can be changed when ADDR=1, or when TCR=1.

**Caution:** Slave Byte Control mode is not compatible with NOSTRETCH mode. Setting SBC when NOSTRETCH=1 is not allowed.

**Figure 308. Slave initialization flowchart**

### Slave transmitter

A transmit interrupt status (TXIS) is generated when the I2C\_TXDR register becomes empty. An interrupt is generated if the TXIE bit is set in the I2C\_CR1 register.

The TXIS bit is cleared when the I2C\_TXDR register is written with the next data byte to be transmitted.

When a NACK is received, the NACKF bit is set in the I2C\_ISR register and an interrupt is generated if the NACKIE bit is set in the I2C\_CR1 register. The slave automatically releases the SCL and SDA lines in order to let the master perform a STOP or a RESTART condition. The TXIS bit is not set when a NACK is received.

When a STOP is received and the STOPIE bit is set in the I2C\_CR1 register, the STOPF flag is set in the I2C\_ISR register and an interrupt is generated. In most applications, the SBC bit is usually programmed to '0'. In this case, If TXE = 0 when the slave address is received (ADDR=1), the user can choose either to send the content of the I2C\_TXDR register as the first data byte, or to flush the I2C\_TXDR register by setting the TXE bit in order to program a new data byte.

In Slave Byte Control mode (SBC=1), the number of bytes to be transmitted must be programmed in NBYTES in the address match interrupt subroutine (ADDR=1). In this case, the number of TXIS events during the transfer corresponds to the value programmed in NBYTES.

**Caution:** When NOSTRETCH=1, the SCL clock is not stretched while the ADDR flag is set, so the user cannot flush the I2C\_TXDR register content in the ADDR subroutine, in order to program the first data byte. The first data byte to be sent must be previously programmed in the I2C\_TXDR register:

- This data can be the data written in the last TXIS event of the previous transmission message.
- If this data byte is not the one to be sent, the I2C\_TXDR register can be flushed by setting the TXE bit in order to program a new data byte. The STOPF bit must be cleared only after these actions, in order to guarantee that they are executed before the first data transmission starts, following the address acknowledge.

If STOPF is still set when the first data transmission starts, an underrun error is generated (the OVR flag is set).

If a TXIS event is needed, (Transmit Interrupt or Transmit DMA request), the user must set the TXIS bit in addition to the TXE bit, in order to generate a TXIS event.

**Figure 309. Transfer sequence flowchart for I2C slave transmitter, NOSTRETCH=0**

Figure 310. Transfer sequence flowchart for I2C slave transmitter, NOSTRETCH=1

**Figure 311. Transfer bus diagrams for I2C slave transmitter**

Example I2C slave transmitter 3 bytes with 1st data flushed,  
NOSTRETCH=0:

EV1: ADDR ISR: check ADDCODE and DIR, set TXE, set ADDRCONF

EV2: TXIS ISR: wr data1

EV3: TXIS ISR: wr data2

EV4: TXIS ISR: wr data3

EV5: TXIS ISR: wr data4 (not sent)

Example I2C slave transmitter 3 bytes without 1st data flush,  
NOSTRETCH=0:

EV1: ADDR ISR: check ADDCODE and DIR, set ADDRCONF

EV2: TXIS ISR: wr data2

EV3: TXIS ISR: wr data3

EV4: TXIS ISR: wr data4 (not sent)

Example I2C slave transmitter 3 bytes, NOSTRETCH=1:

EV1: wr data1

EV2: TXIS ISR: wr data2

EV3: TXIS ISR: wr data3

EV4: TXIS ISR: wr data4 (not sent)

EV5: STOPF ISR: (optional: set TXE and TXIS), set STOPCF

MS19853V1

### Slave receiver

RXNE is set in I2C\_ISR when the I2C\_RXDR is full, and generates an interrupt if RXIE is set in I2C\_CR1. RXNE is cleared when I2C\_RXDR is read.

When a STOP is received and STOPIE is set in I2C\_CR1, STOPF is set in I2C\_ISR and an interrupt is generated.

**Figure 312. Transfer sequence flowchart for slave receiver with NOSTRETCH=0**

### 30.4.8 I2C master mode

#### I2C master initialization

Before enabling the peripheral, the I2C master clock must be configured by setting the SCLH and SCLL bits in the I2C\_TIMINGR register.

The STM32CubeMX tool calculates and provides the I2C\_TIMINGR content in the I2C Configuration window.

A clock synchronization mechanism is implemented in order to support multi-master environment and slave clock stretching.

In order to allow clock synchronization:

- The low level of the clock is counted using the SCLL counter, starting from the SCL low level internal detection.
- The high level of the clock is counted using the SCLH counter, starting from the SCL high level internal detection.

The I2C detects its own SCL low level after a  $t_{\text{SYNC1}}$  delay depending on the SCL falling edge, SCL input noise filters (analog + digital) and SCL synchronization to the I2CxCLK clock. The I2C releases SCL to high level once the SCLL counter reaches the value programmed in the SCLL[7:0] bits in the I2C\_TIMINGR register.

The I2C detects its own SCL high level after a  $t_{\text{SYNC2}}$  delay depending on the SCL rising edge, SCL input noise filters (analog + digital) and SCL synchronization to I2CxCLK clock. The I2C ties SCL to low level once the SCLH counter is reached reaches the value programmed in the SCLH[7:0] bits in the I2C\_TIMINGR register.

Consequently the master clock period is:

$$t_{\text{SCL}} = t_{\text{SYNC1}} + t_{\text{SYNC2}} + \{[(\text{SCLH}+1) + (\text{SCLL}+1)] \times (\text{PRESC}+1) \times t_{\text{I2CCLK}}\}$$

The duration of  $t_{\text{SYNC1}}$  depends on these parameters:

- SCL falling slope
- When enabled, input delay induced by the analog filter.
- When enabled, input delay induced by the digital filter:  $\text{DNF} \times t_{\text{I2CCLK}}$
- Delay due to SCL synchronization with I2CCLK clock (2 to 3 I2CCLK periods)

The duration of  $t_{\text{SYNC2}}$  depends on these parameters:

- SCL rising slope
- When enabled, input delay induced by the analog filter.
- When enabled, input delay induced by the digital filter:  $\text{DNF} \times t_{\text{I2CCLK}}$
- Delay due to SCL synchronization with I2CCLK clock (2 to 3 I2CCLK periods)

Figure 315. Master clock generation

**Caution:** In order to be I<sup>2</sup>C or SMBus compliant, the master clock must respect the timings given below:

Table 180. I<sup>2</sup>C-SMBUS specification clock timings

| Symbol              | Parameter                                        | Standard-mode (Sm) |      | Fast-mode (Fm) |     | Fast-mode Plus (Fm+) |      | SMBUS |      | Unit |
|---------------------|--------------------------------------------------|--------------------|------|----------------|-----|----------------------|------|-------|------|------|
|                     |                                                  | Min                | Max  | Min            | Max | Min                  | Max  | Min   | Max  |      |
| f <sub>SCL</sub>    | SCL clock frequency                              | -                  | 100  | -              | 400 | -                    | 1000 | -     | 100  | kHz  |
| t <sub>HD:STA</sub> | Hold time (repeated) START condition             | 4.0                | -    | 0.6            | -   | 0.26                 | -    | 4.0   | -    | μs   |
| t <sub>SU:STA</sub> | Set-up time for a repeated START condition       | 4.7                | -    | 0.6            | -   | 0.26                 | -    | 4.7   | -    | μs   |
| t <sub>SU:STO</sub> | Set-up time for STOP condition                   | 4.0                | -    | 0.6            | -   | 0.26                 | -    | 4.0   | -    | μs   |
| t <sub>BUF</sub>    | Bus free time between a STOP and START condition | 4.7                | -    | 1.3            | -   | 0.5                  | -    | 4.7   | -    | μs   |
| t <sub>LOW</sub>    | Low period of the SCL clock                      | 4.7                | -    | 1.3            | -   | 0.5                  | -    | 4.7   | -    | μs   |
| t <sub>HIGH</sub>   | Period of the SCL clock                          | 4.0                | -    | 0.6            | -   | 0.26                 | -    | 4.0   | 50   | μs   |
| t <sub>r</sub>      | Rise time of both SDA and SCL signals            | -                  | 1000 | -              | 300 | -                    | 120  | -     | 1000 | ns   |
| t <sub>f</sub>      | Fall time of both SDA and SCL signals            | -                  | 300  | -              | 300 | -                    | 120  | -     | 300  | ns   |

**Note:** SCLL is also used to generate the t<sub>BUF</sub> and t<sub>SU:STA</sub> timings.

SCLH is also used to generate the t<sub>HD:STA</sub> and t<sub>SU:STO</sub> timings.

Refer to [Section 30.4.9: I2C\\_TIMINGR register configuration examples](#) for examples of I2C\_TIMINGR settings vs. I2CCLK frequency.

### Master communication initialization (address phase)

In order to initiate the communication, the user must program the following parameters for the addressed slave in the I2C\_CR2 register:

- Addressing mode (7-bit or 10-bit): ADD10
- Slave address to be sent: SADD[9:0]
- Transfer direction: RD\_WRN
- In case of 10-bit address read: HEAD10R bit. HEAD10R must be configure to indicate if the complete address sequence must be sent, or only the header in case of a direction change.
- The number of bytes to be transferred: NBYTES[7:0]. If the number of bytes is equal to or greater than 255 bytes, NBYTES[7:0] must initially be filled with 0xFF.

The user must then set the START bit in I2C\_CR2 register. Changing all the above bits is not allowed when START bit is set.

Then the master automatically sends the START condition followed by the slave address as soon as it detects that the bus is free (BUSY = 0) and after a delay of t<sub>BUF</sub>.

In case of an arbitration loss, the master automatically switches back to slave mode and can acknowledge its own address if it is addressed as a slave.

**Note:** The START bit is reset by hardware when the slave address has been sent on the bus, whatever the received acknowledge value. The START bit is also reset by hardware if an arbitration loss occurs.  
In 10-bit addressing mode, when the Slave Address first 7 bits is NACKed by the slave, the

master re-launches automatically the slave address transmission until ACK is received. In this case ADDRCONF must be set if a NACK is received from the slave, in order to stop sending the slave address.

If the I2C is addressed as a slave (ADDR=1) while the START bit is set, the I2C switches to slave mode and the START bit is cleared, when the ADDRCONF bit is set.

**Note:** The same procedure is applied for a Repeated Start condition. In this case BUSY=1.

**Figure 316. Master initialization flowchart**

#### Initialization of a master receiver addressing a 10-bit address slave

- If the slave address is in 10-bit format, the user can choose to send the complete read sequence by clearing the HEAD10R bit in the I2C\_CR2 register. In this case the master automatically sends the following complete sequence after the START bit is set:  
(Re)Start + Slave address 10-bit header Write + Slave address 2nd byte + REStart + Slave address 10-bit header Read

**Figure 317. 10-bit address read access with HEAD10R=0**

- If the master addresses a 10-bit address slave, transmits data to this slave and then reads data from the same slave, a master transmission flow must be done first. Then a repeated start is set with the 10 bit slave address configured with HEAD10R=1. In this case the master sends this sequence: ReStart + Slave address 10-bit header Read.

Figure 318. 10-bit address read access with HEAD10R=1

### Master transmitter

In the case of a write transfer, the TXIS flag is set after each byte transmission, after the 9th SCL pulse when an ACK is received.

A TXIS event generates an interrupt if the TXIE bit is set in the I2C\_CR1 register. The flag is cleared when the I2C\_TXDR register is written with the next data byte to be transmitted.

The number of TXIS events during the transfer corresponds to the value programmed in NBYTES[7:0]. If the total number of data bytes to be sent is greater than 255, reload mode must be selected by setting the RELOAD bit in the I2C\_CR2 register. In this case, when NBYTES data have been transferred, the TCR flag is set and the SCL line is stretched low until NBYTES[7:0] is written to a non-zero value.

The TXIS flag is not set when a NACK is received.

- When RELOAD=0 and NBYTES data have been transferred:
  - In automatic end mode (AUTOEND=1), a STOP is automatically sent.
  - In software end mode (AUTOEND=0), the TC flag is set and the SCL line is stretched low in order to perform software actions:
 

A RESTART condition can be requested by setting the START bit in the I2C\_CR2 register with the proper slave address configuration, and number of bytes to be transferred. Setting the START bit clears the TC flag and the START condition is sent on the bus.

A STOP condition can be requested by setting the STOP bit in the I2C\_CR2 register. Setting the STOP bit clears the TC flag and the STOP condition is sent on the bus.
- If a NACK is received: the TXIS flag is not set, and a STOP condition is automatically sent after the NACK reception. the NACKF flag is set in the I2C\_ISR register, and an interrupt is generated if the NACKIE bit is set.

Figure 319. Transfer sequence flowchart for I2C master transmitter for  $N \leq 255$  bytes

Figure 320. Transfer sequence flowchart for I2C master transmitter for N&gt;255 bytes

**Figure 321. Transfer bus diagrams for I2C master transmitter****Example I2C master transmitter 2 bytes, automatic end mode (STOP)****Example I2C master transmitter 2 bytes, software end mode (RESTART)**

MS19862V1

### Master receiver

In the case of a read transfer, the RXNE flag is set after each byte reception, after the 8th SCL pulse. An RXNE event generates an interrupt if the RXIE bit is set in the I2C\_CR1 register. The flag is cleared when I2C\_RXDR is read.

If the total number of data bytes to be received is greater than 255, reload mode must be selected by setting the RELOAD bit in the I2C\_CR2 register. In this case, when NBYTES[7:0] data have been transferred, the TCR flag is set and the SCL line is stretched low until NBYTES[7:0] is written to a non-zero value.

- When RELOAD=0 and NBYTES[7:0] data have been transferred:
  - In automatic end mode (AUTOEND=1), a NACK and a STOP are automatically sent after the last received byte.
  - In software end mode (AUTOEND=0), a NACK is automatically sent after the last received byte, the TC flag is set and the SCL line is stretched low in order to allow software actions:

A RESTART condition can be requested by setting the START bit in the I2C\_CR2 register with the proper slave address configuration, and number of bytes to be transferred. Setting the START bit clears the TC flag and the START condition, followed by slave address, are sent on the bus.

A STOP condition can be requested by setting the STOP bit in the I2C\_CR2 register. Setting the STOP bit clears the TC flag and the STOP condition is sent on the bus.

### 30.4.9 I2C\_TIMINGR register configuration examples

The tables below provide examples of how to program the I2C\_TIMINGR to obtain timings compliant with the I<sup>2</sup>C specification. In order to get more accurate configuration values, the STM32CubeMX tool (I2C Configuration window) must be used.

**Table 181. Examples of timing settings for  $f_{I2CCLK} = 8\text{ MHz}$**

| Parameter       | Standard-mode (Sm)          |                            | Fast-mode (Fm)          | Fast-mode Plus (Fm+)    |
|-----------------|-----------------------------|----------------------------|-------------------------|-------------------------|
|                 | 10 kHz                      | 100 kHz                    | 400 kHz                 | 500 kHz                 |
| PRESC           | 1                           | 1                          | 0                       | 0                       |
| SCLL            | 0xC7                        | 0x13                       | 0x9                     | 0x6                     |
| $t_{SCLL}$      | 200x250 ns = 50 $\mu$ s     | 20x250 ns = 5.0 $\mu$ s    | 10x125 ns = 1250 ns     | 7x125 ns = 875 ns       |
| SCLH            | 0xC3                        | 0xF                        | 0x3                     | 0x3                     |
| $t_{SCLH}$      | 196x250 ns = 49 $\mu$ s     | 16x250 ns = 4.0 $\mu$ s    | 4x125ns = 500ns         | 4x125 ns = 500 ns       |
| $t_{SCL}^{(1)}$ | ~100 $\mu$ s <sup>(2)</sup> | ~10 $\mu$ s <sup>(2)</sup> | ~2500 ns <sup>(3)</sup> | ~2000 ns <sup>(4)</sup> |
| SDADEL          | 0x2                         | 0x2                        | 0x1                     | 0x0                     |
| $t_{SDADEL}$    | 2x250 ns = 500 ns           | 2x250 ns = 500 ns          | 1x125 ns = 125 ns       | 0 ns                    |
| SCLDEL          | 0x4                         | 0x4                        | 0x3                     | 0x1                     |
| $t_{SCLDEL}$    | 5x250 ns = 1250 ns          | 5x250 ns = 1250 ns         | 4x125 ns = 500 ns       | 2x125 ns = 250 ns       |

1. SCL period  $t_{SCL}$  is greater than  $t_{SCLL} + t_{SCLH}$  due to SCL internal detection delay. Values provided for  $t_{SCL}$  are examples only.
2.  $t_{SYNC1} + t_{SYNC2}$  minimum value is  $4 \times t_{I2CCLK} = 500\text{ ns}$ . Example with  $t_{SYNC1} + t_{SYNC2} = 1000\text{ ns}$ .
3.  $t_{SYNC1} + t_{SYNC2}$  minimum value is  $4 \times t_{I2CCLK} = 500\text{ ns}$ . Example with  $t_{SYNC1} + t_{SYNC2} = 750\text{ ns}$ .
4.  $t_{SYNC1} + t_{SYNC2}$  minimum value is  $4 \times t_{I2CCLK} = 500\text{ ns}$ . Example with  $t_{SYNC1} + t_{SYNC2} = 655\text{ ns}$ .

**Table 182. Examples of timings settings for  $f_{I2CCLK} = 16\text{ MHz}$**

| Parameter       | Standard-mode (Sm)          |                            | Fast-mode (Fm)          | Fast-mode Plus (Fm+)    |
|-----------------|-----------------------------|----------------------------|-------------------------|-------------------------|
|                 | 10 kHz                      | 100 kHz                    | 400 kHz                 | 1000 kHz                |
| PRESC           | 3                           | 3                          | 1                       | 0                       |
| SCLL            | 0xC7                        | 0x13                       | 0x9                     | 0x4                     |
| $t_{SCLL}$      | 200 x 250 ns = 50 $\mu$ s   | 20 x 250 ns = 5.0 $\mu$ s  | 10 x 125 ns = 1250 ns   | 5 x 62.5 ns = 312.5 ns  |

| $t_{SCL}^{(1)}$ | ~100 $\mu$ s <sup>(2)</sup> | ~10 $\mu$ s <sup>(2)</sup> | ~2500 ns <sup>(3)</sup> | ~1000 ns <sup>(4)</sup> |
| SDADEL          | 0x2                         | 0x2                        | 0x2                     | 0x0                     |
| $t_{SDADEL}$    | 2 x 250 ns = 500 ns         | 2 x 250 ns = 500 ns        | 2 x 125 ns = 250 ns     | 0 ns                    |
| SCLDEL          | 0x4                         | 0x4                        | 0x3                     | 0x2                     |
| $t_{SCLDEL}$    | 5 x 250 ns = 1250 ns        | 5 x 250 ns = 1250 ns       | 4 x 125 ns = 500 ns     | 3 x 62.5 ns = 187.5 ns  |

1. SCL period  $t_{SCL}$  is greater than  $t_{SCLL} + t_{SCLH}$  due to SCL internal detection delay. Values provided for  $t_{SCL}$  are examples only.

2.  $t_{\text{SYNC1}} + t_{\text{SYNC2}}$  minimum value is  $4 \times t_{\text{I2CCLK}} = 250$  ns. Example with  $t_{\text{SYNC1}} + t_{\text{SYNC2}} = 1000$  ns.
3.  $t_{\text{SYNC1}} + t_{\text{SYNC2}}$  minimum value is  $4 \times t_{\text{I2CCLK}} = 250$  ns. Example with  $t_{\text{SYNC1}} + t_{\text{SYNC2}} = 750$  ns.
4.  $t_{\text{SYNC1}} + t_{\text{SYNC2}}$  minimum value is  $4 \times t_{\text{I2CCLK}} = 250$  ns. Example with  $t_{\text{SYNC1}} + t_{\text{SYNC2}} = 500$  ns.

Table 183. Examples of timings settings for  $f_{\text{I2CCLK}} = 48$  MHz

| Parameter              | Standard-mode (Sm)               |                                  | Fast-mode (Fm)                | Fast-mode Plus (Fm+)         |
|------------------------|----------------------------------|----------------------------------|-------------------------------|------------------------------|
|                        | 10 kHz                           | 100 kHz                          | 400 kHz                       | 1000 kHz                     |
| PRESC                  | 0xB                              | 0xB                              | 5                             | 5                            |
| SCLL                   | 0xC7                             | 0x13                             | 0x9                           | 0x3                          |
| $t_{\text{SCLL}}$      | $200 \times 250$ ns = 50 $\mu$ s | $20 \times 250$ ns = 5.0 $\mu$ s | $10 \times 125$ ns = 1250 ns  | $4 \times 125$ ns = 500 ns   |
| SCLH                   | 0xC3                             | 0xF                              | 0x3                           | 0x1                          |
| $t_{\text{SCLH}}$      | $196 \times 250$ ns = 49 $\mu$ s | $16 \times 250$ ns = 4.0 $\mu$ s | $4 \times 125$ ns = 500 ns    | $2 \times 125$ ns = 250 ns   |
| $t_{\text{SCL}}^{(1)}$ | $\sim 100 \mu\text{s}^{(2)}$     | $\sim 10 \mu\text{s}^{(2)}$      | $\sim 2500$ ns <sup>(3)</sup> | $\sim 875$ ns <sup>(4)</sup> |
| SDADEL                 | 0x2                              | 0x2                              | 0x3                           | 0x0                          |
| $t_{\text{SDADEL}}$    | $2 \times 250$ ns = 500 ns       | $2 \times 250$ ns = 500 ns       | $3 \times 125$ ns = 375 ns    | 0 ns                         |
| SCLDEL                 | 0x4                              | 0x4                              | 0x3                           | 0x1                          |
| $t_{\text{SCLDEL}}$    | $5 \times 250$ ns = 1250 ns      | $5 \times 250$ ns = 1250 ns      | $4 \times 125$ ns = 500 ns    | $2 \times 125$ ns = 250 ns   |

1. The SCL period  $t_{\text{SCL}}$  is greater than  $t_{\text{SCLL}} + t_{\text{SCLH}}$  due to the SCL internal detection delay. Values provided for  $t_{\text{SCL}}$  are only examples.
2.  $t_{\text{SYNC1}} + t_{\text{SYNC2}}$  minimum value is  $4 \times t_{\text{I2CCLK}} = 83.3$  ns. Example with  $t_{\text{SYNC1}} + t_{\text{SYNC2}} = 1000$  ns
3.  $t_{\text{SYNC1}} + t_{\text{SYNC2}}$  minimum value is  $4 \times t_{\text{I2CCLK}} = 83.3$  ns. Example with  $t_{\text{SYNC1}} + t_{\text{SYNC2}} = 750$  ns
4.  $t_{\text{SYNC1}} + t_{\text{SYNC2}}$  minimum value is  $4 \times t_{\text{I2CCLK}} = 83.3$  ns. Example with  $t_{\text{SYNC1}} + t_{\text{SYNC2}} = 250$  ns

### 30.4.10 SMBus specific features

This section is relevant only when SMBus feature is supported. Refer to [Section 30.3: I2C implementation](#).

#### Introduction

The System Management Bus (SMBus) is a two-wire interface through which various devices can communicate with each other and with the rest of the system. It is based on I<sup>2</sup>C principles of operation. SMBus provides a control bus for system and power management related tasks.

This peripheral is compatible with the SMBUS specification (<http://smbus.org>).

The System Management Bus Specification refers to three types of devices.

- A slave is a device that receives or responds to a command.
- A master is a device that issues commands, generates the clocks and terminates the transfer.
- A host is a specialized master that provides the main interface to the system's CPU. A host must be a master-slave and must support the SMBus host notify protocol. Only one host is allowed in a system.

This peripheral can be configured as master or slave device, and also as a host.

## Bus protocols

There are eleven possible command protocols for any given device. A device may use any or all of the eleven protocols to communicate. The protocols are Quick Command, Send Byte, Receive Byte, Write Byte, Write Word, Read Byte, Read Word, Process Call, Block Read, Block Write and Block Write-Block Read Process Call. These protocols should be implemented by the user software.

For more details of these protocols, refer to SMBus specification (<http://smbus.org>).

## Address resolution protocol (ARP)

SMBus slave address conflicts can be resolved by dynamically assigning a new unique address to each slave device. In order to provide a mechanism to isolate each device for the purpose of address assignment each device must implement a unique device identifier (UDID). This 128-bit number is implemented by software.

This peripheral supports the Address Resolution Protocol (ARP). The SMBus Device Default Address (0b1100 001) is enabled by setting SMBDEN bit in I2C\_CR1 register. The ARP commands should be implemented by the user software.

Arbitration is also performed in slave mode for ARP support.

For more details of the SMBus Address Resolution Protocol, refer to SMBus specification (<http://smbus.org>).

## Received Command and Data acknowledge control

A SMBus receiver must be able to NACK each received command or data. In order to allow the ACK control in slave mode, the Slave Byte Control mode must be enabled by setting SBC bit in I2C\_CR1 register. Refer to [Slave Byte Control mode on page 971](#) for more details.

## Host Notify protocol

This peripheral supports the Host Notify protocol by setting the SMBHEN bit in the I2C\_CR1 register. In this case the host acknowledges the SMBus Host address (0b0001 000).

When this protocol is used, the device acts as a master and the host as a slave.

## SMBus alert

The SMBus ALERT optional signal is supported. A slave-only device can signal the host through the SMBALERT# pin that it wants to talk. The host processes the interrupt and simultaneously accesses all SMBALERT# devices through the Alert Response Address (0b0001 100). Only the device(s) which pulled SMBALERT# low acknowledges the Alert Response Address.

When configured as a slave device (SMBHEN=0), the SMBA pin is pulled low by setting the ALERTEN bit in the I2C\_CR1 register. The Alert Response Address is enabled at the same time.

When configured as a host (SMBHEN=1), the ALERT flag is set in the I2C\_ISR register when a falling edge is detected on the SMBA pin and ALERTEN=1. An interrupt is generated if the ERRIE bit is set in the I2C\_CR1 register. When ALERTEN=0, the ALERT line is considered high even if the external SMBA pin is low.

*If the SMBus ALERT pin is not needed, the SMBA pin can be used as a standard GPIO if ALERTEN=0.*

### Packet error checking

A packet error checking mechanism has been introduced in the SMBus specification to improve reliability and communication robustness. Packet Error Checking is implemented by appending a Packet Error Code (PEC) at the end of each message transfer. The PEC is calculated by using the  $C(x) = x^8 + x^2 + x + 1$  CRC-8 polynomial on all the message bytes (including addresses and read/write bits).

The peripheral embeds a hardware PEC calculator and allows to send a Not Acknowledge automatically when the received byte does not match with the hardware calculated PEC.

### Timeouts

This peripheral embeds hardware timers in order to be compliant with the 3 timeouts defined in SMBus specification.

Table 184. SMBus timeout specifications

| Symbol                      | Parameter                                        | Limits |     | Unit |
|-----------------------------|--------------------------------------------------|--------|-----|------|
|                             |                                                  | Min    | Max |      |
| $t_{\text{TIMEOUT}}$        | Detect clock low timeout                         | 25     | 35  | ms   |
| $t_{\text{LOW:SEXT}}^{(1)}$ | Cumulative clock low extend time (slave device)  | -      | 25  | ms   |
| $t_{\text{LOW:MEXT}}^{(2)}$ | Cumulative clock low extend time (master device) | -      | 10  | ms   |

1.  $t_{\text{LOW:SEXT}}$  is the cumulative time a given slave device is allowed to extend the clock cycles in one message from the initial START to the STOP. It is possible that, another slave device or the master also extends the clock causing the combined clock low extend time to be greater than  $t_{\text{LOW:SEXT}}$ . Therefore, this parameter is measured with the slave device as the sole target of a full-speed master.
2.  $t_{\text{LOW:MEXT}}$  is the cumulative time a master device is allowed to extend its clock cycles within each byte of a message as defined from START-to-ACK, ACK-to-ACK, or ACK-to-STOP. It is possible that a slave device or another master also extends the clock causing the combined clock low time to be greater than  $t_{\text{LOW:MEXT}}$  on a given byte. Therefore, this parameter is measured with a full speed slave device as the sole target of the master.

Figure 325. Timeout intervals for  $t_{\text{LOW:SEXT}}$ ,  $t_{\text{LOW:MEXT}}$

### Bus idle detection

A master can assume that the bus is free if it detects that the clock and data signals have been high for  $t_{IDLE}$  greater than  $t_{HIGH,MAX}$ . (refer to [Table 178: I2C-SMBUS specification data setup and hold times](#))

This timing parameter covers the condition where a master has been dynamically added to the bus and may not have detected a state transition on the SMBCLK or SMBDAT lines. In this case, the master must wait long enough to ensure that a transfer is not currently in progress. The peripheral supports a hardware bus idle detection.

## 30.4.11 SMBus initialization

This section is relevant only when SMBus feature is supported. Refer to [Section 30.3: I2C implementation](#).

In addition to I2C initialization, some other specific initialization must be done in order to perform SMBus communication:

### Received Command and Data Acknowledge control (Slave mode)

A SMBus receiver must be able to NACK each received command or data. In order to allow ACK control in slave mode, the Slave Byte Control mode must be enabled by setting the SBC bit in the I2C\_CR1 register. Refer to [Slave Byte Control mode on page 971](#) for more details.

### Specific address (Slave mode)

The specific SMBus addresses must be enabled if needed. Refer to [Bus idle detection on page 994](#) for more details.

- The SMBus Device Default address (0b1100 001) is enabled by setting the SMBDEN bit in the I2C\_CR1 register.
- The SMBus Host address (0b0001 000) is enabled by setting the SMBHEN bit in the I2C\_CR1 register.
- The Alert Response Address (0b0001100) is enabled by setting the ALERTEN bit in the I2C\_CR1 register.

### Packet error checking

PEC calculation is enabled by setting the PECEN bit in the I2C\_CR1 register. Then the PEC transfer is managed with the help of a hardware byte counter: NBYTES[7:0] in the I2C\_CR2 register. The PECEN bit must be configured before enabling the I2C.

The PEC transfer is managed with the hardware byte counter, so the SBC bit must be set when interfacing the SMBus in slave mode. The PEC is transferred after NBYTES-1 data have been transferred when the PECBYTE bit is set and the RELOAD bit is cleared. If RELOAD is set, PECBYTE has no effect.

**Caution:** Changing the PECEN configuration is not allowed when the I2C is enabled.

Table 185. SMBUS with PEC configuration

| Mode                                | SBC bit | RELOAD bit | AUTOEND bit | PECBYTE bit |
|-------------------------------------|---------|------------|-------------|-------------|
| Master Tx/Rx NBYTES + PEC+ STOP     | x       | 0          | 1           | 1           |
| Master Tx/Rx NBYTES + PEC + ReSTART | x       | 0          | 0           | 1           |
| Slave Tx/Rx with PEC                | 1       | 0          | x           | 1           |

### Timeout detection

The timeout detection is enabled by setting the TIMOUTEN and TEXTEN bits in the I2C\_TIMEOUTR register. The timers must be programmed in such a way that they detect a timeout before the maximum time given in the SMBus specification.

- $t_{\text{TIMEOUT}}$  check  
In order to enable the  $t_{\text{TIMEOUT}}$  check, the 12-bit TIMEOUTA[11:0] bits must be programmed with the timer reload value in order to check the  $t_{\text{TIMEOUT}}$  parameter. The TIDLE bit must be configured to '0' in order to detect the SCL low level timeout.  
Then the timer is enabled by setting the TIMOUTEN in the I2C\_TIMEOUTR register.  
If SCL is tied low for a time greater than  $(\text{TIMEOUTA}+1) \times 2048 \times t_{\text{I2CCLK}}$ , the TIMEOUT flag is set in the I2C\_ISR register.  
Refer to [Table 186: Examples of TIMEOUTA settings for various I2CCLK frequencies \(max  \$t\_{\text{TIMEOUT}} = 25 \text{ ms}\$ \)](#).

**Caution:** Changing the TIMEOUTA[11:0] bits and TIDLE bit configuration is not allowed when the TIMOUTEN bit is set.

- $t_{\text{LOW:SEXT}}$  and  $t_{\text{LOW:MEXT}}$  check  
Depending on if the peripheral is configured as a master or as a slave, The 12-bit TIMEOUTB timer must be configured in order to check  $t_{\text{LOW:SEXT}}$  for a slave and  $t_{\text{LOW:MEXT}}$  for a master. As the standard specifies only a maximum, the user can choose the same value for the both.  
Then the timer is enabled by setting the TEXTEN bit in the I2C\_TIMEOUTR register.  
If the SMBus peripheral performs a cumulative SCL stretch for a time greater than  $(\text{TIMEOUTB}+1) \times 2048 \times t_{\text{I2CCLK}}$ , and in the timeout interval described in [Bus idle detection on page 994](#) section, the TIMEOUT flag is set in the I2C\_ISR register.  
Refer to [Table 187: Examples of TIMEOUTB settings for various I2CCLK frequencies](#)

**Caution:** Changing the TIMEOUTB configuration is not allowed when the TEXTEN bit is set.

### Bus Idle detection

In order to enable the  $t_{\text{IDLE}}$  check, the 12-bit TIMEOUTA[11:0] field must be programmed with the timer reload value in order to obtain the  $t_{\text{IDLE}}$  parameter. The TIDLE bit must be configured to '1' in order to detect both SCL and SDA high level timeout.

Then the timer is enabled by setting the TIMOUTEN bit in the I2C\_TIMEOUTR register.

If both the SCL and SDA lines remain high for a time greater than  $(\text{TIMEOUTA}+1) \times 4 \times t_{\text{I2CCLK}}$ , the TIMEOUT flag is set in the I2C\_ISR register.

Refer to [Table 188: Examples of TIMEOUTA settings for various I2CCLK frequencies \(max  \$t\_{\text{IDLE}} = 50 \mu\text{s}\$ \)](#)

**Caution:** Changing the TIMEOUTA and TIDLE configuration is not allowed when the TIMEOUTEN is set.

### 30.4.12 SMBus: I2C\_TIMEOUTR register configuration examples

This section is relevant only when SMBus feature is supported. Refer to [Section 30.3: I2C implementation](#).

- Configuring the maximum duration of  $t_{\text{TIMEOUT}}$  to 25 ms:

**Table 186. Examples of TIMEOUTA settings for various I2CCLK frequencies**  
(max  $t_{\text{TIMEOUT}} = 25$  ms)

| $f_{\text{I2CCLK}}$ | TIMEOUTA[11:0] bits | TIDLE bit | TIMEOUTEN bit | $t_{\text{TIMEOUT}}$                                      |
|---------------------|---------------------|-----------|---------------|-----------------------------------------------------------|
| 8 MHz               | 0x61                | 0         | 1             | $98 \times 2048 \times 125 \text{ ns} = 25 \text{ ms}$    |
| 16 MHz              | 0xC3                | 0         | 1             | $196 \times 2048 \times 62.5 \text{ ns} = 25 \text{ ms}$  |
| 32 MHz              | 0x186               | 0         | 1             | $391 \times 2048 \times 31.25 \text{ ns} = 25 \text{ ms}$ |

- Configuring the maximum duration of  $t_{\text{LOW:SEXT}}$  and  $t_{\text{LOW:MEXT}}$  to 8 ms:

**Table 187. Examples of TIMEOUTB settings for various I2CCLK frequencies**

| $f_{\text{I2CCLK}}$ | TIMEOUTB[11:0] bits | TEXTEN bit | $t_{\text{LOW:EXT}}$                                     |
|---------------------|---------------------|------------|----------------------------------------------------------|
| 8 MHz               | 0x1F                | 1          | $32 \times 2048 \times 125 \text{ ns} = 8 \text{ ms}$    |
| 16 MHz              | 0x3F                | 1          | $64 \times 2048 \times 62.5 \text{ ns} = 8 \text{ ms}$   |
| 32 MHz              | 0x7C                | 1          | $125 \times 2048 \times 31.25 \text{ ns} = 8 \text{ ms}$ |

- Configuring the maximum duration of  $t_{\text{IDLE}}$  to 50  $\mu\text{s}$

**Table 188. Examples of TIMEOUTA settings for various I2CCLK frequencies**  
(max  $t_{\text{IDLE}} = 50$   $\mu\text{s}$ )

| $f_{\text{I2CCLK}}$ | TIMEOUTA[11:0] bits | TIDLE bit | TIMEOUTEN bit | $t_{\text{TIDLE}}$                                      |
|---------------------|---------------------|-----------|---------------|---------------------------------------------------------|
| 8 MHz               | 0x63                | 1         | 1             | $100 \times 4 \times 125 \text{ ns} = 50 \mu\text{s}$   |
| 16 MHz              | 0xC7                | 1         | 1             | $200 \times 4 \times 62.5 \text{ ns} = 50 \mu\text{s}$  |
| 32 MHz              | 0x18F               | 1         | 1             | $400 \times 4 \times 31.25 \text{ ns} = 50 \mu\text{s}$ |

### 30.4.13 SMBus slave mode

This section is relevant only when SMBus feature is supported. Refer to [Section 30.3: I2C implementation](#).

In addition to I2C slave transfer management (refer to [Section 30.4.7: I2C slave mode](#)) some additional software flowcharts are provided to support SMBus.

#### SMBus Slave transmitter

When the IP is used in SMBus, SBC must be programmed to '1' in order to allow the PEC transmission at the end of the programmed number of data bytes. When the PECBYTE bit is set, the number of bytes programmed in NBYTES[7:0] includes the PEC transmission. In

that case the total number of TXIS interrupts is NBYTES-1 and the content of the I2C\_PECR register is automatically transmitted if the master requests an extra byte after the NBYTES-1 data transfer.

**Caution:** The PECBYTE bit has no effect when the RELOAD bit is set.

**Figure 326. Transfer sequence flowchart for SMBus slave transmitter N bytes + PEC**

**Figure 327. Transfer bus diagrams for SMBus slave transmitter (SBC=1)**

### SMBus Slave receiver

When the I2C is used in SMBus mode, SBC must be programmed to '1' in order to allow the PEC checking at the end of the programmed number of data bytes. In order to allow the ACK control of each byte, the reload mode must be selected (RELOAD=1). Refer to [Slave Byte Control mode on page 971](#) for more details.

In order to check the PEC byte, the RELOAD bit must be cleared and the PECBYTE bit must be set. In this case, after NBYTES-1 data have been received, the next received byte is compared with the internal I2C\_PECR register content. A NACK is automatically generated if the comparison does not match, and an ACK is automatically generated if the comparison matches, whatever the ACK bit value. Once the PEC byte is received, it is copied into the I2C\_RXDR register like any other data, and the RXNE flag is set.

In the case of a PEC mismatch, the PECERR flag is set and an interrupt is generated if the ERRIE bit is set in the I2C\_CR1 register.

If no ACK software control is needed, the user can program PECBYTE=1 and, in the same write operation, program NBYTES with the number of bytes to be received in a continuous flow. After NBYTES-1 are received, the next received byte is checked as being the PEC.

**Caution:** The PECBYTE bit has no effect when the RELOAD bit is set.

Figure 328. Transfer sequence flowchart for SMBus slave receiver N Bytes + PEC

**Figure 329. Bus transfer diagrams for SMBus slave receiver (SBC=1)**

This section is relevant only when SMBus feature is supported. Refer to [Section 30.3: I2C implementation](#).

In addition to I2C master transfer management (refer to [Section 30.4.8: I2C master mode](#)) some additional software flowcharts are provided to support SMBus.

### SMBus Master transmitter

When the SMBus master wants to transmit the PEC, the PECBYTE bit must be set and the number of bytes must be programmed in the NBYTES[7:0] field, before setting the START bit. In this case the total number of TXIS interrupts is NBYTES-1. So if the PECBYTE bit is set when NBYTES=0x1, the content of the I2C\_PECR register is automatically transmitted.

If the SMBus master wants to send a STOP condition after the PEC, automatic end mode must be selected (AUTOEND=1). In this case, the STOP condition automatically follows the PEC transmission.

When the SMBus master wants to send a RESTART condition after the PEC, software mode must be selected (AUTOEND=0). In this case, once NBYTES-1 have been transmitted, the I2C\_PECR register content is transmitted and the TC flag is set after the PEC transmission, stretching the SCL line low. The RESTART condition must be programmed in the TC interrupt subroutine.

**Caution:** The PECBYTE bit has no effect when the RELOAD bit is set.

**Figure 330. Bus transfer diagrams for SMBus master transmitter**

**SMBus Master receiver**

When the SMBus master wants to receive the PEC followed by a STOP at the end of the transfer, automatic end mode can be selected (AUTOEND=1). The PECBYTE bit must be set and the slave address must be programmed, before setting the START bit. In this case, after NBYTES-1 data have been received, the next received byte is automatically checked versus the I2C\_PECR register content. A NACK response is given to the PEC byte, followed by a STOP condition.

When the SMBus master receiver wants to receive the PEC byte followed by a RESTART condition at the end of the transfer, software mode must be selected (AUTOEND=0). The PECBYTE bit must be set and the slave address must be programmed, before setting the START bit. In this case, after NBYTES-1 data have been received, the next received byte is automatically checked versus the I2C\_PECR register content. The TC flag is set after the PEC byte reception, stretching the SCL line low. The RESTART condition can be programmed in the TC interrupt subroutine.

**Caution:** The PECBYTE bit has no effect when the RELOAD bit is set.

Figure 331. Bus transfer diagrams for SMBus master receiver

Example SMBus master receiver 2 bytes + PEC, automatic end mode (STOP)

INIT: program Slave address, program NBYTES = 3, AUTOEND=1, set PECBYTE, set START

EV1: RXNE ISR: rd data1

EV2: RXNE ISR: rd data2

EV3: RXNE ISR: rd PEC

Example SMBus master receiver 2 bytes + PEC, software end mode (RESTART)

INIT: program Slave address, program NBYTES = 3, AUTOEND=0, set PECBYTE, set START

EV1: RXNE ISR: rd data1

EV2: RXNE ISR: rd data2

EV3: RXNE ISR: read PEC

EV4: TC ISR: program Slave address, program NBYTES = N, set START

MS19872V1

### 30.4.14 Error conditions

The following are the error conditions which may cause communication to fail.

#### Bus error (BERR)

A bus error is detected when a START or a STOP condition is detected and is not located after a multiple of 9 SCL clock pulses. A START or a STOP condition is detected when a SDA edge occurs while SCL is high.

The bus error flag is set only if the I2C is involved in the transfer as master or addressed slave (i.e not during the address phase in slave mode).

In case of a misplaced START or RESTART detection in slave mode, the I2C enters address recognition state like for a correct START condition.

When a bus error is detected, the BERR flag is set in the I2C\_ISR register, and an interrupt is generated if the ERRIE bit is set in the I2C\_CR1 register.

### Arbitration lost (ARLO)

An arbitration loss is detected when a high level is sent on the SDA line, but a low level is sampled on the SCL rising edge.

- In master mode, arbitration loss is detected during the address phase, data phase and data acknowledge phase. In this case, the SDA and SCL lines are released, the START control bit is cleared by hardware and the master switches automatically to slave mode.
- In slave mode, arbitration loss is detected during data phase and data acknowledge phase. In this case, the transfer is stopped, and the SCL and SDA lines are released.

When an arbitration loss is detected, the ARLO flag is set in the I2C\_ISR register, and an interrupt is generated if the ERRIE bit is set in the I2C\_CR1 register.

### Overrun/underrun error (OVR)

An overrun or underrun error is detected in slave mode when NOSTRETCH=1 and:

- In reception when a new byte is received and the RXDR register has not been read yet. The new received byte is lost, and a NACK is automatically sent as a response to the new byte.
- In transmission:
  - When STOPF=1 and the first data byte should be sent. The content of the I2C\_TXDR register is sent if TXE=0, 0xFF if not.
  - When a new byte must be sent and the I2C\_TXDR register has not been written yet, 0xFF is sent.

When an overrun or underrun error is detected, the OVR flag is set in the I2C\_ISR register, and an interrupt is generated if the ERRIE bit is set in the I2C\_CR1 register.

### Packet Error Checking Error (PECERR)

This section is relevant only when the SMBus feature is supported. Refer to [Section 30.3: I2C implementation](#).

A PEC error is detected when the received PEC byte does not match with the I2C\_PECR register content. A NACK is automatically sent after the wrong PEC reception.

When a PEC error is detected, the PECERR flag is set in the I2C\_ISR register, and an interrupt is generated if the ERRIE bit is set in the I2C\_CR1 register.

### Timeout Error (TIMEOUT)

This section is relevant only when the SMBus feature is supported. Refer to [Section 30.3: I2C implementation](#).

A timeout error occurs for any of these conditions:

- TIDLE=0 and SCL remained low for the time defined in the TIMEOUTA[11:0] bits: this is used to detect a SMBus timeout.
- TIDLE=1 and both SDA and SCL remained high for the time defined in the TIMEOUTA [11:0] bits: this is used to detect a bus idle condition.
- Master cumulative clock low extend time reached the time defined in the TIMEOUTB[11:0] bits (SMBus  $t_{\text{LOW:MEXT}}$  parameter)
- Slave cumulative clock low extend time reached the time defined in TIMEOUTB[11:0] bits (SMBus  $t_{\text{LOW:SEXT}}$  parameter)

When a timeout violation is detected in master mode, a STOP condition is automatically sent.

When a timeout violation is detected in slave mode, SDA and SCL lines are automatically released.

When a timeout error is detected, the TIMEOUT flag is set in the I2C\_ISR register, and an interrupt is generated if the ERRIE bit is set in the I2C\_CR1 register.

### Alert (ALERT)

This section is relevant only when the SMBus feature is supported. Refer to [Section 30.3: I2C implementation](#).

The ALERT flag is set when the I2C interface is configured as a Host (SMBHEN=1), the alert pin detection is enabled (ALERTEN=1) and a falling edge is detected on the SMBA pin. An interrupt is generated if the ERRIE bit is set in the I2C\_CR1 register.

## 30.4.15 DMA requests

### Transmission using DMA

DMA (Direct Memory Access) can be enabled for transmission by setting the TXDMAEN bit in the I2C\_CR1 register. Data is loaded from an SRAM area configured using the DMA peripheral (see [Section 8: Direct memory access controller \(DMA\) on page 222](#)) to the I2C\_TXDR register whenever the TXIS bit is set.

Only the data are transferred with DMA.

- In master mode: the initialization, the slave address, direction, number of bytes and START bit are programmed by software (the transmitted slave address cannot be transferred with DMA). When all data are transferred using DMA, the DMA must be initialized before setting the START bit. The end of transfer is managed with the

NBYTES counter. Refer to [Master transmitter on page 982](#).

- In slave mode:
  - With NOSTRETCH=0, when all data are transferred using DMA, the DMA must be initialized before the address match event, or in ADDR interrupt subroutine, before clearing ADDR.
  - With NOSTRETCH=1, the DMA must be initialized before the address match event.
- For instances supporting SMBus: the PEC transfer is managed with NBYTES counter. Refer to [SMBus Slave transmitter on page 996](#) and [SMBus Master transmitter on page 1000](#).

**Note:** *If DMA is used for transmission, the TXIE bit does not need to be enabled.*

### Reception using DMA

DMA (Direct Memory Access) can be enabled for reception by setting the RXDMAEN bit in the I2C\_CR1 register. Data is loaded from the I2C\_RXDR register to an SRAM area configured using the DMA peripheral (refer to [Section 8: Direct memory access controller \(DMA\)](#)) whenever the RXNE bit is set. Only the data (including PEC) are transferred with DMA.

- In master mode, the initialization, the slave address, direction, number of bytes and START bit are programmed by software. When all data are transferred using DMA, the DMA must be initialized before setting the START bit. The end of transfer is managed with the NBYTES counter.
- In slave mode with NOSTRETCH=0, when all data are transferred using DMA, the DMA must be initialized before the address match event, or in the ADDR interrupt subroutine, before clearing the ADDR flag.
- If SMBus is supported (see [Section 30.3: I2C implementation](#)): the PEC transfer is managed with the NBYTES counter. Refer to [SMBus Slave receiver on page 998](#) and [SMBus Master receiver on page 1002](#).

**Note:** *If DMA is used for reception, the RXIE bit does not need to be enabled.*

### 30.4.16 Debug mode

When the microcontroller enters debug mode (core halted), the SMBus timeout either continues to work normally or stops, depending on the DBG\_I2Cx\_STOP configuration bits in the DBG module.

## 30.5 I2C low-power modes

**Table 189. Effect of low-power modes on the I2C**

| Mode    | Description                                                                         |
|---------|-------------------------------------------------------------------------------------|
| Sleep   | No effect<br>I2C interrupts cause the device to exit the Sleep mode.                |
| Stop    | The contents of I2C registers are kept.                                             |
| Standby | The I2C peripheral is powered down and must be reinitialized after exiting Standby. |

## 30.6 I2C interrupts

The table below gives the list of I2C interrupt requests.

**Table 190. I2C Interrupt requests**

| Interrupt acronym |        | Interrupt event                  | Event flag | Enable control bit | Interrupt clear method             | Exit the Sleep mode | Exit the Stop mode |
|-------------------|--------|----------------------------------|------------|--------------------|------------------------------------|---------------------|--------------------|
| I2C               | I2C_EV | Receive buffer not empty         | RXNE       | RXIE               | Read I2C_RXDR register             | Yes                 | No                 |
|                   |        | Transmit buffer interrupt status | TXIS       | TXIE               | Write I2C_TXDR register            |                     |                    |
|                   |        | Stop detection interrupt flag    | STOPF      | STOPIE             | Write STOPCF=1                     |                     |                    |
|                   |        | Transfer Complete Reload         | TCR        | TCIE               | Write I2C_CR2 with NBYTES[7:0] ≠ 0 |                     |                    |
|                   |        | Transfer complete                | TC         |                    | Write START=1 or STOP=1            |                     |                    |
|                   |        | Address matched                  | ADDR       | ADDRIE             | Write ADDRCONF=1                   |                     |                    |
|                   |        | NACK reception                   | NACKF      | NACKIE             | Write NACKCF=1                     |                     |                    |
|                   | I2C_ER | Bus error                        | BERR       | ERRIE              | Write BERRCONF=1                   | Yes                 | No                 |
|                   |        | Arbitration loss                 | ARLO       |                    | Write ARLOCF=1                     |                     |                    |
|                   |        | Overrun/Underrun                 | OVR        |                    | Write OVRCONF=1                    |                     |                    |
|                   |        | PEC error                        | PECERR     |                    | Write PECERRCONF=1                 |                     |                    |
|                   |        | Timeout/t <sub>LOW</sub> error   | TIMEOUT    |                    | Write TIMEOUTCONF=1                |                     |                    |
|                   |        | SMBus Alert                      | ALERT      |                    | Write ALERTCONF=1                  |                     |                    |

## 30.7 I2C registers

Refer to [Section 1.2 on page 62](#) for a list of abbreviations used in register descriptions.

The peripheral registers are accessed by words (32-bit).

### 30.7.1 I2C2 control register 1 (I2C\_CR1)

Address offset: 0x00

Reset value: 0x0000 0000

Access: No wait states, except if a write access occurs while a write access to this register is ongoing. In this case, wait states are inserted in the second write access until the previous

one is completed. The latency of the second write access can be up to  $2 \times \text{PCLK1} + 6 \times \text{I2CCLK}$ .

|             |             |      |            |          |      |      |      |       |             |            |            |            |      |               |     |
|-------------|-------------|------|------------|----------|------|------|------|-------|-------------|------------|------------|------------|------|---------------|-----|
| 31          | 30          | 29   | 28         | 27       | 26   | 25   | 24   | 23    | 22          | 21         | 20         | 19         | 18   | 17            | 16  |

Bits 31:24 Reserved, must be kept at reset value.

Bit 23 **PECEN**: PEC enable

- 0: PEC calculation disabled
- 1: PEC calculation enabled

*Note: If the SMBus feature is not supported, this bit is reserved and forced by hardware to '0'.  
Refer to [Section 30.3: I2C implementation](#).*

Bit 22 **ALERTEN**: SMBus alert enable

**Device mode (SMBHEN=0):**

- 0: Releases SMBA pin high and Alert Response Address Header disabled: 0001100x followed by NACK.
- 1: Drives SMBA pin low and Alert Response Address Header enables: 0001100x followed by ACK.

**Host mode (SMBHEN=1):**

- 0: SMBus Alert pin (SMBA) not supported.
- 1: SMBus Alert pin (SMBA) supported.

*Note: When ALERTEN=0, the SMBA pin can be used as a standard GPIO.  
If the SMBus feature is not supported, this bit is reserved and forced by hardware to '0'.  
Refer to [Section 30.3: I2C implementation](#).*

Bit 21 **SMBDEN**: SMBus Device Default address enable

- 0: Device default address disabled. Address 0b1100001x is NACKed.
- 1: Device default address enabled. Address 0b1100001x is ACKed.

*Note: If the SMBus feature is not supported, this bit is reserved and forced by hardware to '0'.  
Refer to [Section 30.3: I2C implementation](#).*

Bit 20 **SMBHEN**: SMBus Host address enable

- 0: Host address disabled. Address 0b0001000x is NACKed.
- 1: Host address enabled. Address 0b0001000x is ACKed.

*Note: If the SMBus feature is not supported, this bit is reserved and forced by hardware to '0'.  
Refer to [Section 30.3: I2C implementation](#).*

Bit 19 **GCEN**: General call enable

- 0: General call disabled. Address 0b00000000 is NACKed.
- 1: General call enabled. Address 0b00000000 is ACKed.

Bit 18 Reserved, must be kept at reset value.

Bit 17 **NOSTRETCH**: Clock stretching disable

This bit is used to disable clock stretching in slave mode. It must be kept cleared in master mode.

- 0: Clock stretching enabled
- 1: Clock stretching disabled

*Note: This bit can only be programmed when the I2C is disabled (PE = 0).*

Bit 16 **SBC**: Slave byte control

This bit is used to enable hardware byte control in slave mode.

- 0: Slave byte control disabled
- 1: Slave byte control enabled

Bit 15 **RXDMAEN**: DMA reception requests enable

- 0: DMA mode disabled for reception
- 1: DMA mode enabled for reception

Bit 14 **TXDMAEN**: DMA transmission requests enable

- 0: DMA mode disabled for transmission
- 1: DMA mode enabled for transmission

## Bit 13 Reserved, must be kept at reset value.

Bit 12 **ANFOFF**: Analog noise filter OFF

- 0: Analog noise filter enabled
- 1: Analog noise filter disabled

*Note: This bit can only be programmed when the I2C is disabled (PE = 0).*

Bits 11:8 **DNF[3:0]**: Digital noise filter

These bits are used to configure the digital noise filter on SDA and SCL input. The digital filter, filters spikes with a length of up to  $DNF[3:0] * t_{I2CCLK}$

0000: Digital filter disabled

0001: Digital filter enabled and filtering capability up to 1  $t_{I2CCLK}$

...

1111: digital filter enabled and filtering capability up to 15  $t_{I2CCLK}$

*Note: If the analog filter is also enabled, the digital filter is added to the analog filter.*

*This filter can only be programmed when the I2C is disabled (PE = 0).*

Bit 7 **ERRIE**: Error interrupts enable

- 0: Error detection interrupts disabled
- 1: Error detection interrupts enabled

*Note: Any of these errors generate an interrupt:*

*Arbitration Loss (ARLO)*

*Bus Error detection (BERR)*

*Overrun/Underrun (OVR)*

*Timeout detection (TIMEOUT)*

*PEC error detection (PECERR)*

*Alert pin event detection (ALERT)*

Bit 6 **TCIE**: Transfer Complete interrupt enable

- 0: Transfer Complete interrupt disabled
- 1: Transfer Complete interrupt enabled

*Note: Any of these events generate an interrupt:*

*Transfer Complete (TC)*

*Transfer Complete Reload (TCR)*

Bit 5 **STOPIE**: Stop detection Interrupt enable

0: Stop detection (STOPF) interrupt disabled

1: Stop detection (STOPF) interrupt enabled

Bit 4 **NACKIE**: Not acknowledge received Interrupt enable

0: Not acknowledge (NACKF) received interrupts disabled

1: Not acknowledge (NACKF) received interrupts enabled

Bit 3 **ADDRIE**: Address match Interrupt enable (slave only)

0: Address match (ADDR) interrupts disabled

1: Address match (ADDR) interrupts enabled

Bit 2 **RXIE**: RX Interrupt enable

0: Receive (RXNE) interrupt disabled

1: Receive (RXNE) interrupt enabled

Bit 1 **TXIE**: TX Interrupt enable

0: Transmit (TXIS) interrupt disabled

1: Transmit (TXIS) interrupt enabled

Bit 0 **PE**: Peripheral enable

0: Peripheral disable

1: Peripheral enable

*Note: When PE=0, the I2C SCL and SDA lines are released. Internal state machines and status bits are put back to their reset value. When cleared, PE must be kept low for at least 3 APB clock cycles.*

### 30.7.2 I2C2 control register 2 (I2C\_CR2)

Address offset: 0x0C4

Reset value: 0x0000 0000

Access: No wait states, except if a write access occurs while a write access to this register is ongoing. In this case, wait states are inserted in the second write access until the previous one is completed. The latency of the second write access can be up to  $2 \times \text{PCLK1} + 6 \times \text{I2CCLK}$ .

|      |      |       |             |       |             |             |            |             |    |    |    |    |    |    |    |
|------|------|-------|-------------|-------|-------------|-------------|------------|-------------|----|----|----|----|----|----|----|

| NACK | STOP | START | HEAD1<br>OR | ADD10 | RD_<br>WRN  | SADD[9:0]   |            |             |    |    |    |    |    |    |    |
| rs   | rs   | rs    | rw          | rw    | rw          | rw          | rw         | rw          | rw | rw | rw | rw | rw | rw | rw |

Bits 31:27 Reserved, must be kept at reset value.

Bit 26 **PECBYTE**: Packet error checking byte

This bit is set by software, and cleared by hardware when the PEC is transferred, or when a STOP condition or an Address matched is received, also when PE=0.

0: No PEC transfer.

1: PEC transmission/reception is requested

*Note: Writing '0' to this bit has no effect.*

*This bit has no effect when RELOAD is set.*

*This bit has no effect in slave mode when SBC=0.*

*If the SMBus feature is not supported, this bit is reserved and forced by hardware to '0'.*

*Refer to [Section 30.3: I2C implementation](#).*

Bit 25 **AUTOEND**: Automatic end mode (master mode)

This bit is set and cleared by software.

0: software end mode: TC flag is set when NBYTES data are transferred, stretching SCL low.

1: Automatic end mode: a STOP condition is automatically sent when NBYTES data are transferred.

*Note: This bit has no effect in slave mode or when the RELOAD bit is set.*

Bit 24 **RELOAD**: NBYTES reload mode

This bit is set and cleared by software.

0: The transfer is completed after the NBYTES data transfer (STOP or RESTART follows).

1: The transfer is not completed after the NBYTES data transfer (NBYTES is reloaded). TCR flag is set when NBYTES data are transferred, stretching SCL low.

Bits 23:16 **NBYTES[7:0]**: Number of bytes

The number of bytes to be transmitted/received is programmed there. This field is don't care in slave mode with SBC=0.

*Note: Changing these bits when the START bit is set is not allowed.*

Bit 15 **NACK**: NACK generation (slave mode)

The bit is set by software, cleared by hardware when the NACK is sent, or when a STOP condition or an Address matched is received, or when PE=0.

0: an ACK is sent after current received byte.

1: a NACK is sent after current received byte.

*Note: Writing '0' to this bit has no effect.*

*This bit is used in slave mode only: in master receiver mode, NACK is automatically generated after last byte preceding STOP or RESTART condition, whatever the NACK bit value.*

*When an overrun occurs in slave receiver NOSTRETCH mode, a NACK is automatically generated whatever the NACK bit value.*

*When hardware PEC checking is enabled (PECBYTE=1), the PEC acknowledge value does not depend on the NACK value.*

Bit 14 **STOP**: Stop generation (master mode)

The bit is set by software, cleared by hardware when a STOP condition is detected, or when PE = 0.

**In Master Mode:**

0: No Stop generation.

1: Stop generation after current byte transfer.

*Note: Writing '0' to this bit has no effect.*

**Bit 13 START:** Start generation

This bit is set by software, and cleared by hardware after the Start followed by the address sequence is sent, by an arbitration loss, by a timeout error detection, or when PE = 0. It can also be cleared by software by writing '1' to the ADDRCONF bit in the I2C\_ICR register.

0: No Start generation.

1: Restart/Start generation:

If the I2C is already in master mode with AUTOEND = 0, setting this bit generates a Repeated Start condition when RELOAD=0, after the end of the NBYTES transfer.

Otherwise setting this bit generates a START condition once the bus is free.

*Note: Writing '0' to this bit has no effect.*

*The START bit can be set even if the bus is BUSY or I2C is in slave mode.*

*This bit has no effect when RELOAD is set.*

**Bit 12 HEAD10R:** 10-bit address header only read direction (master receiver mode)

0: The master sends the complete 10 bit slave address read sequence: Start + 2 bytes 10bit address in write direction + Restart + 1st 7 bits of the 10 bit address in read direction.

1: The master only sends the 1st 7 bits of the 10 bit address, followed by Read direction.

*Note: Changing this bit when the START bit is set is not allowed.*

**Bit 11 ADD10:** 10-bit addressing mode (master mode)

0: The master operates in 7-bit addressing mode,

1: The master operates in 10-bit addressing mode

*Note: Changing this bit when the START bit is set is not allowed.*

**Bit 10 RD\_WRN:** Transfer direction (master mode)

0: Master requests a write transfer.

1: Master requests a read transfer.

*Note: Changing this bit when the START bit is set is not allowed.*

**Bits 9:8 SADD[9:8]:** Slave address bit 9:8 (master mode)

**In 7-bit addressing mode (ADD10 = 0):**

These bits are don't care

**In 10-bit addressing mode (ADD10 = 1):**

These bits should be written with bits 9:8 of the slave address to be sent

*Note: Changing these bits when the START bit is set is not allowed.*

**Bits 7:1 SADD[7:1]:** Slave address bit 7:1 (master mode)

**In 7-bit addressing mode (ADD10 = 0):**

These bits should be written with the 7-bit slave address to be sent

**In 10-bit addressing mode (ADD10 = 1):**

These bits should be written with bits 7:1 of the slave address to be sent.

*Note: Changing these bits when the START bit is set is not allowed.*

**Bit 0 SADD0:** Slave address bit 0 (master mode)

**In 7-bit addressing mode (ADD10 = 0):**

This bit is don't care

**In 10-bit addressing mode (ADD10 = 1):**

This bit should be written with bit 0 of the slave address to be sent

*Note: Changing these bits when the START bit is set is not allowed.*

### 30.7.3 I2C2 own address 1 register (I2C\_OAR1)

Address offset: 0x08

Reset value: 0x0000 0000

Access: No wait states, except if a write access occurs while a write access to this register is ongoing. In this case, wait states are inserted in the second write access until the previous one is completed. The latency of the second write access can be up to  $2 \times \text{PCLK1} + 6 \times \text{I2CCLK}$ .

|       |      |      |      |      |             |          |      |          |      |      |      |      |      |      |        |

| rw    |      |      |      |      | rw          | rw       | rw   | rw       | rw   | rw   | rw   | rw   | rw   | rw   | rw     |

Bits 31:16 Reserved, must be kept at reset value.

Bit 15 **OA1EN**: Own Address 1 enable

0: Own address 1 disabled. The received slave address OA1 is NACKed.

1: Own address 1 enabled. The received slave address OA1 is ACKed.

Bits 14:11 Reserved, must be kept at reset value.

Bit 10 **OA1MODE**: Own Address 1 10-bit mode

0: Own address 1 is a 7-bit address.

1: Own address 1 is a 10-bit address.

*Note: This bit can be written only when OA1EN=0.*

Bits 9:8 **OA1[9:8]**: Interface address

7-bit addressing mode: do not care

10-bit addressing mode: bits 9:8 of address

*Note: These bits can be written only when OA1EN=0.*

Bits 7:1 **OA1[7:1]**: Interface address

7-bit addressing mode: 7-bit address

10-bit addressing mode: bits 7:1 of 10-bit address

*Note: These bits can be written only when OA1EN=0.*

Bit 0 **OA1[0]**: Interface address

7-bit addressing mode: do not care

10-bit addressing mode: bit 0 of address

*Note: This bit can be written only when OA1EN=0.*

### 30.7.4 I2C2 own address 2 register (I2C\_OAR2)

Address offset: 0x0C

Reset value: 0x0000 0000

Access: No wait states, except if a write access occurs while a write access to this register is ongoing. In this case, wait states are inserted in the second write access until the previous one is completed. The latency of the second write access can be up to  $2 \times \text{PCLK1} + 6 \times \text{I2CCLK}$ .

|       |      |      |      |      |             |      |      |      |          |      |      |      |      |      |      |

| 15    | 14   | 13   | 12   | 11   | 10          | 9    | 8    | 7    | 6        | 5    | 4    | 3    | 2    | 1    | 0    |
| OA2EN | Res. | Res. | Res. | Res. | OA2MSK[2:0] |      |      |      | OA2[7:1] |      |      |      |      |      | Res. |
| rw    |      |      |      |      | rw          | rw   | rw   | rw   | rw       | rw   | rw   | rw   | rw   | rw   |      |

Bits 31:16 Reserved, must be kept at reset value.

Bit 15 **OA2EN**: Own Address 2 enable

0: Own address 2 disabled. The received slave address OA2 is NACKed.

1: Own address 2 enabled. The received slave address OA2 is ACKed.

Bits 14:11 Reserved, must be kept at reset value.

Bits 10:8 **OA2MSK[2:0]**: Own Address 2 masks

000: No mask

001: OA2[1] is masked and don't care. Only OA2[7:2] are compared.

010: OA2[2:1] are masked and don't care. Only OA2[7:3] are compared.

011: OA2[3:1] are masked and don't care. Only OA2[7:4] are compared.

100: OA2[4:1] are masked and don't care. Only OA2[7:5] are compared.

101: OA2[5:1] are masked and don't care. Only OA2[7:6] are compared.

110: OA2[6:1] are masked and don't care. Only OA2[7] is compared.

111: OA2[7:1] are masked and don't care. No comparison is done, and all (except reserved) 7-bit received addresses are acknowledged.

*Note: These bits can be written only when OA2EN=0.*

*As soon as OA2MSK is not equal to 0, the reserved I2C addresses (0b0000xxx and 0b1111xxx) are not acknowledged even if the comparison matches.*

Bits 7:1 **OA2[7:1]**: Interface address

7-bit addressing mode: 7-bit address

*Note: These bits can be written only when OA2EN=0.*

Bit 0 Reserved, must be kept at reset value.

### 30.7.5 I2C2 timing register (I2C\_TIMINGR)

Address offset: 0x10

Reset value: 0x0000 0000

Access: No wait states

|            |    |    |    |      |      |      |      |             |    |    |    |             |    |    |    |
|------------|----|----|----|------|------|------|------|-------------|----|----|----|-------------|----|----|----|
| 31         | 30 | 29 | 28 | 27   | 26   | 25   | 24   | 23          | 22 | 21 | 20 | 19          | 18 | 17 | 16 |
| PRESC[3:0] |    |    |    | Res. | Res. | Res. | Res. | SCLDEL[3:0] |    |    |    | SDADEL[3:0] |    |    |    |
| rw         | rw | rw | rw |      |      |      |      | rw          | rw | rw | rw | rw          | rw | rw | rw |
| 15         | 14 | 13 | 12 | 11   | 10   | 9    | 8    | 7           | 6  | 5  | 4  | 3           | 2  | 1  | 0  |
| SCLH[7:0]  |    |    |    |      |      |      |      | SCLL[7:0]   |    |    |    |             |    |    |    |
| rw         | rw | rw | rw | rw   | rw   | rw   | rw   | rw          | rw | rw | rw | rw          | rw | rw | rw |

Bits 31:28 **PRESC[3:0]**: Timing prescaler

This field is used to prescale I2CCLK in order to generate the clock period  $t_{\text{PRESC}}$  used for data setup and hold counters (refer to [I2C timings on page 963](#)) and for SCL high and low level counters (refer to [I2C master initialization on page 978](#)).

$$t_{\text{PRESC}} = (\text{PRESC} + 1) \times t_{\text{I2CCLK}}$$

Bits 27:24 Reserved, must be kept at reset value.

Bits 23:20 **SCLDEL[3:0]**: Data setup time

This field is used to generate a delay  $t_{\text{SCLDEL}}$  between SDA edge and SCL rising edge. In master mode and in slave mode with NOSTRETCH = 0, the SCL line is stretched low during

$$t_{\text{SCLDEL}}$$

$$t_{\text{SCLDEL}} = (\text{SCLDEL} + 1) \times t_{\text{PRESC}}$$

*Note:  $t_{\text{SCLDEL}}$  is used to generate  $t_{\text{SU:DAT}}$  timing.*

Bits 19:16 **SDADEL[3:0]**: Data hold time

This field is used to generate the delay  $t_{\text{SDADEL}}$  between SCL falling edge and SDA edge. In master mode and in slave mode with NOSTRETCH = 0, the SCL line is stretched low during

$$t_{\text{SDADEL}}$$

$$t_{\text{SDADEL}} = \text{SDADEL} \times t_{\text{PRESC}}$$

*Note: SDADEL is used to generate  $t_{\text{HD:DAT}}$  timing.*

Bits 15:8 **SCLH[7:0]**: SCL high period (master mode)

This field is used to generate the SCL high period in master mode.

$$t_{\text{SCLH}} = (\text{SCLH} + 1) \times t_{\text{PRESC}}$$

*Note: SCLH is also used to generate  $t_{\text{SU:STO}}$  and  $t_{\text{HD:STA}}$  timing.*

Bits 7:0 **SCLL[7:0]**: SCL low period (master mode)

This field is used to generate the SCL low period in master mode.

$$t_{\text{SCLL}} = (\text{SCLL} + 1) \times t_{\text{PRESC}}$$

*Note: SCLL is also used to generate  $t_{\text{BUF}}$  and  $t_{\text{SU:STA}}$  timings.*

*Note: This register must be configured when the I2C is disabled (PE = 0).*

*Note: The STM32CubeMX tool calculates and provides the I2C\_TIMINGR content in the I2C Configuration window.*

### 30.7.6 I2C2 timeout register (I2C\_TIMEOUTR)

Address offset: 0x14

Reset value: 0x0000 0000

Access: No wait states, except if a write access occurs while a write access to this register is ongoing. In this case, wait states are inserted in the second write access until the previous one is completed. The latency of the second write access can be up to  $2 \times \text{PCLK1} + 6 \times \text{I2CCLK}$ .

| 31       | 30   | 29   | 28    | 27             | 26  | 25  | 24  | 23  | 22  | 21  | 20  | 19  | 18  | 17  | 16  |
|----------|------|------|-------|----------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| TEXTEN   | Res. | Res. | Res.  | TIMEOUTB[11:0] |     |     |     |     |     |     |     |     |     |     |     |
| r/w      |      |      |       | r/w            | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w |
| 15       | 14   | 13   | 12    | 11             | 10  | 9   | 8   | 7   | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
| TIMOUTEN | Res. | Res. | TIDLE | TIMEOUTA[11:0] |     |     |     |     |     |     |     |     |     |     |     |
| r/w      |      |      | r/w   | r/w            | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w |

Bit 31 **TEXTEN**: Extended clock timeout enable

0: Extended clock timeout detection is disabled

1: Extended clock timeout detection is enabled. When a cumulative SCL stretch for more than  $t_{\text{LOW:EXT}}$  is done by the I2C interface, a timeout error is detected (TIMEOUT=1).

Bits 30:28 Reserved, must be kept at reset value.

Bits 27:16 **TIMEOUTB[11:0]**: Bus timeout B

This field is used to configure the cumulative clock extension timeout:

In master mode, the master cumulative clock low extend time ( $t_{\text{LOW:MEXT}}$ ) is detected

In slave mode, the slave cumulative clock low extend time ( $t_{\text{LOW:SEXT}}$ ) is detected

$$t_{\text{LOW:EXT}} = (\text{TIMEOUTB} + 1) \times 2048 \times t_{\text{I2CCLK}}$$

*Note: These bits can be written only when TEXTEN=0.*

Bit 15 **TIMOUTEN**: Clock timeout enable

0: SCL timeout detection is disabled

1: SCL timeout detection is enabled: when SCL is low for more than  $t_{\text{TIMEOUT}}$  (TIDLE=0) or high for more than  $t_{\text{IDLE}}$  (TIDLE=1), a timeout error is detected (TIMEOUT=1).

Bits 14:13 Reserved, must be kept at reset value.

Bit 12 **TIDLE**: Idle clock timeout detection

0: TIMEOUTA is used to detect SCL low timeout

1: TIMEOUTA is used to detect both SCL and SDA high timeout (bus idle condition)

*Note: This bit can be written only when TIMOUTEN=0.*

Bits 11:0 **TIMEOUTA[11:0]**: Bus Timeout A

This field is used to configure:

The SCL low timeout condition  $t_{\text{TIMEOUT}}$  when TIDLE=0

$$t_{\text{TIMEOUT}} = (\text{TIMEOUTA} + 1) \times 2048 \times t_{\text{I2CCLK}}$$

The bus idle condition (both SCL and SDA high) when TIDLE=1

$$t_{\text{IDLE}} = (\text{TIMEOUTA} + 1) \times 4 \times t_{\text{I2CCLK}}$$

*Note: These bits can be written only when TIMOUTEN=0.*

*Note: If the SMBus feature is not supported, this register is reserved and forced by hardware to "0x00000000". Refer to [Section 30.3: I2C implementation](#).*

### 30.7.7 I2C2 interrupt and status register (I2C\_ISR)

Address offset: 0x18

Reset value: 0x0000 0001

Access: No wait states

|      |      |       |          |         |      |      |      |              |    |       |       |      |      |      |     |
|------|------|-------|----------|---------|------|------|------|--------------|----|-------|-------|------|------|------|-----|
| 31   | 30   | 29    | 28       | 27      | 26   | 25   | 24   | 23           | 22 | 21    | 20    | 19   | 18   | 17   | 16  |
| Res. | Res. | Res.  | Res.     | Res.    | Res. | Res. | Res. | ADDCODE[6:0] |    |       |       |      |      |      | DIR |
|      |      |       |          |         |      |      |      | r            | r  | r     | r     | r    | r    | r    | r   |
| 15   | 14   | 13    | 12       | 11      | 10   | 9    | 8    | 7            | 6  | 5     | 4     | 3    | 2    | 1    | 0   |
| BUSY | Res. | ALERT | TIME OUT | PEC ERR | OVR  | ARLO | BERR | TCR          | TC | STOPF | NACKF | ADDR | RXNE | TXIS | TXE |
| r    |      | r     | r        | r       | r    | r    | r    | r            | r  | r     | r     | r    | r    | rs   | rs  |

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:17 **ADDCODE[6:0]**: Address match code (Slave mode)

These bits are updated with the received address when an address match event occurs (ADDR = 1).

In the case of a 10-bit address, ADDCODE provides the 10-bit header followed by the 2 MSBs of the address.

Bit 16 **DIR**: Transfer direction (Slave mode)

This flag is updated when an address match event occurs (ADDR=1).

0: Write transfer, slave enters receiver mode.

1: Read transfer, slave enters transmitter mode.

Bit 15 **BUSY**: Bus busy

This flag indicates that a communication is in progress on the bus. It is set by hardware when a START condition is detected. It is cleared by hardware when a STOP condition is detected, or when PE=0.

Bit 14 Reserved, must be kept at reset value.

Bit 13 **ALERT**: SMBus alert

This flag is set by hardware when SMBHEN=1 (SMBus host configuration), ALERTEN=1 and a SMBALERT event (falling edge) is detected on SMBA pin. It is cleared by software by setting the ALERTCF bit.

*Note: This bit is cleared by hardware when PE=0.*

*If the SMBus feature is not supported, this bit is reserved and forced by hardware to '0'.*

*Refer to [Section 30.3: I2C implementation](#).*

Bit 12 **TIMEOUT**: Timeout or  $t_{LOW}$  detection flag

This flag is set by hardware when a timeout or extended clock timeout occurred. It is cleared by software by setting the TIMEOUTCF bit.

*Note: This bit is cleared by hardware when PE=0.*

*If the SMBus feature is not supported, this bit is reserved and forced by hardware to '0'.*

*Refer to [Section 30.3: I2C implementation](#).*

**Bit 11 PECERR:** PEC Error in reception

This flag is set by hardware when the received PEC does not match with the PEC register content. A NACK is automatically sent after the wrong PEC reception. It is cleared by software by setting the PECCF bit.

*Note: This bit is cleared by hardware when PE=0.*

*If the SMBus feature is not supported, this bit is reserved and forced by hardware to '0'. Refer to [Section 30.3: I2C implementation](#).*

**Bit 10 OVR:** Overrun/Underrun (slave mode)

This flag is set by hardware in slave mode with NOSTRETCH=1, when an overrun/underrun error occurs. It is cleared by software by setting the OVRCF bit.

*Note: This bit is cleared by hardware when PE=0.*

**Bit 9 ARLO:** Arbitration lost

This flag is set by hardware in case of arbitration loss. It is cleared by software by setting the ARLOCF bit.

*Note: This bit is cleared by hardware when PE=0.*

**Bit 8 BERR:** Bus error

This flag is set by hardware when a misplaced Start or STOP condition is detected whereas the peripheral is involved in the transfer. The flag is not set during the address phase in slave mode. It is cleared by software by setting *BERRCF* bit.

*Note: This bit is cleared by hardware when PE=0.*

**Bit 7 TCR:** Transfer Complete Reload

This flag is set by hardware when RELOAD=1 and NBYTES data have been transferred. It is cleared by software when NBYTES is written to a non-zero value.

*Note: This bit is cleared by hardware when PE=0.*

*This flag is only for master mode, or for slave mode when the SBC bit is set.*

**Bit 6 TC:** Transfer Complete (master mode)

This flag is set by hardware when RELOAD=0, AUTOEND=0 and NBYTES data have been transferred. It is cleared by software when START bit or STOP bit is set.

*Note: This bit is cleared by hardware when PE=0.*

**Bit 5 STOPF:** Stop detection flag

This flag is set by hardware when a STOP condition is detected on the bus and the peripheral is involved in this transfer:

- either as a master, provided that the STOP condition is generated by the peripheral.
- or as a slave, provided that the peripheral has been addressed previously during this transfer.

It is cleared by software by setting the STOPCF bit.

*Note: This bit is cleared by hardware when PE=0.*

**Bit 4 NACKF:** Not Acknowledge received flag

This flag is set by hardware when a NACK is received after a byte transmission. It is cleared by software by setting the NACKCF bit.

*Note: This bit is cleared by hardware when PE=0.*

**Bit 3 ADDR:** Address matched (slave mode)

This bit is set by hardware as soon as the received slave address matched with one of the enabled slave addresses. It is cleared by software by setting *ADDRCF* bit.

*Note: This bit is cleared by hardware when PE=0.*

Bit 2 **RXNE**: Receive data register not empty (receivers)

This bit is set by hardware when the received data is copied into the I2C\_RXDR register, and is ready to be read. It is cleared when I2C\_RXDR is read.

*Note: This bit is cleared by hardware when PE=0.*

Bit 1 **TXIS**: Transmit interrupt status (transmitters)

This bit is set by hardware when the I2C\_TXDR register is empty and the data to be transmitted must be written in the I2C\_TXDR register. It is cleared when the next data to be sent is written in the I2C\_TXDR register.

This bit can be written to '1' by software when NOSTRETCH=1 only, in order to generate a TXIS event (interrupt if TXIE=1 or DMA request if TXDMAEN=1).

*Note: This bit is cleared by hardware when PE=0.*

Bit 0 **TXE**: Transmit data register empty (transmitters)

This bit is set by hardware when the I2C\_TXDR register is empty. It is cleared when the next data to be sent is written in the I2C\_TXDR register.

This bit can be written to '1' by software in order to flush the transmit data register I2C\_TXDR.

*Note: This bit is set by hardware when PE=0.*

### 30.7.8 I2C2 interrupt clear register (I2C\_ICR)

Address offset: 0x1C

Reset value: 0x0000 0000

Access: No wait states

|      |      |             |              |       |       |            |            |      |      |            |            |            |      |      |      |

Bits 31:14 Reserved, must be kept at reset value.

Bit 13 **ALERTCF**: Alert flag clear

Writing 1 to this bit clears the ALERT flag in the I2C\_ISR register.

*Note: If the SMBus feature is not supported, this bit is reserved and forced by hardware to '0'.  
Refer to [Section 30.3: I2C implementation](#).*

Bit 12 **TIMOUTCF**: Timeout detection flag clear

Writing 1 to this bit clears the TIMEOUT flag in the I2C\_ISR register.

*Note: If the SMBus feature is not supported, this bit is reserved and forced by hardware to '0'.  
Refer to [Section 30.3: I2C implementation](#).*

Bit 11 **PECCF**: PEC Error flag clear

Writing 1 to this bit clears the PECERR flag in the I2C\_ISR register.

*Note: If the SMBus feature is not supported, this bit is reserved and forced by hardware to '0'.  
Refer to [Section 30.3: I2C implementation](#).*

Bit 10 **OVRCF**: Overrun/Underrun flag clear

Writing 1 to this bit clears the OVR flag in the I2C\_ISR register.

Bit 9 **ARLOCF**: Arbitration lost flag clear

Writing 1 to this bit clears the ARLO flag in the I2C\_ISR register.

Bit 8 **BERRCF**: Bus error flag clear

Writing 1 to this bit clears the BERRF flag in the I2C\_ISR register.

Bits 7:6 Reserved, must be kept at reset value.

Bit 5 **STOPCF**: STOP detection flag clear

Writing 1 to this bit clears the STOPF flag in the I2C\_ISR register.

Bit 4 **NACKCF**: Not Acknowledge flag clear

Writing 1 to this bit clears the NACKF flag in I2C\_ISR register.

Bit 3 **ADDRCF**: Address matched flag clear

Writing 1 to this bit clears the ADDR flag in the I2C\_ISR register. Writing 1 to this bit also clears the START bit in the I2C\_CR2 register.

Bits 2:0 Reserved, must be kept at reset value.

### 30.7.9 I2C2 PEC register (I2C\_PECR)

Address offset: 0x20

Reset value: 0x0000 0000

Access: No wait states

|      |      |      |      |      |      |      |      |          |      |      |      |      |      |      |      |

|      |      |      |      |      |      |      |      | r        | r    | r    | r    | r    | r    | r    | r    |

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **PEC[7:0]** Packet error checking register

This field contains the internal PEC when PECEN=1.

The PEC is cleared by hardware when PE=0.

**Note:** *If the SMBus feature is not supported, this register is reserved and forced by hardware to "0x00000000". Refer to [Section 30.3: I2C implementation](#).*

### 30.7.10 I2C2 receive data register (I2C\_RXDR)

Address offset: 0x24

Reset value: 0x0000 0000

Access: No wait states

|      |      |      |      |      |      |      |      |             |      |      |      |      |      |      |      |

## **31 Universal synchronous receiver transmitter (USART) /universal asynchronous receiver transmitter (UART)**

### **31.1 Introduction**

The universal synchronous asynchronous receiver transmitter (USART) offers a flexible means of Full-duplex data exchange with external equipment requiring an industry standard NRZ asynchronous serial data format. The USART offers a very wide range of baud rates using a programmable baud rate generator.

It supports synchronous one-way communication and Half-duplex Single-wire communication, as well as multiprocessor communications. It also supports the LIN (Local Interconnect Network), Smartcard protocol and IrDA (Infrared Data Association) SIR ENDEC specifications and Modem operations (CTS/RTS).

High speed data communication is possible by using the DMA (direct memory access) for multibuffer configuration.

### **31.2 USART main features**

- Full-duplex asynchronous communications
- NRZ standard format (mark/space)
- Configurable oversampling method by 16 or 8 to give flexibility between speed and clock tolerance
- A common programmable transmit and receive baud rate of up to 27 Mbit/s when USART clock source is the system clock frequency (Max is 216 MHz) and the oversampling by 8 is used
- Dual clock domain allowing:
  - Convenient baud rate programming independent from the PCLK reprogramming
- Auto baud rate detection
- Programmable data word length (7, 8 or 9 bits)
- Programmable data order with MSB-first or LSB-first shifting
- Configurable stop bits (1 or 2 stop bits)
- Synchronous mode and clock output for synchronous communications
- Single-wire Half-duplex communications
- Continuous communications using DMA
- Received/transmitted bytes are buffered in reserved SRAM using centralized DMA
- Separate enable bits for transmitter and receiver
- Separate signal polarity control for transmission and reception
- Swappable Tx/Rx pin configuration
- Hardware flow control for modem and RS-485 transceiver

- Communication control/error detection flags
- Parity control:
  - Transmits parity bit
  - Checks parity of received data byte
- Fourteen interrupt sources with flags
- Multiprocessor communications  
The USART enters mute mode if the address does not match.
- Wakeup from mute mode (by idle line detection or address mark detection)

### **31.3 USART extended features**

- LIN master synchronous break send capability and LIN slave break detection capability
  - 13-bit break generation and 10/11-bit break detection when USART is hardware configured for LIN
- IrDA SIR encoder decoder supporting 3/16 bit duration for normal mode
- Smartcard mode
  - Supports the T=0 and T=1 asynchronous protocols for smartcards as defined in the ISO/IEC 7816-3 standard
  - 0.5 and 1.5 stop bits for smartcard operation
- Support for ModBus communication
  - Timeout feature
  - CR/LF character recognition

## 31.4 USART implementation

Table 192. STM32F75xxx and STM32F74xxx USART features

1. X = supported.

2. In 7-bit data length mode, Smartcard mode, LIN master mode and Auto baud rate (0x7F and 0x55 frames) detection are not supported.

## 31.5 USART functional description

Any USART bidirectional communication requires a minimum of two pins: Receive data In (RX) and Transmit data Out (TX):

- **RX:** Receive data Input.

This is the serial data input. Oversampling techniques are used for data recovery by discriminating between valid incoming data and noise.

- **TX:** Transmit data Output.

When the transmitter is disabled, the output pin returns to its I/O port configuration. When the transmitter is enabled and nothing is to be transmitted, the TX pin is at high level. In Single-wire and Smartcard modes, this I/O is used to transmit and receive the data.

Serial data are transmitted and received through these pins in normal USART mode. The frames are comprised of:

- An Idle Line prior to transmission or reception
- A start bit
- A data word (7, 8 or 9 bits) least significant bit first
- 0.5, 1, 1.5, 2 stop bits indicating that the frame is complete
- The USART interface uses a baud rate generator
- A status register (USART\_ISR)
- Receive and transmit data registers (USART\_RDR, USART\_TDR)
- A baud rate register (USART\_BRR)
- A guard-time register (USART\_GTPR) in case of Smartcard mode.

Refer to [Section 31.8: USART registers on page 1067](#) for the definitions of each bit.

The following pin is required to interface in synchronous mode and Smartcard mode:

- **CK:** Clock output. This pin outputs the transmitter data clock for synchronous transmission corresponding to SPI master mode (no clock pulses on start bit and stop bit, and a software option to send a clock pulse on the last data bit). In parallel, data can be received synchronously on RX. This can be used to control peripherals that have shift registers. The clock phase and polarity are software programmable. In Smartcard mode, CK output can provide the clock to the smartcard.

The following pins are required in RS232 Hardware flow control mode:

- **CTS:** Clear To Send blocks the data transmission at the end of the current transfer when high
- **RTS:** Request to send indicates that the USART is ready to receive data (when low).

The following pin is required in RS485 Hardware control mode:

- **DE:** Driver Enable activates the transmission mode of the external transceiver.

*Note:* **DE** and **RTS** share the same pin.

Figure 332. USART block diagram

MSv35479V2

1. For details on coding USARTDIV in the USART\_BRR register, refer to [Section 31.5.4: USART baud rate generation](#).
2.  $f_{CK}$  can be  $f_{LSE}$ ,  $f_{HSI}$ ,  $f_{PCLK}$ ,  $f_{SYS}$ .

### 31.5.1 USART character description

The word length can be selected as being either 7 or 8 or 9 bits by programming the M[1:0] bits in the USART\_CR1 register (see [Figure 333](#)).

- 7-bit character length: M[1:0] = 10
- 8-bit character length: M[1:0] = 00
- 9-bit character length: M[1:0] = 01

*Note:* The 7-bit mode is supported only on some USARTs. In addition, not all modes are supported in 7-bit data length mode. Refer to [Section 31.4: USART implementation](#) for additional information.

By default, the signal (TX or RX) is in low state during the start bit. It is in high state during the stop bit.

These values can be inverted, separately for each signal, through polarity configuration control.

An **Idle character** is interpreted as an entire frame of “1”s (the number of “1”s includes the number of stop bits).

A **Break character** is interpreted on receiving “0”s for a frame period. At the end of the break frame, the transmitter inserts 2 stop bits.

Transmission and reception are driven by a common baud rate generator, the clock for each is generated when the enable bit is set respectively for the transmitter and receiver.

The details of each block is given below.

Figure 333. Word length programming

### 31.5.2 USART transmitter

The transmitter can send data words of either 7, 8 or 9 bits depending on the M bits status. The Transmit Enable bit (TE) must be set in order to activate the transmitter function. The data in the transmit shift register is output on the TX pin and the corresponding clock pulses are output on the CK pin.

#### Character transmission

During an USART transmission, data shifts out least significant bit first (default configuration) on the TX pin. In this mode, the USART\_TDR register consists of a buffer (TDR) between the internal bus and the transmit shift register (see [Figure 332](#)).

Every character is preceded by a start bit which is a logic level low for one bit period. The character is terminated by a configurable number of stop bits.

The following stop bits are supported by USART: 0.5, 1, 1.5 and 2 stop bits.

*Note: The TE bit must be set before writing the data to be transmitted to the USART\_TDR.  
The TE bit should not be reset during transmission of data. Resetting the TE bit during the transmission will corrupt the data on the TX pin as the baud rate counters will get frozen.  
The current data being transmitted will be lost.  
An idle frame will be sent after the TE bit is enabled.*

#### Configurable stop bits

The number of stop bits to be transmitted with every character can be programmed in Control register 2, bits 13,12.

- **1 stop bit:** This is the default value of number of stop bits.
- **2 stop bits:** This will be supported by normal USART, Single-wire and Modem modes.
- **1.5 stop bits:** To be used in Smartcard mode.
- **0.5 stop bit:** To be used when receiving data in Smartcard mode.

An idle frame transmission will include the stop bits.

A break transmission will be 10 low bits (when M[1:0] = 00) or 11 low bits (when M[1:0] = 01) or 9 low bits (when M[1:0] = 10) followed by 2 stop bits (see [Figure 334](#)). It is not possible to transmit long breaks (break of length greater than 9/10/11 low bits).

**Figure 334. Configurable stop bits**

#### Character transmission procedure

1. Program the M bits in USART\_CR1 to define the word length.
2. Select the desired baud rate using the USART\_BRR register.
3. Program the number of stop bits in USART\_CR2.
4. Enable the USART by writing the UE bit in USART\_CR1 register to 1.
5. Select DMA enable (DMAT) in USART\_CR3 if multibuffer communication is to take place. Configure the DMA register as explained in multibuffer communication.
6. Set the TE bit in USART\_CR1 to send an idle frame as first transmission.
7. Write the data to send in the USART\_TDR register (this clears the TXE bit). Repeat this for each data to be transmitted in case of single buffer.
8. After writing the last data into the USART\_TDR register, wait until TC=1. This indicates that the transmission of the last frame is complete. This is required for instance when the USART is disabled or enters the Halt mode to avoid corrupting the last transmission.

#### Single byte communication

Clearing the TXE bit is always performed by a write to the transmit data register.

The TXE bit is set by hardware and it indicates:

- The data has been moved from the USART\_TDR register to the shift register and the data transmission has started.
- The USART\_TDR register is empty.
- The next data can be written in the USART\_TDR register without overwriting the previous data.

This flag generates an interrupt if the TXEIE bit is set.

When a transmission is taking place, a write instruction to the USART\_TDR register stores the data in the TDR register; next, the data is copied in the shift register at the end of the currently ongoing transmission.

When no transmission is taking place, a write instruction to the USART\_TDR register places the data in the shift register, the data transmission starts, and the TXE bit is set.

If a frame is transmitted (after the stop bit) and the TXE bit is set, the TC bit goes high. An interrupt is generated if the TCIE bit is set in the USART\_CR1 register.

After writing the last data in the USART\_TDR register, it is mandatory to wait for TC=1 before disabling the USART or causing the microcontroller to enter the low-power mode (see [Figure 335: TC/TXE behavior when transmitting](#)).

**Figure 335. TC/TXE behavior when transmitting**

### Break characters

Setting the SBKRQ transmits a break character. The break frame length depends on the M bits (see [Figure 333](#)).

If a '1' is written to the SBKRQ bit, a break character is sent on the TX line after completing the current character transmission. The SBKF bit is set by the write operation and it is reset by hardware when the break character is completed (during the stop bits after the break character). The USART inserts a logic 1 signal (STOP) for the duration of 2 bits at the end of the break frame to guarantee the recognition of the start bit of the next frame.

In the case the application needs to send the break character following all previously inserted data, including the ones not yet transmitted, the software should wait for the TXE flag assertion before setting the SBKRQ bit.

### Idle characters

Setting the TE bit drives the USART to send an idle frame before the first data frame.

## 31.5.3 USART receiver

The USART can receive data words of either 7, 8 or 9 bits depending on the M bits in the USART\_CR1 register.

### Start bit detection

The start bit detection sequence is the same when oversampling by 16 or by 8.

In the USART, the start bit is detected when a specific sequence of samples is recognized.  
This sequence is: 1 1 1 0 X 0 X 0X 0X 0 X 0X 0.

Figure 336. Start bit detection when oversampling by 16 or 8

**Note:** If the sequence is not complete, the start bit detection aborts and the receiver returns to the idle state (no flag is set), where it waits for a falling edge.

The start bit is confirmed (RXNE flag set, interrupt generated if RXNEIE=1) if the 3 sampled bits are at 0 (first sampling on the 3rd, 5th and 7th bits finds the 3 bits at 0 and second sampling on the 8th, 9th and 10th bits also finds the 3 bits at 0).

The start bit is validated (RXNE flag set, interrupt generated if RXNEIE=1) but the NF noise flag is set if,

- a) for both samplings, 2 out of the 3 sampled bits are at 0 (sampling on the 3rd, 5th and 7th bits and sampling on the 8th, 9th and 10th bits)
- or
- b) for one of the samplings (sampling on the 3rd, 5th and 7th bits or sampling on the 8th, 9th and 10th bits), 2 out of the 3 bits are found at 0.

If neither conditions a. or b. are met, the start detection aborts and the receiver returns to the idle state (no flag is set).

### **Character reception**

During an USART reception, data shifts in least significant bit first (default configuration) through the RX pin. In this mode, the USART\_RDR register consists of a buffer (RDR) between the internal bus and the receive shift register.

#### **Character reception procedure**

1. Program the M bits in USART\_CR1 to define the word length.
2. Select the desired baud rate using the baud rate register USART\_BRR
3. Program the number of stop bits in USART\_CR2.
4. Enable the USART by writing the UE bit in USART\_CR1 register to 1.
5. Select DMA enable (DMAR) in USART\_CR3 if multibuffer communication is to take place. Configure the DMA register as explained in multibuffer communication.
6. Set the RE bit USART\_CR1. This enables the receiver which begins searching for a start bit.

When a character is received:

- The RXNE bit is set to indicate that the content of the shift register is transferred to the RDR. In other words, data has been received and can be read (as well as its associated error flags).
- An interrupt is generated if the RXNEIE bit is set.
- The error flags can be set if a frame error, noise or an overrun error has been detected during reception. PE flag can also be set with RXNE.
- In multibuffer, RXNE is set after every byte received and is cleared by the DMA read of the Receive data Register.
- In single buffer mode, clearing the RXNE bit is performed by a software read to the USART\_RDR register. The RXNE flag can also be cleared by writing 1 to the RXFRQ in the USART\_RQR register. The RXNE bit must be cleared before the end of the reception of the next character to avoid an overrun error.

### **Break character**

When a break character is received, the USART handles it as a framing error.

### **Idle character**

When an idle frame is detected, there is the same procedure as for a received data character plus an interrupt if the IDLEIE bit is set.

### Overrun error

An overrun error occurs when a character is received when RXNE has not been reset. Data can not be transferred from the shift register to the RDR register until the RXNE bit is cleared.

The RXNE flag is set after every byte received. An overrun error occurs if RXNE flag is set when the next data is received or the previous DMA request has not been serviced. When an overrun error occurs:

- The ORE bit is set.
- The RDR content will not be lost. The previous data is available when a read to USART\_RDR is performed.
- The shift register will be overwritten. After that point, any data received during overrun is lost.
- An interrupt is generated if either the RXNEIE bit is set or EIE bit is set.
- The ORE bit is reset by setting the ORECF bit in the ICR register.

*Note: The ORE bit, when set, indicates that at least 1 data has been lost. There are two possibilities:*

- if  $RXNE=1$ , then the last valid data is stored in the receive register RDR and can be read,
- if  $RXNE=0$ , then it means that the last valid data has already been read and thus there is nothing to be read in the RDR. This case can occur when the last valid data is read in the RDR at the same time as the new (and lost) data is received.

### Selecting the clock source and the proper oversampling method

The choice of the clock source is done through the Clock Control system (see Section Reset and clock control (RCC)). The clock source must be chosen before enabling the USART (by setting the UE bit).

The clock source frequency is  $f_{CK}$ .

When the dual clock domain is supported, the clock source can be one of the following sources: PCLK (default), LSE, HSI or SYSCLK.

The communication speed range (specially the maximum communication speed) is also determined by the clock source.

The receiver implements different user-configurable oversampling techniques for data recovery by discriminating between valid incoming data and noise. This allows a trade-off between the maximum communication speed and noise/clock inaccuracy immunity.

The oversampling method can be selected by programming the OVER8 bit in the USART\_CR1 register and can be either 16 or 8 times the baud rate clock ([Figure 337](#) and [Figure 338](#)).

Depending on the application:

- Select oversampling by 8 (OVER8=1) to achieve higher speed (up to  $f_{CK}/8$ ). In this case the maximum receiver tolerance to clock deviation is reduced (refer to [Section 31.5.5: Tolerance of the USART receiver to clock deviation on page 1042](#))
- Select oversampling by 16 (OVER8=0) to increase the tolerance of the receiver to clock deviations. In this case, the maximum speed is limited to maximum  $f_{CK}/16$  where  $f_{CK}$  is the clock source frequency.

Programming the ONEBIT bit in the USART\_CR3 register selects the method used to evaluate the logic level. There are two options:

- The majority vote of the three samples in the center of the received bit. In this case, when the 3 samples used for the majority vote are not equal, the NF bit is set
- A single sample in the center of the received bit

Depending on the application:

- select the three samples' majority vote method (ONEBIT=0) when operating in a noisy environment and reject the data when a noise is detected (refer to [Figure 193](#)) because this indicates that a glitch occurred during the sampling.
- select the single sample method (ONEBIT=1) when the line is noise-free to increase the receiver's tolerance to clock deviations (see [Section 31.5.5: Tolerance of the USART receiver to clock deviation on page 1042](#)). In this case the NF bit will never be set.

When noise is detected in a frame:

- The NF bit is set at the rising edge of the RXNE bit.
- The invalid data is transferred from the Shift register to the USART\_RDR register.
- No interrupt is generated in case of single byte communication. However this bit rises at the same time as the RXNE bit which itself generates an interrupt. In case of multibuffer communication an interrupt will be issued if the EIE bit is set in the USART\_CR3 register.

The NF bit is reset by setting NFCF bit in ICR register.

*Note: Oversampling by 8 is not available in LIN, Smartcard and IrDA modes. In those modes, the OVER8 bit is forced to '0' by hardware.*

**Figure 337. Data sampling when oversampling by 16**

Figure 338. Data sampling when oversampling by 8

Table 193. Noise detection from sampled data

| Sampled value | NE status | Received bit value |
|---------------|-----------|--------------------|
| 000           | 0         | 0                  |
| 001           | 1         | 0                  |
| 010           | 1         | 0                  |
| 011           | 1         | 1                  |
| 100           | 1         | 0                  |
| 101           | 1         | 1                  |
| 110           | 1         | 1                  |
| 111           | 0         | 1                  |

### Framing error

A framing error is detected when the stop bit is not recognized on reception at the expected time, following either a de-synchronization or excessive noise.

When the framing error is detected:

- The FE bit is set by hardware
- The invalid data is transferred from the Shift register to the USART\_RDR register.
- No interrupt is generated in case of single byte communication. However this bit rises at the same time as the RXNE bit which itself generates an interrupt. In case of multibuffer communication an interrupt will be issued if the EIE bit is set in the USART\_CR3 register.

The FE bit is reset by writing 1 to the FECF in the USART\_ICR register.

### Configurable stop bits during reception

The number of stop bits to be received can be configured through the control bits of Control Register 2 - it can be either 1 or 2 in normal mode and 0.5 or 1.5 in Smartcard mode.

- **0.5 stop bit (reception in Smartcard mode):** No sampling is done for 0.5 stop bit. As a consequence, no framing error and no break frame can be detected when 0.5 stop bit is selected.
- **1 stop bit:** Sampling for 1 stop Bit is done on the 8th, 9th and 10th samples.
- **1.5 stop bits (Smartcard mode):** When transmitting in Smartcard mode, the device must check that the data is correctly sent. Thus the receiver block must be enabled (RE =1 in the USART\_CR1 register) and the stop bit is checked to test if the smartcard has detected a parity error. In the event of a parity error, the smartcard forces the data signal low during the sampling - NACK signal-, which is flagged as a framing error. Then, the FE flag is set with the RXNE at the end of the 1.5 stop bits. Sampling for 1.5 stop bits is done on the 16th, 17th and 18th samples (1 baud clock period after the beginning of the stop bit). The 1.5 stop bits can be decomposed into 2 parts: one 0.5 baud clock period during which nothing happens, followed by 1 normal stop bit period during which sampling occurs halfway through. Refer to [Section 31.5.13: USART Smartcard mode on page 1053](#) for more details.
- **2 stop bits:** Sampling for 2 stop bits is done on the 8th, 9th and 10th samples of the first stop bit. If a framing error is detected during the first stop bit the framing error flag will be set. The second stop bit is not checked for framing error. The RXNE flag will be set at the end of the first stop bit.

### 31.5.4 USART baud rate generation

The baud rate for the receiver and transmitter (Rx and Tx) are both set to the same value as programmed in the USART\_BRR register.

#### Equation 1: Baud rate for standard USART (SPI mode included) (OVER8 = 0 or 1)

In case of oversampling by 16, the equation is:

$$\text{Tx/Rx baud} = \frac{f_{\text{CK}}}{\text{USARTDIV}}$$

In case of oversampling by 8, the equation is:

$$\text{Tx/Rx baud} = \frac{2 \times f_{\text{CK}}}{\text{USARTDIV}}$$

#### Equation 2: Baud rate in Smartcard, LIN and IrDA modes (OVER8 = 0)

In Smartcard, LIN and IrDA modes, only Oversampling by 16 is supported:

$$\text{Tx/Rx baud} = \frac{f_{\text{CK}}}{\text{USARTDIV}}$$

USARTDIV is an unsigned fixed point number that is coded on the USART\_BRR register.

- When OVER8 = 0, BRR = USARTDIV.
- When OVER8 = 1
  - BRR[2:0] = USARTDIV[3:0] shifted 1 bit to the right.
  - BRR[3] must be kept cleared.
  - BRR[15:4] = USARTDIV[15:4]

*Note: The baud counters are updated to the new value in the baud registers after a write operation to USART\_BRR. Hence the baud rate register value should not be changed during communication.*

*In case of oversampling by 16 or 8, USARTDIV must be greater than or equal to 16d.*

### How to derive USARTDIV from USART\_BRR register values

#### Example 1

To obtain 9600 baud with  $f_{CK} = 8$  MHz.

- In case of oversampling by 16:  
USARTDIV =  $8\,000\,000/9600$   
BRR = USARTDIV = 833d = 0341h
- In case of oversampling by 8:  
USARTDIV =  $2 * 8\,000\,000/9600$   
USARTDIV = 1666,66 (1667d = 683h)  
BRR[3:0] = 3h >> 1 = 1h  
BRR = 0x681

#### Example 2

To obtain 921.6 Kbaud with  $f_{CK} = 48$  MHz.

- In case of oversampling by 16:  
USARTDIV =  $48\,000\,000/921\,600$   
BRR = USARTDIV = 52d = 34h
- In case of oversampling by 8:  
USARTDIV =  $2 * 48\,000\,000/921\,600$   
USARTDIV = 104 (104d = 68h)  
BRR[3:0] = USARTDIV[3:0] >> 1 = 8h >> 1 = 4h  
BRR = 0x64

**Table 194. Error calculation for programmed baud rates at  $f_{CK} = 216$  MHz in both cases of oversampling by 8 (OVER8 = 1)<sup>(1)</sup>**

| Desired baud rate (Bps) | Actual baud rate (Bps) | BRR  | Error       |
|-------------------------|------------------------|------|-------------|
| 9600                    | 9600                   | AFC4 | 0.00000000  |
| 19200                   | 19200                  | 57E2 | 0.00000000  |
| 38400                   | 38400                  | 2BF1 | 0.00000000  |
| 57600                   | 57600                  | 1D46 | 0.00000000  |
| 115200                  | 115200                 | EA3  | 0.00000000  |
| 230400                  | 230400                 | 751  | 0.00000000  |
| 460800                  | 461538.461             | 3A4  | 0.160256293 |
| 921600                  | 923076.923             | 1D2  | 0.001602564 |
| 13500000                | 13500000.000           | 20   | 0.00000000  |
| 27000000                | 27000000.000           | 10   | 0.00000000  |

1. The lower the CPU clock the lower the accuracy for a particular baud rate. The upper limit of the achievable baud rate can be fixed with these data.

**Table 195. Error calculation for programmed baud rates at  $f_{CK} = 216$  MHz in both cases of oversampling by 16 (OVER8 = 0)<sup>(1)</sup>**

| Desired baud rate (Bps) | Actual baud rate (Bps) | BRR  | Error      |
|-------------------------|------------------------|------|------------|
| 9600                    | 9600.000               | 57E4 | 0.00000000 |
| 19200                   | 19200.000              | 2BF2 | 0.00000000 |
| 38400                   | 38400.000              | 15F9 | 0.00000000 |

| 460800                  | 461538.462             | 1D4  | 0.16025641 |
| 921600                  | 923076.923             | EA   | 0.16025641 |
| 4000000                 | 4000000.000            | 36   | 0.00000000 |
| 6000000                 | 6000000.000            | 24   | 0.00000000 |
| 10000000                | 10285714.286           | 15   | 2.85714286 |
| 13500000                | 13500000.000           | 10   | 0.00000000 |

1. The lower the CPU clock the lower the accuracy for a particular baud rate. The upper limit of the achievable baud rate can be fixed with these data.

### 31.5.5 Tolerance of the USART receiver to clock deviation

The asynchronous receiver of the USART works correctly only if the total clock system deviation is less than the tolerance of the USART receiver. The causes which contribute to the total deviation are:

- DTRA: Deviation due to the transmitter error (which also includes the deviation of the transmitter's local oscillator)
- DQUANT: Error due to the baud rate quantization of the receiver
- DREC: Deviation of the receiver's local oscillator
- DTCL: Deviation due to the transmission line (generally due to the transceivers which can introduce an asymmetry between the low-to-high transition timing and the high-to-low transition timing)

$$DTRA + DQUANT + DREC + DTCL < \text{USART receiver's tolerance}$$

The USART receiver can receive data correctly at up to the maximum tolerated deviation specified in [Table 196](#) and [Table 196](#) depending on the following choices:

- 9-, 10- or 11-bit character length defined by the M bits in the USART\_CR1 register
- Oversampling by 8 or 16 defined by the OVER8 bit in the USART\_CR1 register
- Bits BRR[3:0] of USART\_BRR register are equal to or different from 0000.
- Use of 1 bit or 3 bits to sample the data, depending on the value of the ONEBIT bit in the USART\_CR3 register.

**Table 196. Tolerance of the USART receiver when BRR [3:0] = 0000**

| M bits | OVER8 bit = 0 |          | OVER8 bit = 1 |          |
|--------|---------------|----------|---------------|----------|
|        | ONEBIT=0      | ONEBIT=1 | ONEBIT=0      | ONEBIT=1 |
| 00     | 3.75%         | 4.375%   | 2.50%         | 3.75%    |
| 01     | 3.41%         | 3.97%    | 2.27%         | 3.41%    |
| 10     | 4.16%         | 4.86%    | 2.77%         | 4.16%    |

**Table 197. Tolerance of the USART receiver when BRR [3:0] is different from 0000**

| M bits | OVER8 bit = 0 |          | OVER8 bit = 1 |          |
|--------|---------------|----------|---------------|----------|
|        | ONEBIT=0      | ONEBIT=1 | ONEBIT=0      | ONEBIT=1 |
| 00     | 3.33%         | 3.88%    | 2%            | 3%       |
| 01     | 3.03%         | 3.53%    | 1.82%         | 2.73%    |
| 10     | 3.7%          | 4.31%    | 2.22%         | 3.33%    |

*Note:* The data specified in [Table 196](#) and [Table 197](#) may slightly differ in the special case when the received frames contain some Idle frames of exactly 10-bit durations when M bits = 00 (11-bit durations when M bits = 01 or 9-bit durations when M bits = 10).

### 31.5.6 USART auto baud rate detection

The USART is able to detect and automatically set the USART\_BRR register value based on the reception of one character. Automatic baud rate detection is useful under two circumstances:

- The communication speed of the system is not known in advance
- The system is using a relatively low accuracy clock source and this mechanism allows the correct baud rate to be obtained without measuring the clock deviation.

The clock source frequency must be compatible with the expected communication speed (when oversampling by 16, the baud rate is between  $f_{CK}/65535$  and  $f_{CK}/16$ . when oversampling by 8, the baud rate is between  $f_{CK}/65535$  and  $f_{CK}/8$ ).

Before activating the auto baud rate detection, the auto baud rate detection mode must be chosen. There are various modes based on different character patterns.

They can be chosen through the ABRMOD[1:0] field in the USART\_CR2 register. In these auto baud rate modes, the baud rate is measured several times during the synchronization data reception and each measurement is compared to the previous one.

These modes are:

- **Mode 0:** Any character starting with a bit at 1. In this case the USART measures the duration of the Start bit (falling edge to rising edge).
- **Mode 1:** Any character starting with a 10xx bit pattern. In this case, the USART measures the duration of the Start and of the 1st data bit. The measurement is done falling edge to falling edge, ensuring better accuracy in the case of slow signal slopes.
- **Mode 2:** A 0x7F character frame (it may be a 0x7F character in LSB first mode or a 0xFE in MSB first mode). In this case, the baud rate is updated first at the end of the start bit (BRs), then at the end of bit 6 (based on the measurement done from falling edge to falling edge: BR6). Bit 0 to bit 6 are sampled at BRs while further bits of the character are sampled at BR6.
- **Mode 3:** A 0x55 character frame. In this case, the baud rate is updated first at the end of the start bit (BRs), then at the end of bit 0 (based on the measurement done from falling edge to falling edge: BR0), and finally at the end of bit 6 (BR6). Bit 0 is sampled at BRs, bit 1 to bit 6 are sampled at BR0, and further bits of the character are sampled at BR6.

In parallel, another check is performed for each intermediate transition of RX line. An error is generated if the transitions on RX are not sufficiently synchronized with the receiver (the receiver being based on the baud rate calculated on bit 0).

Prior to activating auto baud rate detection, the USART\_BRR register must be initialized by writing a non-zero baud rate value.

The automatic baud rate detection is activated by setting the ABREN bit in the USART\_CR2 register. The USART will then wait for the first character on the RX line. The auto baud rate operation completion is indicated by the setting of the ABRF flag in the USART\_ISR register. If the line is noisy, the correct baud rate detection cannot be guaranteed. In this case the BRR value may be corrupted and the ABRE error flag will be set. This also happens if the communication speed is not compatible with the automatic baud rate detection range (bit duration not between 16 and 65536 clock periods (oversampling by 16) and not between 8 and 65536 clock periods (oversampling by 8)).

The RXNE interrupt will signal the end of the operation.

At any later time, the auto baud rate detection may be relaunched by resetting the ABRF flag (by writing a 0).

*Note: If the USART is disabled (UE=0) during an auto baud rate operation, the BRR value may be corrupted.*

### **31.5.7 Multiprocessor communication using USART**

In multiprocessor communication, the following bits are to be kept cleared:

- LINEN bit in the USART\_CR2 register,
- HDSEL, IREN and SCEN bits in the USART\_CR3 register.

It is possible to perform multiprocessor communication with the USART (with several USARTs connected in a network). For instance one of the USARTs can be the master, its TX output connected to the RX inputs of the other USARTs. The others are slaves, their respective TX outputs are logically ANDed together and connected to the RX input of the master.

In multiprocessor configurations it is often desirable that only the intended message recipient should actively receive the full message contents, thus reducing redundant USART service overhead for all non addressed receivers.

The non addressed devices may be placed in mute mode by means of the muting function. In order to use the mute mode feature, the MME bit must be set in the USART\_CR1 register.

In mute mode:

- None of the reception status bits can be set.
- All the receive interrupts are inhibited.
- The RWU bit in USART\_ISR register is set to 1. RWU can be controlled automatically by hardware or by software, through the MMRQ bit in the USART\_RQR register, under certain conditions.

The USART can enter or exit from mute mode using one of two methods, depending on the WAKE bit in the USART\_CR1 register:

- Idle Line detection if the WAKE bit is reset,
- Address Mark detection if the WAKE bit is set.

**Idle line detection (WAKE=0)**

The USART enters mute mode when the MMRQ bit is written to 1 and the RWU is automatically set.

It wakes up when an Idle frame is detected. Then the RWU bit is cleared by hardware but the IDLE bit is not set in the USART\_ISR register. An example of mute mode behavior using Idle line detection is given in [Figure 339](#).

**Figure 339. Mute mode using Idle line detection**

**Note:** If the MMRQ is set while the IDLE character has already elapsed, mute mode will not be entered (RWU is not set).

If the USART is activated while the line is IDLE, the idle state is detected after the duration of one IDLE frame (not only after the reception of one character frame).

**4-bit/7-bit address mark detection (WAKE=1)**

In this mode, bytes are recognized as addresses if their MSB is a '1' otherwise they are considered as data. In an address byte, the address of the targeted receiver is put in the 4 or 7 LSBs. The choice of 7 or 4-bit address detection is done using the ADDM7 bit. This 4-bit/7-bit word is compared by the receiver with its own address which is programmed in the ADD bits in the USART\_CR2 register.

**Note:** In 7-bit and 9-bit data modes, address detection is done on 6-bit and 8-bit addresses (ADD[5:0] and ADD[7:0]) respectively.

The USART enters mute mode when an address character is received which does not match its programmed address. In this case, the RWU bit is set by hardware. The RXNE flag is not set for this address byte and no interrupt or DMA request is issued when the USART enters mute mode.

The USART also enters mute mode when the MMRQ bit is written to 1. The RWU bit is also automatically set in this case.

The USART exits from mute mode when an address character is received which matches the programmed address. Then the RWU bit is cleared and subsequent bytes are received normally. The RXNE bit is set for the address character since the RWU bit has been cleared.

An example of mute mode behavior using address mark detection is given in [Figure 340](#).

**Figure 340. Mute mode using address mark detection**

### 31.5.8 Modbus communication using USART

The USART offers basic support for the implementation of Modbus/RTU and Modbus/ASCII protocols. Modbus/RTU is a half duplex, block transfer protocol. The control part of the protocol (address recognition, block integrity control and command interpretation) must be implemented in software.

The USART offers basic support for the end of the block detection, without software overhead or other resources.

#### Modbus/RTU

In this mode, the end of one block is recognized by a “silence” (idle line) for more than 2 character times. This function is implemented through the programmable timeout function.

The timeout function and interrupt must be activated, through the RTOEN bit in the USART\_CR2 register and the RTOIE in the USART\_CR1 register. The value corresponding to a timeout of 2 character times (for example 22 x bit duration) must be programmed in the RTO register. When the receive line is idle for this duration, after the last stop bit is received, an interrupt is generated, informing the software that the current block reception is completed.

#### Modbus/ASCII

In this mode, the end of a block is recognized by a specific (CR/LF) character sequence. The USART manages this mechanism using the character match function.

By programming the LF ASCII code in the ADD[7:0] field and by activating the character match interrupt (CMIE=1), the software is informed when a LF has been received and can check the CR/LF in the DMA buffer.

### 31.5.9 USART parity control

Parity control (generation of parity bit in transmission and parity checking in reception) can be enabled by setting the PCE bit in the USART\_CR1 register. Depending on the frame length defined by the M bits, the possible USART frame formats are as listed in [Table 198](#).

**Table 198. Frame formats**

| M bits | PCE bit | USART frame <sup>(1)</sup> |
|--------|---------|----------------------------|
| 00     | 0       | SB   8-bit data   STB      |
| 00     | 1       | SB   7-bit data   PB   STB |
| 01     | 0       | SB   9-bit data   STB      |
| 01     | 1       | SB   8-bit data   PB   STB |
| 10     | 0       | SB   7-bit data   STB      |
| 10     | 1       | SB   6-bit data   PB   STB |

1. Legends: SB: start bit, STB: stop bit, PB: parity bit. In the data register, the PB is always taking the MSB position (9th, 8th or 7th, depending on the M bits value).

#### Even parity

The parity bit is calculated to obtain an even number of “1s” inside the frame of the 6, 7 or 8 LSB bits (depending on M bits values) and the parity bit.

As an example, if data=00110101, and 4 bits are set, then the parity bit will be 0 if even parity is selected (PS bit in USART\_CR1 = 0).

#### Odd parity

The parity bit is calculated to obtain an odd number of “1s” inside the frame made of the 6, 7 or 8 LSB bits (depending on M bits values) and the parity bit.

As an example, if data=00110101 and 4 bits set, then the parity bit will be 1 if odd parity is selected (PS bit in USART\_CR1 = 1).

#### Parity checking in reception

If the parity check fails, the PE flag is set in the USART\_ISR register and an interrupt is generated if PEIE is set in the USART\_CR1 register. The PE flag is cleared by software writing 1 to the PECF in the USART\_ICR register.

#### Parity generation in transmission

If the PCE bit is set in USART\_CR1, then the MSB bit of the data written in the data register is transmitted but is changed by the parity bit (even number of “1s” if even parity is selected (PS=0) or an odd number of “1s” if odd parity is selected (PS=1)).

### 31.5.10 USART LIN (local interconnection network) mode

This section is relevant only when LIN mode is supported. Please refer to [Section 31.4: USART implementation on page 1026](#).

The LIN mode is selected by setting the LINEN bit in the USART\_CR2 register. In LIN mode, the following bits must be kept cleared:

- STOP[1:0] and CLKEN in the USART\_CR2 register,
- SCEN, HDSEL and IREN in the USART\_CR3 register.

#### LIN transmission

The procedure explained in [Section 31.5.2: USART transmitter](#) has to be applied for LIN Master transmission. It must be the same as for normal USART transmission with the following differences:

- Clear the M bits to configure 8-bit word length.
- Set the LINEN bit to enter LIN mode. In this case, setting the SBKRQ bit sends 13 '0' bits as a break character. Then 2 bits of value '1' are sent to allow the next start detection.

#### LIN reception

When LIN mode is enabled, the break detection circuit is activated. The detection is totally independent from the normal USART receiver. A break can be detected whenever it occurs, during Idle state or during a frame.

When the receiver is enabled (RE=1 in USART\_CR1), the circuit looks at the RX input for a start signal. The method for detecting start bits is the same when searching break characters or data. After a start bit has been detected, the circuit samples the next bits exactly like for the data (on the 8th, 9th and 10th samples). If 10 (when the LBDL = 0 in USART\_CR2) or 11 (when LBDL=1 in USART\_CR2) consecutive bits are detected as '0', and are followed by a delimiter character, the LBDF flag is set in USART\_ISR. If the LBDIE bit=1, an interrupt is generated. Before validating the break, the delimiter is checked for as it signifies that the RX line has returned to a high level.

If a '1' is sampled before the 10 or 11 have occurred, the break detection circuit cancels the current detection and searches for a start bit again.

If the LIN mode is disabled (LINEN=0), the receiver continues working as normal USART, without taking into account the break detection.

If the LIN mode is enabled (LINEN=1), as soon as a framing error occurs (i.e. stop bit detected at '0', which will be the case for any break frame), the receiver stops until the break detection circuit receives either a '1', if the break word was not complete, or a delimiter character if a break has been detected.

The behavior of the break detector state machine and the break flag is shown on the [Figure 341: Break detection in LIN mode \(11-bit break length - LBDL bit is set\) on page 1049](#).

Examples of break frames are given on [Figure 342: Break detection in LIN mode vs. Framing error detection on page 1050](#).

Figure 341. Break detection in LIN mode (11-bit break length - LBDL bit is set)

**Figure 342. Break detection in LIN mode vs. Framing error detection**

### 31.5.11 USART synchronous mode

The synchronous mode is selected by writing the CLKEN bit in the USART\_CR2 register to 1. In synchronous mode, the following bits must be kept cleared:

- LINEN bit in the USART\_CR2 register,
- SCEN, HDSEL and IREN bits in the USART\_CR3 register.

In this mode, the USART can be used to control bidirectional synchronous serial communications in master mode. The CK pin is the output of the USART transmitter clock. No clock pulses are sent to the CK pin during start bit and stop bit. Depending on the state of the LBCL bit in the USART\_CR2 register, clock pulses are, or are not, generated during the last valid data bit (address mark). The CPOL bit in the USART\_CR2 register is used to select the clock polarity, and the CPHA bit in the USART\_CR2 register is used to select the phase of the external clock (see [Figure 343](#), [Figure 344](#) and [Figure 345](#)).

During the Idle state, preamble and send break, the external CK clock is not activated.

In synchronous mode the USART transmitter works exactly like in asynchronous mode. But as CK is synchronized with TX (according to CPOL and CPHA), the data on TX is synchronous.

In this mode the USART receiver works in a different manner compared to the asynchronous mode. If RE=1, the data is sampled on CK (rising or falling edge, depending on CPOL and CPHA), without any oversampling. A setup and a hold time must be respected (which depends on the baud rate: 1/16 bit duration).

**Note:** The CK pin works in conjunction with the TX pin. Thus, the clock is provided only if the transmitter is enabled (TE=1) and data is being transmitted (the data register USART\_TDR written). This means that it is not possible to receive synchronous data without transmitting data.

The LBCL, CPOL and CPHA bits have to be selected when the USART is disabled (UE=0) to ensure that the clock pulses function correctly.

Figure 343. USART example of synchronous transmission

Figure 344. USART data clock timing diagram (M bits = 00)

Figure 345. USART data clock timing diagram (M bits = 01)

Figure 346. RX data setup/hold time

Note: The function of CK is different in Smartcard mode. Refer to [Section 31.5.13: USART Smartcard mode](#) for more details.

### 31.5.12 USART Single-wire Half-duplex communication

Single-wire Half-duplex mode is selected by setting the HDSEL bit in the USART\_CR3 register. In this mode, the following bits must be kept cleared:

- LINEN and CLKEN bits in the USART\_CR2 register,
- SCEN and IREN bits in the USART\_CR3 register.

The USART can be configured to follow a Single-wire Half-duplex protocol where the TX and RX lines are internally connected. The selection between half- and Full-duplex communication is made with a control bit HDSEL in USART\_CR3.

As soon as HDSEL is written to 1:

- The TX and RX lines are internally connected
- The RX pin is no longer used
- The TX pin is always released when no data is transmitted. Thus, it acts as a standard I/O in idle or in reception. It means that the I/O must be configured so that TX is configured as alternate function open-drain with an external pull-up.

Apart from this, the communication protocol is similar to normal USART mode. Any conflicts on the line must be managed by software (by the use of a centralized arbiter, for instance). In particular, the transmission is never blocked by hardware and continues as soon as data is written in the data register while the TE bit is set.

### 31.5.13 USART Smartcard mode

This section is relevant only when Smartcard mode is supported. Please refer to [Section 31.4: USART implementation on page 1026](#).

Smartcard mode is selected by setting the SCEN bit in the USART\_CR3 register. In Smartcard mode, the following bits must be kept cleared:

- LINEN bit in the USART\_CR2 register,
- HDSEL and IREN bits in the USART\_CR3 register.

Moreover, the CLKEN bit may be set in order to provide a clock to the smartcard.

The smartcard interface is designed to support asynchronous protocol for smartcards as defined in the ISO 7816-3 standard. Both T=0 (character mode) and T=1 (block mode) are supported.

The USART should be configured as:

- 8 bits plus parity: where word length is set to 8 bits and PCE=1 in the USART\_CR1 register
- 1.5 stop bits: where STOP=11 in the USART\_CR2 register. It is also possible to choose 0.5 stop bit for receiving.

In T=0 (character) mode, the parity error is indicated at the end of each character during the guard time period.

[Figure 347](#) shows examples of what can be seen on the data line with and without parity error.

Figure 347. ISO 7816-3 asynchronous protocol

When connected to a smartcard, the TX output of the USART drives a bidirectional line that is also driven by the smartcard. The TX pin must be configured as open drain.

Smartcard mode implements a single wire half duplex communication protocol.

- Transmission of data from the transmit shift register is guaranteed to be delayed by a minimum of 1/2 baud clock. In normal operation a full transmit shift register starts shifting on the next baud clock edge. In Smartcard mode this transmission is further delayed by a guaranteed 1/2 baud clock.
- In transmission, if the smartcard detects a parity error, it signals this condition to the USART by driving the line low (NACK). This NACK signal (pulling transmit line low for 1 baud clock) causes a framing error on the transmitter side (configured with 1.5 stop bits). The USART can handle automatic re-sending of data according to the protocol. The number of retries is programmed in the SCARCNT bit field. If the USART continues receiving the NACK after the programmed number of retries, it stops transmitting and signals the error as a framing error. The TXE bit can be set using the TXFRQ bit in the USART\_RQR register.
- Smartcard auto-retry in transmission: a delay of 2.5 baud periods is inserted between the NACK detection by the USART and the start bit of the repeated character. The TC bit is set immediately at the end of reception of the last repeated character (no guard-time). If the software wants to repeat it again, it must insure the minimum 2 baud periods required by the standard.
- If a parity error is detected during reception of a frame programmed with a 1.5 stop bits period, the transmit line is pulled low for a baud clock period after the completion of the receive frame. This is to indicate to the smartcard that the data transmitted to the USART has not been correctly received. A parity error is NACKed by the receiver if the NACK control bit is set, otherwise a NACK is not transmitted (to be used in T=1 mode). If the received character is erroneous, the RXNE/receive DMA request is not activated. According to the protocol specification, the smartcard must resend the same character. If the received character is still erroneous after the maximum number of retries specified in the SCARCNT bit field, the USART stops transmitting the NACK and signals the error as a parity error.
- Smartcard auto-retry in reception: the BUSY flag remains set if the USART NACKs the card but the card doesn't repeat the character.

- In transmission, the USART inserts the Guard Time (as programmed in the Guard Time register) between two successive characters. As the Guard Time is measured after the stop bit of the previous character, the GT[7:0] register must be programmed to the desired CGT (Character Guard Time, as defined by the 7816-3 specification) minus 12 (the duration of one character).
- The assertion of the TC flag can be delayed by programming the Guard Time register. In normal operation, TC is asserted when the transmit shift register is empty and no further transmit requests are outstanding. In Smartcard mode an empty transmit shift register triggers the Guard Time counter to count up to the programmed value in the Guard Time register. TC is forced low during this time. When the Guard Time counter reaches the programmed value TC is asserted high.
- The de-assertion of TC flag is unaffected by Smartcard mode.
- If a framing error is detected on the transmitter end (due to a NACK from the receiver), the NACK is not detected as a start bit by the receive block of the transmitter. According to the ISO protocol, the duration of the received NACK can be 1 or 2 baud clock periods.
- On the receiver side, if a parity error is detected and a NACK is transmitted the receiver does not detect the NACK as a start bit.

**Note:** *A break character is not significant in Smartcard mode. A 0x00 data with a framing error is treated as data and not as a break.*

*No Idle frame is transmitted when toggling the TE bit. The Idle frame (as defined for the other configurations) is not defined by the ISO protocol.*

*Figure 348 details how the NACK signal is sampled by the USART. In this example the USART is transmitting data and is configured with 1.5 stop bits. The receiver part of the USART is enabled in order to check the integrity of the data and the NACK signal.*

**Figure 348. Parity error detection using the 1.5 stop bits**

The USART can provide a clock to the smartcard through the CK output. In Smartcard mode, CK is not associated to the communication but is simply derived from the internal peripheral input clock through a 5-bit prescaler. The division ratio is configured in the prescaler register USART\_GTPR. CK frequency can be programmed from  $f_{CK}/2$  to  $f_{CK}/62$ , where  $f_{CK}$  is the peripheral input clock.

### Block mode (T=1)

In T=1 (block) mode, the parity error transmission is deactivated, by clearing the NACK bit in the UART\_CR3 register.

When requesting a read from the smartcard, in block mode, the software must enable the receiver Timeout feature by setting the RTOEN bit in the USART\_CR2 register and program the RTO bits field in the RTOR register to the BWT (block wait time) - 11 value. If no answer is received from the card before the expiration of this period, the RTOF flag will be set and a timeout interrupt will be generated (if RTOIE bit in the USART\_CR1 register is set). If the first character is received before the expiration of the period, it is signaled by the RXNE interrupt.

*Note: The RXNE interrupt must be enabled even when using the USART in DMA mode to read from the smartcard in block mode. In parallel, the DMA must be enabled only after the first received byte.*

After the reception of the first character (RXNE interrupt), the RTO bit fields in the RTOR register must be programmed to the CWT (character wait time) - 11 value, in order to allow the automatic check of the maximum wait time between two consecutive characters. This time is expressed in baudtime units. If the smartcard does not send a new character in less than the CWT period after the end of the previous character, the USART signals this to the software through the RTOF flag and interrupt (when RTOIE bit is set).

*Note: The RTO counter starts counting:*

- From the end of the stop bit in case STOP = 00.
- From the end of the second stop bit in case of STOP = 10.
- 1 bit duration after the beginning of the STOP bit in case STOP = 11.
- From the beginning of the STOP bit in case STOP = 01.

*As in the Smartcard protocol definition, the BWT/CWT values are defined from the beginning (start bit) of the last character. The RTO register must be programmed to BWT - 11 or CWT - 11, respectively, taking into account the length of the last character itself.*

A block length counter is used to count all the characters received by the USART. This counter is reset when the USART is transmitting (TXE=0). The length of the block is communicated by the smartcard in the third byte of the block (prologue field). This value must be programmed to the BLEN field in the USART\_RTOR register. when using DMA mode, before the start of the block, this register field must be programmed to the minimum value (0x0). with this value, an interrupt is generated after the 4th received character. The software must read the LEN field (third byte), its value must be read from the receive buffer.

In interrupt driven receive mode, the length of the block may be checked by software or by programming the BLEN value. However, before the start of the block, the maximum value of BLEN (0xFF) may be programmed. The real value will be programmed after the reception of the third character.

If the block is using the LRC longitudinal redundancy check (1 epilogue byte), the BLEN=LEN. If the block is using the CRC mechanism (2 epilogue bytes), BLEN=LEN+1 must be programmed. The total block length (including prologue, epilogue and information fields) equals BLEN+4. The end of the block is signaled to the software through the EOBFF flag and interrupt (when EOBIE bit is set).

In case of an error in the block length, the end of the block is signaled by the RTO interrupt (Character wait Time overflow).

*Note:* The error checking code (LRC/CRC) must be computed/verified by software.

### **Direct and inverse convention**

The Smartcard protocol defines two conventions: direct and inverse.

The direct convention is defined as: LSB first, logical bit value of 1 corresponds to a H state of the line and parity is even. In order to use this convention, the following control bits must be programmed: MSBFIRST=0, DATAINV=0 (default values).

The inverse convention is defined as: MSB first, logical bit value 1 corresponds to an L state on the signal line and parity is even. In order to use this convention, the following control bits must be programmed: MSBFIRST=1, DATAINV=1.

*Note:* When logical data values are inverted (0=H, 1=L), the parity bit is also inverted in the same way.

In order to recognize the card convention, the card sends the initial character, TS, as the first character of the ATR (Answer To Reset) frame. The two possible patterns for the TS are: LHHL LLL LLH and LHHL HHH LLH.

- (H) LHHL LLL LLH sets up the inverse convention: state L encodes value 1 and moment 2 conveys the most significant bit (MSB first). when decoded by inverse convention, the conveyed byte is equal to '3F'.
- (H) LHHL HHH LLH sets up the direct convention: state H encodes value 1 and moment 2 conveys the least significant bit (LSB first). when decoded by direct convention, the conveyed byte is equal to '3B'.

Character parity is correct when there is an even number of bits set to 1 in the nine moments 2 to 10.

As the USART does not know which convention is used by the card, it needs to be able to recognize either pattern and act accordingly. The pattern recognition is not done in hardware, but through a software sequence. Moreover, supposing that the USART is configured in direct convention (default) and the card answers with the inverse convention, TS = LHHL LLL LLH => the USART received character will be '03' and the parity will be odd.

Therefore, two methods are available for TS pattern recognition:

#### **Method 1**

The USART is programmed in standard Smartcard mode/direct convention. In this case, the TS pattern reception generates a parity error interrupt and error signal to the card.

- The parity error interrupt informs the software that the card didn't answer correctly in direct convention. Software then reprograms the USART for inverse convention
- In response to the error signal, the card retries the same TS character, and it will be correctly received this time, by the reprogrammed USART

Alternatively, in answer to the parity error interrupt, the software may decide to reprogram the USART and to also generate a new reset command to the card, then wait again for the TS.

**Method 2**

The USART is programmed in 9-bit/no-parity mode, no bit inversion. In this mode it receives any of the two TS patterns as:

(H) LHHL LLL LLH = 0x103 -> inverse convention to be chosen

(H) LHHL HHH LLH = 0x13B -> direct convention to be chosen

The software checks the received character against these two patterns and, if any of them match, then programs the USART accordingly for the next character reception.

If none of the two is recognized, a card reset may be generated in order to restart the negotiation.

**31.5.14 USART IrDA SIR ENDEC block**

This section is relevant only when IrDA mode is supported. Please refer to [Section 31.4: USART implementation on page 1026](#).

IrDA mode is selected by setting the IREN bit in the USART\_CR3 register. In IrDA mode, the following bits must be kept cleared:

- LINEN, STOP and CLKEN bits in the USART\_CR2 register,
- SCEN and HDSEL bits in the USART\_CR3 register.

The IrDA SIR physical layer specifies use of a Return to Zero, Inverted (RZI) modulation scheme that represents logic 0 as an infrared light pulse (see [Figure 349](#)).

The SIR Transmit encoder modulates the Non Return to Zero (NRZ) transmit bit stream output from USART. The output pulse stream is transmitted to an external output driver and infrared LED. USART supports only bit rates up to 115.2 Kbps for the SIR ENDEC. In normal mode the transmitted pulse width is specified as 3/16 of a bit period.

The SIR receive decoder demodulates the return-to-zero bit stream from the infrared detector and outputs the received NRZ serial bit stream to the USART. The decoder input is normally high (marking state) in the Idle state. The transmit encoder output has the opposite polarity to the decoder input. A start bit is detected when the decoder input is low.

- IrDA is a half duplex communication protocol. If the Transmitter is busy (when the USART is sending data to the IrDA encoder), any data on the IrDA receive line is ignored by the IrDA decoder and if the Receiver is busy (when the USART is receiving decoded data from the IrDA decoder), data on the TX from the USART to IrDA is not encoded. while receiving data, transmission should be avoided as the data to be transmitted could be corrupted.
- A 0 is transmitted as a high pulse and a 1 is transmitted as a 0. The width of the pulse is specified as 3/16th of the selected bit period in normal mode (see [Figure 350](#)).
- The SIR decoder converts the IrDA compliant receive signal into a bit stream for USART.
- The SIR receive logic interprets a high state as a logic one and low pulses as logic zeros.
- The transmit encoder output has the opposite polarity to the decoder input. The SIR output is in low state when Idle.

- The IrDA specification requires the acceptance of pulses greater than 1.41  $\mu$ s. The acceptable pulse width is programmable. Glitch detection logic on the receiver end filters out pulses of width less than 2 PSC periods (PSC is the prescaler value programmed in the USART\_GTPR). Pulses of width less than 1 PSC period are always rejected, but those of width greater than one and less than two periods may be accepted or rejected, those greater than 2 periods will be accepted as a pulse. The IrDA encoder/decoder doesn't work when PSC=0.
- The receiver can communicate with a low-power transmitter.
- In IrDA mode, the STOP bits in the USART\_CR2 register must be configured to "1 stop bit".

### IrDA low-power mode

#### Transmitter

In low-power mode the pulse width is not maintained at 3/16 of the bit period. Instead, the width of the pulse is 3 times the low-power baud rate which can be a minimum of 1.42 MHz.

Generally, this value is 1.8432 MHz ( $1.42 \text{ MHz} < \text{PSC} < 2.12 \text{ MHz}$ ). A low-power mode programmable divisor divides the system clock to achieve this value.

#### Receiver

Receiving in low-power mode is similar to receiving in normal mode. For glitch detection the USART should discard pulses of duration shorter than 1 PSC period. A valid low is accepted only if its duration is greater than 2 periods of the IrDA low-power Baud clock (PSC value in the USART\_GTPR).

*Note: A pulse of width less than two and greater than one PSC period(s) may or may not be rejected.*

*The receiver set up time should be managed by software. The IrDA physical layer specification specifies a minimum of 10 ms delay between transmission and reception (IrDA is a half duplex protocol).*

**Figure 349. IrDA SIR ENDEC- block diagram**

Figure 350. IrDA data modulation (3/16) -Normal Mode

### 31.5.15 USART continuous communication in DMA mode

The USART is capable of performing continuous communication using the DMA. The DMA requests for Rx buffer and Tx buffer are generated independently.

*Note:* Please refer to [Section 31.4: USART implementation on page 1026](#) to determine if the DMA mode is supported. If DMA is not supported, use the USART as explained in [Section 31.5.2: USART transmitter](#) or [Section 31.5.3: USART receiver](#). To perform continuous communication, the user can clear the TXE/ RXNE flags in the USART\_ISR register.

#### Transmission using DMA

DMA mode can be enabled for transmission by setting DMAT bit in the USART\_CR3 register. Data is loaded from a SRAM area configured using the DMA peripheral (refer to [Section 8: Direct memory access controller \(DMA\) on page 242](#)) to the USART\_TDR register whenever the TXE bit is set. To map a DMA channel for USART transmission, use the following procedure (x denotes the channel number):

1. Write the USART\_TDR register address in the DMA control register to configure it as the destination of the transfer. The data is moved to this address from memory after each TXE event.
2. Write the memory address in the DMA control register to configure it as the source of the transfer. The data is loaded into the USART\_TDR register from this memory area after each TXE event.
3. Configure the total number of bytes to be transferred to the DMA control register.
4. Configure the channel priority in the DMA register
5. Configure DMA interrupt generation after half/ full transfer as required by the application.
6. Clear the TC flag in the USART\_ISR register by setting the TCCF bit in the USART\_ICR register.
7. Activate the channel in the DMA register.

When the number of data transfers programmed in the DMA Controller is reached, the DMA controller generates an interrupt on the DMA channel interrupt vector.

In transmission mode, once the DMA has written all the data to be transmitted (the TCIF flag is set in the DMA\_ISR register), the TC flag can be monitored to make sure that the USART

communication is complete. This is required to avoid corrupting the last transmission before disabling the USART or entering Stop mode. Software must wait until TC=1. The TC flag remains cleared during all data transfers and it is set by hardware at the end of transmission of the last frame.

**Figure 351. Transmission using DMA**

### Reception using DMA

DMA mode can be enabled for reception by setting the DMAR bit in USART\_CR3 register. Data is loaded from the USART\_RDR register to a SRAM area configured using the DMA peripheral (refer to [Section 8: Direct memory access controller \(DMA\)](#)) whenever a data byte is received. To map a DMA channel for USART reception, use the following procedure:

1. Write the USART\_RDR register address in the DMA control register to configure it as the source of the transfer. The data is moved from this address to the memory after each RXNE event.
2. Write the memory address in the DMA control register to configure it as the destination of the transfer. The data is loaded from USART\_RDR to this memory area after each RXNE event.
3. Configure the total number of bytes to be transferred to the DMA control register.
4. Configure the channel priority in the DMA control register.
5. Configure interrupt generation after half/ full transfer as required by the application.
6. Activate the channel in the DMA control register.

When the number of data transfers programmed in the DMA Controller is reached, the DMA controller generates an interrupt on the DMA channel interrupt vector.

Figure 352. Reception using DMA

Error flagging and interrupt generation in multibuffer communication

In multibuffer communication if any error occurs during the transaction the error flag is asserted after the current byte. An interrupt is generated if the interrupt enable flag is set. For framing error, overrun error and noise flag which are asserted with RXNE in single byte reception, there is a separate error flag interrupt enable bit (EIE bit in the USART\_CR3 register), which, if set, enables an interrupt after the current byte if any of these errors occur.

31.5.16 RS232 hardware flow control and RS485 driver enable using USART

It is possible to control the serial data flow between 2 devices by using the CTS input and the RTS output. The [Figure 353](#) shows how to connect 2 devices in this mode:

Figure 353. Hardware flow control between 2 USARTs

RS232 RTS and CTS flow control can be enabled independently by writing the RTSE and CTSE bits respectively to 1 (in the USART\_CR3 register).

### RS232 RTS flow control

If the RTS flow control is enabled (RTSE=1), then RTS is asserted (tied low) as long as the USART receiver is ready to receive a new data. When the receive register is full, RTS is de-asserted, indicating that the transmission is expected to stop at the end of the current frame. [Figure 354](#) shows an example of communication with RTS flow control enabled.

**Figure 354. RS232 RTS flow control**

### RS232 CTS flow control

If the CTS flow control is enabled (CTSE=1), then the transmitter checks the CTS input before transmitting the next frame. If CTS is asserted (tied low), then the next data is transmitted (assuming that data is to be transmitted, in other words, if TXE=0), else the transmission does not occur. when CTS is de-asserted during a transmission, the current transmission is completed before the transmitter stops.

When CTSE=1, the CTSIF status bit is automatically set by hardware as soon as the CTS input toggles. It indicates when the receiver becomes ready or not ready for communication. An interrupt is generated if the CTSIE bit in the USART\_CR3 register is set. [Figure 355](#) shows an example of communication with CTS flow control enabled.

**Figure 355. RS232 CTS flow control**

**Note:** For correct behavior, CTS must be asserted at least 3 USART clock source periods before the end of the current character. In addition it should be noted that the CTSCF flag may not be set for pulses shorter than 2 x PCLK periods.

### RS485 Driver Enable

The driver enable feature is enabled by setting bit DEM in the USART\_CR3 control register. This allows the user to activate the external transceiver control, through the DE (Driver Enable) signal. The assertion time is the time between the activation of the DE signal and the beginning of the START bit. It is programmed using the DEAT [4:0] bit fields in the USART\_CR1 control register. The de-assertion time is the time between the end of the last stop bit, in a transmitted message, and the de-activation of the DE signal. It is programmed using the DEDT [4:0] bit fields in the USART\_CR1 control register. The polarity of the DE signal can be configured using the DEP bit in the USART\_CR3 control register.

In USART, the DEAT and DEDT are expressed in sample time units (1/8 or 1/16 bit duration, depending on the oversampling rate).

## 31.6 USART low-power modes

**Table 199. Effect of low-power modes on the USART**

| Mode    | Description                                                                                       |
|---------|---------------------------------------------------------------------------------------------------|
| Sleep   | No effect. USART interrupt causes the device to exit Sleep mode.                                  |
| Stop    | No effect.                                                                                        |
| Standby | The USART is powered down and must be reinitialized when the device has exited from Standby mode. |

## 31.7 USART interrupts

**Table 200. USART interrupt requests**

| Interrupt event                                                           | Event flag      | Enable Control bit |
|---------------------------------------------------------------------------|-----------------|--------------------|
| Transmit data register empty                                              | TXE             | TXEIE              |
| CTS interrupt                                                             | CTSIF           | CTSIE              |
| Transmission Complete                                                     | TC              | TCIE               |
| Receive data register not empty (data ready to be read)                   | RXNE            | RXNEIE             |
| Overrun error detected                                                    | ORE             |                    |
| Idle line detected                                                        | IDLE            | IDLEIE             |
| Parity error                                                              | PE              | PEIE               |
| LIN break                                                                 | LBDF            | LBDIE              |
| Noise Flag, Overrun error and Framing Error in multibuffer communication. | NF or ORE or FE | EIE                |
| Character match                                                           | CMF             | CMIE               |
| Receiver timeout                                                          | RTOF            | RTOIE              |
| End of Block                                                              | EOBF            | EOBIE              |

The USART interrupt events are connected to the same interrupt vector (see [Figure 356](#)).

- During transmission: Transmission Complete, Clear to Send, Transmit data Register empty or Framing error (in Smartcard mode) interrupt.
- During reception: Idle Line detection, Overrun error, Receive data register not empty, Parity error, LIN break detection, Noise Flag, Framing Error, Character match, etc.

These events generate an interrupt if the corresponding Enable Control Bit is set.

Figure 356. USART interrupt mapping diagram

## 31.8 USART registers

Refer to [Section 1.2 on page 62](#) for a list of abbreviations used in register descriptions.

### 31.8.1 Control register 1 (USART\_CR1)

Address offset: 0x00

Reset value: 0x0000 0000

| 31    | 30   | 29   | 28 | 27    | 26    | 25        | 24   | 23    | 22   | 21     | 20        | 19 | 18 | 17   | 16 |
|-------|------|------|----|-------|-------|-----------|------|-------|------|--------|-----------|----|----|------|----|
| Res.  | Res. | Res. | M1 | EOBIE | RTOIE | DEAT[4:0] |      |       |      |        | DEDT[4:0] |    |    |      |    |
|       |      |      | rw | rw    | rw    | rw        | rw   | rw    | rw   | rw     | rw        | rw | rw | rw   | rw |
| 15    | 14   | 13   | 12 | 11    | 10    | 9         | 8    | 7     | 6    | 5      | 4         | 3  | 2  | 1    | 0  |
| OVER8 | CMIE | MME  | M0 | WAKE  | PCE   | PS        | PEIE | TXEIE | TCIE | RXNEIE | IDLEIE    | TE | RE | Res. | UE |
| rw    | rw   | rw   | rw | rw    | rw    | rw        | rw   | rw    | rw   | rw     | rw        | rw | rw |      | rw |

Bits 31:29 Reserved, must be kept at reset value.

Bit 28 **M1**: Word length

This bit, with bit 12 (M0), determines the word length. It is set or cleared by software.

M[1:0] = 00: 1 Start bit, 8 data bits, n stop bits

M[1:0] = 01: 1 Start bit, 9 data bits, n stop bits

M[1:0] = 10: 1 Start bit, 7 data bits, n stop bits

This bit can only be written when the USART is disabled (UE=0).

*Note: Not all modes are supported in 7-bit data length mode. Refer to [Section 31.4: USART implementation](#) for details.*

Bit 27 **EOBIE**: End of Block interrupt enable

This bit is set and cleared by software.

0: Interrupt is inhibited

1: A USART interrupt is generated when the EOBIF flag is set in the USART\_ISR register.

*Note: If the USART does not support Smartcard mode, this bit is reserved and must be kept at reset value. Please refer to [Section 31.4: USART implementation on page 1026](#).*

Bit 26 **RTOIE**: Receiver timeout interrupt enable

This bit is set and cleared by software.

0: Interrupt is inhibited

1: An USART interrupt is generated when the RTOF bit is set in the USART\_ISR register.

*Note: If the USART does not support the Receiver timeout feature, this bit is reserved and must be kept at reset value. [Section 31.4: USART implementation on page 1026](#).*

Bits 25:21 **DEAT[4:0]**: Driver Enable assertion time

This 5-bit value defines the time between the activation of the DE (Driver Enable) signal and the beginning of the start bit. It is expressed in sample time units (1/8 or 1/16 bit duration, depending on the oversampling rate).

This bit field can only be written when the USART is disabled (UE=0).

*Note: If the Driver Enable feature is not supported, this bit is reserved and must be kept at reset value. Please refer to [Section 31.4: USART implementation on page 1026](#).*

Bits 20:16 **DEDT[4:0]**: Driver Enable de-assertion time

This 5-bit value defines the time between the end of the last stop bit, in a transmitted message, and the de-activation of the DE (Driver Enable) signal. It is expressed in sample time units (1/8 or 1/16 bit duration, depending on the oversampling rate).

If the USART\_TDR register is written during the DEDT time, the new data is transmitted only when the DEDT and DEAT times have both elapsed.

This bit field can only be written when the USART is disabled (UE=0).

*Note: If the Driver Enable feature is not supported, this bit is reserved and must be kept at reset value. Please refer to [Section 31.4: USART implementation on page 1026](#).*

Bit 15 **OVER8**: Oversampling mode

0: Oversampling by 16

1: Oversampling by 8

This bit can only be written when the USART is disabled (UE=0).

*Note: In LIN, IrDA and modes, this bit must be kept at reset value.*

Bit 14 **CMIE**: Character match interrupt enable

This bit is set and cleared by software.

0: Interrupt is inhibited

1: A USART interrupt is generated when the CMF bit is set in the USART\_ISR register.

Bit 13 **MME**: Mute mode enable

This bit activates the mute mode function of the USART. when set, the USART can switch between the active and mute modes, as defined by the WAKE bit. It is set and cleared by software.

0: Receiver in active mode permanently

1: Receiver can switch between mute mode and active mode.

Bit 12 **M0**: Word length

This bit, with bit 28 (M1), determines the word length. It is set or cleared by software. See Bit 28 (M1) description.

This bit can only be written when the USART is disabled (UE=0).

Bit 11 **WAKE**: Receiver wakeup method

This bit determines the USART wakeup method from Mute mode. It is set or cleared by software.

0: Idle line

1: Address mark

This bit field can only be written when the USART is disabled (UE=0).

Bit 10 **PCE**: Parity control enable

This bit selects the hardware parity control (generation and detection). When the parity control is enabled, the computed parity is inserted at the MSB position (9th bit if M=1; 8th bit if M=0) and parity is checked on the received data. This bit is set and cleared by software.

Once it is set, PCE is active after the current byte (in reception and in transmission).

0: Parity control disabled

1: Parity control enabled

This bit field can only be written when the USART is disabled (UE=0).

Bit 9 **PS**: Parity selection

This bit selects the odd or even parity when the parity generation/detection is enabled (PCE bit set). It is set and cleared by software. The parity will be selected after the current byte.

0: Even parity

1: Odd parity

This bit field can only be written when the USART is disabled (UE=0).

Bit 8 **PEIE**: PE interrupt enable

This bit is set and cleared by software.

0: Interrupt is inhibited

1: A USART interrupt is generated whenever PE=1 in the USART\_ISR register

Bit 7 **TXEIE**: interrupt enable

This bit is set and cleared by software.

0: Interrupt is inhibited

1: A USART interrupt is generated whenever TXE=1 in the USART\_ISR register

Bit 6 **TCIE**: Transmission complete interrupt enable

This bit is set and cleared by software.

0: Interrupt is inhibited

1: A USART interrupt is generated whenever TC=1 in the USART\_ISR register

Bit 5 **RXNEIE**: RXNE interrupt enable

This bit is set and cleared by software.

0: Interrupt is inhibited

1: A USART interrupt is generated whenever ORE=1 or RXNE=1 in the USART\_ISR register

Bit 4 **IDLEIE**: IDLE interrupt enable

This bit is set and cleared by software.

0: Interrupt is inhibited

1: A USART interrupt is generated whenever IDLE=1 in the USART\_ISR register

Bit 3 **TE**: Transmitter enable

This bit enables the transmitter. It is set and cleared by software.

0: Transmitter is disabled

1: Transmitter is enabled

*Note: During transmission, a “0” pulse on the TE bit (“0” followed by “1”) sends a preamble (idle line) after the current word, except in Smartcard mode. In order to generate an idle character, the TE must not be immediately written to 1. In order to ensure the required duration, the software can poll the TEACK bit in the USART\_ISR register.*

*In Smartcard mode, when TE is set there is a 1 bit-time delay before the transmission starts.*

Bit 2 **RE**: Receiver enable

This bit enables the receiver. It is set and cleared by software.

0: Receiver is disabled

1: Receiver is enabled and begins searching for a start bit

Bit 1 Reserved, must be kept at reset value.

Bit 0 **UE**: USART enable

When this bit is cleared, the USART prescalers and outputs are stopped immediately, and current operations are discarded. The configuration of the USART is kept, but all the status flags, in the USART\_ISR are set to their default values. This bit is set and cleared by software.

0: USART prescaler and outputs disabled, low-power mode

1: USART enabled

*Note: In order to go into low-power mode without generating errors on the line, the TE bit must be reset before and the software must wait for the TC bit in the USART\_ISR to be set before resetting the UE bit.*

*The DMA requests are also reset when UE = 0 so the DMA channel must be disabled before resetting the UE bit.*

## 31.8.2 Control register 2 (USART\_CR2)

Address offset: 0x04

Reset value: 0x0000 0000

| 31       | 30    | 29        | 28 | 27       | 26   | 25   | 24   | 23    | 22          | 21   | 20    | 19       | 18      | 17    | 16    |
|----------|-------|-----------|----|----------|------|------|------|-------|-------------|------|-------|----------|---------|-------|-------|
| ADD[7:4] |       |           |    | ADD[3:0] |      |      |      | RTOEN | ABRMOD[1:0] |      | ABREN | MSBFIRST | DATAINV | TXINV | RXINV |
| rw       | rw    | rw        | rw | rw       | rw   | rw   | rw   | rw    | rw          | rw   | rw    | rw       | rw      | rw    | rw    |
| 15       | 14    | 13        | 12 | 11       | 10   | 9    | 8    | 7     | 6           | 5    | 4     | 3        | 2       | 1     | 0     |
| SWAP     | LINEN | STOP[1:0] |    | CLKEN    | CPOL | CPHA | LBCL | Res.  | LBDIE       | LBDL | ADDM7 | Res.     | Res.    | Res.  | Res.  |
| rw       | rw    | rw        | rw | rw       | rw   | rw   | rw   |       | rw          | rw   | rw    |          |         |       |       |

**Bits 31:28 ADD[7:4]:** Address of the USART node

This bit-field gives the address of the USART node or a character code to be recognized.

This is used in multiprocessor communication during Mute mode, for wakeup with 7-bit address mark detection. The MSB of the character sent by the transmitter should be equal to 1. It may also be used for character detection during normal reception, Mute mode inactive (for example, end of block detection in ModBus protocol). In this case, the whole received character (8-bit) is compared to the ADD[7:0] value and CMF flag is set on match.

This bit field can only be written when reception is disabled (RE = 0) or the USART is disabled (UE=0)

**Bits 27:24 ADD[3:0]:** Address of the USART node

This bit-field gives the address of the USART node or a character code to be recognized.

This is used in multiprocessor communication during Mute mode, for wakeup with address mark detection.

This bit field can only be written when reception is disabled (RE = 0) or the USART is disabled (UE=0)

**Bit 23 RTOEN:** Receiver timeout enable

This bit is set and cleared by software.

0: Receiver timeout feature disabled.

1: Receiver timeout feature enabled.

When this feature is enabled, the RTOF flag in the USART\_ISR register is set if the RX line is idle (no reception) for the duration programmed in the RTOR (receiver timeout register).

*Note: If the USART does not support the Receiver timeout feature, this bit is reserved and must be kept at reset value. Please refer to [Section 31.4: USART implementation on page 1026](#).*

**Bits 22:21 ABRMOD[1:0]:** Auto baud rate mode

These bits are set and cleared by software.

00: Measurement of the start bit is used to detect the baud rate.

01: Falling edge to falling edge measurement. (the received frame must start with a single bit = 1 -> Frame = Start10xxxxxx)

10: 0x7F frame detection.

11: 0x55 frame detection

This bit field can only be written when ABREN = 0 or the USART is disabled (UE=0).

*Note: If DATAINV=1 and/or MSBFIRST=1 the patterns must be the same on the line, for example 0xAA for MSBFIRST)*

*If the USART does not support the auto baud rate feature, this bit is reserved and must be kept at reset value. Please refer to [Section 31.4: USART implementation on page 1026](#).*

**Bit 20 ABREN:** Auto baud rate enable

This bit is set and cleared by software.

0: Auto baud rate detection is disabled.

1: Auto baud rate detection is enabled.

*Note: If the USART does not support the auto baud rate feature, this bit is reserved and must be kept at reset value. Please refer to [Section 31.4: USART implementation on page 1026](#).*

**Bit 19 MSBFIRST:** Most significant bit first

This bit is set and cleared by software.

0: data is transmitted/received with data bit 0 first, following the start bit.

1: data is transmitted/received with the MSB (bit 7/8/9) first, following the start bit.

This bit field can only be written when the USART is disabled (UE=0).

**Bit 18 DATAINV:** Binary data inversion

This bit is set and cleared by software.

0: Logical data from the data register are send/received in positive/direct logic. (1=H, 0=L)

1: Logical data from the data register are send/received in negative/inverse logic. (1=L, 0=H). The parity bit is also inverted.

This bit field can only be written when the USART is disabled (UE=0).

**Bit 17 TXINV:** TX pin active level inversion

This bit is set and cleared by software.

0: TX pin signal works using the standard logic levels ( $V_{DD}$  =1/idle, Gnd=0/mark)

1: TX pin signal values are inverted. ( $V_{DD}$  =0/mark, Gnd=1/idle).

This allows the use of an external inverter on the TX line.

This bit field can only be written when the USART is disabled (UE=0).

**Bit 16 RXINV:** RX pin active level inversion

This bit is set and cleared by software.

0: RX pin signal works using the standard logic levels ( $V_{DD}$  =1/idle, Gnd=0/mark)

1: RX pin signal values are inverted. ( $V_{DD}$  =0/mark, Gnd=1/idle).

This allows the use of an external inverter on the RX line.

This bit field can only be written when the USART is disabled (UE=0).

**Bit 15 SWAP:** Swap TX/RX pins

This bit is set and cleared by software.

0: TX/RX pins are used as defined in standard pinout

1: The TX and RX pins functions are swapped. This allows to work in the case of a cross-wired connection to another USART.

This bit field can only be written when the USART is disabled (UE=0).

**Bit 14 LINEN:** LIN mode enable

This bit is set and cleared by software.

0: LIN mode disabled

1: LIN mode enabled

The LIN mode enables the capability to send LIN synchronous breaks (13 low bits) using the SBKRQ bit in the USART\_RQR register, and to detect LIN Sync breaks.

This bit field can only be written when the USART is disabled (UE=0).

*Note: If the USART does not support LIN mode, this bit is reserved and must be kept at reset value. Please refer to [Section 31.4: USART implementation on page 1026](#).*

Bits 13:12 **STOP[1:0]**: STOP bits

These bits are used for programming the stop bits.

00: 1 stop bit

01: 0.5 stop bit

10: 2 stop bits

11: 1.5 stop bits

This bit field can only be written when the USART is disabled (UE=0).

Bit 11 **CLKEN**: Clock enable

This bit allows the user to enable the CK pin.

0: CK pin disabled

1: CK pin enabled

This bit can only be written when the USART is disabled (UE=0).

*Note: If neither synchronous mode nor Smartcard mode is supported, this bit is reserved and must be kept at reset value. Please refer to [Section 31.4: USART implementation on page 1026](#).*

*In order to provide correctly the CK clock to the Smartcard when CK is always available When CLKEN = 1, regardless of the UE bit value, the steps below must be respected:*

- UE = 0

- SCEN = 1

- GTPR configuration (If PSC needs to be configured, it is recommended to configure PSC and GT in a single access to USART\_ GTPR register).

- CLKEN= 1

- UE = 1

Bit 10 **CPOL**: Clock polarity

This bit allows the user to select the polarity of the clock output on the CK pin in synchronous mode. It works in conjunction with the CPHA bit to produce the desired clock/data relationship

0: Steady low value on CK pin outside transmission window

1: Steady high value on CK pin outside transmission window

This bit can only be written when the USART is disabled (UE=0).

*Note: If synchronous mode is not supported, this bit is reserved and must be kept at reset value.*

*Please refer to [Section 31.4: USART implementation on page 1026](#).*

Bit 9 **CPHA**: Clock phase

This bit is used to select the phase of the clock output on the CK pin in synchronous mode. It works in conjunction with the CPOL bit to produce the desired clock/data relationship (see [Figure 344](#) and [Figure 345](#))

0: The first clock transition is the first data capture edge

1: The second clock transition is the first data capture edge

This bit can only be written when the USART is disabled (UE=0).

*Note: If synchronous mode is not supported, this bit is reserved and must be kept at reset value.*

*Please refer to [Section 31.4: USART implementation on page 1026](#).*

Bit 8 **LBCL**: Last bit clock pulse

This bit is used to select whether the clock pulse associated with the last data bit transmitted (MSB) has to be output on the CK pin in synchronous mode.

0: The clock pulse of the last data bit is not output to the CK pin

1: The clock pulse of the last data bit is output to the CK pin

**Caution:** The last bit is the 7th or 8th or 9th data bit transmitted depending on the 7 or 8 or 9 bit format selected by the M bits in the USART\_CR1 register.

This bit can only be written when the USART is disabled (UE=0).

*Note: If synchronous mode is not supported, this bit is reserved and must be kept at reset value.*

*Please refer to [Section 31.4: USART implementation on page 1026](#).*

Bit 7 Reserved, must be kept at reset value.

Bit 6 **LBDIE**: LIN break detection interrupt enable

Break interrupt mask (break detection using break delimiter).

0: Interrupt is inhibited

1: An interrupt is generated whenever LBDF=1 in the USART\_ISR register

*Note: If LIN mode is not supported, this bit is reserved and must be kept at reset value. Please refer to [Section 31.4: USART implementation on page 1026](#).*

Bit 5 **LBDL**: LIN break detection length

This bit is for selection between 11 bit or 10 bit break detection.

0: 10-bit break detection

1: 11-bit break detection

This bit can only be written when the USART is disabled (UE=0).

*Note: If LIN mode is not supported, this bit is reserved and must be kept at reset value. Please refer to [Section 31.4: USART implementation on page 1026](#).*

Bit 4 **ADDM7**: 7-bit Address Detection/4-bit Address Detection

This bit is for selection between 4-bit address detection or 7-bit address detection.

0: 4-bit address detection

1: 7-bit address detection (in 8-bit data mode)

This bit can only be written when the USART is disabled (UE=0)

*Note: In 7-bit and 9-bit data modes, the address detection is done on 6-bit and 8-bit address (ADD[5:0] and ADD[7:0]) respectively.*

Bits 3:0 Reserved, must be kept at reset value.

*Note: The 3 bits (CPOL, CPHA, LBCL) should not be written while the transmitter is enabled.*

### 31.8.3 Control register 3 (USART\_CR3)

Address offset: 0x08

Reset value: 0x0000 0000

Bits 31:25 Reserved, must be kept at reset value.

Bit 24 Reserved, must be kept at reset value.

Bit 23 Reserved, must be kept at reset value.

Bits 22:20 Reserved, must be kept at reset value.

**Bits 19:17 SCARCNT[2:0]:** Smartcard auto-retry count

This bit-field specifies the number of retries in transmit and receive, in Smartcard mode.

In transmission mode, it specifies the number of automatic retransmission retries, before generating a transmission error (FE bit set).

In reception mode, it specifies the number of erroneous reception trials, before generating a reception error (RXNE and PE bits set).

This bit field must be programmed only when the USART is disabled (UE=0).

When the USART is enabled (UE=1), this bit field may only be written to 0x0, in order to stop retransmission.

0x0: retransmission disabled - No automatic retransmission in transmit mode.

0x1 to 0x7: number of automatic retransmission attempts (before signaling error)

*Note: If Smartcard mode is not supported, this bit is reserved and must be kept at reset value. Please refer to [Section 31.4: USART implementation on page 1026](#).*

**Bit 16** Reserved, must be kept at reset value.**Bit 15 DEP:** Driver enable polarity selection

0: DE signal is active high.

1: DE signal is active low.

This bit can only be written when the USART is disabled (UE=0).

*Note: If the Driver Enable feature is not supported, this bit is reserved and must be kept at reset value. Please refer to [Section 31.4: USART implementation on page 1026](#).*

**Bit 14 DEM:** Driver enable mode

This bit allows the user to activate the external transceiver control, through the DE signal.

0: DE function is disabled.

1: DE function is enabled. The DE signal is output on the RTS pin.

This bit can only be written when the USART is disabled (UE=0).

*Note: If the Driver Enable feature is not supported, this bit is reserved and must be kept at reset value. [Section 31.4: USART implementation on page 1026](#).*

**Bit 13 DDRE:** DMA Disable on Reception Error

0: DMA is not disabled in case of reception error. The corresponding error flag is set but RXNE is kept 0 preventing from overrun. As a consequence, the DMA request is not asserted, so the erroneous data is not transferred (no DMA request), but next correct received data will be transferred (used for Smartcard mode).

1: DMA is disabled following a reception error. The corresponding error flag is set, as well as RXNE. The DMA request is masked until the error flag is cleared. This means that the software must first disable the DMA request (DMAR = 0) or clear RXNE before clearing the error flag.

This bit can only be written when the USART is disabled (UE=0).

*Note: The reception errors are: parity error, framing error or noise error.*

**Bit 12 OVRDIS:** Overrun Disable

This bit is used to disable the receive overrun detection.

0: Overrun Error Flag, ORE, is set when received data is not read before receiving new data.

1: Overrun functionality is disabled. If new data is received while the RXNE flag is still set the ORE flag is not set and the new received data overwrites the previous content of the USART\_RDR register.

This bit can only be written when the USART is disabled (UE=0).

*Note: This control bit allows checking the communication flow without reading the data.*

**Bit 11 ONEBIT:** One sample bit method enable

This bit allows the user to select the sample method. When the one sample bit method is selected the noise detection flag (NF) is disabled.

0: Three sample bit method

1: One sample bit method

This bit can only be written when the USART is disabled (UE=0).

*Note: ONEBIT feature applies only to data bits, It does not apply to Start bit.*

**Bit 10 CTSIE:** CTS interrupt enable

0: Interrupt is inhibited

1: An interrupt is generated whenever CTSIF=1 in the USART\_ISR register

*Note: If the hardware flow control feature is not supported, this bit is reserved and must be kept at reset value. Please refer to [Section 31.4: USART implementation on page 1026](#).*

**Bit 9 CTSE:** CTS enable

0: CTS hardware flow control disabled

1: CTS mode enabled, data is only transmitted when the CTS input is asserted (tied to 0). If the CTS input is de-asserted while data is being transmitted, then the transmission is completed before stopping. If data is written into the data register while CTS is de-asserted, the transmission is postponed until CTS is asserted.

This bit can only be written when the USART is disabled (UE=0)

*Note: If the hardware flow control feature is not supported, this bit is reserved and must be kept at reset value. Please refer to [Section 31.4: USART implementation on page 1026](#).*

**Bit 8 RTSE:** RTS enable

0: RTS hardware flow control disabled

1: RTS output enabled, data is only requested when there is space in the receive buffer. The transmission of data is expected to cease after the current character has been transmitted. The RTS output is asserted (pulled to 0) when data can be received.

This bit can only be written when the USART is disabled (UE=0).

*Note: If the hardware flow control feature is not supported, this bit is reserved and must be kept at reset value. Please refer to [Section 31.4: USART implementation on page 1026](#).*

**Bit 7 DMAT:** DMA enable transmitter

This bit is set/reset by software

1: DMA mode is enabled for transmission

0: DMA mode is disabled for transmission

**Bit 6 DMAR:** DMA enable receiver

This bit is set/reset by software

1: DMA mode is enabled for reception

0: DMA mode is disabled for reception

**Bit 5 SCEN:** Smartcard mode enable

This bit is used for enabling Smartcard mode.

0: Smartcard Mode disabled

1: Smartcard Mode enabled

This bit field can only be written when the USART is disabled (UE=0).

*Note: If the USART does not support Smartcard mode, this bit is reserved and must be kept at reset value. Please refer to [Section 31.4: USART implementation on page 1026](#).*

## Bit 4 **NACK**: Smartcard NACK enable

0: NACK transmission in case of parity error is disabled

1: NACK transmission during parity error is enabled

This bit field can only be written when the USART is disabled (UE=0).

*Note: If the USART does not support Smartcard mode, this bit is reserved and must be kept at reset value. Please refer to [Section 31.4: USART implementation on page 1026](#).*

## Bit 3 **HDSEL**: Half-duplex selection

Selection of Single-wire Half-duplex mode

0: Half duplex mode is not selected

1: Half duplex mode is selected

This bit can only be written when the USART is disabled (UE=0).

## Bit 2 **IRLP**: IrDA low-power

This bit is used for selecting between normal and low-power IrDA modes

0: Normal mode

1: Low-power mode

This bit can only be written when the USART is disabled (UE=0).

*Note: If IrDA mode is not supported, this bit is reserved and must be kept at reset value. Please refer to [Section 31.4: USART implementation on page 1026](#).*

## Bit 1 **IREN**: IrDA mode enable

This bit is set and cleared by software.

0: IrDA disabled

1: IrDA enabled

This bit can only be written when the USART is disabled (UE=0).

*Note: If IrDA mode is not supported, this bit is reserved and must be kept at reset value. Please refer to [Section 31.4: USART implementation on page 1026](#).*

## Bit 0 **EIE**: Error interrupt enable

Error Interrupt Enable Bit is required to enable interrupt generation in case of a framing error, overrun error or noise flag (FE=1 or ORE=1 or NF=1 in the USART\_ISR register).

0: Interrupt is inhibited

1: An interrupt is generated when FE=1 or ORE=1 or NF=1 in the USART\_ISR register.

## 31.8.4 Baud rate register (USART\_BRR)

This register can only be written when the USART is disabled (UE=0). It may be automatically updated by hardware in auto baud rate detection mode.

Address offset: 0x0C

Reset value: 0x0000 0000

|           |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
|-----------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|
| 31        | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21   | 20   | 19   | 18   | 17   | 16   |

| BRR[15:0] |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
| rw        | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   |

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:4 **BRR[15:4]**

BRR[15:4] = USARTDIV[15:4]

Bits 3:0 **BRR[3:0]**

When OVER8 = 0, BRR[3:0] = USARTDIV[3:0].

When OVER8 = 1:

BRR[2:0] = USARTDIV[3:0] shifted 1 bit to the right.

BRR[3] must be kept cleared.

### **31.8.5 Guard time and prescaler register (USART\_GTPR)**

Address offset: 0x10

Reset value: 0x0000 0000

|         |      |      |      |      |      |      |      |          |      |      |      |      |      |      |      |
|---------|------|------|------|------|------|------|------|----------|------|------|------|------|------|------|------|
| 31      | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23       | 22   | 21   | 20   | 19   | 18   | 17   | 16   |
| Res.    | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res.     | Res. | Res. | Res. | Res. | Res. | Res. | Res. |
|         |      |      |      |      |      |      |      |          |      |      |      |      |      |      |      |
| 15      | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7        | 6    | 5    | 4    | 3    | 2    | 1    | 0    |
| GT[7:0] |      |      |      |      |      |      |      | PSC[7:0] |      |      |      |      |      |      |      |
| rw      | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw       | rw   | rw   | rw   | rw   | rw   | rw   | rw   |

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:8 **GT[7:0]**: Guard time value

This bit-field is used to program the Guard time value in terms of number of baud clock periods.

This is used in Smartcard mode. The Transmission Complete flag is set after this guard time value.

This bit field can only be written when the USART is disabled (UE=0).

*Note: If Smartcard mode is not supported, this bit is reserved and must be kept at reset value. Please refer to [Section 31.4: USART implementation on page 1026](#).*

Bits 7:0 **PSC[7:0]**: Prescaler value

**In IrDA Low-power and normal IrDA mode:**

PSC[7:0] = IrDA Normal and Low-Power Baud Rate

Used for programming the prescaler for dividing the USART source clock to achieve the low-power frequency:

The source clock is divided by the value given in the register (8 significant bits):

00000000: Reserved - do not program this value

00000001: divides the source clock by 1

00000010: divides the source clock by 2

...

**In Smartcard mode:**

PSC[4:0]: Prescaler value

Used for programming the prescaler for dividing the USART source clock to provide the Smartcard clock.

The value given in the register (5 significant bits) is multiplied by 2 to give the division factor of the source clock frequency:

00000: Reserved - do not program this value

00001: divides the source clock by 2

00010: divides the source clock by 4

00011: divides the source clock by 6

...

This bit field can only be written when the USART is disabled (UE=0).

*Note: Bits [7:5] must be kept at reset value if Smartcard mode is used.*

*This bit field is reserved and must be kept at reset value when the Smartcard and IrDA modes are not supported. Please refer to [Section 31.4: USART implementation on page 1026](#).*

## 31.8.6 Receiver timeout register (USART\_RTOR)

Address offset: 0x14

Reset value: 0x0000 0000

|           |    |    |    |    |    |    |    |            |    |    |    |    |    |    |    |
|-----------|----|----|----|----|----|----|----|------------|----|----|----|----|----|----|----|
| 31        | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23         | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| BLEN[7:0] |    |    |    |    |    |    |    | RTO[23:16] |    |    |    |    |    |    |    |
| rw        | rw | rw | rw | rw | rw | rw | rw | rw         | rw | rw | rw | rw | rw | rw | rw |
| 15        | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7          | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| RTO[15:0] |    |    |    |    |    |    |    |            |    |    |    |    |    |    |    |
| rw        | rw | rw | rw | rw | rw | rw | rw | rw         | rw | rw | rw | rw | rw | rw | rw |

Bits 31:24 **BLLEN[7:0]**: Block Length

This bit-field gives the Block length in Smartcard T=1 Reception. Its value equals the number of information characters + the length of the Epilogue Field (1-LEC/2-CRC) - 1.

Examples:

BLLEN = 0 -> 0 information characters + LEC

BLLEN = 1 -> 0 information characters + CRC

BLLEN = 255 -> 254 information characters + CRC (total 256 characters))

In Smartcard mode, the Block length counter is reset when TXE=0.

This bit-field can be used also in other modes. In this case, the Block length counter is reset when RE=0 (receiver disabled) and/or when the EOBCF bit is written to 1.

*Note: This value can be programmed after the start of the block reception (using the data from the LEN character in the Prologue Field). It must be programmed only once per received block.*

Bits 23:0 **RTO[23:0]**: Receiver timeout value

This bit-field gives the Receiver timeout value in terms of number of bit duration.

In standard mode, the RTOF flag is set if, after the last received character, no new start bit is detected for more than the RTO value.

In Smartcard mode, this value is used to implement the CWT and BWT. See Smartcard section for more details.

In this case, the timeout measurement is done starting from the Start Bit of the last received character.

*Note: This value must only be programmed once per received character.*

*Note: RTOF can be written on the fly. If the new value is lower than or equal to the counter, the RTOF flag is set.*

*This register is reserved and forced by hardware to "0x00000000" when the Receiver timeout feature is not supported. Please refer to [Section 31.4: USART implementation on page 1026](#).*

### 31.8.7 Request register (USART\_RQR)

Address offset: 0x18

Reset value: 0x0000 0000

|      |      |      |      |      |      |      |      |      |      |      |       |       |      |       |       |
|------|------|------|------|------|------|------|------|------|------|------|-------|-------|------|-------|-------|
| 31   | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21   | 20    | 19    | 18   | 17    | 16    |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res.  | Res.  | Res. | Res.  | Res.  |
|      |      |      |      |      |      |      |      |      |      |      |       |       |      |       |       |
| 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5    | 4     | 3     | 2    | 1     | 0     |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | TXFRQ | RXFRQ | MMRQ | SBKRQ | ABRRQ |
|      |      |      |      |      |      |      |      |      |      |      | w     | w     | w    | w     | w     |

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 **TXFRQ**: Transmit data flush request

Writing 1 to this bit sets the TXE flag.

This allows to discard the transmit data. This bit must be used only in Smartcard mode, when data has not been sent due to errors (NACK) and the FE flag is active in the USART\_ISR register.

If the USART does not support Smartcard mode, this bit is reserved and must be kept at reset value. Please refer to [Section 31.4: USART implementation on page 1026](#).

Bit 3 **RXFRQ**: Receive data flush request

Writing 1 to this bit clears the RXNE flag.

This allows to discard the received data without reading it, and avoid an overrun condition.

Bit 2 **MMRQ**: Mute mode request

Writing 1 to this bit puts the USART in mute mode and sets the RWU flag.

Bit 1 **SBKRQ**: Send break request

Writing 1 to this bit sets the SBKF flag and request to send a BREAK on the line, as soon as the transmit machine is available.

*Note: In the case the application needs to send the break character following all previously inserted data, including the ones not yet transmitted, the software should wait for the TXE flag assertion before setting the SBKRQ bit.*

Bit 0 **ABRRQ**: Auto baud rate request

Writing 1 to this bit resets the ABRF flag in the USART\_ISR and request an automatic baud rate measurement on the next received data frame.

*Note: If the USART does not support the auto baud rate feature, this bit is reserved and must be kept at reset value. Please refer to [Section 31.4: USART implementation on page 1026](#).*

## 31.8.8 Interrupt and status register (USART\_ISR)

Address offset: 0x1C

Reset value: 0x0200 00C0

| 31   | 30   | 29   | 28   | 27   | 26   | 25    | 24   | 23   | 22   | 21    | 20   | 19  | 18   | 17  | 16   |
|------|------|------|------|------|------|-------|------|------|------|-------|------|-----|------|-----|------|
| Res. | Res. | Res. | Res. | Res. | Res. | Res.  | Res. | Res. | Res. | TEACK | Res. | RWU | SBKF | CMF | BUSY |
|      |      |      |      |      |      |       |      |      |      | r     |      | r   | r    | r   | r    |
| 15   | 14   | 13   | 12   | 11   | 10   | 9     | 8    | 7    | 6    | 5     | 4    | 3   | 2    | 1   | 0    |
| ABRF | ABRE | Res. | EOBF | RTOF | CTS  | CTSIF | LBDF | TXE  | TC   | RXNE  | IDLE | ORE | NF   | FE  | PE   |
| r    | r    |      | r    | r    | r    | r     | r    | r    | r    | r     | r    | r   | r    | r   | r    |

Bits 31:25 Reserved, must be kept at reset value.

Bits 24:22 Reserved, must be kept at reset value.

Bit 21 **TEACK**: Transmit enable acknowledge flag

This bit is set/reset by hardware, when the Transmit Enable value is taken into account by the USART.

It can be used when an idle frame request is generated by writing TE=0, followed by TE=1 in the USART\_CR1 register, in order to respect the TE=0 minimum period.

Bit 20 Reserved, must be kept at reset value.

**Bit 19 RWU: Receiver wakeup from Mute mode**

This bit indicates if the USART is in mute mode. It is cleared/set by hardware when a wakeup/mute sequence is recognized. The mute mode control sequence (address or IDLE) is selected by the WAKE bit in the USART\_CR1 register.

When wakeup on IDLE mode is selected, this bit can only be set by software, writing 1 to the MMRQ bit in the USART\_RQR register.

0: Receiver in active mode

1: Receiver in mute mode

**Bit 18 SBKF: Send break flag**

This bit indicates that a send break character was requested. It is set by software, by writing 1 to the SBKRQ bit in the USART\_RQR register. It is automatically reset by hardware during the stop bit of break transmission.

0: No break character is transmitted

1: Break character will be transmitted

**Bit 17 CMF: Character match flag**

This bit is set by hardware, when the character defined by ADD[7:0] is received. It is cleared by software, writing 1 to the CMCF in the USART\_ICR register.

An interrupt is generated if CMIE=1 in the USART\_CR1 register.

0: No Character match detected

1: Character Match detected

**Bit 16 BUSY: Busy flag**

This bit is set and reset by hardware. It is active when a communication is ongoing on the RX line (successful start bit detected). It is reset at the end of the reception (successful or not).

0: USART is idle (no reception)

1: Reception on going

**Bit 15 ABRF: Auto baud rate flag**

This bit is set by hardware when the automatic baud rate has been set (RXNE will also be set, generating an interrupt if RXNEIE = 1) or when the auto baud rate operation was completed without success (ABRE=1) (ABRE, RXNE and FE are also set in this case)

It is cleared by software, in order to request a new auto baud rate detection, by writing 1 to the ABRRQ in the USART\_RQR register.

*Note: If the USART does not support the auto baud rate feature, this bit is reserved and kept at reset value.*

**Bit 14 ABRE: Auto baud rate error**

This bit is set by hardware if the baud rate measurement failed (baud rate out of range or character comparison failed)

It is cleared by software, by writing 1 to the ABRRQ bit in the USART\_CR3 register.

*Note: If the USART does not support the auto baud rate feature, this bit is reserved and kept at reset value.*

**Bit 13 Reserved, must be kept at reset value.**

**Bit 12 EOBF:** End of block flag

This bit is set by hardware when a complete block has been received (for example T=1 Smartcard mode). The detection is done when the number of received bytes (from the start of the block, including the prologue) is equal or greater than BLEN + 4.

An interrupt is generated if the EOBI=1 in the USART\_CR2 register.

It is cleared by software, writing 1 to the EOBCF in the USART\_ICR register.

0: End of Block not reached

1: End of Block (number of characters) reached

*Note: If Smartcard mode is not supported, this bit is reserved and kept at reset value. Please refer to [Section 31.4: USART implementation on page 1026](#).*

**Bit 11 RTOF:** Receiver timeout

This bit is set by hardware when the timeout value, programmed in the RTOR register has lapsed, without any communication. It is cleared by software, writing 1 to the RTOCF bit in the USART\_ICR register.

An interrupt is generated if RTOIE=1 in the USART\_CR1 register.

In Smartcard mode, the timeout corresponds to the CWT or BWT timings.

0: Timeout value not reached

1: Timeout value reached without any data reception

*Note: If a time equal to the value programmed in RTOR register separates 2 characters, RTOF is not set. If this time exceeds this value + 2 sample times (2/16 or 2/8, depending on the oversampling method), RTOF flag is set.*

*The counter counts even if RE = 0 but RTOF is set only when RE = 1. If the timeout has already elapsed when RE is set, then RTOF will be set.*

*If the USART does not support the Receiver timeout feature, this bit is reserved and kept at reset value.*

**Bit 10 CTS:** CTS flag

This bit is set/reset by hardware. It is an inverted copy of the status of the CTS input pin.

0: CTS line set

1: CTS line reset

*Note: If the hardware flow control feature is not supported, this bit is reserved and kept at reset value.*

**Bit 9 CTSIF:** CTS interrupt flag

This bit is set by hardware when the CTS input toggles, if the CTSE bit is set. It is cleared by software, by writing 1 to the CTSCF bit in the USART\_ICR register.

An interrupt is generated if CTSIE=1 in the USART\_CR3 register.

0: No change occurred on the CTS status line

1: A change occurred on the CTS status line

*Note: If the hardware flow control feature is not supported, this bit is reserved and kept at reset value.*

**Bit 8 LBDF:** LIN break detection flag

This bit is set by hardware when the LIN break is detected. It is cleared by software, by writing 1 to the LBD CF in the USART\_ICR.

An interrupt is generated if LBDIE = 1 in the USART\_CR2 register.

0: LIN Break not detected

1: LIN break detected

*Note: If the USART does not support LIN mode, this bit is reserved and kept at reset value. Please refer to [Section 31.4: USART implementation on page 1026](#).*

**Bit 7 TXE:** Transmit data register empty

This bit is set by hardware when the content of the USART\_TDR register has been transferred into the shift register. It is cleared by a write to the USART\_TDR register.  
The TXE flag can also be cleared by writing 1 to the TXFRQ in the USART\_RQR register, in order to discard the data (only in Smartcard T=0 mode, in case of transmission failure).  
An interrupt is generated if the TXEIE bit =1 in the USART\_CR1 register.  
0: data is not transferred to the shift register  
1: data is transferred to the shift register)

*Note: This bit is used during single buffer transmission.*

**Bit 6 TC:** Transmission complete

This bit is set by hardware if the transmission of a frame containing data is complete and if TXE is set. An interrupt is generated if TCIE=1 in the USART\_CR1 register. It is cleared by software, writing 1 to the TCCF in the USART\_ICR register or by a write to the USART\_TDR register.  
An interrupt is generated if TCIE=1 in the USART\_CR1 register.  
0: Transmission is not complete  
1: Transmission is complete

*Note: If TE bit is reset and no transmission is on going, the TC bit will be set immediately.*

**Bit 5 RXNE:** Read data register not empty

This bit is set by hardware when the content of the RDR shift register has been transferred to the USART\_RDR register. It is cleared by a read to the USART\_RDR register. The RXNE flag can also be cleared by writing 1 to the RXFRQ in the USART\_RQR register.  
An interrupt is generated if RXNEIE=1 in the USART\_CR1 register.  
0: data is not received  
1: Received data is ready to be read.

**Bit 4 IDLE:** Idle line detected

This bit is set by hardware when an Idle Line is detected. An interrupt is generated if IDLEIE=1 in the USART\_CR1 register. It is cleared by software, writing 1 to the IDLECF in the USART\_ICR register.  
0: No Idle line is detected  
1: Idle line is detected

*Note: The IDLE bit will not be set again until the RXNE bit has been set (i.e. a new idle line occurs).*

*If mute mode is enabled (MME=1), IDLE is set if the USART is not mute (RWU=0), whatever the mute mode selected by the WAKE bit. If RWU=1, IDLE is not set.*

**Bit 3 ORE:** Overrun error

This bit is set by hardware when the data currently being received in the shift register is ready to be transferred into the RDR register while RXNE=1. It is cleared by a software, writing 1 to the ORECF, in the USART\_ICR register.  
An interrupt is generated if RXNEIE=1 or EIE = 1 in the USART\_CR1 register.  
0: No overrun error  
1: Overrun error is detected

*Note: When this bit is set, the RDR register content is not lost but the shift register is overwritten. An interrupt is generated if the ORE flag is set during multibuffer communication if the EIE bit is set.*

*This bit is permanently forced to 0 (no overrun detection) when the OVRDIS bit is set in the USART\_CR3 register.*

### Bit 2 **NF**: START bit Noise detection flag

This bit is set by hardware when noise is detected on a received frame. It is cleared by software, writing 1 to the NFCF bit in the USART\_ICR register.

0: No noise is detected

1: Noise is detected

*Note: This bit does not generate an interrupt as it appears at the same time as the RXNE bit which itself generates an interrupt. An interrupt is generated when the NF flag is set during multibuffer communication if the EIE bit is set.*

*Note: When the line is noise-free, the NF flag can be disabled by programming the ONEBIT bit to 1 to increase the USART tolerance to deviations (Refer to [Section 31.5.5: Tolerance of the USART receiver to clock deviation on page 1042](#)).*

### Bit 1 **FE**: Framing error

This bit is set by hardware when a de-synchronization, excessive noise or a break character is detected. It is cleared by software, writing 1 to the FECF bit in the USART\_ICR register.

In Smartcard mode, in transmission, this bit is set when the maximum number of transmit attempts is reached without success (the card NACKs the data frame).

An interrupt is generated if EIE = 1 in the USART\_CR1 register.

0: No Framing error is detected

1: Framing error or break character is detected

### Bit 0 **PE**: Parity error

This bit is set by hardware when a parity error occurs in receiver mode. It is cleared by software, writing 1 to the PECF in the USART\_ICR register.

An interrupt is generated if PEIE = 1 in the USART\_CR1 register.

0: No parity error

1: Parity error

## 31.8.9 Interrupt flag clear register (USART\_ICR)

Address offset: 0x20

Reset value: 0x0000 0000

| 31   | 30   | 29   | 28    | 27    | 26   | 25    | 24    | 23   | 22    | 21   | 20     | 19    | 18    | 17    | 16    |
|------|------|------|-------|-------|------|-------|-------|------|-------|------|--------|-------|-------|-------|-------|
| Res. | Res. | Res. | Res.  | Res.  | Res. | Res.  | Res.  | Res. | Res.  | Res. | Res.   | Res.  | Res.  | CMCF  | Res.  |
|      |      |      |       |       |      |       |       |      |       |      |        |       |       | rc_w1 |       |
| 15   | 14   | 13   | 12    | 11    | 10   | 9     | 8     | 7    | 6     | 5    | 4      | 3     | 2     | 1     | 0     |

|      |      |      | rc_w1 | rc_w1 |      | rc_w1 | rc_w1 |      | rc_w1 |      | rc_w1  | rc_w1 | rc_w1 | rc_w1 | rc_w1 |

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:18 Reserved, must be kept at reset value.

### Bit 17 **CMCF**: Character match clear flag

Writing 1 to this bit clears the CMF flag in the USART\_ISR register.

Bits 16:13 Reserved, must be kept at reset value.

### Bit 12 **EOBCF**: End of block clear flag

Writing 1 to this bit clears the EOBF flag in the USART\_ISR register.

*Note: If the USART does not support Smartcard mode, this bit is reserved and must be kept at reset value. Please refer to [Section 31.4: USART implementation on page 1026](#).*

Bit 11 **RTOCF**: Receiver timeout clear flag

Writing 1 to this bit clears the RTOF flag in the USART\_ISR register.

*Note: If the USART does not support the Receiver timeout feature, this bit is reserved and must be kept at reset value. Please refer to [Section 31.4: USART implementation on page 1026](#).*

Bit 10 Reserved, must be kept at reset value.

Bit 9 **CTSCF**: CTS clear flag

Writing 1 to this bit clears the CTSIF flag in the USART\_ISR register.

*Note: If the hardware flow control feature is not supported, this bit is reserved and must be kept at reset value. Please refer to [Section 31.4: USART implementation on page 1026](#).*

Bit 8 **LBDCF**: LIN break detection clear flag

Writing 1 to this bit clears the LBDF flag in the USART\_ISR register.

*Note: If LIN mode is not supported, this bit is reserved and must be kept at reset value. Please refer to [Section 31.4: USART implementation on page 1026](#).*

Bit 7 Reserved, must be kept at reset value.

Bit 6 **TCCF**: Transmission complete clear flag

Writing 1 to this bit clears the TC flag in the USART\_ISR register.

Bit 5 Reserved, must be kept at reset value.

Bit 4 **IDLECF**: Idle line detected clear flag

Writing 1 to this bit clears the IDLE flag in the USART\_ISR register.

Bit 3 **ORECF**: Overrun error clear flag

Writing 1 to this bit clears the ORE flag in the USART\_ISR register.

Bit 2 **NCF**: Noise detected clear flag

Writing 1 to this bit clears the NF flag in the USART\_ISR register.

Bit 1 **FE CF**: Framing error clear flag

Writing 1 to this bit clears the FE flag in the USART\_ISR register.

Bit 0 **PECF**: Parity error clear flag

Writing 1 to this bit clears the PE flag in the USART\_ISR register.

### 31.8.10 Receive data register (USART\_RDR)

Address offset: 0x24

Reset value: 0x0000 0000

|      |      |      |      |      |      |      |          |      |      |      |      |      |      |      |      |
|------|------|------|------|------|------|------|----------|------|------|------|------|------|------|------|------|
| 31   | 30   | 29   | 28   | 27   | 26   | 25   | 24       | 23   | 22   | 21   | 20   | 19   | 18   | 17   | 16   |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res.     | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. |
|      |      |      |      |      |      |      |          |      |      |      |      |      |      |      |      |
| 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8        | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0    |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | RDR[8:0] |      |      |      |      |      |      |      |      |
|      |      |      |      |      |      |      | r        | r    | r    | r    | r    | r    | r    | r    | r    |

Bits 31:9 Reserved, must be kept at reset value.

Bits 8:0 **RDR[8:0]**: Receive data value

Contains the received data character.

The RDR register provides the parallel interface between the input shift register and the internal bus (see [Figure 332](#)).

When receiving with the parity enabled, the value read in the MSB bit is the received parity bit.

### 31.8.11 Transmit data register (USART\_TDR)

Address offset: 0x28

Reset value: 0x0000 0000

|      |      |      |      |      |      |      |          |      |      |      |      |      |      |      |      |
|------|------|------|------|------|------|------|----------|------|------|------|------|------|------|------|------|
| 31   | 30   | 29   | 28   | 27   | 26   | 25   | 24       | 23   | 22   | 21   | 20   | 19   | 18   | 17   | 16   |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res.     | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. |
|      |      |      |      |      |      |      |          |      |      |      |      |      |      |      |      |
| 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8        | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0    |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | TDR[8:0] |      |      |      |      |      |      |      |      |
|      |      |      |      |      |      |      | rw       | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   |

Bits 31:9 Reserved, must be kept at reset value.

Bits 8:0 **TDR[8:0]**: Transmit data value

Contains the data character to be transmitted.

The TDR register provides the parallel interface between the internal bus and the output shift register (see [Figure 332](#)).

When transmitting with the parity enabled (PCE bit set to 1 in the USART\_CR1 register), the value written in the MSB (bit 7 or bit 8 depending on the data length) has no effect because it is replaced by the parity.

*Note: This register must be written only when TXE=1.*

### 31.8.12 USART register map

The table below gives the USART register map and reset values.

**Table 201. USART register map and reset values**

| Offset | Register    | 31       | 30   | 29   | 28 | 27       | 26    | 25    | 24    | 23    | 22      | 21      | 20    | 19       | 18      | 17    | 16    | 15    | 14    | 13        | 12    | 11   | 10   | 9    | 8    | 7     | 6    | 5      | 4      | 3    | 2    | 1    | 0  |
|--------|-------------|----------|------|------|----|----------|-------|-------|-------|-------|---------|---------|-------|----------|---------|-------|-------|-------|-------|-----------|-------|------|------|------|------|-------|------|--------|--------|------|------|------|----|
| 0x00   | USART_CR1   | Res.     | Res. | Res. | M1 | EOBIE    | RTOIE | DEAT4 | DEAT3 | DEAT2 | DEAT1   | DEAT0   | DEAT4 | DEAT3    | DEAT2   | DEAT1 | DEAT0 | OVER8 | CMIE  | MME       | M0    | WAKE | PCE  | PS   | PEIE | TXEIE | TCIE | RXNEIE | IDLEIE | TE   | RE   | Res. | UE |
|        | Reset value |          |      |      | 0  | 0        | 0     | 0     | 0     | 0     | 0       | 0       | 0     | 0        | 0       | 0     | 0     | 0     | 0     | 0         | 0     | 0    | 0    | 0    | 0    | 0     | 0    | 0      | 0      | 0    | 0    |      | 0  |
| 0x04   | USART_CR2   | ADD[7:4] |      |      |    | ADD[3:0] |       |       |       | RTOEN | ABRM0D1 | ABRM0D0 | ABREN | MSBFIRST | DATAINV | TXINV | RXINV | SWAP  | LINEN | STOP[1:0] | CLKEN | CPOL | CPHA | LBCL | Res. | Res.  | Res. | Res.   | Res.   | Res. | Res. | Res. |    |
|        | Reset value | 0        | 0    | 0    | 0  | 0        | 0     | 0     | 0     | 0     | 0       | 0       | 0     | 0        | 0       | 0     | 0     | 0     | 0     | 0         | 0     | 0    | 0    | 0    | 0    | 0     | 0    | 0      | 0      |      |      |      |    |

Table 201. USART register map and reset values (continued)

| Offset | Register    | 31        | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23        | 22   | 21    | 20   | 19   | 18           | 17   | 16   | 15        | 14   | 13    | 12     | 11     | 10    | 9        | 8        | 7    | 6    | 5      | 4     | 3     | 2    | 1     | 0     |   |  |

Refer to [Section 2.2 on page 68](#) for the register boundary addresses.

## 32 Serial peripheral interface / inter-IC sound (SPI/I2S)

### 32.1 Introduction

The SPI/I<sup>2</sup>S interface can be used to communicate with external devices using the SPI protocol or the I<sup>2</sup>S audio protocol. SPI or I<sup>2</sup>S mode is selectable by software. SPI Motorola mode is selected by default after a device reset.

The serial peripheral interface (SPI) protocol supports half-duplex, full-duplex and simplex synchronous, serial communication with external devices. The interface can be configured as master and in this case it provides the communication clock (SCK) to the external slave device. The interface is also capable of operating in multimaster configuration.

The Inter-IC sound (I<sup>2</sup>S) protocol is also a synchronous serial communication interface. It can operate in slave or master mode with half-duplex communication. Full-duplex operations are possible by combining two I2S blocks. It can address four different audio standards including the Philips I<sup>2</sup>S standard, the MSB- and LSB-justified standards and the PCM standard.

### 32.2 SPI main features

- Master or slave operation
- Full-duplex synchronous transfers on three lines
- Half-duplex synchronous transfer on two lines (with bidirectional data line)
- Simplex synchronous transfers on two lines (with unidirectional data line)
- 4-bit to 16-bit data size selection
- Multimaster mode capability
- 8 master mode baud rate prescalers up to  $f_{PCLK}/2$
- Slave mode frequency up to  $f_{PCLK}/2$ .
- NSS management by hardware or software for both master and slave: dynamic change of master/slave operations
- Programmable clock polarity and phase
- Programmable data order with MSB-first or LSB-first shifting
- Dedicated transmission and reception flags with interrupt capability
- SPI bus busy status flag
- SPI Motorola support
- Hardware CRC feature for reliable communication:
  - CRC value can be transmitted as last byte in Tx mode
  - Automatic CRC error checking for last received byte
- Master mode fault, overrun flags with interrupt capability
- CRC Error flag
- Two 32-bit embedded Rx and Tx FIFOs with DMA capability
- SPI TI mode support

### 32.3 I2S main features

- Half-duplex communication (only transmitter or receiver)
- Master or slave operations
- 8-bit programmable linear prescaler to reach accurate audio sample frequencies (from 8 kHz to 192 kHz)
- Data format may be 16-bit, 24-bit or 32-bit
- Packet frame is fixed to 16-bit (16-bit data frame) or 32-bit (16-bit, 24-bit, 32-bit data frame) by audio channel
- Programmable clock polarity (steady state)
- Underrun flag in slave transmission mode, overrun flag in reception mode (master and slave) and Frame Error Flag in reception and transmitter mode (slave only)
- 16-bit register for transmission and reception with one data register for both channel sides
- Supported I<sup>2</sup>S protocols:
  - I<sup>2</sup>S Philips standard
  - MSB-justified standard (left-justified)
  - LSB-justified standard (right-justified)
  - PCM standard (with short and long frame synchronization on 16-bit channel frame or 16-bit data frame extended to 32-bit channel frame)
- Data direction is always MSB first
- DMA capability for transmission and reception (16-bit wide)
- Master clock can be output to drive an external audio component. Ratio is fixed at  $256 \times F_S$  (where  $F_S$  is the audio sampling frequency)

### 32.4 SPI/I2S implementation

This manual describes the SPI/I2S implementation in STM32F75xxx and STM32F74xxx devices.

**Table 202. STM32F75xxx and STM32F74xxx SPI implementation**

| SPI Features <sup>(1)</sup> | SPI1 | SPI2 | SPI3 | SPI4 | SPI5 | SPI6 |
|-----------------------------|------|------|------|------|------|------|
| Hardware CRC calculation    | X    | X    | X    | X    | X    | X    |
| Rx/Tx FIFO                  | X    | X    | X    | X    | X    | X    |
| NSS pulse mode              | X    | X    | X    | X    | X    | X    |
| I <sup>2</sup> S mode       | X    | X    | X    | -    | -    | -    |
| TI mode                     | X    | X    | X    | X    | X    | X    |

1. X = supported.

## 32.5 SPI functional description

### 32.5.1 General description

The SPI allows synchronous, serial communication between the MCU and external devices. Application software can manage the communication by polling the status flag or using dedicated SPI interrupt. The main elements of SPI and their interactions are shown in the following block diagram *Figure 357*.

**Figure 357. SPI block diagram**

Four I/O pins are dedicated to SPI communication with external devices.

- **MISO:** Master In / Slave Out data. In the general case, this pin is used to transmit data in slave mode and receive data in master mode.
- **MOSI:** Master Out / Slave In data. In the general case, this pin is used to transmit data in master mode and receive data in slave mode.
- **SCK:** Serial Clock output pin for SPI masters and input pin for SPI slaves.
- **NSS:** Slave select pin. Depending on the SPI and NSS settings, this pin can be used to either:
  - select an individual slave device for communication
  - synchronize the data frame or
  - detect a conflict between multiple masters

See [Section 32.5.5: Slave select \(NSS\) pin management](#) for details.

The SPI bus allows the communication between one master device and one or more slave devices. The bus consists of at least two wires - one for the clock signal and the other for synchronous data transfer. Other signals can be added depending on the data exchange between SPI nodes and their slave select signal management.

### 32.5.2 Communications between one master and one slave

The SPI allows the MCU to communicate using different configurations, depending on the device targeted and the application requirements. These configurations use 2 or 3 wires (with software NSS management) or 3 or 4 wires (with hardware NSS management). Communication is always initiated by the master.

#### Full-duplex communication

By default, the SPI is configured for full-duplex communication. In this configuration, the shift registers of the master and slave are linked using two unidirectional lines between the MOSI and the MISO pins. During SPI communication, data is shifted synchronously on the SCK clock edges provided by the master. The master transmits the data to be sent to the slave via the MOSI line and receives data from the slave via the MISO line. When the data frame transfer is complete (all the bits are shifted) the information between the master and slave is exchanged.

Figure 358. Full-duplex single master/ single slave application

1. The NSS pins can be used to provide a hardware control flow between master and slave. Optionally, the pins can be left unused by the peripheral. Then the flow has to be handled internally for both master and slave. For more details see [Section 32.5.5: Slave select \(NSS\) pin management](#).

#### Half-duplex communication

The SPI can communicate in half-duplex mode by setting the BIDIMODE bit in the SPIx\_CR1 register. In this configuration, one single cross connection line is used to link the shift registers of the master and slave together. During this communication, the data is synchronously shifted between the shift registers on the SCK clock edge in the transfer direction selected reciprocally by both master and slave with the BDIOE bit in their SPIx\_CR1 registers. In this configuration, the master's MISO pin and the slave's MOSI pin are free for other application uses and act as GPIOs.

Figure 359. Half-duplex single master/ single slave application

1. The NSS pins can be used to provide a hardware control flow between master and slave. Optionally, the pins can be left unused by the peripheral. Then the flow has to be handled internally for both master and slave. For more details see [Section 32.5.5: Slave select \(NSS\) pin management](#).
2. In this configuration, the master's MISO pin and the slave's MOSI pin can be used as GPIOs.
3. A critical situation can happen when communication direction is changed not synchronously between two nodes working at bidirectional mode and new transmitter accesses the common data line while former transmitter still keeps an opposite value on the line (the value depends on SPI configuration and communication data). Both nodes then fight while providing opposite output levels on the common line temporary till next node changes its direction settings correspondingly, too. It is suggested to insert a serial resistance between MISO and MOSI pins at this mode to protect the outputs and limit the current blowing between them at this situation.

### Simplex communications

The SPI can communicate in simplex mode by setting the SPI in transmit-only or in receive-only using the RXONLY bit in the SPIx\_CR2 register. In this configuration, only one line is used for the transfer between the shift registers of the master and slave. The remaining MISO and MOSI pins pair is not used for communication and can be used as standard GPIOs.

- **Transmit-only mode (RXONLY=0):** The configuration settings are the same as for full-duplex. The application has to ignore the information captured on the unused input pin. This pin can be used as a standard GPIO.
- **Receive-only mode (RXONLY=1):** The application can disable the SPI output function by setting the RXONLY bit. In slave configuration, the MISO output is disabled and the pin can be used as a GPIO. The slave continues to receive data from the MOSI pin while its slave select signal is active (see [32.5.5: Slave select \(NSS\) pin management](#)). Received data events appear depending on the data buffer configuration. In the master configuration, the MOSI output is disabled and the pin can be used as a GPIO. The clock signal is generated continuously as long as the SPI is enabled. The only way to stop the clock is to clear the RXONLY bit or the SPE bit and wait until the incoming pattern from the MISO pin is finished and fills the data buffer structure, depending on its configuration.

**Figure 360. Simplex single master/single slave application (master in transmit-only/ slave in receive-only mode)**

1. The NSS pins can be used to provide a hardware control flow between master and slave. Optionally, the pins can be left unused by the peripheral. Then the flow has to be handled internally for both master and slave. For more details see [Section 32.5.5: Slave select \(NSS\) pin management](#).
2. An accidental input information is captured at the input of transmitter Rx shift register. All the events associated with the transmitter receive flow must be ignored in standard transmit only mode (e.g. OVF flag).
3. In this configuration, both the MISO pins can be used as GPIOs.

**Note:** *Any simplex communication can be alternatively replaced by a variant of the half-duplex communication with a constant setting of the transaction direction (bidirectional mode is enabled while BDIO bit is not changed).*

### 32.5.3 Standard multi-slave communication

In a configuration with two or more independent slaves, the master uses GPIO pins to manage the chip select lines for each slave (see [Figure 361](#)). The master must select one of the slaves individually by pulling low the GPIO connected to the slave NSS input. When this is done, a standard master and dedicated slave communication is established.

Figure 361. Master and three independent slaves

1. NSS pin is not used on master side at this configuration. It has to be managed internally (SSM=1, SSI=1) to prevent any MODF error.
2. As MISO pins of the slaves are connected together, all slaves must have the GPIO configuration of their MISO pin set as alternate function open-drain (see [Section 7.3.7: I/O alternate function input/output](#)).

### 32.5.4 Multi-master communication

Unless SPI bus is not designed for a multi-master capability primarily, the user can use build in feature which detects a potential conflict between two nodes trying to master the bus at the same time. For this detection, NSS pin is used configured at hardware input mode.

The connection of more than two SPI nodes working at this mode is impossible as only one node can apply its output on a common data line at time.

When nodes are non active, both stay at slave mode by default. Once one node wants to overtake control on the bus, it switches itself into master mode and applies active level on the slave select input of the other node via dedicated GPIO pin. After the session is completed, the active slave select signal is released and the node mastering the bus temporary returns back to passive slave mode waiting for next session start.

If potentially both nodes raised their mastering request at the same time a bus conflict event appears (see mode fault MODF event). Then the user can apply some simple arbitration process (e.g. to postpone next attempt by predefined different time-outs applied at both nodes).

**Figure 362. Multi-master application**

1. The NSS pin is configured at hardware input mode at both nodes. Its active level enables the MISO line output control as the passive node is configured as a slave.

### 32.5.5 Slave select (NSS) pin management

In slave mode, the NSS works as a standard “chip select” input and lets the slave communicate with the master. In master mode, NSS can be used either as output or input. As an input it can prevent multimaster bus collision, and as an output it can drive a slave select signal of a single slave.

Hardware or software slave select management can be set using the SSM bit in the SPIx\_CR1 register:

- **Software NSS management (SSM = 1):** in this configuration, slave select information is driven internally by the SSI bit value in register SPIx\_CR1. The external NSS pin is free for other application uses.
- **Hardware NSS management (SSM = 0):** in this case, there are two possible configurations. The configuration used depends on the NSS output configuration (SSOE bit in register SPIx\_CR1).
  - **NSS output enable (SSM=0, SSOE = 1):** this configuration is only used when the MCU is set as master. The NSS pin is managed by the hardware. The NSS signal is driven low as soon as the SPI is enabled in master mode (SPE=1), and is kept low until the SPI is disabled (SPE =0). A pulse can be generated between continuous communications if NSS pulse mode is activated (NSSP=1). The SPI cannot work in multimaster configuration with this NSS setting.
  - **NSS output disable (SSM=0, SSOE = 0):** if the microcontroller is acting as the master on the bus, this configuration allows multimaster capability. If the NSS pin is pulled low in this mode, the SPI enters master mode fault state and the device is automatically reconfigured in slave mode. In slave mode, the NSS pin works as a standard “chip select” input and the slave is selected while NSS line is at low level.

Figure 363. Hardware/software slave select management

### 32.5.6 Communication formats

During SPI communication, receive and transmit operations are performed simultaneously. The serial clock (SCK) synchronizes the shifting and sampling of the information on the data lines. The communication format depends on the clock phase, the clock polarity and the data frame format. To be able to communicate together, the master and slaves devices must follow the same communication format.

#### Clock phase and polarity controls

Four possible timing relationships may be chosen by software, using the CPOL and CPHA bits in the SPIx\_CR1 register. The CPOL (clock polarity) bit controls the idle state value of the clock when no data is being transferred. This bit affects both master and slave modes. If CPOL is reset, the SCK pin has a low-level idle state. If CPOL is set, the SCK pin has a high-level idle state.

If the CPHA bit is set, the second edge on the SCK pin captures the first data bit transacted (falling edge if the CPOL bit is reset, rising edge if the CPOL bit is set). Data are latched on each occurrence of this clock transition type. If the CPHA bit is reset, the first edge on the SCK pin captures the first data bit transacted (falling edge if the CPOL bit is set, rising edge if the CPOL bit is reset). Data are latched on each occurrence of this clock transition type.

The combination of CPOL (clock polarity) and CPHA (clock phase) bits selects the data capture clock edge.

Figure 364, shows an SPI full-duplex transfer with the four combinations of the CPHA and CPOL bits.

**Note:** Prior to changing the CPOL/CPHA bits the SPI must be disabled by resetting the SPE bit. The idle state of SCK must correspond to the polarity selected in the SPIx\_CR1 register (by pulling up SCK if CPOL=1 or pulling down SCK if CPOL=0).

**Figure 364. Data clock timing diagram**

### Data frame format

The SPI shift register can be set up to shift out MSB-first or LSB-first, depending on the value of the LSBFIRST bit. The data frame size is chosen by using the DS bits. It can be set from 4-bit up to 16-bit length and the setting applies for both transmission and reception. Whatever the selected data frame size, read access to the FIFO must be aligned with the FRXTH level. When the SPIx\_DR register is accessed, data frames are always right-aligned into either a byte (if the data fits into a byte) or a half-word (see Figure 365). During communication, only bits within the data frame are clocked and transferred.

**Figure 365. Data alignment when data length is not equal to 8-bit or 16-bit**

**Note:** The minimum data length is 4 bits. If a data length of less than 4 bits is selected, it is forced to an 8-bit data frame size.

### 32.5.7 Configuration of SPI

The configuration procedure is almost the same for master and slave. For specific mode setups, follow the dedicated sections. When a standard communication is to be initialized, perform these steps:

1. Write proper GPIO registers: Configure GPIO for MOSI, MISO and SCK pins.
2. Write to the SPI\_CR1 register:
  - a) Configure the serial clock baud rate using the BR[2:0] bits (Note: 4).
  - b) Configure the CPOL and CPHA bits combination to define one of the four relationships between the data transfer and the serial clock (CPHA must be cleared in NSSP mode). (Note: 2 - except the case when CRC is enabled at TI mode).
  - c) Select simplex or half-duplex mode by configuring RXONLY or BIDIMODE and BIDIOE (RXONLY and BIDIMODE can't be set at the same time).
  - d) Configure the LSBFIRST bit to define the frame format (Note: 2).
  - e) Configure the CRCL and CRCEN bits if CRC is needed (while SCK clock signal is at idle state).
  - f) Configure SSM and SSI (Notes: 2 & 3).
  - g) Configure the MSTR bit (in multimaster NSS configuration, avoid conflict state on NSS if master is configured to prevent MODF error).
3. Write to SPI\_CR2 register:
  - a) Configure the DS[3:0] bits to select the data length for the transfer.
  - b) Configure SSOE (Notes: 1 & 2 & 3).
  - c) Set the FRF bit if the TI protocol is required (keep NSSP bit cleared in TI mode).
  - d) Set the NSSP bit if the NSS pulse mode between two data units is required (keep CPHA and TI bits cleared in NSSP mode).
  - e) Configure the FRXTH bit. The RXFIFO threshold must be aligned to the read access size for the SPIx\_DR register.
  - f) Initialize LDMA\_TX and LDMA\_RX bits if DMA is used in packed mode.
4. Write to SPI\_CRCPR register: Configure the CRC polynomial if needed.
5. Write proper DMA registers: Configure DMA streams dedicated for SPI Tx and Rx in DMA registers if the DMA streams are used.

Note:

- (1) Step is not required in slave mode.
- (2) Step is not required in TI mode.
- (3) Step is not required in NSSP mode.
- (4) The step is not required in slave mode except slave working at TI mode

### 32.5.8 Procedure for enabling SPI

It is recommended to enable the SPI slave before the master sends the clock. If not, undesired data transmission might occur. The data register of the slave must already contain data to be sent before starting communication with the master (either on the first edge of the communication clock, or before the end of the ongoing communication if the clock signal is continuous). The SCK signal must be settled at an idle state level corresponding to the selected polarity before the SPI slave is enabled.

The master at full-duplex (or in any transmit-only mode) starts to communicate when the SPI is enabled and TXFIFO is not empty, or with the next write to TXFIFO.

In any master receive only mode (RXONLY=1 or BIDIMODE=1 & BIDIOE=0), master starts to communicate and the clock starts running immediately after SPI is enabled.

For handling DMA, follow the dedicated section.

### 32.5.9 Data transmission and reception procedures

#### RXFIFO and TXFIFO

All SPI data transactions pass through the 32-bit embedded FIFOs. This enables the SPI to work in a continuous flow, and prevents overruns when the data frame size is short. Each direction has its own FIFO called TXFIFO and RXFIFO. These FIFOs are used in all SPI modes except for receiver-only mode (slave or master) with CRC calculation enabled (see [Section 32.5.14: CRC calculation](#)).

The handling of FIFOs depends on the data exchange mode (duplex, simplex), data frame format (number of bits in the frame), access size performed on the FIFO data registers (8-bit or 16-bit), and whether or not data packing is used when accessing the FIFOs (see [Section 32.5.13: TI mode](#)).

A read access to the SPIx\_DR register returns the oldest value stored in RXFIFO that has not been read yet. A write access to the SPIx\_DR stores the written data in the TXFIFO at the end of a send queue. The read access must be always aligned with the RXFIFO threshold configured by the FRXTH bit in SPIx\_CR2 register. FTLVL[1:0] and FRLVL[1:0] bits indicate the current occupancy level of both FIFOs.

A read access to the SPIx\_DR register must be managed by the RXNE event. This event is triggered when data is stored in RXFIFO and the threshold (defined by FRXTH bit) is reached. When RXNE is cleared, RXFIFO is considered to be empty. In a similar way, write access of a data frame to be transmitted is managed by the TXE event. This event is triggered when the TXFIFO level is less than or equal to half of its capacity. Otherwise TXE is cleared and the TXFIFO is considered as full. In this way, RXFIFO can store up to four data frames, whereas TXFIFO can only store up to three when the data frame format is not greater than 8 bits. This difference prevents possible corruption of 3x 8-bit data frames already stored in the TXFIFO when software tries to write more data in 16-bit mode into TXFIFO. Both TXE and RXNE events can be polled or handled by interrupts. See [Figure 367](#) through [Figure 370](#).

Another way to manage the data exchange is to use DMA (see [Communication using DMA \(direct memory addressing\)](#)).

If the next data is received when the RXFIFO is full, an overrun event occurs (see description of OVR flag at [Section 32.5.10: SPI status flags](#)). An overrun event can be polled or handled by an interrupt.

The BSY bit being set indicates ongoing transaction of a current data frame. When the clock signal runs continuously, the BSY flag stays set between data frames at master but becomes low for a minimum duration of one SPI clock at slave between each data frame transfer.

### Sequence handling

A few data frames can be passed at single sequence to complete a message. When transmission is enabled, a sequence begins and continues while any data is present in the TXFIFO of the master. The clock signal is provided continuously by the master until TXFIFO becomes empty, then it stops waiting for additional data.

In receive-only modes, half-duplex (BIDIMODE=1, BIDIOE=0) or simplex (BIDIMODE=0, RXONLY=1) the master starts the sequence immediately when both SPI is enabled and receive-only mode is activated. The clock signal is provided by the master and it does not stop until either SPI or receive-only mode is disabled by the master. The master receives data frames continuously up to this moment.

While the master can provide all the transactions in continuous mode (SCK signal is continuous) it has to respect slave capability to handle data flow and its content at anytime. When necessary, the master must slow down the communication and provide either a slower clock or separate frames or data sessions with sufficient delays. Be aware there is no underflow error signal for master or slave in SPI mode, and data from the slave is always transacted and processed by the master even if the slave could not prepare it correctly in time. It is preferable for the slave to use DMA, especially when data frames are shorter and bus rate is high.

Each sequence must be encased by the NSS pulse in parallel with the multislave system to select just one of the slaves for communication. In a single slave system it is not necessary to control the slave with NSS, but it is often better to provide the pulse here too, to synchronize the slave with the beginning of each data sequence. NSS can be managed by both software and hardware (see [Section 32.5.5: Slave select \(NSS\) pin management](#)).

When the BSY bit is set it signifies an ongoing data frame transaction. When the dedicated frame transaction is finished, the RXNE flag is raised. The last bit is just sampled and the complete data frame is stored in the RXFIFO.

### Procedure for disabling the SPI

When SPI is disabled, it is mandatory to follow the disable procedures described in this paragraph. It is important to do this before the system enters a low-power mode when the peripheral clock is stopped. Ongoing transactions can be corrupted in this case. In some modes the disable procedure is the only way to stop continuous communication running.

Master in full-duplex or transmit only mode can finish any transaction when it stops providing data for transmission. In this case, the clock stops after the last data transaction. Special care must be taken in packing mode when an odd number of data frames are transacted to prevent some dummy byte exchange (refer to [Data packing](#) section). Before the SPI is disabled in these modes, the user must follow standard disable procedure. When

the SPI is disabled at the master transmitter while a frame transaction is ongoing or next data frame is stored in TXFIFO, the SPI behavior is not guaranteed.

When the master is in any receive only mode, the only way to stop the continuous clock is to disable the peripheral by SPE=0. This must occur in specific time window within last data frame transaction just between the sampling time of its first bit and before its last bit transfer starts (in order to receive a complete number of expected data frames and to prevent any additional “dummy” data reading after the last valid data frame). Specific procedure must be followed when disabling SPI in this mode.

Data received but not read remains stored in RXFIFO when the SPI is disabled, and must be processed the next time the SPI is enabled, before starting a new sequence. To prevent having unread data, ensure that RXFIFO is empty when disabling the SPI, by using the correct disabling procedure, or by initializing all the SPI registers with a software reset via the control of a specific register dedicated to peripheral reset (see the SPIIRST bits in the RCC\_APB1RSTR registers).

Standard disable procedure is based on pulling BSY status together with FTLVL[1:0] to check if a transmission session is fully completed. This check can be done in specific cases, too, when it is necessary to identify the end of ongoing transactions, for example:

- When NSS signal is managed by software and master has to provide proper end of NSS pulse for slave, or
- When transactions' streams from DMA or FIFO are completed while the last data frame or CRC frame transaction is still ongoing in the peripheral bus.

The correct disable procedure is (except when receive only mode is used):

1. Wait until FTLVL[1:0] = 00 (no more data to transmit).
2. Wait until BSY=0 (the last data frame is processed).
3. Disable the SPI (SPE=0).
4. Read data until FRLVL[1:0] = 00 (read all the received data).

The correct disable procedure for certain receive only modes is:

1. Interrupt the receive flow by disabling SPI (SPE=0) in the specific time window while the last data frame is ongoing.
2. Wait until BSY=0 (the last data frame is processed).
3. Read data until FRLVL[1:0] = 00 (read all the received data).

**Note:** *If packing mode is used and an odd number of data frames with a format less than or equal to 8 bits (fitting into one byte) has to be received, FRXTH must be set when FRLVL[1:0] = 01, in order to generate the RXNE event to read the last odd data frame and to keep good FIFO pointer alignment.*

### Data packing

When the data frame size fits into one byte (less than or equal to 8 bits), data packing is used automatically when any read or write 16-bit access is performed on the SPIx\_DR register. The double data frame pattern is handled in parallel in this case. At first, the SPI operates using the pattern stored in the LSB of the accessed word, then with the other half stored in the MSB. [Figure 366](#) provides an example of data packing mode sequence handling. Two data frames are sent after the single 16-bit access the SPIx\_DR register of the transmitter. This sequence can generate just one RXNE event in the receiver if the RXFIFO threshold is set to 16 bits (FRXTH=0). The receiver then has to access both data frames by a single 16-bit read of SPIx\_DR as a response to this single RXNE event. The

RxFIFO threshold setting and the following read access must be always kept aligned at the receiver side, as data can be lost if it is not in line.

A specific problem appears if an odd number of such “fit into one byte” data frames must be handled. On the transmitter side, writing the last data frame of any odd sequence with an 8-bit access to SPIx\_DR is enough. The receiver has to change the Rx\_FIFO threshold level for the last data frame received in the odd sequence of frames in order to generate the RXNE event.

**Figure 366. Packing data in FIFO for transmission and reception**

1. In this example: Data size DS[3:0] is 4-bit configured, CPOL=0, CPHA=1 and LSBFIRST =0. The Data storage is always right aligned while the valid bits are performed on the bus only, the content of LSB byte goes first on the bus, the unused bits are not taken into account on the transmitter side and padded by zeros at the receiver side.

### Communication using DMA (direct memory addressing)

To operate at its maximum speed and to facilitate the data register read/write process required to avoid overrun, the SPI features a DMA capability, which implements a simple request/acknowledge protocol.

A DMA access is requested when the TXE or RXNE enable bit in the SPIx\_CR2 register is set. Separate requests must be issued to the Tx and Rx buffers.

- In transmission, a DMA request is issued each time TXE is set to 1. The DMA then writes to the SPIx\_DR register.
- In reception, a DMA request is issued each time RXNE is set to 1. The DMA then reads the SPIx\_DR register.

See [Figure 367](#) through [Figure 370](#).

When the SPI is used only to transmit data, it is possible to enable only the SPI Tx DMA channel. In this case, the OVR flag is set because the data received is not read. When the SPI is used only to receive data, it is possible to enable only the SPI Rx DMA channel.

In transmission mode, when the DMA has written all the data to be transmitted (the TCIF flag is set in the DMA\_ISR register), the BSY flag can be monitored to ensure that the SPI communication is complete. This is required to avoid corrupting the last transmission before disabling the SPI or entering the Stop mode. The software must first wait until FTLVL[1:0]=00 and then until BSY=0.

When starting communication using DMA, to prevent DMA channel management raising error events, these steps must be followed in order:

1. Enable DMA Rx buffer in the RXDMAEN bit in the SPI\_CR2 register, if DMA Rx is used.
2. Enable DMA streams for Tx and Rx in DMA registers, if the streams are used.
3. Enable DMA Tx buffer in the TXDMAEN bit in the SPI\_CR2 register, if DMA Tx is used.
4. Enable the SPI by setting the SPE bit.

To close communication it is mandatory to follow these steps in order:

1. Disable DMA streams for Tx and Rx in the DMA registers, if the streams are used.
2. Disable the SPI by following the SPI disable procedure.
3. Disable DMA Tx and Rx buffers by clearing the TXDMAEN and RXDMAEN bits in the SPI\_CR2 register, if DMA Tx and/or DMA Rx are used.

### Packing with DMA

If the transfers are managed by DMA (TXDMAEN and RXDMAEN set in the SPIx\_CR2 register) packing mode is enabled/disabled automatically depending on the PSIZE value configured for SPI TX and the SPI RX DMA channel. If the DMA channel PSIZE value is equal to 16-bit and SPI data size is less than or equal to 8-bit, then packing mode is enabled. The DMA then automatically manages the write operations to the SPIx\_DR register.

If data packing mode is used and the number of data to transfer is not a multiple of two, the LDMA\_TX/LDMA\_RX bits must be set. The SPI then considers only one data for the transmission or reception to serve the last DMA transfer (for more details refer to [Data packing on page 1101](#).)

## Communication diagrams

Some typical timing schemes are explained in this section. These schemes are valid no matter if the SPI events are handled by polling, interrupts or DMA. For simplicity, the LSBFIRST=0, CPOL=0 and CPHA=1 setting is used as a common assumption here. No complete configuration of DMA streams is provided.

The following numbered notes are common for [Figure 367 on page 1105](#) through [Figure 370 on page 1108](#).

1. The slave starts to control MISO line as NSS is active and SPI is enabled, and is disconnected from the line when one of them is released. Sufficient time must be provided for the slave to prepare data dedicated to the master in advance before its transaction starts.  
At the master, the SPI peripheral takes control at MOSI and SCK signals (occasionally at NSS signal as well) only if SPI is enabled. If SPI is disabled the SPI peripheral is disconnected from GPIO logic, so the levels at these lines depends on GPIO setting exclusively.
2. At the master, BSY stays active between frames if the communication (clock signal) is continuous. At the slave, BSY signal always goes down for at least one clock cycle between data frames.
3. The TXE signal is cleared only if TXFIFO is full.
4. The DMA arbitration process starts just after the TXDMAEN bit is set. The TXE interrupt is generated just after the TXEIE is set. As the TXE signal is at an active level, data transfers to TxFIFO start, until TxFIFO becomes full or the DMA transfer completes.
5. If all the data to be sent can fit into TxFIFO, the DMA Tx TCIF flag can be raised even before communication on the SPI bus starts. This flag always rises before the SPI transaction is completed.
6. The CRC value for a package is calculated continuously frame by frame in the SPIx\_TXCRCR and SPIx\_RXCRCR registers. The CRC information is processed after the entire data package has completed, either automatically by DMA (Tx channel must be set to the number of data frames to be processed) or by SW (the user must handle CRCNEXT bit during the last data frame processing).  
While the CRC value calculated in SPIx\_TXCRCR is simply sent out by transmitter, received CRC information is loaded into RxFIFO and then compared with the SPIx\_RXCRCR register content (CRC error flag can be raised here if any difference). This is why the user must take care to flush this information from the FIFO, either by software reading out all the stored content of RxFIFO, or by DMA when the proper number of data frames is preset for Rx channel (number of data frames + number of CRC frames) (see the settings at the example assumption).
7. In data packed mode, TxE and RxNE events are paired and each read/write access to the FIFO is 16 bits wide until the number of data frames are even. If the TxFIFO is  $\frac{3}{4}$  full FTLVL status stays at FIFO full level. That is why the last odd data frame cannot be stored before the TxFIFO becomes  $\frac{1}{2}$  full. This frame is stored into TxFIFO with an 8-bit access either by software or automatically by DMA when LDMA\_TX control is set.
8. To receive the last odd data frame in packed mode, the Rx threshold must be changed to 8-bit when the last data frame is processed, either by software setting FRXTH=1 or automatically by a DMA internal signal when LDMA\_RX is set.

Figure 367. Master full-duplex communication

Assumptions for master full-duplex communication example:

- Data size > 8 bit

If DMA is used:

- Number of Tx frames transacted by DMA is set to 3
- Number of Rx frames transacted by DMA is set to 3

See also : [Communication diagrams on page 1104](#) for details about common assumptions and notes.

Figure 368. Slave full-duplex communication

Assumptions for slave full-duplex communication example:

- Data size > 8 bit

If DMA is used:

- Number of Tx frames transacted by DMA is set to 3
- Number of Rx frames transacted by DMA is set to 3

See also : [Communication diagrams on page 1104](#) for details about common assumptions and notes.

Figure 369. Master full-duplex communication with CRC

Assumptions for master full-duplex communication with CRC example:

- Data size = 16 bit
- CRC enabled

If DMA is used:

- Number of Tx frames transacted by DMA is set to 2
- Number of Rx frames transacted by DMA is set to 3

See also : [Communication diagrams on page 1104](#) for details about common assumptions and notes.

Figure 370. Master full-duplex communication in packed mode

Assumptions for master full-duplex communication in packed mode example:

- Data size = 5 bit
- Read/write FIFO is performed mostly by 16-bit access
- FRXTH=0

If DMA is used:

- Number of Tx frames to be transacted by DMA is set to 3
- Number of Rx frames to be transacted by DMA is set to 3
- PSIZE for both Tx and Rx DMA channel is set to 16-bit
- LDMA\_TX=1 and LDMA\_RX=1

See also : [Communication diagrams on page 1104](#) for details about common assumptions and notes.

### 32.5.10 SPI status flags

Three status flags are provided for the application to completely monitor the state of the SPI bus.

#### Tx buffer empty flag (TXE)

The TXE flag is set when transmission TXFIFO has enough space to store data to send. TXE flag is linked to the TXFIFO level. The flag goes high and stays high until the TXFIFO level is lower or equal to 1/2 of the FIFO depth. An interrupt can be generated if the TXEIE bit in the SPIx\_CR2 register is set. The bit is cleared automatically when the TXFIFO level becomes greater than 1/2.

#### Rx buffer not empty (RXNE)

The RXNE flag is set depending on the FRXTH bit value in the SPIx\_CR2 register:

- If FRXTH is set, RXNE goes high and stays high until the RXFIFO level is greater or equal to 1/4 (8-bit).
- If FRXTH is cleared, RXNE goes high and stays high until the RXFIFO level is greater than or equal to 1/2 (16-bit).

An interrupt can be generated if the RXNEIE bit in the SPIx\_CR2 register is set.

The RXNE is cleared by hardware automatically when the above conditions are no longer true.

#### Busy flag (BSY)

The BSY flag is set and cleared by hardware (writing to this flag has no effect).

When BSY is set, it indicates that a data transfer is in progress on the SPI (the SPI bus is busy).

The BSY flag can be used in certain modes to detect the end of a transfer so that the software can disable the SPI or its peripheral clock before entering a low-power mode which does not provide a clock for the peripheral. This avoids corrupting the last transfer.

The BSY flag is also useful for preventing write collisions in a multimaster system.

The BSY flag is cleared under any one of the following conditions:

- When the SPI is correctly disabled
- When a fault is detected in Master mode (MODF bit set to 1)
- In Master mode, when it finishes a data transmission and no new data is ready to be sent
- In Slave mode, when the BSY flag is set to '0' for at least one SPI clock cycle between each data transfer.

*Note: When the next transmission can be handled immediately by the master (e.g. if the master is in Receive-only mode or its Transmit FIFO is not empty), communication is continuous and the BSY flag remains set to '1' between transfers on the master side. Although this is not the case with a slave, it is recommended to use always the TXE and RXNE flags (instead of the BSY flags) to handle data transmission or reception operations.*

### 32.5.11 SPI error flags

An SPI interrupt is generated if one of the following error flags is set and interrupt is enabled by setting the ERRIE bit.

#### Overrun flag (OVR)

An overrun condition occurs when data is received by a master or slave and the RXFIFO has not enough space to store this received data. This can happen if the software or the DMA did not have enough time to read the previously received data (stored in the RXFIFO) or when space for data storage is limited e.g. the RXFIFO is not available when CRC is enabled in receive only mode so in this case the reception buffer is limited into a single data frame buffer (see [Section 32.5.14: CRC calculation](#)).

When an overrun condition occurs, the newly received value does not overwrite the previous one in the RXFIFO. The newly received value is discarded and all data transmitted subsequently is lost. Clearing the OVR bit is done by a read access to the SPI\_DR register followed by a read access to the SPI\_SR register.

#### Mode fault (MODF)

Mode fault occurs when the master device has its internal NSS signal (NSS pin in NSS hardware mode, or SSI bit in NSS software mode) pulled low. This automatically sets the MODF bit. Master mode fault affects the SPI interface in the following ways:

- The MODF bit is set and an SPI interrupt is generated if the ERRIE bit is set.
- The SPE bit is cleared. This blocks all output from the device and disables the SPI interface.
- The MSTR bit is cleared, thus forcing the device into slave mode.

Use the following software sequence to clear the MODF bit:

1. Make a read or write access to the SPIx\_SR register while the MODF bit is set.
2. Then write to the SPIx\_CR1 register.

To avoid any multiple slave conflicts in a system comprising several MCUs, the NSS pin must be pulled high during the MODF bit clearing sequence. The SPE and MSTR bits can be restored to their original state after this clearing sequence. As a security, hardware does not allow the SPE and MSTR bits to be set while the MODF bit is set. In a slave device the MODF bit cannot be set except as the result of a previous multimaster conflict.

#### CRC error (CRCERR)

This flag is used to verify the validity of the value received when the CRCEN bit in the SPIx\_CR1 register is set. The CRCERR flag in the SPIx\_SR register is set if the value received in the shift register does not match the receiver SPIx\_RXCRCR value. The flag is cleared by the software.

#### TI mode frame format error (FRE)

A TI mode frame format error is detected when an NSS pulse occurs during an ongoing communication when the SPI is operating in slave mode and configured to conform to the TI mode protocol. When this error occurs, the FRE flag is set in the SPIx\_SR register. The SPI is not disabled when an error occurs, the NSS pulse is ignored, and the SPI waits for the next NSS pulse before starting a new transfer. The data may be corrupted since the error detection may result in the loss of two data bytes.

The FRE flag is cleared when SPIx\_SR register is read. If the ERRIE bit is set, an interrupt is generated on the NSS error detection. In this case, the SPI should be disabled because data consistency is no longer guaranteed and communications should be reinitiated by the master when the slave SPI is enabled again.

### 32.5.12 NSS pulse mode

This mode is activated by the NSSP bit in the SPIx\_CR2 register and it takes effect only if the SPI interface is configured as Motorola SPI master (FRF=0) with capture on the first edge (SPIx\_CR1 CPHA = 0, CPOL setting is ignored). When activated, an NSS pulse is generated between two consecutive data frame transfers when NSS stays at high level for the duration of one clock period at least. This mode allows the slave to latch data. NSSP pulse mode is designed for applications with a single master-slave pair.

[Figure 371](#) illustrates NSS pin management when NSSP pulse mode is enabled.

**Figure 371. NSSP pulse generation in Motorola SPI master mode**

**Note:** Similar behavior is encountered when CPOL = 0. In this case the sampling edge is the *rising* edge of SCK, and NSS assertion and deassertion refer to this sampling edge.

### 32.5.13 TI mode

#### TI protocol in master mode

The SPI interface is compatible with the TI protocol. The FRF bit of the SPIx\_CR2 register can be used to configure the SPI to be compliant with this protocol.

The clock polarity and phase are forced to conform to the TI protocol requirements whatever the values set in the SPIx\_CR1 register. NSS management is also specific to the TI protocol which makes the configuration of NSS management through the SPIx\_CR1 and SPIx\_CR2 registers (SSM, SSI, SSOE) impossible in this case.

In slave mode, the SPI baud rate prescaler is used to control the moment when the MISO pin state changes to HiZ when the current transaction finishes (see [Figure 372](#)). Any baud rate can be used, making it possible to determine this moment with optimal flexibility. However, the baud rate is generally set to the external master clock baud rate. The delay for the MISO signal to become HiZ ( $t_{release}$ ) depends on internal resynchronization and on the

baud rate value set in through the BR[2:0] bits in the SPIx\_CR1 register. It is given by the formula:

$$\frac{t_{\text{baud\_rate}}}{2} + 4 \times t_{\text{pclk}} < t_{\text{release}} < \frac{t_{\text{baud\_rate}}}{2} + 6 \times t_{\text{pclk}}$$

If the slave detects a misplaced NSS pulse during a data frame transaction the TIFRE flag is set.

If the data size is equal to 4-bits or 5-bits, the master in full-duplex mode or transmit-only mode uses a protocol with one more dummy data bit added after LSB. TI NSS pulse is generated above this dummy bit clock cycle instead of the LSB in each period.

This feature is not available for Motorola SPI communications (FRF bit set to 0).

*Figure 372: TI mode transfer* shows the SPI communication waveforms when TI mode is selected.

**Figure 372. TI mode transfer**

### 32.5.14 CRC calculation

Two separate CRC calculators are implemented in order to check the reliability of transmitted and received data. The SPI offers CRC8 or CRC16 calculation independently of the frame data length, which can be fixed to 8-bit or 16-bit. For all the other data frame lengths, no CRC is available.

#### CRC principle

CRC calculation is enabled by setting the CRCEN bit in the SPIx\_CR1 register before the SPI is enabled (SPE = 1). The CRC value is calculated using an odd programmable polynomial on each bit. The calculation is processed on the sampling clock edge defined by the CPHA and CPOL bits in the SPIx\_CR1 register. The calculated CRC value is checked automatically at the end of the data block as well as for transfer managed by CPU or by the DMA. When a mismatch is detected between the CRC calculated internally on the received data and the CRC sent by the transmitter, a CRCERR flag is set to indicate a data corruption error. The right procedure for handling the CRC calculation depends on the SPI configuration and the chosen transfer management.

*Note: The polynomial value should only be odd. No even values are supported.*

### **CRC transfer managed by CPU**

Communication starts and continues normally until the last data frame has to be sent or received in the SPIx\_DR register. Then CRCNEXT bit has to be set in the SPIx\_CR1 register to indicate that the CRC frame transaction will follow after the transaction of the currently processed data frame. The CRCNEXT bit must be set before the end of the last data frame transaction. CRC calculation is frozen during CRC transaction.

The received CRC is stored in the RXFIFO like a data byte or word. That is why in CRC mode only, the reception buffer has to be considered as a single 16-bit buffer used to receive only one data frame at a time.

A CRC-format transaction usually takes one more data frame to communicate at the end of data sequence. However, when setting an 8-bit data frame checked by 16-bit CRC, two more frames are necessary to send the complete CRC.

When the last CRC data is received, an automatic check is performed comparing the received value and the value in the SPIx\_RXCRC register. Software has to check the CRCERR flag in the SPIx\_SR register to determine if the data transfers were corrupted or not. Software clears the CRCERR flag by writing '0' to it.

After the CRC reception, the CRC value is stored in the RXFIFO and must be read in the SPIx\_DR register in order to clear the RXNE flag.

### **CRC transfer managed by DMA**

When SPI communication is enabled with CRC communication and DMA mode, the transmission and reception of the CRC at the end of communication is automatic (with the exception of reading CRC data in receive only mode). The CRCNEXT bit does not have to be handled by the software. The counter for the SPI transmission DMA channel has to be set to the number of data frames to transmit excluding the CRC frame. On the receiver side, the received CRC value is handled automatically by DMA at the end of the transaction but user must take care to flush out received CRC information from RXFIFO as it is always loaded into it. In full-duplex mode, the counter of the reception DMA channel can be set to the number of data frames to receive including the CRC, which means, for example, in the specific case of an 8-bit data frame checked by 16-bit CRC:

$$\text{DMA\_RX} = \text{Numb\_of\_data} + 2$$

In receive only mode, the DMA reception channel counter should contain only the amount of data transferred, excluding the CRC calculation. Then based on the complete transfer from DMA, all the CRC values must be read back by software from FIFO as it works as a single buffer in this mode.

At the end of the data and CRC transfers, the CRCERR flag in the SPIx\_SR register is set if corruption occurred during the transfer.

If packing mode is used, the LDMA\_RX bit needs managing if the number of data is odd.

### **Resetting the SPIx\_TXCRC and SPIx\_RXCRC values**

The SPIx\_TXCRC and SPIx\_RXCRC values are cleared automatically when new data is sampled after a CRC phase. This allows the use of DMA circular mode (not available in receive-only mode) in order to transfer data without any interruption, (several data blocks covered by intermediate CRC checking phases).

If the SPI is disabled during a communication the following sequence must be followed:

1. Disable the SPI
2. Clear the CRCEN bit
3. Enable the CRCEN bit
4. Enable the SPI

**Note:** *When the SPI interface is configured as a slave, the NSS internal signal needs to be kept low during transaction of the CRC phase once the CRCNEXT signal is released. That is why the CRC calculation can't be used at NSS Pulse mode when NSS hardware mode should be applied at slave normally (see more details at the product errata sheet).*

*At TI mode, despite the fact that clock phase and clock polarity setting is fixed and independent on SPIx\_CR1 register, the corresponding setting CPOL=0 CPHA=1 has to be kept at the SPIx\_CR1 register anyway if CRC is applied. In addition, the CRC calculation has to be reset between sessions by SPI disable sequence with re-enable the CRCEN bit described above at both master and slave side, else CRC calculation can be corrupted at this specific mode.*

## 32.6 SPI interrupts

During SPI communication an interrupts can be generated by the following events:

- Transmit TXFIFO ready to be loaded
- Data received in Receive RXFIFO
- Master mode fault
- Overrun error
- TI frame format error
- CRC protocol error

Interrupts can be enabled and disabled separately.

**Table 203. SPI interrupt requests**

| Interrupt event                    | Event flag | Enable Control bit |
|------------------------------------|------------|--------------------|
| Transmit TXFIFO ready to be loaded | TXE        | TXEIE              |

## 32.7 I2S functional description

### 32.7.1 I2S general description

The block diagram of the I2S is shown in [Figure 373](#).

Figure 373. I2S block diagram

1. MCK is mapped on the MISO pin.

The SPI can function as an audio I2S interface when the I2S capability is enabled (by setting the I2SMOD bit in the SPIx\_I2SCFGR register). This interface mainly uses the same pins, flags and interrupts as the SPI.

The I2S shares three common pins with the SPI:

- SD: Serial Data (mapped on the MOSI pin) to transmit or receive the two time-multiplexed data channels (in half-duplex mode only).
- WS: Word Select (mapped on the NSS pin) is the data control signal output in master mode and input in slave mode.
- CK: Serial Clock (mapped on the SCK pin) is the serial clock output in master mode and serial clock input in slave mode.

An additional pin can be used when a master clock output is needed for some external audio devices:

- MCK: Master Clock (mapped separately) is used, when the I2S is configured in master mode (and when the MCKOE bit in the SPIx\_I2SPR register is set), to output this additional clock generated at a preconfigured frequency rate equal to  $256 \times f_s$ , where  $f_s$  is the audio sampling frequency.

The I2S uses its own clock generator to produce the communication clock when it is set in master mode. This clock generator is also the source of the master clock output. Two additional registers are available in I<sup>2</sup>S mode. One is linked to the clock generator configuration SPIx\_I2SPR and the other one is a generic I2S configuration register SPIx\_I2SCFGR (audio standard, slave/master mode, data format, packet frame, clock polarity, etc.).

The SPIx\_CR1 register and all CRC registers are not used in the I<sup>2</sup>S mode. Likewise, the SSOE bit in the SPIx\_CR2 register and the MODF and CRCERR bits in the SPIx\_SR are not used.

The I2S uses the same SPI register for data transfer (SPIx\_DR) in 16-bit wide mode.

### 32.7.2 I2S full duplex

*Figure 374* shows how to perform full-duplex communications using two SPI/I2S instances. In this case, the WS and CK IOs of both SPI/I2S must be connected together.

For the master full-duplex mode, one of the SPI/I2S block must be programmed in master (I2SCFG = '10' or '11'), and the other SPI/I2S block must be programmed in slave (I2SCFG = '00' or '01'). The MCK can be generated or not, depending on the application needs.

For the slave full-duplex mode, both SPI/I2S blocks must be programmed in slave. One of them in the slave receiver (I2SCFG = '01'), and the other in the slave transmitter (I2SCFG = '00'). The master external device then provides the bit clock (CK) and the frame synchronization (WS).

Note that the full-duplex mode can be used for all the supported standards: I<sup>2</sup>S Philips, MSB-justified, LSB-justified and PCM.

For the full-duplex mode, both SPI/I2S instances must use the same standard, with the same parameters: I2SMOD, I2SSTD, CKPOL, PCMSYNC, DATLEN and CHLEN must contain the same value on both instances.

Figure 374. Full-duplex communication

### 32.7.3 Supported audio protocols

The three-line bus has to handle only audio data generally time-multiplexed on two channels: the right channel and the left channel. However there is only one 16-bit register for transmission or reception. So, it is up to the software to write into the data register the appropriate value corresponding to each channel side, or to read the data from the data register and to identify the corresponding channel by checking the CHSIDE bit in the SPIx\_SR register. Channel left is always sent first followed by the channel right (CHSIDE has no meaning for the PCM protocol).

Four data and packet frames are available. Data may be sent with a format of:

- 16-bit data packed in a 16-bit frame
- 16-bit data packed in a 32-bit frame
- 24-bit data packed in a 32-bit frame
- 32-bit data packed in a 32-bit frame

When using 16-bit data extended on 32-bit packet, the first 16 bits (MSB) are the significant bits, the 16-bit LSB is forced to 0 without any need for software action or DMA request (only one read/write operation).

The 24-bit and 32-bit data frames need two CPU read or write operations to/from the SPIx\_DR register or two DMA operations if the DMA is preferred for the application. For 24-bit data frame specifically, the 8 non-significant bits are extended to 32 bits with 0-bits (by hardware).

For all data formats and communication standards, the most significant bit is always sent first (MSB first).

The I<sup>2</sup>S interface supports four audio standards, configurable using the I2SSTD[1:0] and PCMSYNC bits in the SPIx\_I2SCFGR register.

### I<sup>2</sup>S Philips standard

For this standard, the WS signal is used to indicate which channel is being transmitted. It is activated one CK clock cycle before the first bit (MSB) is available.

**Figure 375. I<sup>2</sup>S Philips protocol waveforms (16/32-bit full accuracy)**

Data are latched on the falling edge of CK (for the transmitter) and are read on the rising edge (for the receiver). The WS signal is also latched on the falling edge of CK.

**Figure 376. I<sup>2</sup>S Philips standard waveforms (24-bit frame)**

This mode needs two write or read operations to/from the SPIx\_DR register.

- In transmission mode:  
If 0x8EAA33 has to be sent (24-bit):

**Figure 377. Transmitting 0x8EAA33**

- In reception mode:  
If data 0x8EAA33 is received:

**Figure 378. Receiving 0x8EAA33****Figure 379. I<sup>2</sup>S Philips standard (16-bit extended to 32-bit packet frame)**

When 16-bit data frame extended to 32-bit channel frame is selected during the I2S configuration phase, only one access to the SPIx\_DR register is required. The 16 remaining bits are forced by hardware to 0x0000 to extend the data to 32-bit format.

If the data to transmit or the received data are 0x76A3 (0x76A30000 extended to 32-bit), the operation shown in [Figure 380](#) is required.

**Figure 380. Example of 16-bit data frame extended to 32-bit channel frame**

For transmission, each time an MSB is written to SPIx\_DR, the TXE flag is set and its interrupt, if allowed, is generated to load the SPIx\_DR register with the new value to send. This takes place even if 0x0000 have not yet been sent because it is done by hardware.

For reception, the RXNE flag is set and its interrupt, if allowed, is generated when the first 16 MSB half-word is received.

In this way, more time is provided between two write or read operations, which prevents underrun or overrun conditions (depending on the direction of the data transfer).

### MSB justified standard

For this standard, the WS signal is generated at the same time as the first data bit, which is the MSBit.

**Figure 381. MSB Justified 16-bit or 32-bit full-accuracy length**

Data are latched on the falling edge of CK (for transmitter) and are read on the rising edge (for the receiver).

**Figure 382. MSB justified 24-bit frame length**

**Figure 383. MSB justified 16-bit extended to 32-bit packet frame****LSB justified standard**

This standard is similar to the MSB justified standard (no difference for the 16-bit and 32-bit full-accuracy frame formats).

The sampling of the input and output signals is the same as for the I<sup>2</sup>S Philips standard.

**Figure 384. LSB justified 16-bit or 32-bit full-accuracy****Figure 385. LSB justified 24-bit frame length**

- In transmission mode:  
If data 0x3478AE have to be transmitted, two write operations to the SPIx\_DR register are required by software or by DMA. The operations are shown below.

**Figure 386. Operations required to transmit 0x3478AE**

- In reception mode:  
If data 0x3478AE are received, two successive read operations from the SPIx\_DR register are required on each RXNE event.

**Figure 387. Operations required to receive 0x3478AE****Figure 388. LSB justified 16-bit extended to 32-bit packet frame**

When 16-bit data frame extended to 32-bit channel frame is selected during the I2S configuration phase, Only one access to the SPIx\_DR register is required. The 16 remaining bits are forced by hardware to 0x0000 to extend the data to 32-bit format. In this case it corresponds to the half-word MSB.

If the data to transmit or the received data are 0x76A3 (0x0000 76A3 extended to 32-bit), the operation shown in [Figure 389](#) is required.

**Figure 389. Example of 16-bit data frame extended to 32-bit channel frame**

In transmission mode, when a TXE event occurs, the application has to write the data to be transmitted (in this case 0x76A3). The 0x000 field is transmitted first (extension on 32-bit). The TXE flag is set again as soon as the effective data (0x76A3) is sent on SD.

In reception mode, RXNE is asserted as soon as the significant half-word is received (and not the 0x0000 field).

In this way, more time is provided between two write or read operations to prevent underrun or overrun conditions.

### PCM standard

For the PCM standard, there is no need to use channel-side information. The two PCM modes (short and long frame) are available and configurable using the PCMSYNC bit in SPIx\_I2SCFGR register.

In PCM mode, the output signals (WS, SD) are sampled on the rising edge of CK signal. The input signals (WS, SD) are captured on the falling edge of CK.

Note that CK and WS are configured as output in MASTER mode.

**Figure 390. PCM standard waveforms (16-bit)**

For long frame synchronization, the WS signal assertion time is fixed to 13 bits in master mode.

For short frame synchronization, the WS synchronization signal is only one cycle long.

**Figure 391. PCM standard waveforms (16-bit extended to 32-bit packet frame)**

**Note:** For both modes (master and slave) and for both synchronizations (short and long), the number of bits between two consecutive pieces of data (and so two synchronization signals) needs to be specified (DATLEN and CHLEN bits in the SPIx\_I2SCFGR register) even in slave mode.

### 32.7.4 Start-up description

The [Figure 392](#) shows how the serial interface is handled in MASTER mode, when the SPI/I2S is enabled (via I2SE bit). It shows as well the effect of CKPOL on the generated signals.

Figure 392. Start sequence in master mode

In slave mode, the way the frame synchronization is detected, depends on the value of ASTRTEN bit.

If ASTRTEN = 0, when the audio interface is enabled (I2SE = 1), then the hardware waits for the appropriate transition on the incoming WS signal, using the CK signal.

The appropriate transition is a falling edge on WS signal when I<sup>2</sup>S Philips Standard is used, or a rising edge for other standards. The falling edge is detected by sampling first WS to 1 and then to 0, and vice-versa for the rising edge detection.

If ASTRTEN = 1, the user has to enable the audio interface before the WS becomes active. This means that the I2SE bit must be set to 1 when WS = 1 for I<sup>2</sup>S Philips standard, or when WS = 0 for other standards.

### 32.7.5 Clock generator

The I<sup>2</sup>S bit rate determines the data flow on the I<sup>2</sup>S data line and the I<sup>2</sup>S clock signal frequency.

I<sup>2</sup>S bit rate = number of bits per channel × number of channels × sampling audio frequency

For a 16-bit audio, left and right channel, the I<sup>2</sup>S bit rate is calculated as follows:

$$\text{I}^2\text{S bit rate} = 16 \times 2 \times f_s$$

It will be: I<sup>2</sup>S bit rate = 32 × 2 × f<sub>s</sub> if the packet length is 32-bit wide.

**Figure 393. Audio sampling frequency definition**

When the master mode is configured, a specific action needs to be taken to properly program the linear divider in order to communicate with the desired audio frequency.

**Figure 394. I<sup>2</sup>S clock generator architecture**

1. Where x can be 2 or 3.

Figure 394 presents the communication clock architecture. The I2SxCLK clock is provided by the reset and clock controller (RCC) of the product. The I2SxCLK clock can be asynchronous with respect to the SPI/I2S APB clock.

---

**Warning:** In addition, it is mandatory to keep the I2SxCLK frequency higher or equal to the APB clock used by the SPI/I2S block. If this condition is not respected, the SPI/I2S will not work properly.

---

The audio sampling frequency may be 192 kHz, 96 kHz, 48 kHz, 44.1 kHz, 32 kHz, 22.05 kHz, 16 kHz, 11.025 kHz or 8 kHz (or any other value within this range).

In order to reach the desired frequency, the linear divider needs to be programmed according to the formulas below:

**For I<sup>2</sup>S modes:**

When the master clock is generated (MCKOE in the SPIx\_I2SPR register is set):

$$F_s = \frac{F_{I2SxCLK}}{256 \times ((2 \times I2SDIV) + ODD)}$$

When the master clock is disabled (MCKOE bit cleared):

$$F_s = \frac{F_{I2SxCLK}}{32 \times (CHLEN + 1) \times ((2 \times I2SDIV) + ODD)}$$

CHLEN = 0 when the channel frame is 16-bit wide and,

CHLEN = 1 when the channel frame is 32-bit wide.

**For PCM modes:**

When the master clock is generated (MCKOE in the SPIx\_I2SPR register is set):

$$F_s = \frac{F_{I2SxCLK}}{128 \times ((2 \times I2SDIV) + ODD)}$$

When the master clock is disabled (MCKOE bit cleared):

$$F_s = \frac{F_{I2SxCLK}}{16 \times (CHLEN + 1) \times ((2 \times I2SDIV) + ODD)}$$

CHLEN = 0 when the channel frame is 16-bit wide and,

CHLEN = 1 when the channel frame is 32-bit wide.

Where  $F_s$  is the audio sampling frequency, and  $F_{I2SxCLK}$  is the frequency of the kernel clock provided to the SPI/I2S block.

Note: Note that I2SDIV must be strictly higher than 1.

Table 204 provides example precision values for different clock configurations.

Note: Other configurations are possible that allow optimum clock precision.

**Table 204. Audio-frequency precision using standard 8 MHz HSE<sup>(1)</sup>**

| SYSCLK (MHz) | Data length | I2SDIV | I2SODD | MCLK | Target fs (Hz) | Real fs (kHz) | Error   |

1. This table gives only example values for different clock configurations. Other configurations allowing optimum clock precision are possible.

### 32.7.6 I<sup>2</sup>S master mode

The I2S can be configured in master mode. This means that the serial clock is generated on the CK pin as well as the Word Select signal WS. Master clock (MCK) may be output or not, controlled by the MCKOE bit in the SPIx\_I2SPR register.

#### Procedure

1. Select the I2SDIV[7:0] bits in the SPIx\_I2SPR register to define the serial clock baud rate to reach the proper audio sample frequency. The ODD bit in the SPIx\_I2SPR register also has to be defined.
2. Select the CKPOL bit to define the steady level for the communication clock. Set the MCKOE bit in the SPIx\_I2SPR register if the master clock MCK needs to be provided to the external DAC/ADC audio component (the I2SDIV and ODD values should be computed depending on the state of the MCK output, for more details refer to [Section 32.7.5: Clock generator](#)).
3. Set the I2SMOD bit in the SPIx\_I2SCFGR register to activate the I2S functions and choose the I<sup>2</sup>S standard through the I2SSTD[1:0] and PCMSYNC bits, the data length through the DATLEN[1:0] bits and the number of bits per channel by configuring the CHLEN bit. Select also the I<sup>2</sup>S master mode and direction (Transmitter or Receiver) through the I2SCFG[1:0] bits in the SPIx\_I2SCFGR register.
4. If needed, select all the potential interrupt sources and the DMA capabilities by writing the SPIx\_CR2 register.
5. The I2SE bit in SPIx\_I2SCFGR register must be set.

WS and CK are configured in output mode. MCK is also an output, if the MCKOE bit in SPIx\_I2SPR is set.

#### Transmission sequence

The transmission sequence begins when a half-word is written into the Tx buffer.

Lets assume the first data written into the Tx buffer corresponds to the left channel data. When data are transferred from the Tx buffer to the shift register, TXE is set and data corresponding to the right channel have to be written into the Tx buffer. The CHSIDE flag indicates which channel is to be transmitted. It has a meaning when the TXE flag is set because the CHSIDE flag is updated when TXE goes high.

A full frame has to be considered as a left channel data transmission followed by a right channel data transmission. It is not possible to have a partial frame where only the left channel is sent.

The data half-word is parallel loaded into the 16-bit shift register during the first bit transmission, and then shifted out, serially, to the MOSI/SD pin, MSB first. The TXE flag is set after each transfer from the Tx buffer to the shift register and an interrupt is generated if the TXEIE bit in the SPIx\_CR2 register is set.

For more details about the write operations depending on the I<sup>2</sup>S standard mode selected, refer to [Section 32.7.3: Supported audio protocols](#).

To ensure a continuous audio data transmission, it is mandatory to write the SPIx\_DR register with the next data to transmit before the end of the current transmission.

To switch off the I2S, by clearing I2SE, it is mandatory to wait for TXE = 1 and BSY = 0.

### Reception sequence

The operating mode is the same as for transmission mode except for the point 3 (refer to the procedure described in [Section 32.7.6: I2S master mode](#)), where the configuration should set the master reception mode through the I2SCFG[1:0] bits.

Whatever the data or channel length, the audio data are received by 16-bit packets. This means that each time the Rx buffer is full, the RXNE flag is set and an interrupt is generated if the RXNEIE bit is set in SPIx\_CR2 register. Depending on the data and channel length configuration, the audio value received for a right or left channel may result from one or two receptions into the Rx buffer.

Clearing the RXNE bit is performed by reading the SPIx\_DR register.

CHSIDE is updated after each reception. It is sensitive to the WS signal generated by the I2S cell.

For more details about the read operations depending on the I<sup>2</sup>S standard mode selected, refer to [Section 32.7.3: Supported audio protocols](#).

If data are received while the previously received data have not been read yet, an overrun is generated and the OVR flag is set. If the ERRIE bit is set in the SPIx\_CR2 register, an interrupt is generated to indicate the error.

To switch off the I2S, specific actions are required to ensure that the I2S completes the transfer cycle properly without initiating a new data transfer. The sequence depends on the configuration of the data and channel lengths, and on the audio protocol mode selected. In the case of:

- 16-bit data length extended on 32-bit channel length (DATLEN = 00 and CHLEN = 1) using the LSB justified mode (I2SSTD = 10)
  - a) Wait for the second to last RXNE = 1 (n – 1)
  - b) Then wait 17 I2S clock cycles (using a software loop)
  - c) Disable the I2S (I2SE = 0)
- 16-bit data length extended on 32-bit channel length (DATLEN = 00 and CHLEN = 1) in MSB justified, I<sup>2</sup>S or PCM modes (I2SSTD = 00, I2SSTD = 01 or I2SSTD = 11, respectively)
  - a) Wait for the last RXNE
  - b) Then wait 1 I2S clock cycle (using a software loop)
  - c) Disable the I2S (I2SE = 0)
- For all other combinations of DATLEN and CHLEN, whatever the audio mode selected through the I2SSTD bits, carry out the following sequence to switch off the I2S:
  - a) Wait for the second to last RXNE = 1 (n – 1)
  - b) Then wait one I2S clock cycle (using a software loop)
  - c) Disable the I2S (I2SE = 0)

*Note:* The BSY flag is kept low during transfers.

### 32.7.7 I<sup>2</sup>S slave mode

For the slave configuration, the I2S can be configured in transmission or reception mode. The operating mode is following mainly the same rules as described for the I<sup>2</sup>S master

configuration. In slave mode, there is no clock to be generated by the I2S interface. The clock and WS signals are input from the external master connected to the I2S interface. There is then no need, for the user, to configure the clock.

The configuration steps to follow are listed below:

1. Set the I2SMOD bit in the SPIx\_I2SCFGR register to select I<sup>2</sup>S mode and choose the I<sup>2</sup>S standard through the I2SSTD[1:0] bits, the data length through the DATLEN[1:0] bits and the number of bits per channel for the frame configuring the CHLEN bit. Select also the mode (transmission or reception) for the slave through the I2SCFG[1:0] bits in SPIx\_I2SCFGR register.
2. If needed, select all the potential interrupt sources and the DMA capabilities by writing the SPIx\_CR2 register.
3. The I2SE bit in SPIx\_I2SCFGR register must be set.

### Transmission sequence

The transmission sequence begins when the external master device sends the clock and when the NSS\_WS signal requests the transfer of data. The slave has to be enabled before the external master starts the communication. The I2S data register has to be loaded before the master initiates the communication.

For the I2S, MSB justified and LSB justified modes, the first data item to be written into the data register corresponds to the data for the left channel. When the communication starts, the data are transferred from the Tx buffer to the shift register. The TXE flag is then set in order to request the right channel data to be written into the I2S data register.

The CHSIDE flag indicates which channel is to be transmitted. Compared to the master transmission mode, in slave mode, CHSIDE is sensitive to the WS signal coming from the external master. This means that the slave needs to be ready to transmit the first data before the clock is generated by the master. WS assertion corresponds to left channel transmitted first.

*Note: The I2SE has to be written at least two PCLK cycles before the first clock of the master comes on the CK line.*

The data half-word is parallel-loaded into the 16-bit shift register (from the internal bus) during the first bit transmission, and then shifted out serially to the MOSI/SD pin MSB first. The TXE flag is set after each transfer from the Tx buffer to the shift register and an interrupt is generated if the TXEIE bit in the SPIx\_CR2 register is set.

Note that the TXE flag should be checked to be at 1 before attempting to write the Tx buffer.

For more details about the write operations depending on the I<sup>2</sup>S standard mode selected, refer to [Section 32.7.3: Supported audio protocols](#).

To secure a continuous audio data transmission, it is mandatory to write the SPIx\_DR register with the next data to transmit before the end of the current transmission. An underrun flag is set and an interrupt may be generated if the data are not written into the SPIx\_DR register before the first clock edge of the next data communication. This indicates to the software that the transferred data are wrong. If the ERRIE bit is set into the SPIx\_CR2 register, an interrupt is generated when the UDR flag in the SPIx\_SR register goes high. In this case, it is mandatory to switch off the I2S and to restart a data transfer starting from the left channel.

To switch off the I2S, by clearing the I2SE bit, it is mandatory to wait for TXE = 1 and BSY = 0.

### Reception sequence

The operating mode is the same as for the transmission mode except for the point 1 (refer to the procedure described in [Section 32.7.7: I2S slave mode](#)), where the configuration should set the master reception mode using the I2SCFG[1:0] bits in the SPIx\_I2SCFGR register.

Whatever the data length or the channel length, the audio data are received by 16-bit packets. This means that each time the RX buffer is full, the RXNE flag in the SPIx\_SR register is set and an interrupt is generated if the RXNEIE bit is set in the SPIx\_CR2 register. Depending on the data length and channel length configuration, the audio value received for a right or left channel may result from one or two receptions into the RX buffer.

The CHSIDE flag is updated each time data are received to be read from the SPIx\_DR register. It is sensitive to the external WS line managed by the external master component.

Clearing the RXNE bit is performed by reading the SPIx\_DR register.

For more details about the read operations depending the I<sup>2</sup>S standard mode selected, refer to [Section 32.7.3: Supported audio protocols](#).

If data are received while the preceding received data have not yet been read, an overrun is generated and the OVR flag is set. If the bit ERRIE is set in the SPIx\_CR2 register, an interrupt is generated to indicate the error.

To switch off the I2S in reception mode, I2SE has to be cleared immediately after receiving the last RXNE = 1.

*Note:* The external master components should have the capability of sending/receiving data in 16-bit or 32-bit packets via an audio channel.

### 32.7.8 I2S status flags

Three status flags are provided for the application to fully monitor the state of the I2S bus.

#### Busy flag (BSY)

The BSY flag is set and cleared by hardware (writing to this flag has no effect). It indicates the state of the communication layer of the I2S.

When BSY is set, it indicates that the I2S is busy communicating. There is one exception in master receive mode (I2SCFG = 11) where the BSY flag is kept low during reception.

The BSY flag is useful to detect the end of a transfer if the software needs to disable the I2S. This avoids corrupting the last transfer. For this, the procedure described below must be strictly respected.

The BSY flag is set when a transfer starts, except when the I2S is in master receiver mode.

The BSY flag is cleared:

- When a transfer completes (except in master transmit mode, in which the communication is supposed to be continuous)
- When the I2S is disabled

When communication is continuous:

- In master transmit mode, the BSY flag is kept high during all the transfers
- In slave mode, the BSY flag goes low for one I2S clock cycle between each transfer

*Note:* Do not use the BSY flag to handle each data transmission or reception. It is better to use the TXE and RXNE flags instead.

**Tx buffer empty flag (TXE)**

When set, this flag indicates that the Tx buffer is empty and the next data to be transmitted can then be loaded into it. The TXE flag is reset when the Tx buffer already contains data to be transmitted. It is also reset when the I2S is disabled (I2SE bit is reset).

**RX buffer not empty (RXNE)**

When set, this flag indicates that there are valid received data in the RX Buffer. It is reset when SPIx\_DR register is read.

**Channel Side flag (CHSIDE)**

In transmission mode, this flag is refreshed when TXE goes high. It indicates the channel side to which the data to transfer on SD has to belong. In case of an underrun error event in slave transmission mode, this flag is not reliable and I2S needs to be switched off and switched on before resuming the communication.

In reception mode, this flag is refreshed when data are received into SPIx\_DR. It indicates from which channel side data have been received. Note that in case of error (like OVR) this flag becomes meaningless and the I2S should be reset by disabling and then enabling it (with configuration if it needs changing).

This flag has no meaning in the PCM standard (for both Short and Long frame modes).

When the OVR or UDR flag in the SPIx\_SR is set and the ERRIE bit in SPIx\_CR2 is also set, an interrupt is generated. This interrupt can be cleared by reading the SPIx\_SR status register (once the interrupt source has been cleared).

### 32.7.9 I2S error flags

There are three error flags for the I2S cell.

**Underrun flag (UDR)**

In slave transmission mode this flag is set when the first clock for data transmission appears while the software has not yet loaded any value into SPIx\_DR. It is available when the I2SMOD bit in the SPIx\_I2SCFGR register is set. An interrupt may be generated if the ERRIE bit in the SPIx\_CR2 register is set.

The UDR bit is cleared by a read operation on the SPIx\_SR register.

**Overrun flag (OVR)**

This flag is set when data are received and the previous data have not yet been read from the SPIx\_DR register. As a result, the incoming data are lost. An interrupt may be generated if the ERRIE bit is set in the SPIx\_CR2 register.

In this case, the receive buffer contents are not updated with the newly received data from the transmitter device. A read operation to the SPIx\_DR register returns the previous correctly received data. All other subsequently transmitted half-words are lost.

Clearing the OVR bit is done by a read operation on the SPIx\_DR register followed by a read access to the SPIx\_SR register.

**Frame error flag (FRE)**

This flag can be set by hardware only if the I2S is configured in Slave mode. It is set if the external master is changing the WS line while the slave is not expecting this change. If the

synchronization is lost, the following steps are required to recover from this state and resynchronize the external master device with the I2S slave device:

1. Disable the I2S.
2. Re-enable the I2S interface again (Keeping ASTRTEN=0).

Desynchronization between master and slave devices may be due to noisy environment on the CK communication clock or on the WS frame synchronization line. An error interrupt can be generated if the ERRIE bit is set. The desynchronization flag (FRE) is cleared by software when the status register is read.

### 32.7.10 DMA features

In I<sup>2</sup>S mode, the DMA works in exactly the same way as it does in SPI mode. There is no difference except that the CRC feature is not available in I<sup>2</sup>S mode since there is no data transfer protection system.

## 32.8 I2S interrupts

[Table 205](#) provides the list of I2S interrupts.

**Table 205. I2S interrupt requests**

| Interrupt event               | Event flag | Enable control bit |
|-------------------------------|------------|--------------------|
| Transmit buffer empty flag    | TXE        | TXEIE              |
| Receive buffer not empty flag | RXNE       | RXNEIE             |
| Overrun error                 | OVR        | ERRIE              |
| Underrun error                | UDR        |                    |
| Frame error flag              | FRE        |                    |

## 32.9 SPI and I2S registers

The peripheral registers can be accessed by half-words (16-bit) or words (32-bit). SPI\_DR in addition can be accessed by 8-bit access.

### 32.9.1 SPI control register 1 (SPIx\_CR1)

Address offset: 0x00

Reset value: 0x0000

| 15       | 14     | 13     | 12       | 11   | 10     | 9   | 8   | 7        | 6   | 5       | 4  | 3  | 2    | 1    | 0    |
|----------|--------|--------|----------|------|--------|-----|-----|----------|-----|---------|----|----|------|------|------|
| BIDIMODE | BIDIOE | CRCE N | CRCN EXT | CRCL | RXONLY | SSM | SSI | LSBFIRST | SPE | BR[2:0] |    |    | MSTR | CPOL | CPHA |
| rw       | rw     | rw     | rw       | rw   | rw     | rw  | rw  | rw       | rw  | rw      | rw | rw | rw   | rw   | rw   |

Bit 15 **BIDIMODE**: Bidirectional data mode enable.

This bit enables half-duplex communication using common single bidirectional data line.  
Keep RXONLY bit clear when bidirectional mode is active.

0: 2-line unidirectional data mode selected

1: 1-line bidirectional data mode selected

*Note: This bit is not used in I<sup>2</sup>S mode.*

Bit 14 **BIDIOE**: Output enable in bidirectional mode

This bit combined with the BIDIMODE bit selects the direction of transfer in bidirectional mode.

0: Output disabled (receive-only mode)

1: Output enabled (transmit-only mode)

*Note: In master mode, the MOSI pin is used and in slave mode, the MISO pin is used.*

*This bit is not used in I<sup>2</sup>S mode.*

Bit 13 **CRCE N**: Hardware CRC calculation enable

0: CRC calculation disabled

1: CRC calculation enabled

*Note: This bit should be written only when SPI is disabled (SPE = '0') for correct operation.*

*This bit is not used in I<sup>2</sup>S mode.*

Bit 12 **CRCNEXT**: Transmit CRC next

0: Next transmit value is from Tx buffer.

1: Next transmit value is from Tx CRC register.

*Note: This bit has to be written as soon as the last data is written in the SPIx\_DR register.*

*This bit is not used in I<sup>2</sup>S mode.*

Bit 11 **CRCL**: CRC length

This bit is set and cleared by software to select the CRC length.

0: 8-bit CRC length

1: 16-bit CRC length

*Note: This bit should be written only when SPI is disabled (SPE = '0') for correct operation.*

*This bit is not used in I<sup>2</sup>S mode.*

Bit 10 **RXONLY**: Receive only mode enabled.

This bit enables simplex communication using a single unidirectional line to receive data exclusively. Keep BIDIMODE bit clear when receive only mode is active. This bit is also useful in a multislave system in which this particular slave is not accessed, the output from the accessed slave is not corrupted.

0: Full-duplex (Transmit and receive)

1: Output disabled (Receive-only mode)

*Note: This bit is not used in I<sup>2</sup>S mode.*

Bit 9 **SSM**: Software slave management

When the SSM bit is set, the NSS pin input is replaced with the value from the SSI bit.

0: Software slave management disabled

1: Software slave management enabled

*Note: This bit is not used in I<sup>2</sup>S mode and SPI TI mode.*

Bit 8 **SSI**: Internal slave select

This bit has an effect only when the SSM bit is set. The value of this bit is forced onto the NSS pin and the I/O value of the NSS pin is ignored.

*Note: This bit is not used in I<sup>2</sup>S mode and SPI TI mode.*

Bit 7 **LSBFIRST**: Frame format

0: data is transmitted / received with the MSB first

1: data is transmitted / received with the LSB first

*Note: 1. This bit should not be changed when communication is ongoing.*

*2. This bit is not used in I<sup>2</sup>S mode and SPI TI mode.*

Bit 6 **SPE**: SPI enable

0: Peripheral disabled

1: Peripheral enabled

*Note: When disabling the SPI, follow the procedure described in [Procedure for disabling the SPI on page 1100](#).*

*This bit is not used in I<sup>2</sup>S mode.*

Bits 5:3 **BR[2:0]**: Baud rate control

000:  $f_{PCLK}/2$

001:  $f_{PCLK}/4$

010:  $f_{PCLK}/8$

011:  $f_{PCLK}/16$

100:  $f_{PCLK}/32$

101:  $f_{PCLK}/64$

110:  $f_{PCLK}/128$

111:  $f_{PCLK}/256$

*Note: These bits should not be changed when communication is ongoing.*

*This bit is not used in I<sup>2</sup>S mode.*

Bit 2 **MSTR**: Master selection

0: Slave configuration

1: Master configuration

*Note: This bit should not be changed when communication is ongoing.*

*This bit is not used in I<sup>2</sup>S mode.*

Bit 1 **CPOL**: Clock polarity

0: CK to 0 when idle

1: CK to 1 when idle

*Note: This bit should not be changed when communication is ongoing.*

*This bit is not used in SPI TI mode except the case when CRC is applied at TI mode.*

Bit 0 **CPHA**: Clock phase

0: The first clock transition is the first data capture edge

1: The second clock transition is the first data capture edge

*Note: This bit should not be changed when communication is ongoing.*

*This bit is not used in SPI TI mode except the case when CRC is applied at TI mode.*

### 32.9.2 SPI control register 2 (SPIx\_CR2)

Address offset: 0x04

Reset value: 0x0700

| 15   | 14      | 13      | 12    | 11      | 10 | 9  | 8  | 7     | 6      | 5     | 4   | 3    | 2    | 1       | 0       |
|------|---------|---------|-------|---------|----|----|----|-------|--------|-------|-----|------|------|---------|---------|
| Res. | LDMA_TX | LDMA_RX | FRXTH | DS[3:0] |    |    |    | TXEIE | RXNEIE | ERRIE | FRF | NSSP | SSOE | TXDMAEN | RXDMAEN |
|      | rw      | rw      | rw    | rw      | rw | rw | rw | rw    | rw     | rw    | rw  | rw   | rw   | rw      | rw      |

Bit 15 Reserved, must be kept at reset value.

Bit 14 **LDMA\_TX**: Last DMA transfer for transmission

This bit is used in data packing mode, to define if the total number of data to transmit by DMA is odd or even. It has significance only if the TXDMAEN bit in the SPIx\_CR2 register is set and if packing mode is used (data length  $\leq$  8-bit and write access to SPIx\_DR is 16-bit wide). It has to be written when the SPI is disabled (SPE = 0 in the SPIx\_CR1 register).

0: Number of data to transfer is even

1: Number of data to transfer is odd

*Note: Refer to [Procedure for disabling the SPI on page 1100](#) if the CRCEN bit is set.*

*This bit is not used in I<sup>2</sup>S mode.*

Bit 13 **LDMA\_RX**: Last DMA transfer for reception

This bit is used in data packing mode, to define if the total number of data to receive by DMA is odd or even. It has significance only if the RXDMAEN bit in the SPIx\_CR2 register is set and if packing mode is used (data length  $\leq$  8-bit and write access to SPIx\_DR is 16-bit wide). It has to be written when the SPI is disabled (SPE = 0 in the SPIx\_CR1 register).

0: Number of data to transfer is even

1: Number of data to transfer is odd

*Note: Refer to [Procedure for disabling the SPI on page 1100](#) if the CRCEN bit is set.*

*This bit is not used in I<sup>2</sup>S mode.*

Bit 12 **FRXTH**: FIFO reception threshold

This bit is used to set the threshold of the RXFIFO that triggers an RXNE event

0: RXNE event is generated if the FIFO level is greater than or equal to 1/2 (16-bit)

1: RXNE event is generated if the FIFO level is greater than or equal to 1/4 (8-bit)

*Note: This bit is not used in I<sup>2</sup>S mode.*

Bits 11:8 **DS[3:0]**: Data size

These bits configure the data length for SPI transfers.

0000: Not used

0001: Not used

0010: Not used

0011: 4-bit

0100: 5-bit

0101: 6-bit

0110: 7-bit

0111: 8-bit

1000: 9-bit

1001: 10-bit

1010: 11-bit

1011: 12-bit

1100: 13-bit

1101: 14-bit

1110: 15-bit

1111: 16-bit

If software attempts to write one of the “Not used” values, they are forced to the value “0111” (8-bit)

*Note: This bit is not used in I<sup>2</sup>S mode.*

Bit 7 **TXEIE**: Tx buffer empty interrupt enable

0: TXE interrupt masked

1: TXE interrupt not masked. Used to generate an interrupt request when the TXE flag is set.

Bit 6 **RXNEIE**: RX buffer not empty interrupt enable

0: RXNE interrupt masked

1: RXNE interrupt not masked. Used to generate an interrupt request when the RXNE flag is set.

Bit 5 **ERRIE**: Error interrupt enable

This bit controls the generation of an interrupt when an error condition occurs (CRCERR, OVR, MODF in SPI mode, FRE at TI mode and UDR, OVR, and FRE in I<sup>2</sup>S mode).

0: Error interrupt is masked

1: Error interrupt is enabled

Bit 4 **FRF**: Frame format

0: SPI Motorola mode

1 SPI TI mode

*Note: This bit must be written only when the SPI is disabled (SPE=0).*

*This bit is not used in I<sup>2</sup>S mode.*

Bit 3 **NSSP**: NSS pulse management

This bit is used in master mode only. it allows the SPI to generate an NSS pulse between two consecutive data when doing continuous transfers. In the case of a single data transfer, it forces the NSS pin high level after the transfer.

It has no meaning if CPHA = '1', or FRF = '1'.

0: No NSS pulse

1: NSS pulse generated

*Note: 1. This bit must be written only when the SPI is disabled (SPE=0).*

*2. This bit is not used in I<sup>2</sup>S mode and SPI TI mode.*

Bit 2 **SSOE**: SS output enable

0: SS output is disabled in master mode and the SPI interface can work in multimaster configuration

1: SS output is enabled in master mode and when the SPI interface is enabled. The SPI interface cannot work in a multimaster environment.

*Note: This bit is not used in I<sup>2</sup>S mode and SPI TI mode.*

Bit 1 **TXDMAEN**: Tx buffer DMA enable

When this bit is set, a DMA request is generated whenever the TXE flag is set.

0: Tx buffer DMA disabled

1: Tx buffer DMA enabled

Bit 0 **RXDMAEN**: Rx buffer DMA enable

When this bit is set, a DMA request is generated whenever the RXNE flag is set.

0: Rx buffer DMA disabled

1: Rx buffer DMA enabled

### 32.9.3 SPI status register (SPIx\_SR)

Address offset: 0x08

Reset value: 0x0002

| 15   | 14   | 13   | 12         | 11 | 10         | 9 | 8   | 7   | 6   | 5    | 4          | 3   | 2      | 1   | 0    |
|------|------|------|------------|----|------------|---|-----|-----|-----|------|------------|-----|--------|-----|------|
| Res. | Res. | Res. | FTLVL[1:0] |    | FRLVL[1:0] |   | FRE | BSY | OVR | MODF | CRCE<br>RR | UDR | CHSIDE | TXE | RXNE |
|      |      |      | r          | r  | r          | r | r   | r   | r   | r    | rc_w0      | r   | r      | r   | r    |

Bits 15:13 Reserved, must be kept at reset value.

Bits 12:11 **FTLVL[1:0]**: FIFO transmission level

These bits are set and cleared by hardware.

00: FIFO empty

01: 1/4 FIFO

10: 1/2 FIFO

11: FIFO full (considered as FULL when the FIFO threshold is greater than 1/2)

*Note: This bit is not used in I<sup>2</sup>S mode.*

Bits 10:9 **FRLVL[1:0]**: FIFO reception level

These bits are set and cleared by hardware.

00: FIFO empty

01: 1/4 FIFO

10: 1/2 FIFO

11: FIFO full

*Note: These bits are not used in I<sup>2</sup>S mode and in SPI receive-only mode while CRC calculation is enabled.*

Bit 8 **FRE**: Frame format error

This flag is used for SPI in TI slave mode and I<sup>2</sup>S slave mode. Refer to [Section 32.5.11: SPI error flags](#) and [Section 32.7.9: I2S error flags](#).

This flag is set by hardware and reset when SPIx\_SR is read by software.

0: No frame format error

1: A frame format error occurred

Bit 7 **BSY**: Busy flag

0: SPI (or I2S) not busy

1: SPI (or I2S) is busy in communication or Tx buffer is not empty

This flag is set and cleared by hardware.

*Note: The BSY flag must be used with caution: refer to [Section 32.5.10: SPI status flags and Procedure for disabling the SPI on page 1100](#).*

Bit 6 **OVR**: Overrun flag

0: No overrun occurred

1: Overrun occurred

This flag is set by hardware and reset by a software sequence. Refer to [I2S error flags on page 1133](#) for the software sequence.

Bit 5 **MODF**: Mode fault

0: No mode fault occurred

1: Mode fault occurred

This flag is set by hardware and reset by a software sequence. Refer to [Section : Mode fault \(MODF\) on page 1110](#) for the software sequence.

*Note: This bit is not used in I<sup>2</sup>S mode.*

Bit 4 **CRCERR**: CRC error flag

0: CRC value received matches the SPIx\_RXCRCR value

1: CRC value received does not match the SPIx\_RXCRCR value

*Note: This flag is set by hardware and cleared by software writing 0.  
This bit is not used in I<sup>2</sup>S mode.*

Bit 3 **UDR**: Underrun flag

0: No underrun occurred

1: Underrun occurred

This flag is set by hardware and reset by a software sequence. Refer to [I2S error flags on page 1133](#) for the software sequence.

*Note: This bit is not used in SPI mode.*

Bit 2 **CHSIDE**: Channel side

0: Channel Left has to be transmitted or has been received

1: Channel Right has to be transmitted or has been received

*Note: This bit is not used in SPI mode. It has no significance in PCM mode.*

Bit 1 **TXE**: Transmit buffer empty

0: Tx buffer not empty

1: Tx buffer empty

Bit 0 **RXNE**: Receive buffer not empty

0: Rx buffer empty

1: Rx buffer not empty

### 32.9.4 SPI data register (SPIx\_DR)

Address offset: 0x0C

Reset value: 0x0000

|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 15       | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| DR[15:0] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw       | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 15:0 **DR[15:0]**: Data register

Data received or to be transmitted

The data register serves as an interface between the Rx and Tx FIFOs. When the data register is read, RxFIFO is accessed while the write to data register accesses TxFIFO (See [Section 32.5.9: Data transmission and reception procedures](#)).

*Note: Data is always right-aligned. Unused bits are ignored when writing to the register, and read as zero when the register is read. The Rx threshold setting must always correspond with the read access currently used.*

### 32.9.5 SPI CRC polynomial register (SPIx\_CRCPR)

Address offset: 0x10

Reset value: 0x0007

|               |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|---------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 15            | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| CRCPOLY[15:0] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw            | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 15:0 **CRCPOLY[15:0]**: CRC polynomial register

This register contains the polynomial for the CRC calculation.

The CRC polynomial (0x0007) is the reset value of this register. Another polynomial can be configured as required.

*Note: The polynomial value should be odd only. No even value is supported.*

### 32.9.6 SPI Rx CRC register (SPIx\_RXCRCR)

Address offset: 0x14

Reset value: 0x0000

|             |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|-------------|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| 15          | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| RXCRC[15:0] |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| r           | r  | r  | r  | r  | r  | r | r | r | r | r | r | r | r | r | r |

Bits 15:0 **RXCRC[15:0]**: Rx CRC register

When CRC calculation is enabled, the RXCRC[15:0] bits contain the computed CRC value of the subsequently received bytes. This register is reset when the CRCEN bit in SPIx\_CR1 register is written to 1. The CRC is calculated serially using the polynomial programmed in the SPIx\_CRCPR register.

Only the 8 LSB bits are considered when the CRC frame format is set to be 8-bit length (CRCL bit in the SPIx\_CR1 is cleared). CRC calculation is done based on any CRC8 standard.

The entire 16-bits of this register are considered when a 16-bit CRC frame format is selected (CRCL bit in the SPIx\_CR1 register is set). CRC calculation is done based on any CRC16 standard.

*Note: A read to this register when the BSY Flag is set could return an incorrect value.  
These bits are not used in I<sup>2</sup>S mode.*

**32.9.7 SPI Tx CRC register (SPIx\_TXCRCR)**

Address offset: 0x18

Reset value: 0x0000

| 15          | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|-------------|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| TXCRC[15:0] |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| r           | r  | r  | r  | r  | r  | r | r | r | r | r | r | r | r | r | r |

Bits 15:0 **TXCRC[15:0]**: Tx CRC register

When CRC calculation is enabled, the TXCRC[7:0] bits contain the computed CRC value of the subsequently transmitted bytes. This register is reset when the CRCEN bit of SPIx\_CR1 is written to 1. The CRC is calculated serially using the polynomial programmed in the SPIx\_CRCPR register.

Only the 8 LSB bits are considered when the CRC frame format is set to be 8-bit length (CRCL bit in the SPIx\_CR1 is cleared). CRC calculation is done based on any CRC8 standard.

The entire 16-bits of this register are considered when a 16-bit CRC frame format is selected (CRCL bit in the SPIx\_CR1 register is set). CRC calculation is done based on any CRC16 standard.

*Note: A read to this register when the BSY flag is set could return an incorrect value.  
These bits are not used in I<sup>2</sup>S mode.*

**32.9.8 SPIx\_I2S configuration register (SPIx\_I2SCFGR)**

Address offset: 0x1C

Reset value: 0x0000

| 15   | 14   | 13   | 12          | 11     | 10   | 9           | 8  | 7       | 6    | 5           | 4  | 3     | 2           | 1  | 0     |
|------|------|------|-------------|--------|------|-------------|----|---------|------|-------------|----|-------|-------------|----|-------|
| Res. | Res. | Res. | ASTR<br>TEN | I2SMOD | I2SE | I2SCFG[1:0] |    | PCMSYNC | Res. | I2SSTD[1:0] |    | CKPOL | DATLEN[1:0] |    | CHLEN |
|      |      |      | rW          | rW     | rW   | rW          | rW | rW      |      | rW          | rW | rW    | rW          | rW | rW    |

Bits 15:13 Reserved, must be kept at reset value.

Bit 12 **ASTRTEN**: Asynchronous start enable.

0: The Asynchronous start is disabled.

When the I2S is enabled in slave mode, the hardware starts the transfer when the I2S clock is received and an appropriate transition is detected on the WS signal.

1: The Asynchronous start is enabled.

When the I2S is enabled in slave mode, the hardware starts the transfer when the I2S clock is received and the appropriate level is detected on the WS signal.

*Note: The appropriate **transition** is a falling edge on WS signal when I<sup>2</sup>S Philips Standard is used, or a rising edge for other standards.*

*The appropriate **level** is a low level on WS signal when I<sup>2</sup>S Philips Standard is used, or a high level for other standards.*

*Please refer to [Section 32.7.4: Start-up description](#) for additional information.*

Bit 11 **I2SMOD**: I2S mode selection

0: SPI mode is selected

1: I2S mode is selected

*Note: This bit should be configured when the SPI is disabled.*

Bit 10 **I2SE**: I2S enable

0: I2S peripheral is disabled

1: I2S peripheral is enabled

*Note: This bit is not used in SPI mode.*

Bits 9:8 **I2SCFG[1:0]**: I2S configuration mode

00: Slave - transmit

01: Slave - receive

10: Master - transmit

11: Master - receive

*Note: These bits should be configured when the I2S is disabled.*

*They are not used in SPI mode.*

Bit 7 **PCMSYNC**: PCM frame synchronization

0: Short frame synchronization

1: Long frame synchronization

*Note: This bit has a meaning only if I2SSTD = 11 (PCM standard is used).*

*It is not used in SPI mode.*

Bit 6 Reserved, must be kept at reset value.

Bits 5:4 **I2SSTD[1:0]**: I2S standard selection

00: I<sup>2</sup>S Philips standard

01: MSB justified standard (left justified)

10: LSB justified standard (right justified)

11: PCM standard

For more details on I<sup>2</sup>S standards, refer to [Section 32.7.3 on page 1117](#)

*Note: For correct operation, these bits should be configured when the I2S is disabled.*

*They are not used in SPI mode.*

Bit 3 **CKPOL**: Inactive state clock polarity

0: I2S clock inactive state is low level

1: I2S clock inactive state is high level

*Note: For correct operation, this bit should be configured when the I2S is disabled.*

*It is not used in SPI mode.*

*The bit CKPOL does not affect the CK edge sensitivity used to receive or transmit the SD and WS signals.*

Bits 2:1 **DATLEN[1:0]**: Data length to be transferred

00: 16-bit data length

01: 24-bit data length

10: 32-bit data length

11: Not allowed

*Note: For correct operation, these bits should be configured when the I2S is disabled.*

*They are not used in SPI mode.*

Bit 0 **CHLEN**: Channel length (number of bits per audio channel)

0: 16-bit wide

1: 32-bit wide

The bit write operation has a meaning only if DATLEN = 00 otherwise the channel length is fixed to 32-bit by hardware whatever the value filled in.

*Note: For correct operation, this bit should be configured when the I2S is disabled.*

*It is not used in SPI mode.*

### 32.9.9 SPIx\_I2S prescaler register (SPIx\_I2SPR)

Address offset: 0x20

Reset value: 0x0002

| 15   | 14   | 13   | 12   | 11   | 10   | 9     | 8   | 7           | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
|------|------|------|------|------|------|-------|-----|-------------|----|----|----|----|----|----|----|
| Res. | Res. | Res. | Res. | Res. | Res. | MCKOE | ODD | I2SDIV[7:0] |    |    |    |    |    |    |    |
|      |      |      |      |      |      | rw    | rw  | rw          | rw | rw | rw | rw | rw | rw | rw |

Bits 15:10 Reserved, must be kept at reset value.

Bit 9 **MCKOE**: Master clock output enable

0: Master clock output is disabled

1: Master clock output is enabled

*Note: This bit should be configured when the I2S is disabled. It is used only when the I2S is in master mode.*

*It is not used in SPI mode.*

Bit 8 **ODD**: Odd factor for the prescaler

0: Real divider value is =  $I2SDIV * 2$

1: Real divider value is =  $(I2SDIV * 2) + 1$

Refer to [Section 32.7.4 on page 1124](#).

*Note: This bit should be configured when the I2S is disabled. It is used only when the I2S is in master mode.*

*It is not used in SPI mode.*

Bits 7:0 **I2SDIV[7:0]**: I2S linear prescaler

$I2SDIV[7:0] = 0$  or  $I2SDIV[7:0] = 1$  are forbidden values.

Refer to [Section 32.7.4 on page 1124](#).

*Note: These bits should be configured when the I2S is disabled. They are used only when the I2S is in master mode.*

*They are not used in SPI mode.*

## 32.9.10 SPI/I2S register map

Table 206 shows the SPI/I2S register map and reset values.

Table 206. SPI register map and reset values

| Offset | Register     | 31   | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21   | 20   | 19   | 18   | 17   | 16   | 15            | 14       | 13        | 12         | 11      | 10          | 9      | 8           | 7   | 6        | 5      | 4        | 3      | 2           | 1       | 0       |   |  |  |  |

Refer to [Section 2.2.2](#) for the register boundary addresses.

## 33 Serial audio interface (SAI)

### 33.1 Introduction

The SAI interface (Serial Audio Interface) offers a wide set of audio protocols due to its flexibility and wide range of configurations. Many stereo or mono audio applications may be targeted. I2S standards, LSB or MSB-justified, PCM/DSP, TDM, and AC'97 protocols may be addressed for example. SPDIF output is offered when the audio block is configured as a transmitter.

To bring this level of flexibility and reconfigurability, the SAI contains two independent audio sub-blocks. Each block has its own clock generator and I/O line controller.

The SAI can work in master or slave configuration. The audio sub-blocks can be either receiver or transmitter and can work synchronously or not (with respect to the other one).

The SAI can be connected with other SAIs to work synchronously.

## 33.2 SAI main features

- Two independent audio sub-blocks which can be transmitters or receivers with their respective FIFO.
- 8-word integrated FIFOs for each audio sub-block.
- Synchronous or asynchronous mode between the audio sub-blocks.
- Possible synchronization between multiple SAIs.
- Master or slave configuration independent for both audio sub-blocks.
- Clock generator for each audio block to target independent audio frequency sampling when both audio sub-blocks are configured in master mode.
- Data size configurable: 8-, 10-, 16-, 20-, 24-, 32-bit.
- Audio protocol: I2S, LSB or MSB-justified, PCM/DSP, TDM, AC'97
- SPDIF output available if required.
- Up to 16 slots available with configurable size.
- Number of bits by frame can be configurable.
- Frame synchronization active level configurable (offset, bit length, level).
- First active bit position in the slot is configurable.
- LSB first or MSB first for data transfer.
- Mute mode.
- Stereo/Mono audio frame capability.
- Communication clock strobing edge configurable (SCK).
- Error flags with associated interrupts if enabled respectively.
  - Overrun and underrun detection,
  - Anticipated frame synchronization signal detection in slave mode,
  - Late frame synchronization signal detection in slave mode,
  - Codec not ready for the AC'97 mode in reception.
- Interruption sources when enabled:
  - Errors,
  - FIFO requests.
- 2-channel DMA interface.

### 33.3 SAI functional description

#### 33.3.1 SAI block diagram

Figure 395 shows the SAI block diagram while Table 207 and Table 208 list SAI internal and external signals.

Figure 395. SAI functional block diagram

The SAI is mainly composed of two audio sub-blocks with their own clock generator. Each audio block integrates a 32-bit shift register controlled by their own functional state machine. Data are stored or read from the dedicated FIFO. FIFO may be accessed by the CPU, or by DMA in order to leave the CPU free during the communication. Each audio block is independent. They can be synchronous with each other.

An I/O line controller manages a set of 4 dedicated pins (SD, SCK, FS, MCLK) for a given audio block in the SAI. Some of these pins can be shared if the two sub-blocks are declared as synchronous to leave some free to be used as general purpose I/Os. The MCLK pin can be output, or not, depending on the application, the decoder requirement and whether the audio block is configured as the master.

If one SAI is configured to operate synchronously with another one, even more I/Os can be freed (except for pins `SD_x`).

The functional state machine can be configured to address a wide range of audio protocols. Some registers are present to set-up the desired protocols (audio frame waveform generator).

The audio sub-block can be a transmitter or receiver, in master or slave mode. The master mode means the SCK\_x bit clock and the frame synchronization signal are generated from the SAI, whereas in slave mode, they come from another external or internal master. There is a particular case for which the FS signal direction is not directly linked to the master or slave mode definition. In AC'97 protocol, it will be an SAI output even if the SAI (link controller) is set-up to consume the SCK clock (and so to be in Slave mode).

**Note:** For ease of reading of this section, the notation SAI\_x refers to SAI\_A or SAI\_B, where 'x' represents the SAI A or B sub-block.

### 33.3.2 SAI pins and internal signals

**Table 207. SAI internal input/output signals**

| Internal signal name                 | Signal type  | Description                                                                              |
|--------------------------------------|--------------|------------------------------------------------------------------------------------------|
| sai_a_gbl_it/<br>sai_b_gbl_it        | Output       | Audio block A and B global interrupts.                                                   |
| sai_a_dma,<br>sai_b_dma              | Input/output | Audio block A and B DMA acknowledges and requests.                                       |
| sai_sync_out_sck,<br>sai_sync_out_fs | Output       | Internal clock and frame synchronization output signals exchanged with other SAI blocks. |
| sai_sync_in_sck,<br>sai_sync_in_fs   | Input        | Internal clock and frame synchronization input signals exchanged with other SAI blocks.  |
| sai_a_ker_ck/<br>sai_b_ker_ck        | Input        | Audio block A/B kernel clock.                                                            |
| sai_pclk                             | Input        | APB clock.                                                                               |

**Table 208. SAI input/output pins**

| Name         | Signal type  | Comments                                        |
|--------------|--------------|-------------------------------------------------|
| SAI_SCK_A/B  | Input/output | Audio block A/B bit clock.                      |
| SAI_MCLK_A/B | Output       | Audio block A/B master clock.                   |
| SAI_SD_A/B   | Input/output | Data line for block A/B.                        |
| SAI_FS_A/B   | Input/output | Frame synchronization line for audio block A/B. |

### 33.3.3 Main SAI modes

Each audio sub-block of the SAI can be configured to be master or slave via MODE bits in the SAI\_xCR1 register of the selected audio block.

#### Master mode

In master mode, the SAI delivers the timing signals to the external connected device:

- The bit clock and the frame synchronization are output on pin SCK\_x and FS\_x, respectively.
- If needed, the SAI can also generate a master clock on MCLK\_x pin.

Both SCK\_x, FS\_x and MCLK\_x are configured as outputs.

### Slave mode

The SAI expects to receive timing signals from an external device.

- If the SAI sub-block is configured in asynchronous mode, then SCK\_x and FS\_x pins are configured as inputs.
- If the SAI sub-block is configured to operate synchronously with another SAI interface or with the second audio sub-block, the corresponding SCK\_x and FS\_x pins are left free to be used as general purpose I/Os.

In slave mode, MCLK\_x pin is not used and can be assigned to another function.

It is recommended to enable the slave device before enabling the master.

### Configuring and enabling SAI modes

Each audio sub-block can be independently defined as a transmitter or receiver through the MODE bit in the SAI\_xCR1 register of the corresponding audio block. As a result, SAI\_SD\_x pin will be respectively configured as an output or an input.

Two master audio blocks in the same SAI can be configured with two different MCLK and SCK clock frequencies. In this case they have to be configured in asynchronous mode.

Each of the audio blocks in the SAI are enabled by SAIEN bit in the SAI\_xCR1 register. As soon as this bit is active, the transmitter or the receiver is sensitive to the activity on the clock line, data line and synchronization line in slave mode.

In master TX mode, enabling the audio block immediately generates the bit clock for the external slaves even if there is no data in the FIFO. However FS signal generation is conditioned by the presence of data in the FIFO. After the FIFO receives the first data to transmit, this data is output to external slaves. If there is no data to transmit in the FIFO, 0 values are then sent in the audio frame with an underrun flag generation.

In slave mode, the audio frame starts when the audio block is enabled and when a start of frame is detected.

In Slave TX mode, no underrun event is possible on the first frame after the audio block is enabled, because the mandatory operating sequence in this case is:

1. Write into the SAI\_xDR (by software or by DMA).
2. Wait until the FIFO threshold (FLH) flag is different from 0b000 (FIFO empty).
3. Enable the audio block in slave transmitter mode.

### 33.3.4 SAI synchronization mode

There are two levels of synchronization, either at audio sub-block level or at SAI level.

#### Internal synchronization

An audio sub-block can be configured to operate synchronously with the second audio sub-block in the same SAI. In this case, the bit clock and the frame synchronization signals are shared to reduce the number of external pins used for the communication. The audio block configured in synchronous mode sees its own SCK\_x, FS\_x, and MCLK\_x pins released back as GPIOs while the audio block configured in asynchronous mode is the one for which FS\_x and SCK\_x and MCLK\_x I/O pins are relevant (if the audio block is considered as master).

Typically, the audio block in synchronous mode can be used to configure the SAI in full duplex mode. One of the two audio blocks can be configured as a master and the other as slave, or both as slaves with one asynchronous block (corresponding SYNCEN[1:0] bits set to 00 in SAI\_xCR1) and one synchronous block (corresponding SYNCEN[1:0] bits set to 01 in the SAI\_xCR1).

**Note:** *Due to internal resynchronization stages, PCLK APB frequency must be higher than twice the bit rate clock frequency.*

### External synchronization

The audio sub-blocks can also be configured to operate synchronously with another SAI. This can be done as follow:

1. The SAI, which is configured as the source from which the other SAI is synchronized, has to define which of its audio sub-block is supposed to provide the FS and SCK signals to other SAI. This is done by programming SYNCOUT[1:0] bits.
2. The SAI which shall receive the synchronization signals has to select which SAI will provide the synchronization by setting the proper value on SYNCIN[1:0] bits. For each of the two SAI audio sub-blocks, the user must then specify if it operates synchronously with the other SAI via the SYNCEN bit.

**Note:** *SYNCIN[1:0] and SYNCOUT[1:0] bits are located into the SAI\_GCR register, and SYNCEN bits into SAI\_xCR1 register.*

If both audio sub-blocks in a given SAI need to be synchronized with another SAI, it is possible to choose one of the following configurations:

- Configure each audio block to be synchronous with another SAI block through the SYNCEN[1:0] bits.
- Configure one audio block to be synchronous with another SAI through the SYNCEN[1:0] bits. The other audio block is then configured as synchronous with the second SAI audio block through SYNCEN[1:0] bits.

The following table shows how to select the proper synchronization signal depending on the SAI block used. For example SAI2 can select the synchronization from SAI1 by setting SAI2 SYNCIN to 0. If SAI1 wants to select the synchronization coming from SAI2, SAI1 SYNCIN must be set to 1. Positions noted as 'Res.' shall not be used.

**Table 209. External synchronization selection**

| Block instance | SYNCIN= 3 | SYNCIN= 2 | SYNCIN= 1 | SYNCIN= 0 |
|----------------|-----------|-----------|-----------|-----------|
| SAI1           | Res.      | Res.      | SAI2 sync | Res.      |
| SAI2           | Res.      | Res.      | Res.      | SAI1 sync |

### 33.3.5 Audio data size

The audio frame can target different data sizes by configuring bit DS[2:0] in the SAI\_xCR1 register. The data sizes may be 8, 10, 16, 20, 24 or 32 bits. During the transfer, either the MSB or the LSB of the data are sent first, depending on the configuration of bit LSBFIRST in the SAI\_xCR1 register.

### 33.3.6 Frame synchronization

The FS signal acts as the Frame synchronization signal in the audio frame (start of frame). The shape of this signal is completely configurable in order to target the different audio protocols with their own specificities concerning this Frame synchronization behavior. This reconfigurability is done using register SAI\_xFRCR. [Figure 396](#) illustrates this flexibility.

**Figure 396. Audio frame**

In AC'97 mode or in SPDIF mode (bit PRTCFG[1:0] = 10 or PRTCFG[1:0] = 01 in the SAI\_xCR1 register), the frame synchronization shape is forced to match the AC'97 protocol. The SAI\_xFRCR register value is ignored.

Each audio block is independent and consequently each one requires a specific configuration.

#### Frame length

- Master mode

The audio frame length can be configured to up to 256 bit clock cycles, by setting FRL[7:0] field in the SAI\_xFRCR register.

If the frame length is greater than the number of declared slots for the frame, the remaining bits to transmit will be extended to 0 or the SD line will be released to HI-z depending the state of bit TRIS in the SAI\_xCR2 register (refer to [FS signal role](#)). In reception mode, the remaining bit is ignored.

If bit NODIV is cleared, (FRL+1) must be equal to a power of 2, from 8 to 256, to ensure that an audio frame contains an integer number of MCLK pulses per bit clock cycle.

If bit NODIV is set, the (FRL+1) field can take any value from 8 to 256. Refer to [Section 33.3.8: SAI clock generator](#).

- Slave mode

The audio frame length is mainly used to specify to the slave the number of bit clock cycles per audio frame sent by the external master. It is used mainly to detect from the master any anticipated or late occurrence of the Frame synchronization signal during an on-going audio frame. In this case an error will be generated. For more details refer to [Section 33.3.13: Error flags](#).

In slave mode, there are no constraints on the FRL[7:0] configuration in the SAI\_xFRCR register.

The number of bits in the frame is equal to FRL[7:0] + 1.

The minimum number of bits to transfer in an audio frame is 8.

### Frame synchronization polarity

FSPOL bit in the SAI\_xFRCR register sets the active polarity of the FS pin from which a frame is started. The start of frame is edge sensitive.

In slave mode, the audio block waits for a valid frame to start transmitting or receiving. Start of frame is synchronized to this signal. It is effective only if the start of frame is not detected during an ongoing communication and assimilated to an anticipated start of frame (refer to [Section 33.3.13: Error flags](#)).

In master mode, the frame synchronization is sent continuously each time an audio frame is complete until the SAIEN bit in the SAI\_xCR1 register is cleared. If no data are present in the FIFO at the end of the previous audio frame, an underrun condition will be managed as described in [Section 33.3.13: Error flags](#), but the audio communication flow will not be interrupted.

### Frame synchronization active level length

The FSALL[6:0] bits of the SAI\_xFRCR register allow configuring the length of the active level of the Frame synchronization signal. The length can be set from 1 to 128 bit clock cycles.

As an example, the active length can be half of the frame length in I2S, LSB or MSB-justified modes, or one-bit wide for PCM/DSP or TDM mode.

### Frame synchronization offset

Depending on the audio protocol targeted in the application, the Frame synchronization signal can be asserted when transmitting the last bit or the first bit of the audio frame (this is the case in I2S standard protocol and in MSB-justified protocol, respectively). FSOFF bit in the SAI\_xFRCR register allows to choose one of the two configurations.

### FS signal role

The FS signal can have a different meaning depending on the FS function. FSDEF bit in the SAI\_xFRCR register selects which meaning it will have:

- 0: start of frame, like for instance the PCM/DSP, TDM, AC'97, audio protocols,
- 1: start of frame and channel side identification within the audio frame like for the I2S, the MSB or LSB-justified protocols.

When the FS signal is considered as a start of frame and channel side identification within the frame, the number of declared slots must be considered to be half the number for the left channel and half the number for the right channel. If the number of bit clock cycles on half audio frame is greater than the number of slots dedicated to a channel side, and TRIS = 0, 0 is sent for transmission for the remaining bit clock cycles in the SAI\_xCR2 register. Otherwise if TRIS = 1, the SD line is released to HI-Z. In reception mode, the remaining bit clock cycles are not considered until the channel side changes.

**Figure 397. FS role is start of frame + channel side identification (FSDEF = TRIS = 1)**

1. The frame length should be even.

If FSDEF bit in SAI\_xFRCR is kept clear, so FS signal is equivalent to a start of frame, and if the number of slots defined in NBSLOT[3:0] in SAI\_xSLOTR multiplied by the number of bits by slot configured in SLOTSZ[1:0] in SAI\_xSLOTR is less than the frame size (bit FRL[7:0] in the SAI\_xFRCR register), then:

- if TRIS = 0 in the SAI\_xCR2 register, the remaining bit after the last slot will be forced to 0 until the end of frame in case of transmitter,
- if TRIS = 1, the line will be released to HI-Z during the transfer of these remaining bits. In reception mode, these bits are discarded.

Figure 398. FS role is start of frame (FSDEF = 0)

The FS signal is not used when the audio block in transmitter mode is configured to get the SPDIF output on the SD line. The corresponding FS I/O will be released and left free for other purposes.

### 33.3.7 Slot configuration

The slot is the basic element in the audio frame. The number of slots in the audio frame is equal to  $\text{NBSLOT}[3:0] + 1$ .

The maximum number of slots per audio frame is fixed at 16.

For AC'97 protocol or SPDIF (when bit  $\text{PRTCFCFG}[1:0] = 10$  or  $\text{PRTCFCFG}[1:0] = 01$ ), the number of slots is automatically set to target the protocol specification, and the value of  $\text{NBSLOT}[3:0]$  is ignored.

Each slot can be defined as a valid slot, or not, by setting  $\text{SLOTEN}[15:0]$  bits of the  $\text{SAI\_xSLOTR}$  register.

When an invalid slot is transferred, the SD data line is either forced to 0 or released to HI-z depending on TRIS bit configuration (refer to [Output data line management on an inactive slot](#)) in transmitter mode. In receiver mode, the received value from the end of this slot is ignored. Consequently, there will be no FIFO access and so no request to read or write the FIFO linked to this inactive slot status.

The slot size is also configurable as shown in [Figure 399](#). The size of the slots is selected by setting  $\text{SLOTSZ}[1:0]$  bits in the  $\text{SAI\_xSLOTR}$  register. The size is applied identically for each slot in an audio frame.

**Figure 399. Slot size configuration with FBOFF = 0 in SAI\_xSLOTR**

It is possible to choose the position of the first data bit to transfer within the slots. This offset is configured by FBOFF[4:0] bits in the SAI\_xSLOTR register. 0 values will be injected in transmitter mode from the beginning of the slot until this offset position is reached. In reception, the bit in the offset phase is ignored. This feature targets the LSB justified protocol (if the offset is equal to the slot size minus the data size).

**Figure 400. First bit offset**

It is mandatory to respect the following conditions to avoid bad SAI behavior:

- $FBOFF \leq (SLOTSZ - DS)$ ,
- $DS \leq SLOTSZ$ ,
- $NBSLOT \times SLOTSZ \leq FRL$  (frame length),

The number of slots must be even when bit FSDEF in the SAI\_xFRCR register is set.

In AC'97 and SPDIF protocol (bit PRTCFG[1:0] = 10 or PRTCFG[1:0] = 01), the slot size is automatically set as defined in [Section 33.3.10: AC'97 link controller](#).

### 33.3.8 SAI clock generator

Each audio block has its own clock generator that makes these two blocks completely independent. There is no difference in terms of functionality between these two clock generators.

When the audio block is configured as Master, the clock generator provides the communication clock (the bit clock) and the master clock for external decoders.

When the audio block is defined as slave, the clock generator is OFF.

[Figure 401](#) illustrates the architecture of the audio block clock generator.

**Figure 401. Audio block clock generator overview**

**Note:** If *NODIV* is set to 1, the *MCLK\_x* signal will be set at 0 level if this pin is configured as the SAI pin in GPIO peripherals.

The clock source for the clock generator comes from the product clock controller. The *sai\_x\_ker\_ck* clock is equivalent to the master clock which can be divided for the external decoders using bit *MCKDIV[3:0]*:

$MCLK_x = sai\_x\_ker\_ck / (MCKDIV[3:0] * 2)$ , if *MCKDIV[3:0]* is not equal to 0000.

$MCLK_x = sai\_x\_ker\_ck$ , if *MCKDIV[3:0]* is equal to 0000.

*MCLK\_x* signal is used only in TDM.

The division must be even in order to keep 50% on the Duty cycle on the *MCLK\_x* output and on the *SCK\_x* clock. If bit *MCKDIV[3:0]* = 0000, division by one is applied to obtain *MCLK\_x* equal to *sai\_x\_ker\_ck*.

In the SAI, the single ratio *MCLK/FS* = 256 is considered. Mostly, three frequency ranges will be encountered as illustrated in [Table 210](#).

Table 210. Example of possible audio frequency sampling range

| Input sai_x_ker_ck clock frequency | Most usual audio frequency sampling achievable | MCKDIV[3:0]        |
|------------------------------------|------------------------------------------------|--------------------|
| 192 kHz x 256                      | 192 kHz                                        | MCKDIV[3:0] = 0000 |
|                                    | 96 kHz                                         | MCKDIV[3:0] = 0001 |
|                                    | 48 kHz                                         | MCKDIV[3:0] = 0010 |
|                                    | 16 kHz                                         | MCKDIV[3:0] = 0110 |
|                                    | 8 kHz                                          | MCKDIV[3:0] = 1100 |
| 44.1 kHz x 256                     | 44.1 kHz                                       | MCKDIV[3:0] = 0000 |
|                                    | 22.05 kHz                                      | MCKDIV[3:0] = 0001 |
|                                    | 11.025 kHz                                     | MCKDIV[3:0] = 0010 |
| sai_x_ker_ck = MCLK <sup>(1)</sup> | MCLK                                           | MCKDIV[3:0] = 0000 |

1. This may happen when the product clock controller selects an external clock source, instead of PLL clock.

The master clock can be generated externally on an I/O pad for external decoders if the corresponding audio block is declared as master with bit NODIV = 0 in the SAI\_xCR1 register. In slave, the value set in this last bit is ignored since the clock generator is OFF, and the MCLK\_x I/O pin is released for use as a general purpose I/O.

The bit clock is derived from the master clock. The bit clock divider sets the divider factor between the bit clock (SCK\_x) and the master clock (MCLK\_x) following the formula:

$$SCK\_x = MCLK \times (FRL[7:0] + 1) / 256$$

where:

256 is the fixed ratio between MCLK and the audio frequency sampling.

FRL[7:0] is the number of bit clock cycles- 1 in the audio frame, configured in the SAI\_xFRCR register.

In master mode it is mandatory that (FRL[7:0] + 1) is equal to a number with a power of 2 (refer to [Section 33.3.6: Frame synchronization](#)) to obtain an even integer number of MCLK\_x pulses by bit clock cycle. The 50% duty cycle is guaranteed on the bit clock (SCK\_x).

The sai\_x\_ker\_ck clock can also be equal to the bit clock frequency. In this case, NODIV bit in the SAI\_xCR1 register should be set and the value inside the MCKDIV divider and the bit clock divider will be ignored. In this case, the number of bits per frame is fully configurable without the need to be equal to a power of two.

The bit clock strobing edge on SCK can be configured by bit CKSTR in the SAI\_xCR1 register.

Refer to [Section 33.3.11: SPDIF output](#) for details on clock generator programming in SPDIF mode.

### 33.3.9 Internal FIFOs

Each audio block in the SAI has its own FIFO. Depending if the block is defined to be a transmitter or a receiver, the FIFO can be written or read, respectively. There is therefore only one FIFO request linked to **FREQ** bit in the **SAI\_xSR** register.

An interrupt is generated if **FREQIE** bit is enabled in the **SAI\_xIM** register. This depends on:

- FIFO threshold setting (**FLVL** bits in **SAI\_xCR2**)
- Communication direction (transmitter or receiver). Refer to [Interrupt generation in transmitter mode](#) and [Interrupt generation in reception mode](#).

#### Interrupt generation in transmitter mode

The interrupt generation depends on the FIFO configuration in transmitter mode:

- When the FIFO threshold bits in **SAI\_xCR2** register are configured as FIFO empty (**FTH**[2:0] set to 0b000), an interrupt is generated (**FREQ** bit set by hardware to 1 in **SAI\_xSR** register) if no data are available in **SAI\_xDR** register (**FLVL**[2:0] bits in **SAI\_xSR** is less than 001b). This Interrupt (**FREQ** bit in **SAI\_xSR** register) is cleared by hardware when the FIFO is no more empty (**FLVL**[2:0] bits in **SAI\_xSR** are different from 0b000) i.e one or more data are stored in the FIFO.
- When the FIFO threshold bits in **SAI\_xCR2** register are configured as FIFO quarter full (**FTH**[2:0] set to 001b), an interrupt is generated (**FREQ** bit set by hardware to 1 in **SAI\_xSR** register) if less than a quarter of the FIFO contains data (**FLVL**[2:0] bits in **SAI\_xSR** are less than 0b010). This Interrupt (**FREQ** bit in **SAI\_xSR** register) is cleared by hardware when at least a quarter of the FIFO contains data (**FLVL**[2:0] bits in **SAI\_xSR** are higher or equal to 0b010).
- When the FIFO threshold bits in **SAI\_xCR2** register are configured as FIFO half full (**FTH**[2:0] set to 0b010), an interrupt is generated (**FREQ** bit set by hardware to 1 in **SAI\_xSR** register) if less than half of the FIFO contains data (**FLVL**[2:0] bits in **SAI\_xSR** are less than 011b). This Interrupt (**FREQ** bit in **SAI\_xSR** register) is cleared by hardware when at least half of the FIFO contains data (**FLVL**[2:0] bits in **SAI\_xSR** are higher or equal to 011b).
- When the FIFO threshold bits in **SAI\_xCR2** register are configured as FIFO three quarter (**FTH**[2:0] set to 011b), an interrupt is generated (**FREQ** bit is set by hardware to 1 in **SAI\_xSR** register) if less than three quarters of the FIFO contain data (**FLVL**[2:0] bits in **SAI\_xSR** are less than 0b100). This Interrupt (**FREQ** bit in **SAI\_xSR** register) is cleared by hardware when at least three quarters of the FIFO contain data (**FLVL**[2:0] bits in **SAI\_xSR** are higher or equal to 0b100).
- When the FIFO threshold bits in **SAI\_xCR2** register are configured as FIFO full (**FTH**[2:0] set to 0b100), an interrupt is generated (**FREQ** bit is set by hardware to 1 in **SAI\_xSR** register) if the FIFO is not full (**FLVL**[2:0] bits in **SAI\_xSR** is less than 101b). This Interrupt (**FREQ** bit in **SAI\_xSR** register) is cleared by hardware when the FIFO is full (**FLVL**[2:0] bits in **SAI\_xSR** is equal to 101b value).

#### Interrupt generation in reception mode

The interrupt generation depends on the FIFO configuration in reception mode:

- When the FIFO threshold bits in **SAI\_xCR2** register are configured as FIFO empty (**FTH**[2:0] set to 0b000), an interrupt is generated (**FREQ** bit is set by hardware to 1 in **SAI\_xSR** register) if at least one data is available in **SAI\_xDR** register (**FLVL**[2:0] bits in **SAI\_xSR** is higher or equal to 001b). This Interrupt (**FREQ** bit in **SAI\_xSR** register) is

cleared by hardware when the FIFO becomes empty (FLVL[2:0] bits in SAI\_xSR is equal to 0b000) i.e no data are stored in FIFO.

- When the FIFO threshold bits in SAI\_xCR2 register are configured as FIFO quarter fully (FTH[2:0] set to 001b), an interrupt is generated (FREQ bit is set by hardware to 1 in SAI\_xSR register) if at least one quarter of the FIFO data locations are available (FLVL[2:0] bits in SAI\_xSR is higher or equal to 0b010). This Interrupt (FREQ bit in SAI\_xSR register) is cleared by hardware when less than a quarter of the FIFO data locations become available (FLVL[2:0] bits in SAI\_xSR is less than 0b010).
- When the FIFO threshold bits in SAI\_xCR2 register are configured as FIFO half fully (FTH[2:0] set to 0b010 value), an interrupt is generated (FREQ bit is set by hardware to 1 in SAI\_xSR register) if at least half of the FIFO data locations are available (FLVL[2:0] bits in SAI\_xSR is higher or equal to 011b). This Interrupt (FREQ bit in SAI\_xSR register) is cleared by hardware when less than half of the FIFO data locations become available (FLVL[2:0] bits in SAI\_xSR is less than 011b).
- When the FIFO threshold bits in SAI\_xCR2 register are configured as FIFO three quarter full (FTH[2:0] set to 011b value), an interrupt is generated (FREQ bit is set by hardware to 1 in SAI\_xSR register) if at least three quarters of the FIFO data locations are available (FLVL[2:0] bits in SAI\_xSR is higher or equal to 0b100). This Interrupt (FREQ bit in SAI\_xSR register) is cleared by hardware when the FIFO has less than three quarters of the FIFO data locations available (FLVL[2:0] bits in SAI\_xSR is less than 0b100).
- When the FIFO threshold bits in SAI\_xCR2 register are configured as FIFO full (FTH[2:0] set to 0b100), an interrupt is generated (FREQ bit is set by hardware to 1 in SAI\_xSR register) if the FIFO is full (FLVL[2:0] bits in SAI\_xSR is equal to 101b). This Interrupt (FREQ bit in SAI\_xSR register) is cleared by hardware when the FIFO is not full (FLVL[2:0] bits in SAI\_xSR is less than 101b).

Like interrupt generation, the SAI can use the DMA if DMAEN bit in the SAI\_xCR1 register is set. The FREQ bit assertion mechanism is the same as the interruption generation mechanism described above for FREQIE.

Each FIFO is an 8-word FIFO. Each read or write operation from/to the FIFO targets one word FIFO location whatever the access size. Each FIFO word contains one audio slot. FIFO pointers are incremented by one word after each access to the SAI\_xDR register.

Data should be right aligned when it is written in the SAI\_xDR.

Data received will be right aligned in the SAI\_xDR.

The FIFO pointers can be reinitialized when the SAI is disabled by setting bit FFLUSH in the SAI\_xCR2 register. If FFLUSH is set when the SAI is enabled the data present in the FIFO will be lost automatically.

### 33.3.10 AC'97 link controller

The SAI is able to work as an AC'97 link controller. In this protocol:

- The slot number and the slot size are fixed.
- The frame synchronization signal is perfectly defined and has a fixed shape.

To select this protocol, set PRTCFG[1:0] bits in the SAI\_xCR1 register to 10. When AC'97 mode is selected, only data sizes of 16 or 20 bits can be used, otherwise the SAI behavior is not guaranteed.

- NBSLOT[3:0] and SLOTSZ[1:0] bits are consequently ignored.
- The number of slots is fixed to 13 slots. The first one is 16-bit wide and all the others are 20-bit wide (data slots).
- FBOFF[4:0] bits in the SAI\_xSLOTR register are ignored.
- The SAI\_xFRCR register is ignored.
- The MCLK is not used.

The FS signal from the block defined as asynchronous is configured automatically as an output, since the AC'97 controller link drives the FS signal whatever the master or slave configuration.

Figure 402 shows an AC'97 audio frame structure.

**Figure 402. AC'97 audio frame**

**Note:** In AC'97 protocol, bit 2 of the tag is reserved (always 0), so bit 2 of the TAG is forced to 0 level whatever the value written in the SAI FIFO.

For more details about tag representation, refer to the AC'97 protocol standard.

One SAI can be used to target an AC'97 point-to-point communication.

Using two SAIs (for devices featuring two embedded SAIs) allows controlling three external AC'97 decoders as illustrated in Figure 403.

In SAI1, the audio block A must be declared as asynchronous master transmitter whereas the audio block B is defined to be slave receiver and internally synchronous to the audio block A.

The SAI2 is configured for audio block A and B both synchronous with the external SAI1 in slave receiver mode.

**Figure 403. Example of typical AC'97 configuration on devices featuring at least 2 embedded SAI (three external AC'97 decoders)**

In receiver mode, the SAI acting as an AC'97 link controller requires no FIFO request and so no data storage in the FIFO when the Codec ready bit in the slot 0 is decoded low. If bit CNRDYIE is enabled in the SAI\_xIM register, flag CNRDY will be set in the SAI\_xSR register and an interrupt is generated. This flag is dedicated to the AC'97 protocol.

### Clock generator programming in AC'97 mode

In AC'97 mode, the frame length is fixed at 256 bits, and its frequency shall be set to 48 kHz. The formulas given in [Section 33.3.8: SAI clock generator](#) shall be used with  $FRL = 255$ , in order to generate the proper frame rate ( $F_{FS\_x}$ ).

### 33.3.11 SPDIF output

The SPDIF interface is available in transmitter mode only. It supports the audio IEC60958.

To select SPDIF mode, set PRTCFG[1:0] bit to 01 in the SAI\_xCR1 register.

For SPDIF protocol:

- Only SD data line is enabled.
- FS, SCK, MCLK I/Os pins are left free.
- MODE[1] bit is forced to 0 to select the master mode in order to enable the clock generator of the SAI and manage the data rate on the SD line.
- The data size is forced to 24 bits. The value set in DS[2:0] bits in the SAI\_xCR1 register is ignored.
- The clock generator must be configured to define the symbol-rate, knowing that the bit clock should be twice the symbol-rate. The data is coded in Manchester protocol.
- The SAI\_xFRCR and SAI\_xSLOTR registers are ignored. The SAI is configured internally to match the SPDIF protocol requirements as shown in [Figure 404](#).

**Figure 404. SPDIF format**

A SPDIF block contains 192 frames. Each frame is composed of two 32-bit sub-frames, generally one for the left channel and one for the right channel. Each sub-frame is composed of a SOPD pattern (4-bit) to specify if the sub-frame is the start of a block (and so is identifying a channel A) or if it is identifying a channel A somewhere in the block, or if it is referring to channel B (see [Table 211](#)). The next 28 bits of channel information are composed of 24 bits data + 4 status bits.

Table 211. SOPD pattern

| SOPD | Preamble coding |               | Description                           |
|------|-----------------|---------------|---------------------------------------|
|      | last bit is 0   | last bit is 1 |                                       |
| B    | 11101000        | 00010111      | Channel A data at the start of block  |
| W    | 11100100        | 00011011      | Channel B data somewhere in the block |
| M    | 11100010        | 00011101      | Channel A data                        |

The data stored in SAI\_xDR has to be filled as follows:

- SAI\_xDR[26:24] contain the Channel status, User and Validity bits.
- SAI\_xDR[23:0] contain the 24-bit data for the considered channel.

If the data size is 20 bits, then data shall be mapped on SAI\_xDR[23:4].

If the data size is 16 bits, then data shall be mapped on SAI\_xDR[23:8].

SAI\_xDR[23] always represents the MSB.

Figure 405. SAI\_xDR register ordering

**Note:** The transfer is performed always with LSB first.

The SAI first sends the adequate preamble for each sub-frame in a block. The SAI\_xDR is then sent on the SD line (manchester coded). The SAI ends the sub-frame by transferring the Parity bit calculated as described in [Table 212](#).

Table 212. Parity bit calculation

| SAI_xDR[26:0]   | Parity bit P value transferred |
|-----------------|--------------------------------|
| odd number of 0 | 0                              |
| odd number of 1 | 1                              |

The underrun is the only error flag available in the SAI\_xSR register for SPDIF mode since the SAI can only operate in transmitter mode. As a result, the following sequence should be

executed to recover from an underrun error detected via the underrun interrupt or the underrun status bit:

1. Disable the DMA stream (via the DMA peripheral) if the DMA is used.
2. Disable the SAI and check that the peripheral is physically disabled by polling the SAIEN bit in SAI\_xCR1 register.
3. Clear the COVRUNDR flag in the SAI\_xCLRFR register.
4. Flush the FIFO by setting the FFLUSH bit in SAI\_xCR2.  
The software needs to point to the address of the future data corresponding to a start of new block (data for preamble B). If the DMA is used, the DMA source base address pointer should be updated accordingly.
5. Enable again the DMA stream (DMA peripheral) if the DMA used to manage data transfers according to the new source base address.
6. Enable again the SAI by setting SAIEN bit in SAI\_xCR1 register.

### Clock generator programming in SPDIF generator mode

For the SPDIF generator, the SAI shall provide a bit clock twice faster as the symbol-rate. The table hereafter shows usual examples of symbol rates with respect to the audio sampling rate.

**Table 213. Audio sampling frequency versus symbol rates**

| Audio Sampling Frequencies (F <sub>S</sub> ) | Symbol-rate |
|----------------------------------------------|-------------|
| 44.1 kHz                                     | 2.8224 MHz  |
| 48 kHz                                       | 3.072 MHz   |
| 96 kHz                                       | 6.144 MHz   |
| 192 kHz                                      | 12.288 MHz  |

More generally, the relationship between the audio sampling frequency (F<sub>S</sub>) and the bit clock rate (F<sub>SCK\_x</sub>) is given by the formula:

$$F_S = \frac{F_{SCK\_x}}{128}$$

And the bit clock rate is obtained as follow:

$$F_{SCK\_x} = F_{SAI\_CK\_x}$$

### 33.3.12 Specific features

The SAI interface embeds specific features which can be useful depending on the audio protocol selected. These functions are accessible through specific bits of the SAI\_xCR2 register.

#### Mute mode

The mute mode can be used when the audio sub-block is a transmitter or a receiver.

##### Audio sub-block in transmission mode

In transmitter mode, the mute mode can be selected at anytime. The mute mode is active for entire audio frames. The MUTE bit in the SAI\_xCR2 register enables the mute mode when it is set during an ongoing frame.

The mute mode bit is strobed only at the end of the frame. If it is set at this time, the mute mode is active at the beginning of the new audio frame and for a complete frame, until the next end of frame. The bit is then strobed to determine if the next frame will still be a mute frame.

If the number of slots set through NBSLOT[3:0] bits in the SAI\_xSLOTR register is lower than or equal to 2, it is possible to specify if the value sent in mute mode is 0 or if it is the last value of each slot. The selection is done via MUTEVAL bit in the SAI\_xCR2 register.

If the number of slots set in NBSLOT[3:0] bits in the SAI\_xSLOTR register is greater than 2, MUTEVAL bit in the SAI\_xCR2 is meaningless as 0 values are sent on each bit on each slot.

The FIFO pointers are still incremented in mute mode. This means that data present in the FIFO and for which the mute mode is requested are discarded.

##### Audio sub-block in reception mode

In reception mode, it is possible to detect a mute mode sent from the external transmitter when all the declared and valid slots of the audio frame receive 0 for a given consecutive number of audio frames (MUTECNT[5:0] bits in the SAI\_xCR2 register).

When the number of MUTE frames is detected, the MUTEDET flag in the SAI\_xSR register is set and an interrupt can be generated if MUTEDETIE bit is set in SAI\_xCR2.

The mute frame counter is cleared when the audio sub-block is disabled or when a valid slot receives at least one data in an audio frame. The interrupt is generated just once, when the counter reaches the value specified in MUTECNT[5:0] bits. The interrupt event is then reinitialized when the counter is cleared.

*Note:* The mute mode is not available for SPDIF audio blocks.

#### Mono/stereo mode

In transmitter mode, the mono mode can be addressed, without any data preprocessing in memory, assuming the number of slots is equal to 2 (NBSLOT[3:0] = 0001 in SAI\_xSLOTR). In this case, the access time to and from the FIFO will be reduced by 2 since the data for slot 0 is duplicated into data slot 1.

To enable the mono mode,

1. Set MONO bit to 1 in the SAI\_xCR1 register.
2. Set NBSLOT to 1 and SLOTEN to 3 in SAI\_xSLOTR.

In reception mode, the MONO bit can be set and is meaningful only if the number of slots is equal to 2 as in transmitter mode. When it is set, only slot 0 data will be stored in the FIFO. The data belonging to slot 1 will be discarded since, in this case, it is supposed to be the same as the previous slot. If the data flow in reception mode is a real stereo audio flow with a distinct and different left and right data, the MONO bit is meaningless. The conversion from the output stereo file to the equivalent mono file is done by software.

### Companding mode

Telecommunication applications can require to process the data to be transmitted or received using a data companding algorithm.

Depending on the COMP[1:0] bits in the SAI\_xCR2 register (used only when TDM mode is selected), the application software can choose to process or not the data before sending it on SD serial output line (compression) or to expand the data after the reception on SD serial input line (expansion) as illustrated in [Figure 406](#). The two companding modes supported are the  $\mu$ -Law and the A-Law log which are a part of the CCITT G.711 recommendation.

The companding standard used in the United States and Japan is the  $\mu$ -Law. It supports 14 bits of dynamic range (COMP[1:0] = 10 in the SAI\_xCR2 register).

The European companding standard is A-Law and supports 13 bits of dynamic range (COMP[1:0] = 11 in the SAI\_xCR2 register).

Both  $\mu$ -Law or A-Law companding standard can be computed based on 1's complement or 2's complement representation depending on the CPL bit setting in the SAI\_xCR2 register.

In  $\mu$ -Law and A-Law standards, data are coded as 8 bits with MSB alignment. Companded data are always 8-bit wide. For this reason, DS[2:0] bits in the SAI\_xCR1 register will be forced to 010 when the SAI audio block is enabled (SAIEN bit = 1 in the SAI\_xCR1 register) and when one of these two companding modes selected through the COMP[1:0] bits.

If no companding processing is required, COMP[1:0] bits should be kept clear.

**Figure 406. Data companding hardware in an audio block in the SAI**

1. Not applicable when AC'97 or SPDIF are selected.

Expansion and compression mode are automatically selected through the SAI\_xCR2:

- If the SAI audio block is configured to be a transmitter, and if the COMP[1] bit is set in the SAI\_xCR2 register, the compression mode will be applied.
- If the SAI audio block is declared as a receiver, the expansion algorithm will be applied.

### Output data line management on an inactive slot

In transmitter mode, it is possible to choose the behavior of the SD line output when an inactive slot is sent on the data line (via TRIS bit).

- Either the SAI forces 0 on the SD output line when an inactive slot is transmitted, or
- The line is released in HI-z state at the end of the last bit of data transferred, to release the line for other transmitters connected to this node.

It is important to note that the two transmitters cannot attempt to drive the same SD output pin simultaneously, which could result in a short circuit. To ensure a gap between transmissions, if the data is lower than 32-bit, the data can be extended to 32-bit by setting bit SLOTSZ[1:0] = 10 in the SAI\_xSLOTR register. The SD output pin will then be tri-stated at the end of the LSB of the active slot (during the padding to 0 phase to extend the data to 32-bit) if the following slot is declared inactive.

In addition, if the number of slots multiplied by the slot size is lower than the frame length, the SD output line will be tri-stated when the padding to 0 is done to complete the audio frame.

*Figure 407* illustrates these behaviors.

Figure 407. Tristate strategy on SD output line on an inactive slot

When the selected audio protocol uses the FS signal as a start of frame and a channel side identification (bit FSDEF = 1 in the SAI\_xFRCR register), the tristate mode is managed according to [Figure 408](#) (where bit TRIS in the SAI\_xCR1 register = 1, and FSDEF=1, and half frame length is higher than number of slots/2, and NBSLOT=6).

Figure 408. Tristate on output data line in a protocol like I2S

If the TRIS bit in the SAI\_xCR2 register is cleared, all the High impedance states on the SD output line on [Figure 407](#) and [Figure 408](#) are replaced by a drive with a value of 0.

### 33.3.13 Error flags

The SAI implements the following error flags:

- FIFO overrun/underrun
- Anticipated frame synchronization detection
- Late frame synchronization detection
- Codec not ready (AC'97 exclusively)
- Wrong clock configuration in master mode.

#### FIFO overrun/underrun (OVRUDR)

The FIFO overrun/underrun bit is called OVRUDR in the SAI\_xSR register.

The overrun or underrun errors share the same bit since an audio block can be either receiver or transmitter and each audio block in a given SAI has its own SAI\_xSR register.

#### Overrun

When the audio block is configured as receiver, an overrun condition may appear if data are received in an audio frame when the FIFO is full and not able to store the received data. In this case, the received data are lost, the flag OVRUDR in the SAI\_xSR register is set and an interrupt is generated if OVRUDRIE bit is set in the SAI\_xIM register. The slot number, from which the overrun occurs, is stored internally. No more data will be stored into the FIFO until it becomes free to store new data. When the FIFO has at least one data free, the SAI audio block receiver will store new data (from new audio frame) from the slot number which was stored internally when the overrun condition was detected. This avoids data slot de-alignment in the destination memory (refer to [Figure 409](#)).

The OVRUDR flag is cleared when COVRUDR bit is set in the SAI\_xCLRFR register.

Figure 409. Overrun detection error

Underrun

An underrun may occur when the audio block in the SAI is a transmitter and the FIFO is empty when data need to be transmitted. If an underrun is detected, the slot number for which the event occurs is stored and MUTE value (00) is sent until the FIFO is ready to transmit the data corresponding to the slot for which the underrun was detected (refer to [Figure 410](#)). This avoids desynchronization between the memory pointer and the slot in the audio frame.

The underrun event sets the OVRUDR flag in the SAI\_xSR register and an interrupt is generated if the OVRUDRIE bit is set in the SAI\_xIM register. To clear this flag, set COVRUDR bit in the SAI\_xCLRFR register.

The underrun event can occur when the audio sub-block is configured as master or slave.

Figure 410. FIFO underrun event

### Anticipated frame synchronization detection (AFSDET)

The AFSDET flag is used only in slave mode. It is never asserted in master mode. It indicates that a frame synchronization (FS) has been detected earlier than expected since the frame length, the frame polarity, the frame offset are defined and known.

Anticipated frame detection sets the AFSDET flag in the SAI\_xSR register.

This detection has no effect on the current audio frame which is not sensitive to the anticipated FS. This means that “parasitic” events on signal FS are flagged without any perturbation of the current audio frame.

An interrupt is generated if the AFSDETIE bit is set in the SAI\_xIM register. To clear the AFSDET flag, CAFSDET bit must be set in the SAI\_xCLRFR register.

To resynchronize with the master after an anticipated frame detection error, four steps are required:

1. Disable the SAI block by resetting SAIEN bit in SAI\_xCR1 register. To make sure the SAI is disabled, read back the SAIEN bit and check it is set to 0.
2. Flush the FIFO via FFLUS bit in SAI\_xCR2 register.
3. Enable again the SAI peripheral (SAIEN bit set to 1).
4. The SAI block will wait for the assertion on FS to restart the synchronization with master.

*Note: The AFSDET flag is not asserted in AC'97 mode since the SAI audio block acts as a link controller and generates the FS signal even when declared as slave. It has no meaning in SPDIF mode since the FS signal is not used.*

### Late frame synchronization detection

The LFSDET flag in the SAI\_xSR register can be set only when the SAI audio block operates as a slave. The frame length, the frame polarity and the frame offset configuration are known in register SAI\_xFRCR.

If the external master does not send the FS signal at the expecting time thus generating the signal too late, the LFSDET flag is set and an interrupt is generated if LFSDETIE bit is set in the SAI\_xIM register.

The LFSDET flag is cleared when CLFSDET bit is set in the SAI\_xCLRFR register.

The late frame synchronization detection flag is set when the corresponding error is detected. The SAI needs to be resynchronized with the master (see sequence described in [Anticipated frame synchronization detection \(AFSDET\)](#)).

In a noisy environment, glitches on the SCK clock may be wrongly detected by the audio block state machine and shift the SAI data at a wrong frame position. This event can be detected by the SAI and reported as a late frame synchronization detection error.

There is no corruption if the external master is not managing the audio data frame transfer in continuous mode, which should not be the case in most applications. In this case, the LFSDET flag will be set.

*Note: The LFSDET flag is not asserted in AC'97 mode since the SAI audio block acts as a link controller and generates the FS signal even when declared as slave. It has no meaning in SPDIF mode since the signal FS is not used by the protocol.*

### Codec not ready (CNRDY AC'97)

The CNRDY flag in the SAI\_xSR register is relevant only if the SAI audio block is configured to operate in AC'97 mode (PRTCFCFG[1:0] = 10 in the SAI\_xCR1 register). If CNRDYIE bit is set in the SAI\_xIM register, an interrupt is generated when the CNRDY flag is set.

CNRDY is asserted when the Codec is not ready to communicate during the reception of the TAG 0 (slot0) of the AC'97 audio frame. In this case, no data will be automatically stored into the FIFO since the Codec is not ready, until the TAG 0 indicates that the Codec is ready. All the active slots defined in the SAI\_xSLOTR register will be captured when the Codec is ready.

To clear CNRDY flag, CCNRDY bit must be set in the SAI\_xCLRFR register.

### Wrong clock configuration in master mode (with NODIV = 0)

When the audio block operates as a master (MODE[1] = 0) and NODIV bit is equal to 0, the WCKCFG flag is set as soon as the SAI is enabled if the following conditions are met:

- (FRL+1) is not a power of 2, and
- (FRL+1) is not between 8 and 256.

MODE, NODIV, and SAIEN bits belong to SAI\_xCR1 register and FRL to SAI\_xFRCR register.

If WCKCFGIE bit is set, an interrupt is generated when WCKCFG flag is set in the SAI\_xSR register. To clear this flag, set CWCKCFG bit in the SAI\_xCLRFR register.

When WCKCFG bit is set, the audio block is automatically disabled, thus performing a hardware clear of SAIEN bit.

## 33.3.14 Disabling the SAI

The SAI audio block can be disabled at any moment by clearing SAIEN bit in the SAI\_xCR1 register. All the already started frames are automatically completed before the SAI stops working. SAIEN bit remains High until the SAI is completely switched-off at the end of the current audio frame transfer.

If an audio block in the SAI operates synchronously with the other one, the one which is the master must be disabled first.

## 33.3.15 SAI DMA interface

To free the CPU and to optimize bus bandwidth, each SAI audio block has an independent DMA interface to read/write from/to the SAI\_xDR register (to access the internal FIFO). There is one DMA channel per audio sub-block supporting basic DMA request/acknowledge protocol.

To configure the audio sub-block for DMA transfer, set DMAEN bit in the SAI\_xCR1 register. The DMA request is managed directly by the FIFO controller depending on the FIFO threshold level (for more details refer to [Section 33.3.9: Internal FIFOs](#)). DMA transfer direction is linked to the SAI audio sub-block configuration:

- If the audio block operates as a transmitter, the audio block FIFO controller outputs a DMA request to load the FIFO with data written in the SAI\_xDR register.
- If the audio block is operates as a receiver, the DMA request is related to read operations from the SAI\_xDR register.

Follow the sequence below to configure the SAI interface in DMA mode:

1. Configure SAI and FIFO threshold levels to specify when the DMA request will be launched.
2. Configure SAI DMA channel.
3. Enable the DMA.
4. Enable the SAI interface.

*Note:* Before configuring the SAI block, the SAI DMA channel must be disabled.

## 33.4 SAI interrupts

The SAI supports 7 interrupt sources as shown in [Table 214](#).

**Table 214. SAI interrupt sources**

| Interrupt source | Interrupt group | Audio block mode                                 | Interrupt enable              | Interrupt clear                                                                                                                                                                                        |
|------------------|-----------------|--------------------------------------------------|-------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| FREQ             | FREQ            | Master or slave<br>Receiver or transmitter       | FREQIE in SAI_xIM register    | Depends on:<br>– FIFO threshold setting (FLVL bits in SAI_xCR2)<br>– Communication direction (transmitter or receiver)<br><br>For more details refer to <a href="#">Section 33.3.9: Internal FIFOs</a> |
| OVRUDR           | ERROR           | Master or slave<br>Receiver or transmitter       | OVRUDRIE in SAI_xIM register  | COVRUDR = 1 in SAI_xCLRFR register                                                                                                                                                                     |
| AFSDDET          | ERROR           | Slave<br>(not used in AC'97 mode and SPDIF mode) | AFSDETIE in SAI_xIM register  | CAFSDET = 1 in SAI_xCLRFR register                                                                                                                                                                     |
| LFSDET           | ERROR           | Slave<br>(not used in AC'97 mode and SPDIF mode) | LFSDETIE in SAI_xIM register  | CLFSDET = 1 in SAI_xCLRFR register                                                                                                                                                                     |
| CNRDY            | ERROR           | Slave<br>(only in AC'97 mode)                    | CNRDYIE in SAI_xIM register   | CCNRDY = 1 in SAI_xCLRFR register                                                                                                                                                                      |
| MUTEDET          | MUTE            | Master or slave<br>Receiver mode only            | MUTEDETIE in SAI_xIM register | CMUTEDET = 1 in SAI_xCLRFR register                                                                                                                                                                    |
| WCKCFG           | ERROR           | Master with NODIV = 0 in SAI_xCR1 register       | WCKCFGIE in SAI_xIM register  | CWCKCFG = 1 in SAI_xCLRFR register                                                                                                                                                                     |

Follow the sequence below to enable an interrupt:

1. Disable SAI interrupt.
2. Configure SAI.
3. Configure SAI interrupt source.
4. Enable SAI.

## 33.5 SAI registers

### 33.5.1 Global configuration register (SAI\_GCR)

Address offset: 0x00

Reset value: 0x0000 0000

|      |      |      |      |      |      |      |      |      |      |              |      |      |      |             |      |
|------|------|------|------|------|------|------|------|------|------|--------------|------|------|------|-------------|------|
| 31   | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21           | 20   | 19   | 18   | 17          | 16   |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res.         | Res. | Res. | Res. | Res.        | Res. |
|      |      |      |      |      |      |      |      |      |      |              |      |      |      |             |      |
| 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5            | 4    | 3    | 2    | 1           | 0    |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | SYNCOUT[1:0] |      | Res. | Res. | SYNCIN[1:0] |      |
|      |      |      |      |      |      |      |      |      |      | rw           | rw   |      |      | rw          | rw   |

Bits 31:6 Reserved, must be kept at reset value.

Bits 5:4 **SYNCOUT[1:0]**: Synchronization outputs

These bits are set and cleared by software.

00: No synchronization output signals. SYNCOUT[1:0] should be configured as “No synchronization output signals” when audio block is configured as SPDIF

01: Block A used for further synchronization for others SAI

10: Block B used for further synchronization for others SAI

11: Reserved. These bits must be set when both audio block (A and B) are disabled.

Bits 3:2 Reserved, must be kept at reset value.

Bits 1:0 **SYNCIN[1:0]**: Synchronization inputs

These bits are set and cleared by software.

Refer to [Table 209: External synchronization selection](#) for information on how to program this field.

These bits must be set when both audio blocks (A and B) are disabled.

They are meaningful if one of the two audio blocks is defined to operate in synchronous mode with an external SAI (SYNCEN[1:0] = 10 in SAI\_ACR1 or in SAI\_BCR1 registers).

### 33.5.2 Configuration register 1 (SAI\_ACR1)

Address offset: 0x004

Reset value: 0x0000 0040

|      |      |             |      |             |      |       |          |             |    |    |      |              |      |           |       |
|------|------|-------------|------|-------------|------|-------|----------|-------------|----|----|------|--------------|------|-----------|-------|
| 31   | 30   | 29          | 28   | 27          | 26   | 25    | 24       | 23          | 22 | 21 | 20   | 19           | 18   | 17        | 16    |
| Res. | Res. | Res.        | Res. | Res.        | Res. | Res.  | Res.     | MCKDIV[3:0] |    |    |      | NODIV        | Res. | DMAEN     | SAIEN |
|      |      |             |      |             |      |       |          | rw          | rw | rw | rw   | rw           |      | rw        | rw    |
| 15   | 14   | 13          | 12   | 11          | 10   | 9     | 8        | 7           | 6  | 5  | 4    | 3            | 2    | 1         | 0     |
| Res. | Res. | OUTD<br>RIV | MONO | SYNCEN[1:0] |      | CKSTR | LSBFIRST | DS[2:0]     |    |    | Res. | PRTCFCG[1:0] |      | MODE[1:0] |       |
|      |      | rw          | rw   | rw          | rw   | rw    | rw       | rw          | rw | rw |      | rw           | rw   | rw        | rw    |

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:20 MCKDIV[3:0]: Master clock divider

These bits are set and cleared by software. These bits are meaningless when the audio block operates in slave mode. They have to be configured when the audio block is disabled.

0000: Divides by 1 the master clock input.

Others: the master clock frequency is calculated accordingly to the following formula:

$$F_{SCK\_x} = \frac{F_{sai\_x\_ker\_ck}}{MCKDIV \times 2}$$

Bit 19 **NODIV**: No divider

This bit is set and cleared by software.

0: Master clock generator is enabled

1: No divider used in the clock generator (in this case Master Clock Divider bit has no effect)

Bit 18 Reserved, must be kept at reset value.

Bit 17 **DMAEN**: DMA enable

This bit is set and cleared by software.

0: DMA disabled

1: DMA enabled

*Note: Since the audio block defaults to operate as a transmitter after reset, the MODE[1:0] bits must be configured before setting DMAEN to avoid a DMA request in receiver mode.*

Bit 16 **SAIEN**: Audio block enable

This bit is set by software.

To switch off the audio block, the application software must program this bit to 0 and poll the bit till it reads back 0, meaning that the block is completely disabled. Before setting this bit to 1, check that it is set to 0, otherwise the enable command will not be taken into account.

This bit allows controlling the state of the SAI audio block. If it is disabled when an audio frame transfer is ongoing, the ongoing transfer completes and the cell is fully disabled at the end of this audio frame transfer.

0: SAI audio block disabled

1: SAI audio block enabled.

*Note: When the SAI block (A or B) is configured in master mode, the clock must be present on the SAI block input before setting SAIEN bit.*

Bits 15:14 Reserved, must be kept at reset value.

Bit 13 **OUTDRIV**: Output drive

This bit is set and cleared by software.

0: Audio block output driven when SAIEN is set

1: Audio block output driven immediately after the setting of this bit.

*Note: This bit has to be set before enabling the audio block and after the audio block configuration.*

Bit 12 **MONO**: Mono mode

This bit is set and cleared by software. It is meaningful only when the number of slots is equal to 2.

When the mono mode is selected, slot 0 data are duplicated on slot 1 when the audio block operates as a transmitter. In reception mode, the slot1 is discarded and only the data received from slot 0 are stored. Refer to [Section : Mono/stereo mode](#) for more details.

0: Stereo mode

1: Mono mode.

Bits 11:10 **SYNCEN[1:0]**: Synchronization enable

These bits are set and cleared by software. They must be configured when the audio sub-block is disabled.

00: audio sub-block in asynchronous mode.

01: audio sub-block is synchronous with the other internal audio sub-block. In this case, the audio sub-block must be configured in slave mode

10: audio sub-block is synchronous with an external SAI embedded peripheral. In this case the audio sub-block should be configured in Slave mode.

11: Reserved

*Note: The audio sub-block should be configured as asynchronous when SPDIF mode is enabled.*

Bit 9 **CKSTR**: Clock strobing edge

This bit is set and cleared by software. It must be configured when the audio block is disabled. This bit has no meaning in SPDIF audio protocol.

0: Signals generated by the SAI change on SCK rising edge, while signals received by the SAI are sampled on the SCK falling edge.

1: Signals generated by the SAI change on SCK falling edge, while signals received by the SAI are sampled on the SCK rising edge.

Bit 8 **LSBFIRST**: Least significant bit first

This bit is set and cleared by software. It must be configured when the audio block is disabled. This bit has no meaning in AC'97 audio protocol since AC'97 data are always transferred with the MSB first. This bit has no meaning in SPDIF audio protocol since in SPDIF data are always transferred with LSB first.

0: Data are transferred with MSB first

1: Data are transferred with LSB first

Bits 7:5 **DS[2:0]**: Data size

These bits are set and cleared by software. These bits are ignored when the SPDIF protocols are selected (bit PRTCFG[1:0]), because the frame and the data size are fixed in such case. When the companding mode is selected through COMP[1:0] bits, DS[1:0] are ignored since the data size is fixed to 8 bits by the algorithm.

These bits must be configured when the audio block is disabled.

000: Reserved

001: Reserved

010: 8 bits

011: 10 bits

100: 16 bits

101: 20 bits

110: 24 bits

111: 32 bits

Bit 4 Reserved, must be kept at reset value.

Bits 3:2 **PRTCFG[1:0]**: Protocol configuration

These bits are set and cleared by software. These bits have to be configured when the audio block is disabled.

00: Free protocol. Free protocol allows to use the powerful configuration of the audio block to address a specific audio protocol (such as I2S, LSB/MSB justified, TDM, PCM/DSP...) by setting most of the configuration register bits as well as frame configuration register.

01: SPDIF protocol

10: AC'97 protocol

11: Reserved

Bits 1:0 **MODE[1:0]**: SAIx audio block mode

These bits are set and cleared by software. They must be configured when SAIx audio block is disabled.

00: Master transmitter

01: Master receiver

10: Slave transmitter

11: Slave receiver

*Note: When the audio block is configured in SPDIF mode, the master transmitter mode is forced (MODE[1:0] = 00).*

### 33.5.3 Configuration register 1 (SAI\_BCR1)

Address offset: 0x024

Reset value: 0x0000 0040

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:20 **MCKDIV[3:0]**: Master clock divider

These bits are set and cleared by software. These bits are meaningless when the audio block operates in slave mode. They have to be configured when the audio block is disabled.

0000: Divides by 1 the master clock input.

Others: the master clock frequency is calculated accordingly to the following formula:

$$F_{SCK\_x} = \frac{F_{sai\_x\_ker\_ck}}{MCKDIV \times 2}$$

Bit 19 **NODIV**: No divider

This bit is set and cleared by software.

0: Master clock generator is enabled

1: No divider used in the clock generator (in this case Master Clock Divider bit has no effect)

Bit 18 Reserved, must be kept at reset value.

Bit 17 **DMAEN**: DMA enable

This bit is set and cleared by software.

0: DMA disabled

1: DMA enabled

*Note: Since the audio block defaults to operate as a transmitter after reset, the **MODE[1:0]** bits must be configured before setting **DMAEN** to avoid a DMA request in receiver mode.*

Bit 16 **SAIEN**: Audio block enable

This bit is set by software.

To switch off the audio block, the application software must program this bit to 0 and poll the bit till it reads back 0, meaning that the block is completely disabled. Before setting this bit to 1, check that it is set to 0, otherwise the enable command will not be taken into account.

This bit allows controlling the state of the SAI audio block. If it is disabled when an audio frame transfer is ongoing, the ongoing transfer completes and the cell is fully disabled at the end of this audio frame transfer.

0: SAI audio block disabled

1: SAI audio block enabled.

*Note: When the SAI block (A or B) is configured in master mode, the clock must be present on the SAI block input before setting **SAIEN** bit.*

Bits 15:14 Reserved, must be kept at reset value.

Bit 13 **OUTDRIV**: Output drive

This bit is set and cleared by software.

0: Audio block output driven when **SAIEN** is set

1: Audio block output driven immediately after the setting of this bit.

*Note: This bit has to be set before enabling the audio block and after the audio block configuration.*

Bit 12 **MONO**: Mono mode

This bit is set and cleared by software. It is meaningful only when the number of slots is equal to 2. When the mono mode is selected, slot 0 data are duplicated on slot 1 when the audio block operates as a transmitter. In reception mode, the slot 1 is discarded and only the data received from slot 0 are stored. Refer to [Section : Mono/stereo mode](#) for more details.

0: Stereo mode

1: Mono mode.

Bits 11:10 **SYNCEN[1:0]**: Synchronization enable

These bits are set and cleared by software. They must be configured when the audio sub-block is disabled.

00: audio sub-block in asynchronous mode.

01: audio sub-block is synchronous with the other internal audio sub-block. In this case, the audio sub-block must be configured in slave mode

10: audio sub-block is synchronous with an external SAI embedded peripheral. In this case the audio sub-block should be configured in Slave mode.

11: Reserved

*Note: The audio sub-block should be configured as asynchronous when SPDIF mode is enabled.*

Bit 9 **CKSTR**: Clock strobing edge

This bit is set and cleared by software. It must be configured when the audio block is disabled. This bit has no meaning in SPDIF audio protocol.

0: Signals generated by the SAI change on SCK rising edge, while signals received by the SAI are sampled on the SCK falling edge.

1: Signals generated by the SAI change on SCK falling edge, while signals received by the SAI are sampled on the SCK rising edge.

**Bit 8 LSBFIRST:** Least significant bit first

This bit is set and cleared by software. It must be configured when the audio block is disabled. This bit has no meaning in AC'97 audio protocol since AC'97 data are always transferred with the MSB first. This bit has no meaning in SPDIF audio protocol since in SPDIF data are always transferred with LSB first.

0: Data are transferred with MSB first

1: Data are transferred with LSB first

**Bits 7:5 DS[2:0]:** Data size

These bits are set and cleared by software. These bits are ignored when the SPDIF protocols are selected (bit PRTCFCFG[1:0]), because the frame and the data size are fixed in such case. When the companding mode is selected through COMP[1:0] bits, DS[1:0] are ignored since the data size is fixed to 8 bits by the algorithm.

These bits must be configured when the audio block is disabled.

000: Reserved

001: Reserved

010: 8 bits

011: 10 bits

100: 16 bits

101: 20 bits

110: 24 bits

111: 32 bits

**Bit 4** Reserved, must be kept at reset value.

**Bits 3:2 PRTCFCFG[1:0]:** Protocol configuration

These bits are set and cleared by software. These bits have to be configured when the audio block is disabled.

00: Free protocol. Free protocol allows to use the powerful configuration of the audio block to address a specific audio protocol (such as I2S, LSB/MSB justified, TDM, PCM/DSP...) by setting most of the configuration register bits as well as frame configuration register.

01: SPDIF protocol

10: AC'97 protocol

11: Reserved

**Bits 1:0 MODE[1:0]:** SAIx audio block mode

These bits are set and cleared by software. They must be configured when SAIx audio block is disabled.

00: Master transmitter

01: Master receiver

10: Slave transmitter

11: Slave receiver

*Note: When the audio block is configured in SPDIF mode, the master transmitter mode is forced (MODE[1:0] = 00). In Master transmitter mode, the audio block starts generating the FS and the clocks immediately.*

### 33.5.4 Configuration register 2 (SAI\_ACR2)

Address offset: 0x008

Reset value: 0x0000 0000

|           |      |      |              |      |      |      |      |          |      |      |         |          |      |      |      |

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:14 **COMP[1:0]**: Companding mode.

These bits are set and cleared by software. The  $\mu$ -Law and the A-Law log are a part of the CCITT G.711 recommendation, the type of complement that will be used depends on *CPL bit*.

The data expansion or data compression are determined by the state of bit *MODE[0]*.

The data compression is applied if the audio block is configured as a transmitter.

The data expansion is automatically applied when the audio block is configured as a receiver.

Refer to [Section : Companding mode](#) for more details.

00: No companding algorithm

01: Reserved.

10:  $\mu$ -Law algorithm

11: A-Law algorithm

*Note: Companding mode is applicable only when TDM is selected.*

Bit 13 **CPL**: Complement bit.

This bit is set and cleared by software.

It defines the type of complement to be used for companding mode

0: 1's complement representation.

1: 2's complement representation.

*Note: This bit has effect only when the companding mode is  $\mu$ -Law algorithm or A-Law algorithm.*

Bits 12:7 **MUTECNT[5:0]**: Mute counter.

These bits are set and cleared by software. They are used only in reception mode.

The value set in these bits is compared to the number of consecutive mute frames detected in reception. When the number of mute frames is equal to this value, the flag *MUTEDET* will be set and an interrupt will be generated if bit *MUTEDETIE* is set.

Refer to [Section : Mute mode](#) for more details.

Bit 6 **MUTEVAL**: Mute value.

This bit is set and cleared by software. It must be written before enabling the audio block: *SAIEN*.

This bit is meaningful only when the audio block operates as a transmitter, the number of slots is lower or equal to 2 and the *MUTE* bit is set.

If more slots are declared, the bit value sent during the transmission in mute mode is equal to 0, whatever the value of *MUTEVAL*.

if the number of slot is lower or equal to 2 and *MUTEVAL* = 1, the *MUTE* value transmitted for each slot is the one sent during the previous frame.

Refer to [Section : Mute mode](#) for more details.

0: Bit value 0 is sent during the mute mode.

1: Last values are sent during the mute mode.

*Note: This bit is meaningless and should not be used for SPDIF audio blocks.*

**Bit 5 MUTE:** Mute.

This bit is set and cleared by software. It is meaningful only when the audio block operates as a transmitter. The MUTE value is linked to value of MUTEVAL if the number of slots is lower or equal to 2, or equal to 0 if it is greater than 2.

Refer to [Section : Mute mode](#) for more details.

0: No mute mode.

1: Mute mode enabled.

*Note: This bit is meaningless and should not be used for SPDIF audio blocks.*

**Bit 4 TRIS:** Tristate management on data line.

This bit is set and cleared by software. It is meaningful only if the audio block is configured as a transmitter. This bit is not used when the audio block is configured in SPDIF mode. It should be configured when SAI is disabled.

Refer to [Section : Output data line management on an inactive slot](#) for more details.

0: SD output line is still driven by the SAI when a slot is inactive.

1: SD output line is released (HI-Z) at the end of the last data bit of the last active slot if the next one is inactive.

**Bit 3 FFLUSH:** FIFO flush.

This bit is set by software. It is always read as 0. This bit should be configured when the SAI is disabled.

0: No FIFO flush.

1: FIFO flush. Programming this bit to 1 triggers the FIFO Flush. All the internal FIFO pointers (read and write) are cleared. In this case data still present in the FIFO are lost (no more transmission or received data lost). Before flushing, SAI DMA stream/interruption must be disabled

**Bits 2:0 FTH[2:0]:** FIFO threshold.

This bit is set and cleared by software.

000: FIFO empty

001: ¼ FIFO

010: ½ FIFO

011: ¾ FIFO

100: FIFO full

101: Reserved

110: Reserved

111: Reserved

|      | rw         | rw   | rw   | rw   | rw   | rw   | rw   | rw       | rw   | rw   | rw   | rw   | rw    | rw    | rw    |

Bits 31:19 Reserved, must be kept at reset value.

Bit 18 **FSOFF**: Frame synchronization offset.

This bit is set and cleared by software. It is meaningless and is not used in AC'97 or SPDIF audio block configuration. This bit must be configured when the audio block is disabled.

0: FS is asserted on the first bit of the slot 0.

1: FS is asserted one bit before the first bit of the slot 0.

Bit 17 **FSPOL**: Frame synchronization polarity.

This bit is set and cleared by software. It is used to configure the level of the start of frame on the FS signal. It is meaningless and is not used in AC'97 or SPDIF audio block configuration.

This bit must be configured when the audio block is disabled.

0: FS is active low (falling edge)

1: FS is active high (rising edge)

Bit 16 **FSDEF**: Frame synchronization definition.

This bit is set and cleared by software.

0: FS signal is a start frame signal

1: FS signal is a start of frame signal + channel side identification

When the bit is set, the number of slots defined in the SAI\_xSLOTR register has to be even. It means that half of this number of slots will be dedicated to the left channel and the other slots for the right channel (e.g: this bit has to be set for I2S or MSB/LSB-justified protocols...).

This bit is meaningless and is not used in AC'97 or SPDIF audio block configuration. It must be configured when the audio block is disabled.

Bit 15 Reserved, must be kept at reset value.

Bits 14:8 **FSALL[6:0]**: Frame synchronization active level length.

These bits are set and cleared by software. They specify the length in number of bit clock (SCK) + 1 (FSALL[6:0] + 1) of the active level of the FS signal in the audio frame

These bits are meaningless and are not used in AC'97 or SPDIF audio block configuration.

They must be configured when the audio block is disabled.

Bits 7:0 **FRL[7:0]**: Frame length.

These bits are set and cleared by software. They define the audio frame length expressed in number of SCK clock cycles: the number of bits in the frame is equal to FRL[7:0] + 1.

The minimum number of bits to transfer in an audio frame must be equal to 8, otherwise the audio block will behaves in an unexpected way. This is the case when the data size is 8 bits and only one slot 0 is defined in NBSLOT[4:0] of SAI\_xSLOTR register (NBSLOT[3:0] = 0000).

In master mode, if the master clock (available on MCLK\_x pin) is used, the frame length should be aligned with a number equal to a power of 2, ranging from 8 to 256. When the master clock is not used (NODIV = 1), it is recommended to program the frame length to an value ranging from 8 to 256.

These bits are meaningless and are not used in AC'97 or SPDIF audio block configuration.

### 33.5.7 Frame configuration register (SAI\_BFRCR)

Bits 31:19 Reserved, must be kept at reset value.

**Bit 18 FSOFF:** Frame synchronization offset.

This bit is set and cleared by software. It is meaningless and is not used in AC'97 or SPDIF audio block configuration. This bit must be configured when the audio block is disabled.

0: FS is asserted on the first bit of the slot 0.

1: FS is asserted one bit before the first bit of the slot 0.

**Bit 17 FSPOL:** Frame synchronization polarity.

This bit is set and cleared by software. It is used to configure the level of the start of frame on the FS signal. It is meaningless and is not used in AC'97 or SPDIF audio block configuration.

This bit must be configured when the audio block is disabled.

0: FS is active low (falling edge)

1: FS is active high (rising edge)

**Bit 16 FSDEF:** Frame synchronization definition.

This bit is set and cleared by software.

0: FS signal is a start frame signal

1: FS signal is a start of frame signal + channel side identification

When the bit is set, the number of slots defined in the SAI\_xSLOTR register has to be even. It means that half of this number of slots will be dedicated to the left channel and the other slots for the right channel (e.g: this bit has to be set for I2S or MSB/LSB-justified protocols...).

This bit is meaningless and is not used in AC'97 or SPDIF audio block configuration. It must be configured when the audio block is disabled.

**Bit 15** Reserved, must be kept at reset value.

**Bits 14:8 FSALL[6:0]:** Frame synchronization active level length.

These bits are set and cleared by software. They specify the length in number of bit clock

(SCK) + 1 (FSALL[6:0] + 1) of the active level of the FS signal in the audio frame

These bits are meaningless and are not used in AC'97 or SPDIF audio block configuration.

They must be configured when the audio block is disabled.

**Bits 7:0 FRL[7:0]:** Frame length.

These bits are set and cleared by software. They define the audio frame length expressed in number of SCK clock cycles: the number of bits in the frame is equal to FRL[7:0] + 1.

The minimum number of bits to transfer in an audio frame must be equal to 8, otherwise the audio block will behaves in an unexpected way. This is the case when the data size is 8 bits and only one slot 0 is defined in NBSLOT[4:0] of SAI\_xSLOTR register (NBSLOT[3:0] = 0000).

In master mode, if the master clock (available on MCLK\_x pin) is used, the frame length should be aligned with a number equal to a power of 2, ranging from 8 to 256. When the master clock is not used (NODIV = 1), it is recommended to program the frame length to an value ranging from 8 to 256.

These bits are meaningless and are not used in AC'97 or SPDIF audio block configuration.

### 33.5.8 Slot register (SAI\_ASLOTR)

Address offset: 0x010

Reset value: 0x0000 0000

*Note: This register has no meaning in AC'97 and SPDIF audio protocol*

|              |      |      |      | rw          | rw | rw | rw | rw          | rw |      | rw         | rw | rw | rw | rw |

Bits 31:16 **SLOTEN[15:0]**: Slot enable.

These bits are set and cleared by software.

Each SLOTEN bit corresponds to a slot position from 0 to 15 (maximum 16 slots).

0: Inactive slot.

1: Active slot.

The slot must be enabled when the audio block is disabled.

They are ignored in AC'97 or SPDIF mode.

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:8 **NBSLOT[3:0]**: Number of slots in an audio frame.

These bits are set and cleared by software.

The value set in this bitfield represents the number of slots + 1 in the audio frame (including the number of inactive slots). The maximum number of slots is 16.

The number of slots should be even if FSDEF bit in the SAI\_xFRCR register is set.

The number of slots must be configured when the audio block is disabled.

They are ignored in AC'97 or SPDIF mode.

Bits 7:6 **SLOTSZ[1:0]**: Slot size

This bits is set and cleared by software.

The slot size must be higher or equal to the data size. If this condition is not respected, the behavior of the SAI will be undetermined.

Refer to [Section : Output data line management on an inactive slot](#) for information on how to drive SD line.

These bits must be set when the audio block is disabled.

They are ignored in AC'97 or SPDIF mode.

00: The slot size is equivalent to the data size (specified in DS[3:0] in the SAI\_xCR1 register).

01: 16-bit

10: 32-bit

11: Reserved

Bit 5 Reserved, must be kept at reset value.

Bits 4:0 **FBOFF[4:0]**: First bit offset

These bits are set and cleared by software.

The value set in this bitfield defines the position of the first data transfer bit in the slot. It represents an offset value. In transmission mode, the bits outside the data field are forced to 0. In reception mode, the extra received bits are discarded.

These bits must be set when the audio block is disabled.

They are ignored in AC'97 or SPDIF mode.

### 33.5.9 Slot register (SAI\_BSLOTR)

Address offset: 0x030

Reset value: 0x0000 0000

**Note:** *This register has no meaning in AC'97 and SPDIF audio protocol*

|              |      |      |      |             |    |    |    |             |    |      |            |    |    |    |    |

Bits 31:16 **SLOTEN[15:0]**: Slot enable.

These bits are set and cleared by software.

Each SLOTEN bit corresponds to a slot position from 0 to 15 (maximum 16 slots).

0: Inactive slot.

1: Active slot.

The slot must be enabled when the audio block is disabled.

They are ignored in AC'97 or SPDIF mode.

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:8 **NBSLOT[3:0]**: Number of slots in an audio frame.

These bits are set and cleared by software.

The value set in this bitfield represents the number of slots + 1 in the audio frame (including the number of inactive slots). The maximum number of slots is 16.

The number of slots should be even if FSDEF bit in the SAI\_xFRCR register is set.

The number of slots must be configured when the audio block is disabled.

They are ignored in AC'97 or SPDIF mode.

Bits 7:6 **SLOTSZ[1:0]**: Slot size

This bits is set and cleared by software.

The slot size must be higher or equal to the data size. If this condition is not respected, the behavior of the SAI will be undetermined.

Refer to [Section : Output data line management on an inactive slot](#) for information on how to drive SD line.

These bits must be set when the audio block is disabled.

They are ignored in AC'97 or SPDIF mode.

00: The slot size is equivalent to the data size (specified in DS[3:0] in the SAI\_xCR1 register).

01: 16-bit

10: 32-bit

11: Reserved

Bit 5 Reserved, must be kept at reset value.

Bits 4:0 **FBOFF[4:0]**: First bit offset

These bits are set and cleared by software.

The value set in this bitfield defines the position of the first data transfer bit in the slot. It represents an offset value. In transmission mode, the bits outside the data field are forced to 0. In reception mode, the extra received bits are discarded.

These bits must be set when the audio block is disabled.

They are ignored in AC'97 or SPDIF mode.

### 33.5.10 Interrupt mask register (SAI\_AIM)

Address offset: 0x014

Reset value: 0x0000 0000

|      |      |      |      |      |      |      |      |      |              |              |             |            |              |              |              |

| 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6            | 5            | 4           | 3          | 2            | 1            | 0            |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | LFSDET<br>IE | AFSDET<br>IE | CNRDY<br>IE | FREQ<br>IE | WCKCFG<br>IE | MUTEDT<br>IE | OVRUDR<br>IE |
|      |      |      |      |      |      |      |      |      | rw           | rw           | rw          | rw         | rw           | rw           | rw           |

Bits 31:7 Reserved, must be kept at reset value.

Bit 6 **LFSDETIE**: Late frame synchronization detection interrupt enable.

This bit is set and cleared by software.

0: Interrupt is disabled

1: Interrupt is enabled

When this bit is set, an interrupt will be generated if the LFSDET bit is set in the SAI\_xSR register.

This bit is meaningless in AC'97, SPDIF mode or when the audio block operates as a master.

Bit 5 **AFSDETIE**: Anticipated frame synchronization detection interrupt enable.

This bit is set and cleared by software.

0: Interrupt is disabled

1: Interrupt is enabled

When this bit is set, an interrupt will be generated if the AFSDET bit in the SAI\_xSR register is set.

This bit is meaningless in AC'97, SPDIF mode or when the audio block operates as a master.

Bit 4 **CNRDYIE**: Codec not ready interrupt enable (AC'97).

This bit is set and cleared by software.

0: Interrupt is disabled

1: Interrupt is enabled

When the interrupt is enabled, the audio block detects in the slot 0 (tag0) of the AC'97 frame if the Codec connected to this line is ready or not. If it is not ready, the CNRDY flag in the SAI\_xSR register is set and an interruption is generated.

This bit has a meaning only if the AC'97 mode is selected through PRTCFG[1:0] bits and the audio block is operates as a receiver.

Bit 3 **FREQIE**: FIFO request interrupt enable.

This bit is set and cleared by software.

0: Interrupt is disabled

1: Interrupt is enabled

When this bit is set, an interrupt is generated if the FREQ bit in the SAI\_xSR register is set.

Since the audio block defaults to operate as a transmitter after reset, the MODE bit must be configured before setting FREQIE to avoid a parasitic interruption in receiver mode,

Bit 2 **WCKCFGIE**: Wrong clock configuration interrupt enable.

This bit is set and cleared by software.

0: Interrupt is disabled

1: Interrupt is enabled

This bit is taken into account only if the audio block is configured as a master (MODE[1] = 0) and NODIV = 0.

It generates an interrupt if the WCKCFG flag in the SAI\_xSR register is set.

*Note: This bit is used only in TDM mode and is meaningless in other modes.*

Bit 1 **MUTEDETIE**: Mute detection interrupt enable.

This bit is set and cleared by software.

0: Interrupt is disabled

1: Interrupt is enabled

When this bit is set, an interrupt is generated if the MUTEDET bit in the SAI\_xSR register is set.

This bit has a meaning only if the audio block is configured in receiver mode.

Bit 0 **OVRUDRIE**: Overrun/underrun interrupt enable.

This bit is set and cleared by software.

0: Interrupt is disabled

1: Interrupt is enabled

When this bit is set, an interrupt is generated if the OVRUDR bit in the SAI\_xSR register is set.

### 33.5.11 Interrupt mask register (SAI\_BIM)

| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | LFSDET<br>IE | AFSDET<br>IE | CNRDY<br>IE | FREQ<br>IE | WCKCFG<br>IE | MUTEDET<br>IE | OVRUDR<br>IE |
|      |      |      |      |      |      |      |      |      | rw           | rw           | rw          | rw         | rw           | rw            | rw           |

Bits 31:7 Reserved, must be kept at reset value.

Bit 6 **LFSDETIE**: Late frame synchronization detection interrupt enable.

This bit is set and cleared by software.

0: Interrupt is disabled

1: Interrupt is enabled

When this bit is set, an interrupt will be generated if the LFSDET bit is set in the SAI\_xSR register.

This bit is meaningless in AC'97, SPDIF mode or when the audio block operates as a master.

Bit 5 **AFSDETIE**: Anticipated frame synchronization detection interrupt enable.

This bit is set and cleared by software.

0: Interrupt is disabled

1: Interrupt is enabled

When this bit is set, an interrupt will be generated if the AFSDET bit in the SAI\_xSR register is set.

This bit is meaningless in AC'97, SPDIF mode or when the audio block operates as a master.

Bit 4 **CNRDYIE**: Codec not ready interrupt enable (AC'97).

This bit is set and cleared by software.

0: Interrupt is disabled

1: Interrupt is enabled

When the interrupt is enabled, the audio block detects in the slot 0 (tag0) of the AC'97 frame if the Codec connected to this line is ready or not. If it is not ready, the CNRDY flag in the SAI\_xSR register is set and an interruption is generated.

This bit has a meaning only if the AC'97 mode is selected through PRTCFG[1:0] bits and the audio block is operates as a receiver.

Bit 3 **FREQIE**: FIFO request interrupt enable.

This bit is set and cleared by software.

0: Interrupt is disabled

1: Interrupt is enabled

When this bit is set, an interrupt is generated if the FREQ bit in the SAI\_xSR register is set.

Since the audio block defaults to operate as a transmitter after reset, the MODE bit must be configured before setting FREQIE to avoid a parasitic interruption in receiver mode,

Bit 2 **WCKCFGIE**: Wrong clock configuration interrupt enable.

This bit is set and cleared by software.

0: Interrupt is disabled

1: Interrupt is enabled

This bit is taken into account only if the audio block is configured as a master (MODE[1] = 0) and NODIV = 0.

It generates an interrupt if the WCKCFG flag in the SAI\_xSR register is set.

*Note: This bit is used only in TDM mode and is meaningless in other modes.*

Bit 1 **MUTEDETIE**: Mute detection interrupt enable.

This bit is set and cleared by software.

0: Interrupt is disabled

1: Interrupt is enabled

When this bit is set, an interrupt is generated if the MUTEDET bit in the SAI\_xSR register is set.

This bit has a meaning only if the audio block is configured in receiver mode.

Bit 0 **OVRUDRIE**: Overrun/underrun interrupt enable.

This bit is set and cleared by software.

0: Interrupt is disabled

1: Interrupt is enabled

When this bit is set, an interrupt is generated if the OVRUDR bit in the SAI\_xSR register is set.

### 33.5.12 Status register (SAI\_ASR)

|      |      |      |      |      |      |      |      |      | r      | r      | r     | r    | r         | r       | r      |

Bits 31:19 Reserved, must be kept at reset value.

Bits 18:16 **FLVL[2:0]**: FIFO level threshold.

This bit is read only. The FIFO level threshold flag is managed only by hardware and its setting depends on SAI block configuration (transmitter or receiver mode).

If the SAI block is configured as transmitter:

000: FIFO empty

001:  $\text{FIFO} \leq \frac{1}{4}$  but not empty

010:  $\frac{1}{4} < \text{FIFO} \leq \frac{1}{2}$

011:  $\frac{1}{2} < \text{FIFO} \leq \frac{3}{4}$

100:  $\frac{3}{4} < \text{FIFO}$  but not full

101: FIFO full

If SAI block is configured as receiver:

000: FIFO empty

001:  $\text{FIFO} < \frac{1}{4}$  but not empty

010:  $\frac{1}{4} \leq \text{FIFO} < \frac{1}{2}$

011:  $\frac{1}{2} \leq \text{FIFO} < \frac{3}{4}$

100:  $\frac{3}{4} \leq \text{FIFO}$  but not full

101: FIFO full

Bits 15:7 Reserved, must be kept at reset value.

Bit 6 **LFSDET**: Late frame synchronization detection.

This bit is read only.

0: No error.

1: Frame synchronization signal is not present at the right time.

This flag can be set only if the audio block is configured in slave mode.

It is not used in AC'97 or SPDIF mode.

It can generate an interrupt if LFSDETIE bit is set in the SAI\_xIM register.

This flag is cleared when the software sets bit CLFSDET in SAI\_xCLRFR register.

Bit 5 **AFSDET**: Anticipated frame synchronization detection.

This bit is read only.

0: No error.

1: Frame synchronization signal is detected earlier than expected.

This flag can be set only if the audio block is configured in slave mode.

It is not used in AC'97 or SPDIF mode.

It can generate an interrupt if AFSDETIE bit is set in SAI\_xIM register.

This flag is cleared when the software sets CAFSDET bit in SAI\_xCLRFR register.

Bit 4 **CNRDY**: Codec not ready.

This bit is read only.

0: External AC'97 Codec is ready

1: External AC'97 Codec is not ready

This bit is used only when the AC'97 audio protocol is selected in the SAI\_xCR1 register and configured in receiver mode.

It can generate an interrupt if CNRDYIE bit is set in SAI\_xIM register.

This flag is cleared when the software sets CCNRDY bit in SAI\_xCLRFR register.

**Bit 3 FREQ:** FIFO request.

This bit is read only.

0: No FIFO request.

1: FIFO request to read or to write the SAI\_xDR.

The request depends on the audio block configuration:

- If the block is configured in transmission mode, the FIFO request is related to a write request operation in the SAI\_xDR.
- If the block configured in reception, the FIFO request related to a read request operation from the SAI\_xDR.

This flag can generate an interrupt if FREQIE bit is set in SAI\_xIM register.

**Bit 2 WCKCFG:** Wrong clock configuration flag.

This bit is read only.

0: Clock configuration is correct

1: Clock configuration does not respect the rule concerning the frame length specification defined in [Section 33.3.6: Frame synchronization](#) (configuration of FRL[7:0] bit in the SAI\_xFRCR register)

This bit is used only when the audio block operates in master mode (MODE[1] = 0) and NODIV = 0.

It can generate an interrupt if WCKCFGIE bit is set in SAI\_xIM register.

This flag is cleared when the software sets CWCKCFG bit in SAI\_xCLRFR register.

**Bit 1 MUTEDET:** Mute detection.

This bit is read only.

0: No MUTE detection on the SD input line

1: MUTE value detected on the SD input line (0 value) for a specified number of consecutive audio frame

This flag is set if consecutive 0 values are received in each slot of a given audio frame and for a consecutive number of audio frames (set in the MUTEcnt bit in the SAI\_xCR2 register).

It can generate an interrupt if MUTEDETIE bit is set in SAI\_xIM register.

This flag is cleared when the software sets bit CMUTEDET in the SAI\_xCLRFR register.

**Bit 0 OVRUDR:** Overrun / underrun.

This bit is read only.

0: No overrun/underrun error.

1: Overrun/underrun error detection.

The overrun and underrun conditions can occur only when the audio block is configured as a receiver and a transmitter, respectively.

It can generate an interrupt if OVRUDRIE bit is set in SAI\_xIM register.

This flag is cleared when the software sets COVRUDR bit in SAI\_xCLRFR register.

|      |      |      |      |      |      |      |      |      | r      | r       | r     | r    | r         | r       | r      |

Bits 31:19 Reserved, must be kept at reset value.

Bits 18:16 **FLVL[2:0]**: FIFO level threshold.

This bit is read only. The FIFO level threshold flag is managed only by hardware and its setting depends on SAI block configuration (transmitter or receiver mode).

If the SAI block is configured as transmitter:

000: FIFO empty

001:  $FIFO \leq \frac{1}{4}$  but not empty

010:  $\frac{1}{4} < FIFO \leq \frac{1}{2}$

011:  $\frac{1}{2} < FIFO \leq \frac{3}{4}$

100:  $\frac{3}{4} < FIFO$  but not full

101: FIFO full

If SAI block is configured as receiver:

000: FIFO empty

001:  $FIFO < \frac{1}{4}$  but not empty

010:  $\frac{1}{4} \leq FIFO < \frac{1}{2}$

011:  $\frac{1}{2} \leq FIFO < \frac{3}{4}$

100:  $\frac{3}{4} \leq FIFO$  but not full

101: FIFO full

Bits 15:7 Reserved, must be kept at reset value.

Bit 6 **LFSDET**: Late frame synchronization detection.

This bit is read only.

0: No error.

1: Frame synchronization signal is not present at the right time.

This flag can be set only if the audio block is configured in slave mode.

It is not used in AC'97 or SPDIF mode.

It can generate an interrupt if LFSDETIE bit is set in the SAI\_xIM register.

This flag is cleared when the software sets bit CLFSDET in SAI\_xCLRFR register.

Bit 5 **AFSDET**: Anticipated frame synchronization detection.

This bit is read only.

0: No error.

1: Frame synchronization signal is detected earlier than expected.

This flag can be set only if the audio block is configured in slave mode.

It is not used in AC'97 or SPDIF mode.

It can generate an interrupt if AFSDETIE bit is set in SAI\_xIM register.

This flag is cleared when the software sets CAFSDET bit in SAI\_xCLRFR register.

Bit 4 **CNRDY**: Codec not ready.

This bit is read only.

0: External AC'97 Codec is ready

1: External AC'97 Codec is not ready

This bit is used only when the AC'97 audio protocol is selected in the SAI\_xCR1 register and configured in receiver mode.

It can generate an interrupt if CNRDYIE bit is set in SAI\_xIM register.

This flag is cleared when the software sets CCNRDY bit in SAI\_xCLRFR register.

**Bit 3 FREQ:** FIFO request.

This bit is read only.

0: No FIFO request.

1: FIFO request to read or to write the SAI\_xDR.

The request depends on the audio block configuration:

- If the block is configured in transmission mode, the FIFO request is related to a write request operation in the SAI\_xDR.
- If the block configured in reception, the FIFO request related to a read request operation from the SAI\_xDR.

This flag can generate an interrupt if FREQIE bit is set in SAI\_xIM register.

**Bit 2 WCKCFG:** Wrong clock configuration flag.

This bit is read only.

0: Clock configuration is correct

1: Clock configuration does not respect the rule concerning the frame length specification defined in [Section 33.3.6: Frame synchronization](#) (configuration of FRL[7:0] bit in the SAI\_xFRCR register)

This bit is used only when the audio block operates in master mode (MODE[1] = 0) and NODIV = 0.

It can generate an interrupt if WCKCFGIE bit is set in SAI\_xIM register.

This flag is cleared when the software sets CWCKCFG bit in SAI\_xCLRFR register.

**Bit 1 MUTEDET:** Mute detection.

This bit is read only.

0: No MUTE detection on the SD input line

1: MUTE value detected on the SD input line (0 value) for a specified number of consecutive audio frame

This flag is set if consecutive 0 values are received in each slot of a given audio frame and for a consecutive number of audio frames (set in the MUTEcnt bit in the SAI\_xCR2 register).

It can generate an interrupt if MUTEDETIE bit is set in SAI\_xIM register.

This flag is cleared when the software sets bit CMUTEDET in the SAI\_xCLRFR register.

**Bit 0 OVRUDR:** Overrun / underrun.

This bit is read only.

0: No overrun/underrun error.

1: Overrun/underrun error detection.

The overrun and underrun conditions can occur only when the audio block is configured as a receiver and a transmitter, respectively.

It can generate an interrupt if OVRUDRIE bit is set in SAI\_xIM register.

This flag is cleared when the software sets COVRUDR bit in SAI\_xCLRFR register.

**33.5.14 Clear flag register (SAI\_ACLRFR)**

Bits 31:7 Reserved, must be kept at reset value.

Bit 6 **CLFSDET**: Clear late frame synchronization detection flag.

This bit is write only.

Programming this bit to 1 clears the LFSDET flag in the SAI\_xSR register.

This bit is not used in AC'97 or SPDIF mode.

Reading this bit always returns the value 0.

Bit 5 **CAFSDET**: Clear anticipated frame synchronization detection flag.

This bit is write only.

Programming this bit to 1 clears the AFSDET flag in the SAI\_xSR register.

It is not used in AC'97 or SPDIF mode.

Reading this bit always returns the value 0.

Bit 4 **CCNRDY**: Clear Codec not ready flag.

This bit is write only.

Programming this bit to 1 clears the CNRDY flag in the SAI\_xSR register.

This bit is used only when the AC'97 audio protocol is selected in the SAI\_xCR1 register.

Reading this bit always returns the value 0.

Bit 3 Reserved, must be kept at reset value.

Bit 2 **CWCKCFG**: Clear wrong clock configuration flag.

This bit is write only.

Programming this bit to 1 clears the WCKCFG flag in the SAI\_xSR register.

This bit is used only when the audio block is set as master (MODE[1] = 0) and NODIV = 0 in the SAI\_xCR1 register.

Reading this bit always returns the value 0.

Bit 1 **CMUTEDET**: Mute detection flag.

This bit is write only.

Programming this bit to 1 clears the MUTEDET flag in the SAI\_xSR register.

Reading this bit always returns the value 0.

Bit 0 **COVRUDR**: Clear overrun / underrun.

This bit is write only.

Programming this bit to 1 clears the OVRUDR flag in the SAI\_xSR register.

Reading this bit always returns the value 0.

Bits 31:7 Reserved, must be kept at reset value.

Bit 6 **CLFSDET**: Clear late frame synchronization detection flag.

This bit is write only.

Programming this bit to 1 clears the LFSDET flag in the SAI\_xSR register.

This bit is not used in AC'97 or SPDIF mode.

Reading this bit always returns the value 0.

Bit 5 **CAFSDET**: Clear anticipated frame synchronization detection flag.

This bit is write only.

Programming this bit to 1 clears the AFSDET flag in the SAI\_xSR register.

It is not used in AC'97 or SPDIF mode.

Reading this bit always returns the value 0.

Bit 4 **CCNRDY**: Clear Codec not ready flag.

This bit is write only.

Programming this bit to 1 clears the CNRDY flag in the SAI\_xSR register.

This bit is used only when the AC'97 audio protocol is selected in the SAI\_xCR1 register.

Reading this bit always returns the value 0.

Bit 3 Reserved, must be kept at reset value.

Bit 2 **WCKCFG**: Clear wrong clock configuration flag.

This bit is write only.

Programming this bit to 1 clears the WCKCFG flag in the SAI\_xSR register.

This bit is used only when the audio block is set as master (MODE[1] = 0) and NODIV = 0 in the SAI\_xCR1 register.

Reading this bit always returns the value 0.

Bit 1 **CMUTEDET**: Mute detection flag.

This bit is write only.

Programming this bit to 1 clears the MUTEDET flag in the SAI\_xSR register.

Reading this bit always returns the value 0.

Bit 0 **COVRUDR**: Clear overrun / underrun.

This bit is write only.

Programming this bit to 1 clears the OVRUDR flag in the SAI\_xSR register.

Reading this bit always returns the value 0.

### 33.5.16 Data register (SAI\_ADR)

Refer to [Section 2.2 on page 68](#) for the register boundary addresses.

## 34 SPDIF receiver interface (SPDIFRX)

### 34.1 SPDIFRX interface introduction

The SPDIFRX interface handles S/PDIF audio protocol.

### 34.2 SPDIFRX main features

- Up to 4 inputs available
- Automatic symbol rate detection
- Maximum symbol rate: 12.288 MHz
- Stereo stream from 8 to 192 kHz supported
- Supports Audio IEC-60958 and IEC-61937, consumer applications
- SOPDs B, M and W insertion inside S/PDIF flow
- Parity bit management
- Communication using DMA for audio samples
- Communication using DMA for control and user channel information
- Interrupt capabilities

### 34.3 SPDIFRX functional description

The SPDIFRX peripheral, is designed to receive an S/PDIF flow compliant with IEC-60958 and IEC-61937. These standards support simple stereo streams up to high sample rate, and compressed multi-channel surround sound, such as those defined by Dolby or DTS.

The receiver provides all the necessary features to detect the symbol rate, and decode the incoming data. It is possible to use a dedicated path for the user and channel information in order to ease the interface handling. [Figure 411](#) shows a simplified block diagram.

The SPDIFRX\_DC block is responsible of the decoding of the S/PDIF stream received from SPDIFRX\_IN[4:1] inputs. This block re-sample the incoming signal, decode the manchester stream, recognize frames, sub-frames and blocks elements. It delivers to the REG\_IF part, decoded data, and associated status flags.

This peripheral can be fully controlled via the APB1 bus, and can handle two DMA channels:

- A DMA channel dedicated to the transfer of audio samples
- A DMA channel dedicated to the transfer of IEC60958 channel status and user information

Interrupt services are also available either as an alternative function to the DMA, or for signaling error or key status of the peripheral.

The SPDIFRX also offers a signal named **spdifrx\_frame\_sync**, which toggles every time that a sub-frame's preamble is detected. So the duty cycle will be 50%, and the frequency equal to the frame rate.

This signal can be connected to timer events, in order to compute frequency drift.

Figure 411. SPDIFRX block diagram

1. 'n' is fixed to 4.

### 34.3.1 S/PDIF protocol (IEC-60958)

#### S/PDIF block

A S/PDIF frame is composed of two sub-frames (see [Figure 413](#)). Each sub-frame contains 32 bits (or time slots):

- Bits 0 to 3 carry one of the synchronization preambles
- Bits 4 to 27 carry the audio sample word in linear 2's complement representation. The most significant bit (MSB) is carried by bit 27. When a 20-bit coding range is used, bits 8 to 27 carry the audio sample word with the LSB in bit 8.
- Bit 28 (validity bit "V") indicates if the data is valid (for converting it to analog for example)
- Bit 29 (user data bit "U") carries the user data information like the number of tracks of a Compact Disk.
- Bit 30 (channel status bit "C") carries the channel status information like sample rate and protection against copy.
- Bit 31 (parity bit "P") carries a parity bit such that bits 4 to 31 inclusive carry an even number of ones and an even number of zeroes (even parity).

Figure 412. S/PDIF Sub-Frame Format

For linear coded audio applications, the first sub-frame (left or “A” channel in stereophonic operation and primary channel in monophonic operation) normally starts with preamble “M”. However, the preamble changes to preamble “B” once every 192 frames to identify the start of the block structure used to organize the channel status and user information. The second sub-frame (right or “B” channel in stereophonic operation and secondary channel in monophonic operation) always starts with preamble “W”.

A S/PDIF block contains 192 pairs of sub-frames of 32 bits.

Figure 413. S/PDIF block format

### Synchronization preambles

The preambles patterns are inverted or not according to the previous half-bit value. This previous half-bit value is the level of the line before enabling a transfer for the first “B” preamble of the first frame. For the others preambles, this previous half-bit value is the second half-bit of the parity bit of the previous sub-frame. The preambles patterns B, M and W are described in the [Figure 414](#).

Figure 414. S/PDIF Preambles

Coding of information bits

In order to minimize the DC component value on the transmission line, and to facilitate clock recovery from the data stream, bits 4 to 31 are encoded in biphase-mark.

Each bit to be transmitted is represented by a symbol comprising two consecutive binary states. The first state of a symbol is always different from the second state of the previous symbol. The second state of the symbol is identical to the first if the bit to be transmitted is logical 0. However, it is different if the bit is logical 1. These states are named "UI" (Unit Interval) in the IEC-60958 specification.

The 24 data bits are transferred LSB first.

Figure 415. Channel coding example

### 34.3.2 SPDIFRX decoder (SPDIFRX\_DC)

#### Main principle

The technique used by the SPDIFRX in order to decode the S/PDIF stream is based on the measurement of the time interval between two consecutive edges. Three kinds of time intervals may be found into an S/PDIF stream:

- The long time interval, having a duration of  $3 \times \text{UI}$ , noted TL. It appears only during preambles.
- The medium time interval, having a duration of  $2 \times \text{UI}$ , noted TM. It appears both in some preambles or into the information field.
- The short time interval, having a duration of  $1 \times \text{UI}$ , noted TS. It appears both in some preambles or into the information field.

The SPDIFRX\_DC block is responsible of the decoding of the received S/PDIF stream. It takes care of the following functions:

- Resampling and filtering of the incoming signal
- Estimation of the time-intervals
- Estimation of the symbol rate and synchronization
- Decoding of the serial data, and check of integrity
- Detection of the block, and sub-frame preambles
- Continuous tracking of the symbol rate

Figure 416 gives a detailed view of the SPDIFRX decoder.

Figure 416. SPDIFRX decoder

### Noise filtering & rising/falling edge detection

The S/PDIF signal received on the selected SPDIFRX\_IN is re-sampled using the SPDIFRX\_CLK clock (acquisition clock). A simple filtering is applied in order to cancel spurs. This is performed by the stage detecting the edge transitions. The edge transitions are detected as follows:

- A rising edge is detected when the sequence 0 followed by two 1 is sampled.
- A falling edge is detected when the sequence 1 followed by two 0 is sampled.
- After a rising edge, a falling edge sequence is expected.
- After a falling edge, a rising edge sequence is expected.

Figure 417. Noise filtering and edge detection

### Longest and shortest transition detector

The **longest and shortest transition detector** block detects the maximum (MAX\_CNT) and minimum (MIN\_CNT) duration between two transitions. The TRCNT counter is used to measure the time interval duration. It is clocked by the SPDIFRX\_CLK signal. On every transition pulse, the counter value is stored and the counter is reset to start counting again.

The maximum duration is normally found during the preamble period. This maximum duration is sent out as MAX\_CNT. The minimum duration is sent out as MIN\_CNT.

The search of the longest and shortest transition is stopped when the transition timer expires. The transition timer is like a watchdog timer that generates a trigger after 70 transitions of the incoming signal. Note that counting 70 transitions insures a delay a bit longer than a sub-frame.

Note that when the TRCNT overflows due to a too long time interval between two pulses, the SPDIFRX is stopped and the flag TERR of SPDIFRX\_SR register is set to 1.

### Transition coder and preamble detector

The **transition coder and preamble detector** block receives the MAX\_CNT and MIN\_CNT. It also receives the current transition width from the TRCNT counter (see [Figure 416](#)). This block encodes the current transition width by comparing the current transition width with two different thresholds, names TH<sub>HI</sub> and TH<sub>LO</sub>.

- If the current transition width is less than (TH<sub>LO</sub> - 1), then the data received is half part of data bit '1', and is coded as TS.
- If the current transition width is greater than (TH<sub>LO</sub> - 1), and less than TH<sub>HI</sub>, then the data received is data bit '0', and is coded as TM.
- If the current transition width is greater than TH<sub>HI</sub>, then the data received is the long pulse of preambles, and is coded as TL.
- Else an error code is generated (FERR flag is set).

The thresholds TH<sub>HI</sub> and TH<sub>LO</sub> are elaborated using two different methods.

If the peripheral is doing its initial synchronization ('coarse synchronization'), then the thresholds are computed as follow:

- TH<sub>LO</sub> = MAX\_CNT / 2.
- TH<sub>HI</sub> = MIN\_CNT + MAX\_CNT / 2.

Once the 'coarse synchronization' is completed, then the SPDIFRX uses a more accurate reference in order to elaborate the thresholds. The SPDIFRX measures the length of 24 symbols (WIDTH24) for defining TH<sub>LO</sub> and the length of 40 symbols (WIDTH40) for TH<sub>HI</sub>. TH<sub>HI</sub> and TH<sub>LO</sub> are computed as follow:

- TH<sub>LO</sub> = (WIDTH24) / 32
- TH<sub>HI</sub> = (WIDTH40) / 32

This second synchronization phase is called the 'fine synchronization'. Refer to [Figure 420](#) for additional information.

As shown in the figure hereafter, TH<sub>LO</sub> is ideally equal to 1.5 UI, and to TH<sub>HI</sub> 2.5 UI.

Figure 418. Thresholds

The preamble detector checks four consecutive transitions of a specific sequence to determine if they form the part of preamble. Let us say TRANS0, TRANS1, TRANS2 and TRANS3 represent four consecutive transitions encoded as mentioned above. [Table 216](#) shows the values of these four transitions to form a preamble. Absence of this pattern indicates that these transitions form part of the data in the sub frame and bi-phase decoder will decode them.

Table 216. Transition sequence for preamble

| Preamble type | Biphase data pattern | TRANS3 | TRANS2 | TRANS1 | TRANS0 |
|---------------|----------------------|--------|--------|--------|--------|
| Preamble B    | 11101000             | TL     | TS     | TS     | TL     |
| Preamble M    | 11100010             | TL     | TL     | TS     | TS     |
| Preamble W    | 11100100             | TL     | TM     | TS     | TM     |

### Bi-phase decoder

The Bi-phase decoder decodes the input bi-phase marked data stream using the transition information provided by the **transition coder and preamble detector** block. It first waits for the preamble detection information. After the preamble detection, it decodes the following transition information:

- If the incoming transition information is TM then it is decoded as a '0'.
- Two consecutive TS are decoded as a '1'.
- Any other transition sequence generates an error signal (FERR set to 1).

After decoding 28 data bits this way, this module looks for the following preamble data. If the new preamble is not what is expected, then this block generates an error signal (FERR set to 1). Refer to [Section 34.3.8: Reception errors](#), for additional information on error flags.

### Data packing

This block is responsible of the decoding of the IEC-60958 frames and blocks. It also handles the writing into the RX\_BUF or into SPDIFRX\_CSR register.

### 34.3.3 SPDIFRX tolerance to clock deviation

The SPDIFRX tolerance to clock deviation depends on the number of sample clock cycles in one bit slot. The fastest SPDIFRX\_CLK is, the more robust the reception will be. The ratio between SPDIFRX\_CLK frequency and the symbol rate must be at least 11.

Two kinds of phenomenon (at least!) can degrade the reception quality:

- The cycle-to-cycle jitter which reflects the difference of transition length between two consecutive transitions.
- The long term jitter which reflects a cumulative effect of the cycle-to-cycle jitter. It can be seen as a low-frequency symbol modulation.

### 34.3.4 SPDIFRX synchronization

The synchronization phase starts when setting SPDIFRXEN to 01 or 11. [Figure 419](#) shows the synchronization process.

If the bit WFA of SPDIFRX\_CR register is set to 1, then the peripheral must first detect activity on the selected SPDIFRX\_IN line before starting the synchronization process. The activity detection is performed by detecting four transitions on the selected SPDIFRX\_IN. The peripheral remains in this state until transitions are not detected. This function can be particularly helpful because the IP switches in COARSE SYNC mode only if activity is present on the selected SPDIFRX\_IN input, avoiding synchronization errors. See [Section 34.4: Programming procedures](#) for additional information.

The user can still set the SPDIFRX into STATE\_IDLE by setting SPDIFRXEN to 0. If the WFA is set to 0, the peripheral starts the coarse synchronization without checking activity.

The next step consists on doing a first estimate of the thresholds (COARSE SYNC), in order to perform the fine synchronization (FINE SYNC). Due to disturbances of the SPDIFRX line, it could happen that the process is not executed first time right. For this purpose, the user can program the number of allowed re-tries (NBTR) before setting SERR error flag. When the SPDIFRX has been able to measure properly the duration of 24 and 40 consecutive symbols then the FINE SYNC is completed, the threshold values are updated, and the flag SYNCD is set to 1. Refer to [Section : Transition coder and preamble detector](#) for additional information.

Two kinds of errors are detected:

- An overflow of the TRCNT, which generally means that there is no valid S/PDIF stream in the input line. This overflow is indicated by TERR flag.
- The number of retries reached the programmed value. This means that strong jitter is present on the S/PDIF signal. This error is indicated by SERR flag.

When the first FINE SYNC is completed, the reception of channel status (C) and user data (U) will start when the next "B" preamble is detected (see [Figure 423](#)). Then the user can read IEC-60958 C and U bits through SPDIFRX\_CSR register. According to this information the user can then select the proper settings for DRFMT and RXSTEO. For example if the user detects that the current audio stream transports encoded data, then he can put RXSTEO to 0, and DRFMT to 10 prior to start data reception. Note that DRFMT and RXSTEO cannot be modified when SPDIFRXEN = 11. Writes to these fields are ignored if SPDIFRXEN is already 11, though these field can be changed with the same write instruction that causes SPDIFRXEN to become 11.

Then the SPDIFRX waits for SPDIFRXEN = 11 and the "B" preamble before starting saving audio samples.

Figure 419. Synchronization flowchart

Refer to [Frame structure and synchronization error](#) for additional information concerning TRCNT overflow.

The FINE SYNC process is re-triggered every frame in order to update thresholds as shown in [Figure 420](#) in order to continuously track S/PDIF synchronization.

Figure 420. Synchronization process scheduling

### 34.3.5 SPDIFRX handling

The software can control the state of the SPDIFRX through SPDIFRXEN field. The SPDIFRX can be into one of the following states:

- **STATE\_IDLE:**  
The peripheral is disabled, the SPDIFRX\_CLK domain is reset. The PCLK1 domain is functional.
- **STATE\_SYNC:**  
The peripheral is synchronized to the stream, thresholds are updated regularly, user and channel status can be read via interrupt or DMA. The audio samples are not provided to receive buffer.
- **STATE\_RCV:**  
The peripheral is synchronized to the stream, thresholds are updated regularly, user, channel status and audio samples can be read via interrupt or DMA channels. When SPDIFRXEN goes to 11, the SPDIFRX waits for “B” preamble before starting saving audio samples.
- **STOP\_STATE:**  
The peripheral is no longer synchronized, the reception of the user, channel status and audio samples are stopped. It is expected that the software re-starts the SPDIFRX.

The [Figure 421](#) shows the possible states of the SPDIFRX, and how to transition from one state to the other. The bits under software control are followed by the mention “(SW)”, the bits under IP control are followed by the mention “(HW)”.

Figure 421. SPDIFRX States

When SPDIFRX is in STATE\_IDLE:

- The software can transition to STATE\_SYNC by setting SPDIFRXEN to 01 or 11

When SPDIFRX is in STATE\_SYNC:

- If the synchronization fails or if the received data are not properly decoded with no chance of recovery without a re-synchronization (FERR or SERR or TERR = 1), the SPDIFRX goes to STATE\_STOP, and waits for software acknowledge.
- When the synchronization phase is completed, if SPDIFRXEN = 01 the peripheral remains in this state.
- At any time the software can set SPDIFRXEN to 0, then SPDIFRX returns immediately to STATE\_IDLE. If a DMA transfer is on-going, it will be properly completed.
- The SPDIFRX goes to STATE\_RCV if SPDIFRXEN = 11 and if the SYNC = 1

When SPDIFRX is in STATE\_RCV:

- If the received data are not properly decoded with no chance of recovery without a re-synchronization (FERR or SERR or TERR = 1), the SPDIFRX goes to STATE\_STOP, and waits for software acknowledge.
- At any time the software can set SPDIFRXEN to 0, then SPDIFRX returns immediately to STATE\_IDLE. If a DMA transfer is on-going, it will properly be completed.

When SPDIFRX is in STATE\_STOP:

- The SPDIFRX stops reception and synchronization, and waits for the software to set the bit SPDIFRXEN to 0, in order to clear the error flags.

When SPDIFRXEN is set to 0, the IP is disabled, meaning that all the state machines are reset, and RX\_BUF is flushed. Note as well that flags FERR, SERR and TERR are reset.

### 34.3.6 Data reception management

The SPDIFRX offers a double buffer for the audio sample reception. A 32-bit buffer located into the SPDIFRX\_CLK clock domain (RX\_BUF), and the SPDIFRX\_FMTx\_DR register. The valid data contained into the RX\_BUF will be immediately transferred into SPDIFRX\_FMTx\_DR if SPDIFRX\_FMTx\_DR is empty.

The valid data contained into the RX\_BUF will be transferred into SPDIFRX\_FMTx\_DR when the two following conditions are reached:

- The transition between the parity bit (P) and the next preamble is detected (this indicated that the word has been completely received).
- The SPDIFRX\_FMTx\_DR is empty.

Having a 2-word buffer gives more flexibility for the latency constraint.

The maximum latency allowed is  $T_{\text{SAMPLE}} - 2T_{\text{PCLK}} - 2T_{\text{SPDIFRX\_CLK}}$

Where  $T_{\text{SAMPLE}}$  is the audio sampling rate of the received stereo audio samples,  $T_{\text{PCLK}}$  is the period of PCLK1 clock, and  $T_{\text{SPDIFRX\_CLK}}$  is the period of SPDIFRX\_CLK clock.

The SPDIFRX offers the possibility to use either DMA (spdifrx\_dma\_req/clr\_d) or interrupts for transferring the audio samples into the memory. The recommended option is DMA, refer to [Section 34.3.10: DMA Interface](#) for additional information.

The SPDIFRX offers several way on handling the received data. The user can either have a separate flow for control information and audio samples, or get them all together.

For each sub-frame, the data reception register SPDIFRX\_FMTx\_DR contains the 24 data bits, and optionally the V, U, C, PE status bits, and the PT (see [Mixing data and control flow](#)).

Note that PE bit stands for Parity Error bit, and will be set to 1 when a parity error is detected in the decoded sub-frame.

The PT field carries the preamble type (B, M or W).

V, U and C are a direct copy of the value received from the S/PDIF interface.

The bit DRFMT allows the selection between 3 audio formats as shown in [Figure 422](#).

This document describes 3 data registers: SPDIFRX\_FMTx[2:0] (x = 2 to 0), but in reality there is only one physical data register, having 3 possible formats:

- When DRFMT = 0, the format of the data register is the one described by SPDIFRX\_FMT0\_DR
- When DRFMT = 1, the format of the data register is the one described by SPDIFRX\_FMT1\_DR
- When DRFMT = 2, the format of the data register is the one described by SPDIFRX\_FMT2\_DR"

Figure 422. SPDIFRX\_FMTx\_DR register format

Setting DRFMT to 00 or 01, offers the possibility to have the data either right or left aligned into the SPDIFRX\_FMTx\_DR register. The status information can be enabled or forced to zero according to the way the software wants to handle them.

The format given by DRFMT= 10 is interesting in non-linear mode, as only 16 bits per sub-frame are used. By using this format, the data of two consecutive sub-frames are stored into SPDIFRX\_FMTx\_DR, dividing by two the amount of memory footprint. Note that when RXSTEO = 1, there is no misalignment risks (i.e. data from ChA will be always stored into SPDIFRX\_FMTx\_DR[31:16]). If RXSTEO = 0, then there is a misalignment risk in case of overrun situation. In that case SPDIFRX\_FMTx\_DR[31:16] will always contain the oldest value and SPDIFRX\_FMTx\_DR[15:0] the more recent value (see [Figure 424](#)).

In this format the status information cannot be mixed with data, but the user can still get them through SPDIFRX\_CSR register, and use a dedicated DMA channel or interrupt to transfer them to memory (see [Section 34.3.7: Dedicated control flow](#))

### Mixing data and control flow

The user can choose to use this mode in order to get the full flexibility of the handling of the control flow. The user can select which field shall be kept into the data register (SPDIFRX\_FMTx\_DR).

- When bit PMSK = 1, the Parity Error information is masked (set to 0), otherwise it is copied into SPDIFRX\_FMTx\_DR.
- When bit VMSK = 1, the Validity information is masked (set to 0), otherwise it is copied into SPDIFRX\_FMTx\_DR.
- When bit CUMSK = 1, the Channel Status, and Used data information are masked (set to 0), otherwise they are copied into SPDIFRX\_FMTx\_DR.
- When bit PTMSK = 1, the Preamble Type is masked (set to 0), otherwise it is copied into SPDIFRX\_FMTx\_DR.

### 34.3.7 Dedicated control flow

The SPDIFRX offers the possibility to catch both user data and channel status information via a dedicated DMA channel. This feature allows the SPDIFRX to acquire continuously the channel status and user information. The acquisition will start at the beginning of a IEC 60958 block. Two fields are available to control this path: CBDMAEN and SPDIFRXEN. When SPDIFRXEN is set to 01 or 0x11, the acquisition is started, after completion of the synchronization phase. When 8 channel status and 16 user data bits have been received, they are packed and stored into SPDIFRX\_CSR register. A DMA request is triggered if the bit CBDMAEN is set to 1 (see [Figure 423](#)).

If CS[0] corresponds to the first bit of a new block, the bit SOB will be set to 1. Refer to [Section 34.5.8: Channel status register \(SPDIFRX\\_CSR\)](#). A bit is available (CHSEL) in order to select if the user wants to select channel status information (C) from the channel A or B.

**Figure 423. Channel/user data format**

**Note:** Once the first start of block is detected (B preamble), the SPDIFRX is checking the preamble type every 8 frames.

**Note:** Overrun error on SPDIFRX\_FMTx\_DR register does not affect this path.

### 34.3.8 Reception errors

#### Frame structure and synchronization error

The SPDIFRX, detects errors, when one of the following condition occurs:

- The FERR bit is set to 1 on the following conditions:
  - For each of the 28 information bits, if one symbol transition sequence is not correct: for example if short pulses are not grouped by pairs.
  - If preambles occur to an unexpected place, or an expected preamble is not received.
- The SERR bit is set when the synchronization fails, because the number of re-tries exceeded the programmed value.
- The TERR bit is set when the counter used to estimate the width between two transitions overflows (TRCNT).  
The overflow occurs when no transition is detected during 8192 periods of SPDIFRX\_CLK clock. It represents at most a time interval of 11.6 frames.

When one of those flags goes to 1, the traffic on selected SPDIFRX\_IN is then ignored, an interrupt is generated if the IFEIE bit of the SPDIFRX\_CR register is set.

The normal procedure when one of those errors occur is:

- Set SPDIFRXEN to 0 in order to clear the error flags
- Set SPDIFRXEN to 01 or 11 in order to restart the IP

Refer to [Figure 421](#) for additional information.

#### Parity error

For each sub-frame, an even number of zeros and ones is expected inside the 28 information bits. If not, the parity error bit PERR is set in the SPDIFRX\_SR register and an interrupt is generated if the parity interrupt enable PERRIE bit is set in the SPDIFRX\_CR register. The reception of the incoming data is not paused, and the SPDIFRX continue to deliver data to SPDIFRX\_FMTx\_DR even if the interrupt is still pending.

The interrupt is acknowledged by clearing the PERR flag through PERRCF bit.

If the software wants to guarantee the coherency between the data read in the SPDIFRX\_FMTx\_DR register and the value of the bit PERR, the bit PMSK must be set to 0.

#### Overflow error

If both SPDIFRX\_FMTx\_DR and RX\_BUF are full, while the SPDIFRX\_DC needs to write a new sample in RX\_BUF, this new sample is dropped, and an overrun condition is triggered. The overrun error flag OVR is set in the SPDIFRX\_SR register and an interrupt is generated if the OVRIE bit of the SPDIFRX\_CR register is set.

If the RXSTEO bit is set to 0, then as soon as the RX\_BUF is empty, the IP will store the next incoming data, even if the OVR flag is still pending. The main purpose is to reduce as much as possible the amount of lost samples. Note that the behavior is similar independently of DRFMT value. See [Figure 424](#).

Figure 424. S/PDIF overrun error when RXSTEO = 0

If the RXSTEO bit is set to 1, it means that stereo data are transported, then the SPDIFRX has to avoid misalignment between left and right channels. So the peripheral has to drop a second sample even if there is room inside the RX\_BUF in order to avoid misalignment. Then the incoming samples can be written normally into the RX\_BUF even if the OVR flag is still pending. Refer to [Figure 425](#).

The OVR flag is cleared by software, by setting the OVRCF bit to 1.

Figure 425. S/PDIF overrun error when RXSTEO = 1

### 34.3.9 Clocking strategy

The SPDIFRX block needs two different clocks:

- The APB1 clock (PCLK1), which is used for the register interface,
- The SPDIFRX\_CLK which is mainly used by the SPDIFRX\_DC part. Those clocks are not supposed to be phase locked, so all signals crossing those clock domains are re-synchronized (SYNC block on [Figure 411](#)).

In order to decode properly the incoming S/PDIF stream the SPDIFRX\_DC shall re-sample the received data with a clock at least 11 times higher than the maximum symbol rate, or 704 times higher than the audio sample rate. For example if the user expects to receive a symbol rate to up to 12.288 MHz, the sample rate shall be at least 135.2 MHz. The clock used by the SPDIFRX\_DC is the SPDIFRX\_CLK.

The frequency of the PCLK1 must be at least equal to the symbol rate.

Table 217. Minimum SPDIFRX\_CLK frequency versus audio sampling rate

| Symbol Rate | Minimum SPDIFRX_CLK frequency | Comments           |
|-------------|-------------------------------|--------------------|
| 3.072 MHz   | 33.8 MHz                      | For 48 kHz stream  |
| 6.144 MHz   | 67.6 MHz                      | For 96 kHz stream  |
| 12.288 MHz  | 135.2 MHz                     | For 192 kHz stream |

### 34.3.10 DMA Interface

The SPDIFRX interface is able to perform communication using the DMA.

*Note: The user should refer to product specifications for availability of the DMA controller.*

The SPDIFRX offers two independent DMA channels:

- A DMA channel dedicated to the data transfer
- A DMA channel dedicated to the channel status and user data transfer

The DMA mode for the data can be enabled for reception by setting the RXDMAEN bit in the SPDIFRX\_CR register. In this case, as soon as the SPDIFRX\_FMTx\_DR is not empty, the SPDIFRX interface sends a transfer request to the DMA. The DMA reads the data received through the SPDIFRX\_FMTx\_DR register without CPU intervention.

For the use of DMA for the control data refer to [Section 34.3.7: Dedicated control flow](#).

### 34.3.11 Interrupt Generation

An interrupt line is shared between:

- Reception events for data flow (RXNE)
- Reception event for control flow (CSRNE)
- Data corruption detection (PERR)
- Transfer flow interruption (OVR)
- Frame structure and synchronization errors (SERR, TERR and FERR)
- Start of new block interrupt (SBD)
- Synchronization done (SYNCD)

**Figure 426. SPDIFRX interface interrupt mapping diagram**

### Clearing interrupt source

- RXNE is cleared when SPDIFRX\_FMTx\_DR register is read
- CSRNE is cleared when SPDIFRX\_CSR register is read
- FERR is cleared when SPDIFRXEN is set to 0
- SERR is cleared when SPDIFRXEN is set to 0
- TERR is cleared when SPDIFRXEN is set to 0
- Others are cleared through SPDIFRX\_IFCR register

**Note:** The SBD event can only occur when the SPDIFRX is synchronized to the input stream (SYNCD = 1).  
The SBD flag behavior is not guaranteed when the sub-frame which contains the B preamble is lost due to an overrun.

### 34.3.12 Register protection

The SPDIFRX block embeds some hardware protection avoid erroneous use of control registers. The table hereafter shows the bit field properties according to the SPDIFRX state.

**Table 218. Bit field property versus SPDIFRX state**

| Registers   | Field      | SPDIFRXEN          |                    |                   |
|-------------|------------|--------------------|--------------------|-------------------|
|             |            | 00<br>(STATE_IDLE) | 01<br>(STATE_SYNC) | 11<br>(STATE_RCV) |
| SPDIFRX_CR  | INSEL      | rw                 | r                  | r                 |
|             | WFA        | rw                 | r                  | r                 |
|             | NBTR       | rw                 | r                  | r                 |
|             | CHSEL      | rw                 | r                  | r                 |
|             | CBDMAEN    | rw                 | rw                 | rw                |
|             | PTMSK      | rw                 | rw                 | rw                |
|             | CUMSK      | rw                 | rw                 | rw                |
|             | VMSK       | rw                 | rw                 | rw                |
|             | PMSK       | rw                 | rw                 | rw                |
|             | DRFMT      | rw                 | rw                 | r                 |
|             | RXSTEO     | rw                 | rw                 | r                 |
|             | RXDMAEN    | rw                 | rw                 | rw                |
| SPDIFRX_IMR | All fields | rw                 | rw                 | rw                |

The table clearly shows that fields such as INSEL must be programmed when the IP is in STATE\_IDLE. In the others IP states, the hardware prevents writing to this field.

**Note:** Even if the hardware allows the writing of CBDMAEN and RXDMAEN “on-the-fly”, it is not recommended to enable the DMA when the IP is already receiving data.

**Note:** Note that each of the mask bits (PMSK, VMSK, ...) can be changed “on-the-fly” at any IP state, but any change does not affect data which is already being held in SPDIFRX\_FMTx\_DR.

## 34.4 Programming procedures

The following example illustrates a complete activation sequence of the SPDIFRX block. The data path and channel status & user information will both use a dedicated DMA channel. The activation sequence is then split into the following steps:

- Wait for valid data on the selected SPDIFRX\_IN input
- Synchronize to the S/PDIF stream
- Read the channel status and user information in order to setup the complete audio path
- Start data acquisition

A simple way to check if valid data are available into the SPDIFRX\_IN line is to switch the SPDIFRX into the STATE\_SYNC, with bit WFA set to 1. The description hereafter will focus on detection. It is also possible to implement this function as follow:

- The software has to check from time to time (i.e. every 100 ms for example) if the SPDIFRX can find synchronization. This can be done by checking if the bit TERR is set. When it is set it indicates that no activity has been found.
- Connect the SPDIFRX\_IN input to an external interrupt event block in order to detect transitions of SPDIFRX\_IN line. When activity is detected, then SPDIFRXEN can be set to 01 or 11.

For those two implementations, the bit WFA is set to 0.

### 34.4.1 Initialization phase

- The initialization function will look like this:
- Configure the DMA transfer for both audio samples and IEC60958 channel status and user information (DMA channel selection and activation, priority, number of data to transfer, circular/no circular mode, DMA interrupts)
- Configure the destination address:
  - Configure the address of the SPDIFRX\_CSR register as source address for IEC60958 channel status and user information
  - Configure the address of the SPDIFRX\_FMTx\_DR register as source address for audio samples
  - Enable the generation of the SPDIFRX\_CLK. Refer to [Table 217](#) in order to define the minimum clock frequency versus supported audio sampling rate. Note that the audio sampling rate of the received stream is not known in advance. This means that the user has to select a SPDIFRX\_CLK frequency at least 704 times higher than the maximum audio sampling rate the application is supposed to

handle: for example if the application is able to handle streams to up to 96 kHz, then  $F_{\text{SPDIFRX\_CLK}}$  shall be at least  $704 \times 96 \text{ kHz} = 67.6 \text{ MHz}$

- Enable interrupt for errors and event signaling (IFEIE = SYNCIE = OVRIE, PERRIE = 1, others set to 0). Note that SYNCIE can be set to 0.
- Configure the SPDIFRX\_CR register:
  - INSEL shall select the wanted input
  - NBTR = 2, WFA = 1 (16 re-tries allowed, wait for activity before going to synchronization phase),
  - PTMSK = CUMSK = 1 (Preamble, C and U bits are not mixed with data)
  - VMSK = PMSK = 0 (Parity error and validity bit mixed with data)
  - CHSEL = 0 (channels status will be read from sub-frame A)
  - DRFMT = 01 (data aligned to the left)
  - RXSTEO = 1 (expected stereo mode linear)
  - CBDMAEN = RXDMAEN = 1 (enable DMA channels)
  - SPDIFRXEN = 01 (switch SPDIFRX to STATE\_SYNC)
- The CPU can enter in WFI mode

Then the CPU will receive interrupts coming either from DMA or SPDIFRX.

### 34.4.2 Handling of interrupts coming from SPDIFRX

When an interrupt from the SPDIFRX is received, then the software has to check what is the source of the interrupt by reading the SPDIFRX\_SR register.

- If SYNCIE is set to 1, then it means that the synchronization has been properly completed. No action has to be performed in our case as the DMA is already programmed. The software just needs to wait for DMA interrupt in order to read channel status information.  
The SYNCIE flag must be cleared by setting SYNCIECF bit of SPDIFRX\_IFCR register to 1.
- If TERR or SERR or FERR are set to 1, the software has to set SPDIFRXEN to 0, and re-start from the initialization phase.
  - TERR indicates that a time-out occurs either during synchronization phase or after.
  - SERR indicates that the synchronization fails because the maximum allowed re-tries have been reached.
  - FERR indicates that the reading of information after synchronization fails (unexpected preamble, bad data decoding...).
- If PERR is set to 1, it means that a parity error has been detected, so one of the received audio sample or the channel status or user data bits are corrupted. The action taken here depends on the application: one action could be to drop the current channel status block as it is not reliable. There is no need to re-start from the initialization phase, as the synchronization is not lost.  
The PERR flag must be cleared by setting PERRCF bit of SPDIFRX\_IFCR register to 1.

### 34.4.3 Handling of interrupts coming from DMA

If an interrupt is coming from the DMA channel used of the channel status (SPDIFRX\_CSR):

If no error occurred (i.e. PERR), the CPU can start the decoding of channel information. For example bit 1 of the channel status informs the user if the current stream is linear or not. This information is very important in order to set-up the proper processing chain. In the same way, bits 24 to 27 of the channel status give the sampling frequency of the stream incoming stream.

Thanks to that information, the user can then configure the RXSTEO bit and DRFMT field prior to start the data reception. For example if the current stream is non linear PCM then RXSTEO is set to 0, and DRFMT is set to 10. Then the user can enable the data reception by setting SPDIFRXEN to 11.

The bit SOB, when set to 1 indicates the start of a new block. This information will help the software to identify the bit 0 of the channel status. Note that if the DMA generates an interrupt every time 24 values are transferred into the memory, then the first word will always correspond to the start of a new block.

If an interrupt is coming from the DMA channel used of the audio samples (SPDIFRX\_FMTx\_DR):

The process performed here depends of the data type (linear or non-linear), and on the data format selected.

For example in linear mode, if PE or V bit is set a special processing can be performed locally in order to avoid spurs on output. In non-linear mode those bits are not important as data frame have their own checksum.

## 34.5 SPDIFRX interface registers

### 34.5.1 Control register (SPDIFRX\_CR)

Address offset: 0x00

Reset value: 0x0000 0000

|      |      |           |      |       |         |       |       |      |      |            |      |        |            |                |    |
|------|------|-----------|------|-------|---------|-------|-------|------|------|------------|------|--------|------------|----------------|----|
| 31   | 30   | 29        | 28   | 27    | 26      | 25    | 24    | 23   | 22   | 21         | 20   | 19     | 18         | 17             | 16 |

Bits 31:19 Reserved, must be kept at reset value.

Bits 18:16 **INSEL[2:0]**: SPDIFRX input selection<sup>(1)</sup>

000: SPDIFRX\_IN1 selected  
 001: SPDIFRX\_IN2 selected  
 010: SPDIFRX\_IN3 selected  
 011: SPDIFRX\_IN4 selected  
 others reserved

Bit 15 Reserved, must be kept at reset value.

Bit 14 **WFA**: Wait for activity<sup>(1)</sup>

This bit is set/reset by software

1: The SPDIFRX waits for activity on SPDIFRX\_IN line (4 transitions) before performing the synchronization

0: The SPDIFRX does not wait for activity on SPDIFRX\_IN line before performing the synchronization

Bits 13:12 **NBTR[1:0]**: Maximum allowed re-tries during synchronization phase<sup>(1)</sup>

00: No re-try is allowed (only one attempt)

01: 3 re-tries allowed

10: 15 re-tries allowed

11: 63 re-tries allowed

Bit 11 **CHSEL**: Channel selection<sup>(1)</sup>

This bit is set/reset by software

1: The control flow will take the channel status from channel B

0: The control flow will take the channel status from channel A

Bit 10 **CBDMAEN**: Control buffer DMA enable for control flow<sup>(1)</sup>

This bit is set/reset by software

1: DMA mode is enabled for reception of channel status and used data information.

0: DMA mode is disabled for reception of channel status and used data information.

When this bit is set, the DMA request is made whenever the CSRNE flag is set.

Bit 9 **PTMSK**: Mask of preamble type bits<sup>(1)</sup>

This bit is set/reset by software

1: The preamble type bits are not copied into the SPDIFRX\_FMTx\_DR, zeros are written instead

0: The preamble type bits are copied into the SPDIFRX\_FMTx\_DR

Bit 8 **CUMSK**: Mask of channel status and user bits<sup>(1)</sup>

This bit is set/reset by software

1: The channel status and user bits are not copied into the SPDIFRX\_FMTx\_DR, zeros are written instead

0: The channel status and user bits are copied into the SPDIFRX\_FMTx\_DR

Bit 7 **VMSK**: Mask of validity bit<sup>(1)</sup>

This bit is set/reset by software

1: The validity bit is not copied into the SPDIFRX\_FMTx\_DR, a zero is written instead

0: The validity bit is copied into the SPDIFRX\_FMTx\_DR

Bit 6 **PMSK**: Mask parity error bit<sup>(1)</sup>

This bit is set/reset by software

1: The parity error bit is not copied into the SPDIFRX\_FMTx\_DR, a zero is written instead

0: The parity error bit is copied into the SPDIFRX\_FMTx\_DR

Bits 5:4 **DRFMT[1:0]**: RX data format<sup>(1)</sup>

This bit is set/reset by software

11: reserved

10: Data sample are packed by setting two 16-bit sample into a 32-bit word

01: Data samples are aligned in the left (MSB)

00: Data samples are aligned in the right (LSB)

Bit 3 **RXSTEO**: Stereo mode<sup>(1)</sup>

This bit is set/reset by software

1: The peripheral is in STEREO mode

0: The peripheral is in MONO mode

This bit is used in case of overrun situation in order to handle misalignment

Bit 2 **RXDMAEN**: Receiver DMA enable for data flow<sup>(1)</sup>

This bit is set/reset by software

1: DMA mode is enabled for reception.

0: DMA mode is disabled for reception.

When this bit is set, the DMA request is made whenever the RXNE flag is set.

Bits 1:0 **SPDIFRXEN[1:0]**: Peripheral block enable<sup>(1)</sup>

This field is modified by software.

It shall be used to change the peripheral phase among the three possible states: STATE\_IDLE, STATE\_SYNC and STATE\_RCV.

00: Disable SPDIFRX (STATE\_IDLE).

01: Enable SPDIFRX Synchronization only

10: Reserved

11: Enable SPDIF Receiver

*Note: it is not possible to transition from STATE\_RCV to STATE\_SYNC, the user shall first go the STATE\_IDLE.*

*it is possible to transition from STATE\_IDLE to STATE\_RCV: in that case the peripheral transitions from STATE\_IDLE to STATE\_SYNC and as soon as the synchronization is performed goes to STATE\_RCV.*

1. Refer to [Section 34.3.12: Register protection](#) for additional information on fields properties.

### 34.5.2 Interrupt mask register (SPDIFRX\_IMR)

Address offset: 0x04

Reset value: 0x0000 0000

|      |      |      |      |      |      |      |      |      |           |             |            |           |            |             |            |

Bits 31:7 Reserved, must be kept at reset value.

**Bit 6 IFEIE:** Serial Interface Error Interrupt Enable

This bit is set and cleared by software.

0: Interrupt is inhibited

1: A SPDIFRX interface interrupt is generated whenever SERR=1, TERR=1 or FERR=1 in the SPDIFRX\_SR register.

**Bit 5 SYNCDIE:** Synchronization Done

This bit is set and cleared by software.

0: Interrupt is inhibited

1: A SPDIFRX interface interrupt is generated whenever SYNCD = 1 in the SPDIFRX\_SR register.

**Bit 4 SBLKIE:** Synchronization Block Detected Interrupt Enable

This bit is set and cleared by software.

0: Interrupt is inhibited

1: A SPDIFRX interface interrupt is generated whenever SBD = 1 in the SPDIFRX\_SR register.

**Bit 3 OVRIE:** Overrun error Interrupt Enable

This bit is set and cleared by software.

0: Interrupt is inhibited

1: A SPDIFRX interface interrupt is generated whenever OVR=1 in the SPDIFRX\_SR register

**Bit 2 PERRIE:** Parity error interrupt enable

This bit is set and cleared by software.

0: Interrupt is inhibited

1: A SPDIFRX interface interrupt is generated whenever PERR=1 in the SPDIFRX\_SR register

**Bit 1 CSRNEIE:** Control Buffer Ready Interrupt Enable

This bit is set and cleared by software.

0: Interrupt is inhibited

1: A SPDIFRX interface interrupt is generated whenever CSRNE = 1 in the SPDIFRX\_SR register.

**Bit 0 RXNEIE:** RXNE interrupt enable

This bit is set and cleared by software.

0: Interrupt is inhibited

1: A SPDIFRX interface interrupt is generated whenever RXNE=1 in the SPDIFRX\_SR register

### 34.5.3 Status register (SPDIFRX\_SR)

Address offset: 0x08

Reset value: 0x0000 0000

|      |              |      |      |      |      |      |      |      |      |       |     |     |      |       |      |
|------|--------------|------|------|------|------|------|------|------|------|-------|-----|-----|------|-------|------|
| 31   | 30           | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21    | 20  | 19  | 18   | 17    | 16   |
| Res. | WIDTH5[14:0] |      |      |      |      |      |      |      |      |       |     |     |      |       |      |
|      | r            | r    | r    | r    | r    | r    | r    | r    | r    | r     | r   | r   | r    | r     | r    |
| 15   | 14           | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5     | 4   | 3   | 2    | 1     | 0    |
| Res. | Res.         | Res. | Res. | Res. | Res. | Res. | TERR | SERR | FERR | SYNCD | SBD | OVR | PERR | CSRNE | RXNE |
|      |              |      |      |      |      |      | r    | r    | r    | r     | r   | r   | r    | r     | r    |

Bit 31 Reserved, must be kept at reset value.

Bits 30:16 **WIDTH5[14:0]**: Duration of 5 symbols counted with SPDIFRX\_CLK

This value represents the amount of SPDIFRX\_CLK clock periods contained on a length of 5 consecutive symbols. This value can be used to estimate the S/PDIF symbol rate. Its accuracy is limited by the frequency of SPDIFRX\_CLK.

For example if the SPDIFRX\_CLK is fixed to 84 MHz, and WIDTH5 = 147d. The estimated sampling rate of the S/PDIF stream is:

$F_s = 5 \times F_{\text{SPDIFRX\_CLK}} / (\text{WIDTH5} \times 64) \sim 44.6 \text{ kHz}$ , so the closest standard sampling rate is 44.1 kHz.

Note that WIDTH5 is updated by the hardware when SYNCD goes high, and then every frame.

Bits 15:9 Reserved, must be kept at reset value.

Bit 8 **TERR**: Time-out error

This bit is set by hardware when the counter TRCNT reaches its max value. It indicates that the time interval between two transitions is too long. It generally indicates that there is no valid signal on SPDIFRX\_IN input.

This flag is cleared by writing SPDIFRXEN to 0

An interrupt is generated if IFEIE=1 in the SPDIFRX\_IMR register

0: No sequence error is detected

1: Sequence error is detected

Bit 7 **SERR**: Synchronization error

This bit is set by hardware when the synchronization fails due to amount of re-tries for NBTR.

This flag is cleared by writing SPDIFRXEN to 0

An interrupt is generated if IFEIE=1 in the SPDIFRX\_IMR register.

0: No synchronization error is detected

1: Synchronization error is detected

Bit 6 **FERR**: Framing error

This bit is set by hardware when an error occurs during data reception: preamble not at the expected place, short transition not grouped by pairs...

This is set by the hardware only if the synchronization has been completed (SYNCD = 1).

This flag is cleared by writing SPDIFRXEN to 0

An interrupt is generated if IFEIE=1 in the SPDIFRX\_IMR register.

0: no Manchester Violation detected

1: Manchester Violation detected

**Bit 5 SYNCND:** Synchronization Done

This bit is set by hardware when the initial synchronization phase is properly completed.

This flag is cleared by writing a 1 to its corresponding bit on SPDIFRX\_CLR\_SR register.

An interrupt is generated if SYNCNDIE = 1 in the SPDIFRX\_IMR register

0: Synchronization is pending

1: Synchronization is completed

**Bit 4 SBD:** Synchronization Block Detected

This bit is set by hardware when a “B” preamble is detected

This flag is cleared by writing a 1 to its corresponding bit on SPDIFRX\_CLR\_SR register.

An interrupt is generated if SBLKIE = 1 in the SPDIFRX\_IMR register

0: No “B” preamble detected

1: “B” preamble has been detected

**Bit 3 OVR:** Overrun error

This bit is set by hardware when a received data is ready to be transferred in the

SPDIFRX\_FMTx\_DR register while RXNE = 1 and both SPDIFRX\_FMTx\_DR and RX\_BUF are full.

This flag is cleared by writing a 1 to its corresponding bit on SPDIFRX\_CLR\_SR register.

An interrupt is generated if OVRIE=1 in the SPDIFRX\_IMR register.

0: No Overrun error

1: Overrun error is detected

*Note: When this bit is set, the SPDIFRX\_FMTx\_DR register content will not be lost but the last data received will.*

**Bit 2 PERR:** Parity error

This bit is set by hardware when the data and status bits of the sub-frame received contain an odd number of 0 and 1.

This flag is cleared by writing a 1 to its corresponding bit on SPDIFRX\_CLR\_SR register.

An interrupt is generated if PIE = 1 in the SPDIFRX\_IMR register.

0: No parity error

1: Parity error

**Bit 1 CSRNE:** The Control Buffer register is not empty

This bit is set by hardware when a valid control information is ready.

This flag is cleared when reading SPDIFRX\_CSR register.

An interrupt is generated if CBRDYIE = 1 in the SPDIFRX\_IMR register

0: No control word available on SPDIFRX\_CSR register

1: A control word is available on SPDIFRX\_CSR register

**Bit 0 RXNE:** Read data register not empty

This bit is set by hardware when a valid data is available into SPDIFRX\_FMTx\_DR register.

This flag is cleared by reading the SPDIFRX\_FMTx\_DR register.

An interrupt is generated if RXNEIE=1 in the SPDIFRX\_IMR register.

0: Data is not received

1: Received data is ready to be read.

### 34.5.4 Interrupt flag clear register (SPDIFRX\_IFCR)

Address offset: 0x0C

Reset value: 0x0000 0000

|      |      |      |      |      |      |      |      |      |      |             |           |           |            |      |      |

Bits 31:6 Reserved, must be kept at reset value.

Bit 5 **SYNDCF**: Clears the Synchronization Done flag

Writing 1 in this bit clears the flag SYNCD in the SPDIFRX\_SR register.

Reading this bit always returns the value 0.

Bit 4 **SBD CF**: Clears the Synchronization Block Detected flag

Writing 1 in this bit clears the flag SBD in the SPDIFRX\_SR register.

Reading this bit always returns the value 0.

Bit 3 **OVR CF**: Clears the Overrun error flag

Writing 1 in this bit clears the flag OVR in the SPDIFRX\_SR register.

Reading this bit always returns the value 0.

Bit 2 **PERR CF**: Clears the Parity error flag

Writing 1 in this bit clears the flag PERR in the SPDIFRX\_SR register.

Reading this bit always returns the value 0.

Bits 1:0 Reserved, must be kept at reset value.

### 34.5.5 Data input register (SPDIFRX\_FMT0\_DR)

Address offset: 0x10

Reset value: 0x0000 0000

This register can take 3 different formats according to DRFMT. Here is the format when DRFMT = 00:

|          |      |         |    |    |    |    |    |           |    |    |    |    |    |    |    |
|----------|------|---------|----|----|----|----|----|-----------|----|----|----|----|----|----|----|
| 31       | 30   | 29      | 28 | 27 | 26 | 25 | 24 | 23        | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| Res.     | Res. | PT[1:0] |    | C  | U  | V  | PE | DR[23:16] |    |    |    |    |    |    |    |
|          |      | r       | r  | r  | r  | r  | r  | r         | r  | r  | r  | r  | r  | r  | r  |
| 15       | 14   | 13      | 12 | 11 | 10 | 9  | 8  | 7         | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| DR[15:0] |      |         |    |    |    |    |    |           |    |    |    |    |    |    |    |
| r        | r    | r       | r  | r  | r  | r  | r  | r         | r  | r  | r  | r  | r  | r  | r  |

Bits 31:30 Reserved, must be kept at reset value.

Bits 29:28 **PT[1:0]**: Preamble Type

These bits indicate the preamble received.

00: not used

01: Preamble B received

10: Preamble M received

11: Preamble W received

Note that if PTMSK = 1, this field is forced to zero

Bit 27 **C**: Channel Status bit

Contains the received channel status bit, if CUMSK = 0, otherwise it is forced to 0

Bit 26 **U**: User bit

Contains the received user bit, if CUMSK = 0, otherwise it is forced to 0

Bit 25 **V**: Validity bit

Contains the received validity bit if VMSK = 0, otherwise it is forced to 0

Bit 24 **PE**: Parity Error bit

Contains a copy of PERR bit if PMSK = 0, otherwise it is forced to 0

Bits 23:0 **DR[23:0]**: Data value

Contains the 24 received data bits, aligned on D[23]

### 34.5.6 Data input register (SPDIFRX\_FMT1\_DR)

Address offset: 0x10

Reset value: 0x0000 0000

This register can take 3 different formats according to DRFMT. Here is the format when DRFMT = 01:

|          |    |    |    |    |    |    |    |      |      |         |    |    |    |    |    |
|----------|----|----|----|----|----|----|----|------|------|---------|----|----|----|----|----|
| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23   | 22   | 21      | 20 | 19 | 18 | 17 | 16 |
| DR[23:8] |    |    |    |    |    |    |    |      |      |         |    |    |    |    |    |
| r        | r  | r  | r  | r  | r  | r  | r  | r    | r    | r       | r  | r  | r  | r  | r  |
| 15       | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7    | 6    | 5       | 4  | 3  | 2  | 1  | 0  |
| DR[7:0]  |    |    |    |    |    |    |    | Res. | Res. | PT[1:0] |    | C  | U  | V  | PE |
| r        | r  | r  | r  | r  | r  | r  | r  |      |      | r       | r  | r  | r  | r  | r  |

Bits 31:8 **DR[23:0]**: Data value

Contains the 24 received data bits, aligned on D[23]

Bits 7:6 **Reserved**, must be kept at reset value.

Bits 5:4 **PT[1:0]**: Preamble Type

These bits indicate the preamble received.

00: not used

01: Preamble B received

10: Preamble M received

11: Preamble W received

Note that if PTMSK = 1, this field is forced to zero

Bit 3 **C**: Channel Status bit

Contains the received channel status bit, if CUMSK = 0, otherwise it is forced to 0

Bit 2 **U**: User bit

Contains the received user bit, if CUMSK = 0, otherwise it is forced to 0

Bit 1 **V**: Validity bit

Contains the received validity bit if VMSK = 0, otherwise it is forced to 0

Bit 0 **PE**: Parity Error bit

Contains a copy of PERR bit if PMSK = 0, otherwise it is forced to 0

34.5.7 Data input register (SPDIFRX\_FMT2\_DR)

Address offset: 0x10

Reset value: 0x0000 0000

This register can take 3 different formats according to DRFMT.

The data format proposed when DRFMT = 10, is dedicated to non-linear mode, as only 16 bits are used (bits 23 to 8 from S/PDIF sub-frame).

|             |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|-------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31          | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| DRNL2[15:0] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| r           | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  |
| 15          | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| DRNL1[15:0] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| r           | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  |

- Bits 31:16 **DRNL2[15:0]**: Data value  
This field contains the Channel A
- Bits 15:0 **DRNL1[15:0]**: Data value  
This field contains the Channel B

### 34.5.8 Channel status register (SPDIFRX\_CSR)

Address offset: 0x14

Reset value: 0x0000 0000

|           |      |      |      |      |      |      |     |         |    |    |    |    |    |    |    |
|-----------|------|------|------|------|------|------|-----|---------|----|----|----|----|----|----|----|
| 31        | 30   | 29   | 28   | 27   | 26   | 25   | 24  | 23      | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| Res.      | Res. | Res. | Res. | Res. | Res. | Res. | SOB | CS[7:0] |    |    |    |    |    |    |    |
|           |      |      |      |      |      |      | r   | r       | r  | r  | r  | r  | r  | r  | r  |
| 15        | 14   | 13   | 12   | 11   | 10   | 9    | 8   | 7       | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| USR[15:0] |      |      |      |      |      |      |     |         |    |    |    |    |    |    |    |
| r         | r    | r    | r    | r    | r    | r    | r   | r       | r  | r  | r  | r  | r  | r  | r  |

Bits 31:25 Reserved, must be kept at reset value.

Bit 24 **SOB**: Start Of Block

This bit indicates if the bit CS[0] corresponds to the first bit of a new block

0: CS[0] is not the first bit of a new block

1: CS[0] is the first bit of a new block

Bits 23:16 **CS[7:0]**: Channel A status information

Bit CS[0] is the oldest value

Bits 15:0 **USR[15:0]**: User data information

Bit USR[0] is the oldest value, and comes from channel A, USR[1] comes channel B.

So USR[n] bits come from channel A is n is even, otherwise they come from channel B.

### 34.5.9 Debug information register (SPDIFRX\_DIR)

Address offset: 0x18

Reset value: 0x0000 0000

|      |      |      |           |    |    |    |    |    |    |    |    |    |    |    |    |

Bits 31:29 Reserved, must be kept at reset value.

Bits 28:16 **TLO[12:0]**: Threshold LOW ( $TLO = 1.5 \times UI / T_{SPDIFRX\_CLK}$ )

This field contains the current threshold LOW estimation. This value can be used to estimate the sampling rate of the received stream. The accuracy of TLO is limited to a period of the SPDIFRX\_CLK. The sampling rate can be estimated as follow:

$$\text{Sampling Rate} = [2 \times TLO \times T_{SPDIFRX\_CLK} \pm T_{SPDIFRX\_CLK}] \times 2/3$$

Note that TLO is updated by the hardware when SYNC $\overline{D}$  goes high, and then every frame.

Bits 15:13 Reserved, must be kept at reset value.

Bits 12:0 **THI[12:0]**: Threshold HIGH ( $THI = 2.5 \times UI / T_{SPDIFRX\_CLK}$ )

This field contains the current threshold HIGH estimation. This value can be used to estimate the sampling rate of the received stream. The accuracy of THI is limited to a period of the SPDIFRX\_CLK. The sampling rate can be estimated as follow:

$$\text{Sampling Rate} = [2 \times THI \times T_{SPDIFRX\_CLK} \pm T_{SPDIFRX\_CLK}] \times 2/5$$

Note that THI is updated by the hardware when SYNC $\overline{D}$  goes high, and then every frame.

### 34.5.10 SPDIFRX interface register map

Table 219 gives the SPDIFRX interface register map and reset values.

Table 219. SPDIFRX interface register map and reset values

| Offset | Register name   | 31          | 30           | 29      | 28        | 27   | 26   | 25   | 24      | 23   | 22       | 21   | 20   | 19   | 18         | 17          | 16   | 15        | 14   | 13   | 12        | 11   | 10    | 9       | 8     | 7       | 6     | 5       | 4          | 3     | 2      | 1       | 0              |   |

Refer to [Section 2.2.2 on page 69](#) for the register boundary addresses.

## 35 SD/SDIO/MMC card host interface (SDMMC)

### 35.1 SDMMC main features

The SD/SDIO MMC card host interface (SDMMC) provides an interface between the APB2 peripheral bus and MultiMediaCards (MMCs), SD memory cards and SDIO cards.

The MultiMediaCard system specifications are available through the MultiMediaCard Association website, published by the MMCA technical committee.

SD memory card and SD I/O card system specifications are available through the SD card Association website.

The SDMMC features include the following:

- Full compliance with *MultiMediaCard System Specification Version 4.2*. Card support for three different databus modes: 1-bit (default), 4-bit and 8-bit
- Full compatibility with previous versions of MultiMediaCards (forward compatibility)
- Full compliance with *SD Memory Card Specifications Version 2.0*
- Full compliance with *SD I/O Card Specification Version 2.0*: card support for two different databus modes: 1-bit (default) and 4-bit
- Data transfer up to 50 MHz for the 8 bit mode
- Data and command output enable signals to control external bidirectional drivers.

- Note:*
- 1 *The SDMMC does not have an SPI-compatible communication mode.*
  - 2 *The SD memory card protocol is a superset of the MultiMediaCard protocol as defined in the MultiMediaCard system specification V2.11. Several commands required for SD memory devices are not supported by either SD I/O-only cards or the I/O portion of combo cards. Some of these commands have no use in SD I/O devices, such as erase commands, and thus are not supported in the SDIO protocol. In addition, several commands are different between SD memory cards and SD I/O cards and thus are not supported in the SDIO protocol. For details refer to SD I/O card Specification Version 1.0.*

The MultiMediaCard/SD bus connects cards to the controller.

The current version of the SDMMC supports only one SD/SDIO/MMC4.2 card at any one time and a stack of MMC4.1 or previous.

### 35.2 SDMMC bus topology

Communication over the bus is based on command and data transfers.

The basic transaction on the MultiMediaCard/SD/SD I/O bus is the command/response transaction. These types of bus transaction transfer their information directly within the command or response structure. In addition, some operations have a data token.

Data transfers to/from SD/SDIO memory cards are done in data blocks. Data transfers to/from MMC are done data blocks or streams.

Figure 427. “No response” and “no data” operations

Figure 428. (Multiple) block read operation

Figure 429. (Multiple) block write operation

**Note:** The SDMMC will not send any data as long as the Busy signal is asserted (SDMMC\_D0 pulled low).

Figure 430. Sequential read operation

Figure 431. Sequential write operation

### 35.3 SDMMC functional description

The SDMMC consists of two parts:

- The SDMMC adapter block provides all functions specific to the MMC/SD/SD I/O card such as the clock generation unit, command and data transfer.
- The APB2 interface accesses the SDMMC adapter registers, and generates interrupt and DMA request signals.

Figure 432. SDMMC block diagram

By default SDMMC\_D0 is used for data transfer. After initialization, the host can change the databus width.

If a MultiMediaCard is connected to the bus, SDMMC\_D0, SDMMC\_D[3:0] or SDMMC\_D[7:0] can be used for data transfer. MMC V3.31 or previous, supports only 1 bit of data so only SDMMC\_D0 can be used.

If an SD or SD I/O card is connected to the bus, data transfer can be configured by the host to use SDMMC\_D0 or SDMMC\_D[3:0]. All data lines are operating in push-pull mode.

**SDMMC\_CMD** has two operational modes:

- Open-drain for initialization (only for MMCV3.31 or previous)
- Push-pull for command transfer (SD/SD I/O card MMC4.2 use push-pull drivers also for initialization)

**SDMMC\_CK** is the clock to the card: one bit is transferred on both command and data lines with each clock cycle.

The SDMMC uses two clock signals:

- SDMMC adapter clock SDMMCCLK = 50 MHz)
- APB2 bus clock (PCLK2)

PCLK2 and SDMMC\_CK clock frequencies must respect the following condition:

$$\text{Frequency(PCLK2)} > ((3 \times \text{Width}) / 32) \times \text{Frequency(SDMMC\_CK)}$$

The signals shown in [Table 220](#) are used on the MultiMediaCard/SD/SD I/O card bus.

**Table 220. SDMMC I/O definitions**

| Pin          | Direction     | Description                                                                                 |
|--------------|---------------|---------------------------------------------------------------------------------------------|
| SDMMC_CK     | Output        | MultiMediaCard/SD/SDIO card clock. This pin is the clock from host to card.                 |
| SDMMC_CMD    | Bidirectional | MultiMediaCard/SD/SDIO card command. This pin is the bidirectional command/response signal. |
| SDMMC_D[7:0] | Bidirectional | MultiMediaCard/SD/SDIO card data. These pins are the bidirectional databus.                 |

### 35.3.1 SDMMC adapter

Figure 433 shows a simplified block diagram of an SDMMC adapter.

Figure 433. SDMMC adapter

The SDMMC adapter is a multimedia/secure digital memory card bus master that provides an interface to a multimedia card stack or to a secure digital memory card. It consists of five subunits:

- Adapter register block
- Control unit
- Command path
- Data path
- Data FIFO

**Note:** The adapter registers and FIFO use the APB2 bus clock domain (PCLK2). The control unit, command path and data path use the SDMMC adapter clock domain (SDMMCCLK).

#### Adapter register block

The adapter register block contains all system registers. This block also generates the signals that clear the static flags in the multimedia card. The clear signals are generated when 1 is written into the corresponding bit location in the SDMMC Clear register.

#### Control unit

The control unit contains the power management functions and the clock divider for the memory card clock.

There are three power phases:

- power-off
- power-up
- power-on

Figure 434. Control unit

The control unit is illustrated in [Figure 434](#). It consists of a power management subunit and a clock management subunit.

The power management subunit disables the card bus output signals during the power-off and power-up phases.

The clock management subunit generates and controls the SDMMC\_CLK signal. The SDMMC\_CLK output can use either the clock divide or the clock bypass mode. The clock output is inactive:

- after reset
- during the power-off or power-up phases
- if the power saving mode is enabled and the card bus is in the Idle state (eight clock periods after both the command and data path subunits enter the Idle phase)

The clock management subunit controls SDMMC\_CLK dephasing. When not in bypass mode the SDMMC command and data output are generated on the SDMMCCLK falling edge succeeding the rising edge of SDMMC\_CLK. (SDMMC\_CLK rising edge occurs on SDMMCCLK rising edge) when SDMMC\_CLKCR[13] bit is reset (NEGEDGE = 0). When SDMMC\_CLKCR[13] bit is set (NEGEDGE = 1) SDMMC command and data changed on the SDMMC\_CLK falling edge.

When SDMMC\_CLKCR[10] is set (BYPASS = 1), SDMMC\_CLK rising edge occurs on SDMMCCLK rising edge. The data and the command change on SDMMCCLK falling edge whatever NEGEDGE value.

The data and command responses are latched using SDMMC\_CLK rising edge.

Figure 435. SDMMC\_CK clock dephasing (BYPASS = 0)

### Command path

The command path unit sends commands to and receives responses from the cards.

Figure 436. SDMMC adapter command path

- Command path state machine (CPSM)
  - When the command register is written to and the enable bit is set, command transfer starts. When the command has been sent, the command path state machine (CPSM) sets the status flags and enters the Idle state if a response is not required. If a response is required, it waits for the response (see [Figure 437 on page 1243](#)). When the response is received, the received CRC code and the internally generated code are compared, and the appropriate status flags are set.

Figure 437. Command path state machine (SDMMC)

When the Wait state is entered, the command timer starts running. If the timeout is reached before the CPSM moves to the Receive state, the timeout flag is set and the Idle state is entered.

**Note:** The command timeout has a fixed value of 64 SDMMC\_CLK clock periods.

If the interrupt bit is set in the command register, the timer is disabled and the CPSM waits for an interrupt request from one of the cards. If a pending bit is set in the command register, the CPSM enters the Pend state, and waits for a CmdPend signal from the data path subunit. When CmdPend is detected, the CPSM moves to the Send state. This enables the data counter to trigger the stop command transmission.

**Note:** The CPSM remains in the Idle state for at least eight SDMMC\_CLK periods to meet the  $N_{CC}$  and  $N_{RC}$  timing constraints.  $N_{CC}$  is the minimum delay between two host commands, and  $N_{RC}$  is the minimum delay between the host command and the card response.

Figure 438. SDMMC command transfer

- Command format

- Command: a command is a token that starts an operation. Commands are sent from the host either to a single card (addressed command) or to all connected cards (broadcast command are available for MMC V3.31 or previous). Commands are transferred serially on the CMD line. All commands have a fixed length of 48 bits. The general format for a command token for MultiMediaCards, SD-Memory cards and SDIO-Cards is shown in [Table 221](#).

The command path operates in a half-duplex mode, so that commands and responses can either be sent or received. If the CPSM is not in the Send state, the SDMMC\_CMD output is in the Hi-Z state, as shown in [Figure 438 on page 1244](#). Data on SDMMC\_CMD are synchronous with the rising edge of SDMMC\_CK. [Table 221](#) shows the command format.

Table 221. Command format

| Bit position | Width | Value | Description      |
|--------------|-------|-------|------------------|
| 47           | 1     | 0     | Start bit        |
| 46           | 1     | 1     | Transmission bit |
| [45:40]      | 6     | -     | Command index    |
| [39:8]       | 32    | -     | Argument         |
| [7:1]        | 7     | -     | CRC7             |
| 0            | 1     | 1     | End bit          |

- Response: a response is a token that is sent from an addressed card (or synchronously from all connected cards for MMC V3.31 or previous), to the host as an answer to a previously received command. Responses are transferred serially on the CMD line.

The SDMMC supports two response types. Both use CRC error checking:

- 48 bit short response
- 136 bit long response

**Note:** *If the response does not contain a CRC (CMD1 response), the device driver must ignore the CRC failed status.*

Table 222. Short response format

| Bit position | Width | Value | Description      |
|--------------|-------|-------|------------------|
| 47           | 1     | 0     | Start bit        |
| 46           | 1     | 0     | Transmission bit |
| [45:40]      | 6     | -     | Command index    |
| [39:8]       | 32    | -     | Argument         |
| [7:1]        | 7     | -     | CRC7(or 1111111) |
| 0            | 1     | 1     | End bit          |

Table 223. Long response format

| Bit position | Width | Value  | Description                          |
|--------------|-------|--------|--------------------------------------|
| 135          | 1     | 0      | Start bit                            |
| 134          | 1     | 0      | Transmission bit                     |
| [133:128]    | 6     | 111111 | Reserved                             |
| [127:1]      | 127   | -      | CID or CSD (including internal CRC7) |
| 0            | 1     | 1      | End bit                              |

The command register contains the command index (six bits sent to a card) and the command type. These determine whether the command requires a response, and whether the response is 48 or 136 bits long (see [Section 35.8.4 on page 1280](#)). The command path implements the status flags shown in [Table 224](#):

Table 224. Command path status flags

| Flag     | Description                                               |
|----------|-----------------------------------------------------------|
| CMDREND  | Set if response CRC is OK.                                |
| CCRCFAIL | Set if response CRC fails.                                |
| CMDSENT  | Set when command (that does not require response) is sent |
| CTIMEOUT | Response timeout.                                         |
| CMDACT   | Command transfer in progress.                             |

The CRC generator calculates the CRC checksum for all bits before the CRC code. This includes the start bit, transmitter bit, command index, and command argument (or card status). The CRC checksum is calculated for the first 120 bits of CID or CSD for the long response format. Note that the start bit, transmitter bit and the six reserved bits are not used in the CRC calculation.

The CRC checksum is a 7-bit value:

$$\text{CRC}[6:0] = \text{Remainder} [(M(x) * x^7) / G(x)]$$

$$G(x) = x^7 + x^3 + 1$$

$$M(x) = (\text{start bit}) * x^{39} + \dots + (\text{last bit before CRC}) * x^0, \text{ or}$$

$$M(x) = (\text{start bit}) * x^{119} + \dots + (\text{last bit before CRC}) * x^0$$

## Data path

The data path subunit transfers data to and from cards. [Figure 439](#) shows a block diagram of the data path.

**Figure 439. Data path**

The card databus width can be programmed using the clock control register. If the 4-bit wide bus mode is enabled, data is transferred at four bits per clock cycle over all four data signals (SDMMC\_D[3:0]). If the 8-bit wide bus mode is enabled, data is transferred at eight bits per clock cycle over all eight data signals (SDMMC\_D[7:0]). If the wide bus mode is not enabled, only one bit per clock cycle is transferred over SDMMC\_D0.

Depending on the transfer direction (send or receive), the data path state machine (DPSM) moves to the Wait\_S or Wait\_R state when it is enabled:

- Send: the DPSM moves to the Wait\_S state. If there is data in the transmit FIFO, the DPSM moves to the Send state, and the data path subunit starts sending data to a card.
- Receive: the DPSM moves to the Wait\_R state and waits for a start bit. When it receives a start bit, the DPSM moves to the Receive state, and the data path subunit starts receiving data from a card.

### Data path state machine (DPSM)

The DPSM operates at SDMMC\_CK frequency. Data on the card bus signals is synchronous to the rising edge of SDMMC\_CK. The DPSM has six states, as shown in [Figure 440: Data path state machine \(DPSM\)](#).

Figure 440. Data path state machine (DPSM)

- **Idle:** the data path is inactive, and the SDMMC\_D[7:0] outputs are in Hi-Z. When the data control register is written and the enable bit is set, the DPSM loads the data counter with a new value and, depending on the data direction bit, moves to either the Wait\_S or the Wait\_R state.
- **Wait\_R:** if the data counter equals zero, the DPSM moves to the Idle state when the receive FIFO is empty. If the data counter is not zero, the DPSM waits for a start bit on SDMMC\_D. The DPSM moves to the Receive state if it receives a start bit before a timeout, and loads the data block counter. If it reaches a timeout before it detects a start bit, it moves to the Idle state and sets the timeout status flag.
- **Receive:** serial data received from a card is packed in bytes and written to the data FIFO. Depending on the transfer mode bit in the data control register, the data transfer mode can be either block or stream:
  - In block mode, when the data block counter reaches zero, the DPSM waits until it receives the CRC code. If the received code matches the internally generated CRC code, the DPSM moves to the Wait\_R state. If not, the CRC fail status flag is set and the DPSM moves to the Idle state.
  - In stream mode, the DPSM receives data while the data counter is not zero. When the counter is zero, the remaining data in the shift register is written to the data FIFO, and the DPSM moves to the Wait\_R state.

If a FIFO overrun error occurs, the DPSM sets the FIFO error flag and moves to the Idle state:

- **Wait\_S:** the DPSM moves to the Idle state if the data counter is zero. If not, it waits until the data FIFO empty flag is deasserted, and moves to the Send state.

**Note:** The DPSM remains in the Wait\_S state for at least two clock periods to meet the  $N_{WR}$  timing requirements, where  $N_{WR}$  is the number of clock cycles between the reception of the card response and the start of the data transfer from the host.

- **Send:** the DPSM starts sending data to a card. Depending on the transfer mode bit in the data control register, the data transfer mode can be either block or stream:
  - In block mode, when the data block counter reaches zero, the DPSM sends an internally generated CRC code and end bit, and moves to the Busy state.
  - In stream mode, the DPSM sends data to a card while the enable bit is high and the data counter is not zero. It then moves to the Idle state.

If a FIFO underrun error occurs, the DPSM sets the FIFO error flag and moves to the Idle state.

- **Busy:** the DPSM waits for the CRC status flag:
  - If it does not receive a positive CRC status, it moves to the Idle state and sets the CRC fail status flag.
  - If it receives a positive CRC status, it moves to the Wait\_S state if SDMMC\_D0 is not low (the card is not busy).

If a timeout occurs while the DPSM is in the Busy state, it sets the data timeout flag and moves to the Idle state.

The data timer is enabled when the DPSM is in the Wait\_R or Busy state, and generates the data timeout error:

- When transmitting data, the timeout occurs if the DPSM stays in the Busy state for longer than the programmed timeout period
- When receiving data, the timeout occurs if the end of the data is not true, and if the DPSM stays in the Wait\_R state for longer than the programmed timeout period.
- **Data:** data can be transferred from the card to the host or vice versa. Data is transferred via the data lines. They are stored in a FIFO of 32 words, each word is 32 bits wide.

**Table 225. Data token format**

| Description | Start bit | Data | CRC16 | End bit |
|-------------|-----------|------|-------|---------|
| Block Data  | 0         | -    | yes   | 1       |
| Stream Data | 0         | -    | no    | 1       |

## DPSM Flags

The status of the data path subunit transfer is reported by several status flags

**Table 226. DPSM flags**

| Flag     | Description                                                                                                                                                                                                                                    |
|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DBCKEND  | Set to high when data block send/receive CRC check is passed.<br>In SDIO multibyte transfer mode this flag is set at the end of the transfer (a multibyte transfer is considered as a single block transfer by the host).                      |
| DATAEND  | Set to high when SDMMC_DCOUNT register decrements and reaches 0.<br>DATAEND indicates the end of a transfer on SDMMC data line.                                                                                                                |
| DTIMEOUT | Set to high when data timeout period is reached.<br>When data timer reaches zero while DPSM is in Wait_R or Busy state, timeout is set. DTIMEOUT can be set after DATAEND if DPSM remains in busy state for longer than the programmed period. |
| DCRCFAIL | Set to high when data block send/receive CRC check fails.                                                                                                                                                                                      |

## Data FIFO

The data FIFO (first-in-first-out) subunit is a data buffer with a transmit and receive unit.

The FIFO contains a 32-bit wide, 32-word deep data buffer, and transmit and receive logic. Because the data FIFO operates in the APB2 clock domain (PCLK2), all signals from the subunits in the SDMMC clock domain (SDMMCCLK) are resynchronized.

Depending on the TXACT and RXACT flags, the FIFO can be disabled, transmit enabled, or receive enabled. TXACT and RXACT are driven by the data path subunit and are mutually exclusive:

- The transmit FIFO refers to the transmit logic and data buffer when TXACT is asserted
- The receive FIFO refers to the receive logic and data buffer when RXACT is asserted
- Transmit FIFO:
 

Data can be written to the transmit FIFO through the APB2 interface when the SDMMC is enabled for transmission.

The transmit FIFO is accessible via 32 sequential addresses. The transmit FIFO contains a data output register that holds the data word pointed to by the read pointer. When the data path subunit has loaded its shift register, it increments the read pointer and drives new data out.

If the transmit FIFO is disabled, all status flags are deasserted. The data path subunit asserts TXACT when it transmits data.

Table 227. Transmit FIFO status flags

| Flag     | Description                                                                                                                                                                                                                                                                                                     |
|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TXFIFO   | Set to high when all 32 transmit FIFO words contain valid data.                                                                                                                                                                                                                                                 |
| TXFIFOE  | Set to high when the transmit FIFO does not contain valid data.                                                                                                                                                                                                                                                 |
| TXFIFOHE | Set to high when 8 or more transmit FIFO words are empty. This flag can be used as a DMA request.                                                                                                                                                                                                               |
| TXDAVL   | Set to high when the transmit FIFO contains valid data. This flag is the inverse of the TXFIFOE flag.                                                                                                                                                                                                           |
| TXUNDERR | Set to high when an underrun error occurs. This flag is cleared by writing to the SDMMC Clear register.<br><i>Note: In case of TXUNDERR, and DMA is used to fill SDMMC FIFO, user software should disable DMA stream, and then write DMAEN bit in SDMMC_DCTRL with '0' (to disable DMA request generation).</i> |

- Receive FIFO

When the data path subunit receives a word of data, it drives the data on the write databus. The write pointer is incremented after the write operation completes. On the read side, the contents of the FIFO word pointed to by the current value of the read pointer is driven onto the read databus. If the receive FIFO is disabled, all status flags are deasserted, and the read and write pointers are reset. The data path subunit asserts RXACT when it receives data. [Table 228](#) lists the receive FIFO status flags. The receive FIFO is accessible via 32 sequential addresses.

Table 228. Receive FIFO status flags

| Flag     | Description                                                                                                                                                                                                                                                                                                   |
|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| RXFIFO   | Set to high when all 32 receive FIFO words contain valid data                                                                                                                                                                                                                                                 |
| RXFIFOE  | Set to high when the receive FIFO does not contain valid data.                                                                                                                                                                                                                                                |
| RXFIFOHF | Set to high when 8 or more receive FIFO words contain valid data. This flag can be used as a DMA request.                                                                                                                                                                                                     |
| RXDAVL   | Set to high when the receive FIFO is not empty. This flag is the inverse of the RXFIFOE flag.                                                                                                                                                                                                                 |
| RXOVERR  | Set to high when an overrun error occurs. This flag is cleared by writing to the SDMMC Clear register.<br><i>Note: In case of RXOVERR, and DMA is used to read SDMMC FIFO, user software should disable DMA stream, and then write DMAEN bit in SDMMC_DCTRL with '0' (to disable DMA request generation).</i> |

### 35.3.2 SDMMC APB2 interface

The APB2 interface generates the interrupt and DMA requests, and accesses the SDMMC adapter registers and the data FIFO. It consists of a data path, register decoder, and interrupt/DMA logic.

#### SDMMC interrupts

The interrupt logic generates an interrupt request signal that is asserted when at least one of the selected status flags is high. A mask register is provided to allow selection of the conditions that will generate an interrupt. A status flag generates the interrupt request if a corresponding mask flag is set.

#### SDMMC/DMA interface

SDMMC APB interface controls all subunit to perform transfers between the host and card

#### Example of read procedure using DMA

Send CMD17 (READ\_BLOCK) as follows:

- a) Program the SDMMC data length register (SDMMC data timer register should be already programmed before the card identification process)
- b) Program DMA channel (refer to [DMA configuration for SDMMC controller](#))
- c) Program the SDMMC data control register: DTEN with '1' (SDMMC card host enabled to send data); DTDIR with '1' (from card to controller); DTMODE with '0' (block data transfer); DMAEN with '1' (DMA enabled); DBLOCKSIZE with 0x9 (512 bytes). Other fields are don't care.
- d) Program the SDMMC argument register with the address location of the card from where data is to be transferred
- e) Program the SDMMC command register: CmdIndex with 17(READ\_BLOCK); WaitResp with '1' (SDMMC card host waits for a response); CPSMEN with '1' (SDMMC card host enabled to send a command). Other fields are at their reset value.
- f) Wait for SDMMC\_STA[6] = CMDREND interrupt, (CMDREND is set if there is no error on command path).
- g) Wait for SDMMC\_STA[10] = DBCKEND, (DBCKEND is set in case of no errors until the CRC check is passed)
- h) Wait until the FIFO is empty, when FIFO is empty the SDMMC\_STA[5] = RXOVERR value has to be checked to guarantee that read succeeded

*Note:* When FIFO overrun error occurs with last 1-4 bytes, it may happen that RXOVERR flag is set 2 APB clock cycles after DATAEND flag is set. To guarantee success of read operation RXOVERR must be checked after FIFO is empty.

**Example of write procedure using DMA**

Send CMD24 (WRITE\_BLOCK) as follows:

- a) Program the SDMMC data length register (SDMMC data timer register should be already programmed before the card identification process)
- b) Program DMA channel (refer to [DMA configuration for SDMMC controller](#))
- c) Program the SDMMC argument register with the address location of the card from where data is to be transferred
- d) Program the SDMMC command register: CmdIndex with 24(WRITE\_BLOCK); WaitResp with '1' (SDMMC card host waits for a response); CPSMEN with '1' (SDMMC card host enabled to send a command). Other fields are at their reset value.
- e) Wait for SDMMC\_STA[6] = CMDREND interrupt, then Program the SDMMC data control register: DTEN with '1' (SDMMC card host enabled to send data); DTDIR with '0' (from controller to card); DTMODE with '0' (block data transfer); DMAEN with '1' (DMA enabled); DBLOCKSIZE with 0x9 (512 bytes). Other fields are don't care.
- f) Wait for SDMMC\_STA[10] = DBCKEND, (DBCKEND is set in case of no errors)

**DMA configuration for SDMMC controller**

- a) Enable DMA2 controller and clear any pending interrupts.
- b) Program the DMA2\_Stream3 (or DMA2\_Stream6) Channel4 source address register with the memory location base address and DMA2\_Stream3 (or DMA2\_Stream6) Channel4 destination address register with the SDMMC\_FIFO register address.
- c) Program DMA2\_Stream3 (or DMA2\_Stream6) Channel4 control register (memory increment, not peripheral increment, peripheral and source width is word size).
- d) Program DMA2\_Stream3 (or DMA2\_Stream6) Channel4 to select the peripheral as flow controller (set PFCTRL bit in DMA\_S3CR (or DMA\_S6CR) configuration register).
- e) Configure the incremental burst transfer to 4 beats (at least from peripheral side) in DMA2\_Stream3 (or DMA2\_Stream6) Channel4.
- f) Enable DMA2\_Stream3 (or DMA2\_Stream6) Channel4

*Note:* SDMMC host allows only to use the DMA in peripheral flow controller mode. DMA stream used to serve SDMMC must be configured in peripheral flow controller mode

SDMMC generates only DMA burst requests to DMA controller. DMA must be configured in incremental burst mode on peripheral side.

**35.4 Card functional description****35.4.1 Card identification mode**

While in card identification mode the host resets all cards, validates the operation voltage range, identifies cards and sets a relative card address (RCA) for each card on the bus. All data communications in the card identification mode use the command line (CMD) only.

### 35.4.2 Card reset

The GO\_IDLE\_STATE command (CMD0) is the software reset command and it puts the MultiMediaCard and SD memory in the Idle state. The IO\_RW\_DIRECT command (CMD52) resets the SD I/O card. After power-up or CMD0, all cards output bus drivers are in the high-impedance state and the cards are initialized with a default relative card address (RCA=0x0001) and with a default driver stage register setting (lowest speed, highest driving current capability).

### 35.4.3 Operating voltage range validation

All cards can communicate with the SDMMC card host using any operating voltage within the specification range. The supported minimum and maximum  $V_{DD}$  values are defined in the operation conditions register (OCR) on the card.

Cards that store the card identification number (CID) and card specific data (CSD) in the payload memory are able to communicate this information only under data-transfer  $V_{DD}$  conditions. When the SDMMC card host module and the card have incompatible  $V_{DD}$  ranges, the card is not able to complete the identification cycle and cannot send CSD data. For this purpose, the special commands, SEND\_OP\_COND (CMD1), SD\_APP\_OP\_COND (ACMD41 for SD Memory), and IO\_SEND\_OP\_COND (CMD5 for SD I/O), are designed to provide a mechanism to identify and reject cards that do not match the  $V_{DD}$  range desired by the SDMMC card host. The SDMMC card host sends the required  $V_{DD}$  voltage window as the operand of these commands. Cards that cannot perform data transfer in the specified range disconnect from the bus and go to the inactive state.

By using these commands without including the voltage range as the operand, the SDMMC card host can query each card and determine the common voltage range before placing out-of-range cards in the inactive state. This query is used when the SDMMC card host is able to select a common voltage range or when the user requires notification that cards are not usable.

### 35.4.4 Card identification process

The card identification process differs for MultiMediaCards and SD cards. For MultiMediaCard cards, the identification process starts at clock rate  $F_{od}$ . The SDMMC\_CMD line output drivers are open-drain and allow parallel card operation during this process. The registration process is accomplished as follows:

1. The bus is activated.
2. The SDMMC card host broadcasts SEND\_OP\_COND (CMD1) to receive operation conditions.
3. The response is the wired AND operation of the operation condition registers from all cards.
4. Incompatible cards are placed in the inactive state.
5. The SDMMC card host broadcasts ALL\_SEND\_CID (CMD2) to all active cards.
6. The active cards simultaneously send their CID numbers serially. Cards with outgoing CID bits that do not match the bits on the command line stop transmitting and must wait for the next identification cycle. One card successfully transmits a full CID to the SDMMC card host and enters the Identification state.
7. The SDMMC card host issues SET\_RELATIVE\_ADDR (CMD3) to that card. This new address is called the relative card address (RCA); it is shorter than the CID and

addresses the card. The assigned card changes to the Standby state, it does not react to further identification cycles, and its output switches from open-drain to push-pull.

8. The SDMMC card host repeats steps 5 through 7 until it receives a timeout condition.

For the SD card, the identification process starts at clock rate  $F_{od}$ , and the SDMMC\_CMD line output drives are push-pull drivers instead of open-drain. The registration process is accomplished as follows:

1. The bus is activated.
2. The SDMMC card host broadcasts SD\_APP\_OP\_COND (ACMD41).
3. The cards respond with the contents of their operation condition registers.
4. The incompatible cards are placed in the inactive state.
5. The SDMMC card host broadcasts ALL\_SEND\_CID (CMD2) to all active cards.
6. The cards send back their unique card identification numbers (CIDs) and enter the Identification state.
7. The SDMMC card host issues SET\_RELATIVE\_ADDR (CMD3) to an active card with an address. This new address is called the relative card address (RCA); it is shorter than the CID and addresses the card. The assigned card changes to the Standby state. The SDMMC card host can reissue this command to change the RCA. The RCA of the card is the last assigned value.
8. The SDMMC card host repeats steps 5 through 7 with all active cards.

For the SD I/O card, the registration process is accomplished as follows:

1. The bus is activated.
2. The SDMMC card host sends IO\_SEND\_OP\_COND (CMD5).
3. The cards respond with the contents of their operation condition registers.
4. The incompatible cards are set to the inactive state.
5. The SDMMC card host issues SET\_RELATIVE\_ADDR (CMD3) to an active card with an address. This new address is called the relative card address (RCA); it is shorter than the CID and addresses the card. The assigned card changes to the Standby state. The SDMMC card host can reissue this command to change the RCA. The RCA of the card is the last assigned value.

### 35.4.5 Block write

During block write (CMD24 - 27) one or more blocks of data are transferred from the host to the card with a CRC appended to the end of each block by the host. A card supporting block write is always able to accept a block of data defined by WRITE\_BL\_LEN. If the CRC fails, the card indicates the failure on the SDMMC\_D line and the transferred data are discarded and not written, and all further transmitted blocks (in multiple block write mode) are ignored.

If the host uses partial blocks whose accumulated length is not block aligned and, block misalignment is not allowed (CSD parameter WRITE\_BLK\_MISALIGN is not set), the card will detect the block misalignment error before the beginning of the first misaligned block. (ADDRESS\_ERROR error bit is set in the status register). The write operation will also be aborted if the host tries to write over a write-protected area. In this case, however, the card will set the WP\_VIOLATION bit.

Programming of the CID and CSD registers does not require a previous block length setting. The transferred data is also CRC protected. If a part of the CSD or CID register is stored in ROM, then this unchangeable part must match the corresponding part of the receive buffer. If this match fails, then the card reports an error and does not change any register contents.

Some cards may require long and unpredictable times to write a block of data. After receiving a block of data and completing the CRC check, the card begins writing and holds the SDMMC\_D line low if its write buffer is full and unable to accept new data from a new WRITE\_BLOCK command. The host may poll the status of the card with a SEND\_STATUS command (CMD13) at any time, and the card will respond with its status. The READY\_FOR\_DATA status bit indicates whether the card can accept new data or whether the write process is still in progress. The host may deselect the card by issuing CMD7 (to select a different card), which will place the card in the Disconnect state and release the SDMMC\_D line(s) without interrupting the write operation. When reselecting the card, it will reactivate busy indication by pulling SDMMC\_D to low if programming is still in progress and the write buffer is unavailable.

#### 35.4.6 Block read

In Block read mode the basic unit of data transfer is a block whose maximum size is defined in the CSD (READ\_BL\_LEN). If READ\_BL\_PARTIAL is set, smaller blocks whose start and end addresses are entirely contained within one physical block (as defined by READ\_BL\_LEN) may also be transmitted. A CRC is appended to the end of each block, ensuring data transfer integrity. CMD17 (READ\_SINGLE\_BLOCK) initiates a block read and after completing the transfer, the card returns to the Transfer state.

CMD18 (READ\_MULTIPLE\_BLOCK) starts a transfer of several consecutive blocks.

The host can abort reading at any time, within a multiple block operation, regardless of its type. Transaction abort is done by sending the stop transmission command.

If the card detects an error (for example, out of range, address misalignment or internal error) during a multiple block read operation (both types) it stops the data transmission and remains in the data state. The host must then abort the operation by sending the stop transmission command. The read error is reported in the response to the stop transmission command.

If the host sends a stop transmission command after the card transmits the last block of a multiple block operation with a predefined number of blocks, it is responded to as an illegal command, since the card is no longer in the data state. If the host uses partial blocks whose accumulated length is not block-aligned and block misalignment is not allowed, the card detects a block misalignment error condition at the beginning of the first misaligned block (ADDRESS\_ERROR error bit is set in the status register).

#### 35.4.7 Stream access, stream write and stream read (MultiMediaCard only)

In stream mode, data is transferred in bytes and no CRC is appended at the end of each block.

##### Stream write (MultiMediaCard only)

WRITE\_DAT\_UNTIL\_STOP (CMD20) starts the data transfer from the SDMMC card host to the card, beginning at the specified address and continuing until the SDMMC card host issues a stop command. When partial blocks are allowed (CSD parameter WRITE\_BL\_PARTIAL is set), the data stream can start and stop at any address within the card address space, otherwise it can only start and stop at block boundaries. Because the amount of data to be transferred is not determined in advance, a CRC cannot be used. When the end of the memory range is reached while sending data and no stop command is sent by the SDMMC card host, any additional transferred data are discarded.

The maximum clock frequency for a stream write operation is given by the following equation fields of the card-specific data register:

$$\text{Maximumspeed} = \text{MIN}(\text{TRANSPEED}, \frac{(8 \times 2^{\text{writeblen}})(-\text{NSAC})}{\text{TAAC} \times \text{R2WFACTOR}})$$

- Maximumspeed = maximum write frequency
- TRANSPEED = maximum data transfer rate
- writeblen = maximum write data block length
- NSAC = data read access time 2 in CLK cycles
- TAAC = data read access time 1
- R2WFACTOR = write speed factor

If the host attempts to use a higher frequency, the card may not be able to process the data and stop programming, set the OVERRUN error bit in the status register, and while ignoring all further data transfer, wait (in the receive data state) for a stop command. The write operation is also aborted if the host tries to write over a write-protected area. In this case, however, the card sets the WP\_VIOLATION bit.

### Stream read (MultiMediaCard only)

READ\_DAT\_UNTIL\_STOP (CMD11) controls a stream-oriented data transfer.

This command instructs the card to send its data, starting at a specified address, until the SDMMC card host sends STOP\_TRANSMISSION (CMD12). The stop command has an execution delay due to the serial command transmission and the data transfer stops after the end bit of the stop command. When the end of the memory range is reached while sending data and no stop command is sent by the SDMMC card host, any subsequent data sent are considered undefined.

The maximum clock frequency for a stream read operation is given by the following equation and uses fields of the card specific data register.

$$\text{Maximumspeed} = \text{MIN}(\text{TRANSPEED}, \frac{(8 \times 2^{\text{readblen}})(-\text{NSAC})}{\text{TAAC} \times \text{R2WFACTOR}})$$

- Maximumspeed = maximum read frequency
- TRANSPEED = maximum data transfer rate
- readblen = maximum read data block length
- writeblen = maximum write data block length
- NSAC = data read access time 2 in CLK cycles
- TAAC = data read access time 1
- R2WFACTOR = write speed factor

If the host attempts to use a higher frequency, the card is not able to sustain data transfer. If this happens, the card sets the UNDERRUN error bit in the status register, aborts the transmission and waits in the data state for a stop command.

### 35.4.8 Erase: group erase and sector erase

The erasable unit of the MultiMediaCard is the erase group. The erase group is measured in write blocks, which are the basic writable units of the card. The size of the erase group is a card-specific parameter and defined in the CSD.

The host can erase a contiguous range of Erase Groups. Starting the erase process is a three-step sequence.

First the host defines the start address of the range using the ERASE\_GROUP\_START (CMD35) command, next it defines the last address of the range using the ERASE\_GROUP\_END (CMD36) command and, finally, it starts the erase process by issuing the ERASE (CMD38) command. The address field in the erase commands is an Erase Group address in byte units. The card ignores all LSBs below the Erase Group size, effectively rounding the address down to the Erase Group boundary.

If an erase command is received out of sequence, the card sets the ERASE\_SEQ\_ERROR bit in the status register and resets the whole sequence.

If an out-of-sequence (neither of the erase commands, except SEND\_STATUS) command received, the card sets the ERASE\_RESET status bit in the status register, resets the erase sequence and executes the last command.

If the erase range includes write protected blocks, they are left intact and only nonprotected blocks are erased. The WP\_ERASE\_SKIP status bit in the status register is set.

The card indicates that an erase is in progress by holding SDMMC\_D low. The actual erase time may be quite long, and the host may issue CMD7 to deselect the card.

### 35.4.9 Wide bus selection or deselection

Wide bus (4-bit bus width) operation mode is selected or deselected using SET\_BUS\_WIDTH (ACMD6). The default bus width after power-up or GO\_IDLE\_STATE (CMD0) is 1 bit. SET\_BUS\_WIDTH (ACMD6) is only valid in a transfer state, which means that the bus width can be changed only after a card is selected by SELECT/DESELECT\_CARD (CMD7).

### 35.4.10 Protection management

Three write protection methods for the cards are supported in the SDMMC card host module:

1. internal card write protection (card responsibility)
2. mechanical write protection switch (SDMMC card host module responsibility only)
3. password-protected card lock operation

#### Internal card write protection

Card data can be protected against write and erase. By setting the permanent or temporary write-protect bits in the CSD, the entire card can be permanently write-protected by the manufacturer or content provider. For cards that support write protection of groups of sectors by setting the WP\_GRP\_ENABLE bit in the CSD, portions of the data can be protected, and the write protection can be changed by the application. The write protection is in units of WP\_GRP\_SIZE sectors as specified in the CSD. The SET\_WRITE\_PROT and CLR\_WRITE\_PROT commands control the protection of the addressed group. The SEND\_WRITE\_PROT command is similar to a single block read command. The card sends

a data block containing 32 write protection bits (representing 32 write protect groups starting at the specified address) followed by 16 CRC bits. The address field in the write protect commands is a group address in byte units.

The card ignores all LSBs below the group size.

### Mechanical write protect switch

A mechanical sliding tab on the side of the card allows the user to set or clear the write protection on a card. When the sliding tab is positioned with the window open, the card is write-protected, and when the window is closed, the card contents can be changed. A matched switch on the socket side indicates to the SDMMC card host module that the card is write-protected. The SDMMC card host module is responsible for protecting the card. The position of the write protect switch is unknown to the internal circuitry of the card.

### Password protect

The password protection feature enables the SDMMC card host module to lock and unlock a card with a password. The password is stored in the 128-bit PWD register and its size is set in the 8-bit PWD\_LEN register. These registers are nonvolatile so that a power cycle does not erase them. Locked cards respond to and execute certain commands. This means that the SDMMC card host module is allowed to reset, initialize, select, and query for status, however it is not allowed to access data on the card. When the password is set (as indicated by a nonzero value of PWD\_LEN), the card is locked automatically after power-up. As with the CSD and CID register write commands, the lock/unlock commands are available in the transfer state only. In this state, the command does not include an address argument and the card must be selected before using it. The card lock/unlock commands have the structure and bus transaction types of a regular single-block write command. The transferred data block includes all of the required information for the command (the password setting mode, the PWD itself, and card lock/unlock). The command data block size is defined by the SDMMC card host module before it sends the card lock/unlock command, and has the structure shown in [Table 242](#).

The bit settings are as follows:

- ERASE: setting it forces an erase operation. All other bits must be zero, and only the command byte is sent
- LOCK\_UNLOCK: setting it locks the card. LOCK\_UNLOCK can be set simultaneously with SET\_PWD, however not with CLR\_PWD
- CLR\_PWD: setting it clears the password data
- SET\_PWD: setting it saves the password data to memory
- PWD\_LEN: it defines the length of the password in bytes
- PWD: the password (new or currently used, depending on the command)

The following sections list the command sequences to set/reset a password, lock/unlock the card, and force an erase.

### Setting the password

1. Select a card (SELECT/DESELECT\_CARD, CMD7), if none is already selected.
2. Define the block length (SET\_BLOCKLEN, CMD16) to send, given by the 8-bit card lock/unlock mode, the 8-bit PWD\_LEN, and the number of bytes of the new password.

When a password replacement is done, the block size must take into account that both the old and the new passwords are sent with the command.

3. Send LOCK/UNLOCK (CMD42) with the appropriate data block size on the data line including the 16-bit CRC. The data block indicates the mode (SET\_PWD = 1), the length (PWD\_LEN), and the password (PWD) itself. When a password replacement is done, the length value (PWD\_LEN) includes the length of both passwords, the old and the new one, and the PWD field includes the old password (currently used) followed by the new password.
4. When the password is matched, the new password and its size are saved into the PWD and PWD\_LEN fields, respectively. When the old password sent does not correspond (in size and/or content) to the expected password, the LOCK\_UNLOCK\_FAILED error bit is set in the card status register, and the password is not changed.

The password length field (PWD\_LEN) indicates whether a password is currently set. When this field is nonzero, there is a password set and the card locks itself after power-up. It is possible to lock the card immediately in the current power session by setting the LOCK\_UNLOCK bit (while setting the password) or sending an additional command for card locking.

### Resetting the password

1. Select a card (SELECT/DESELECT\_CARD, CMD7), if none is already selected.
2. Define the block length (SET\_BLOCKLEN, CMD16) to send, given by the 8-bit card lock/unlock mode, the 8-bit PWD\_LEN, and the number of bytes in the currently used password.
3. Send LOCK/UNLOCK (CMD42) with the appropriate data block size on the data line including the 16-bit CRC. The data block indicates the mode (CLR\_PWD = 1), the length (PWD\_LEN) and the password (PWD) itself. The LOCK\_UNLOCK bit is ignored.
4. When the password is matched, the PWD field is cleared and PWD\_LEN is set to 0. When the password sent does not correspond (in size and/or content) to the expected password, the LOCK\_UNLOCK\_FAILED error bit is set in the card status register, and the password is not changed.

### Locking a card

1. Select a card (SELECT/DESELECT\_CARD, CMD7), if none is already selected.
2. Define the block length (SET\_BLOCKLEN, CMD16) to send, given by the 8-bit card lock/unlock mode (byte 0 in [Table 242](#)), the 8-bit PWD\_LEN, and the number of bytes of the current password.
3. Send LOCK/UNLOCK (CMD42) with the appropriate data block size on the data line including the 16-bit CRC. The data block indicates the mode (LOCK\_UNLOCK = 1), the length (PWD\_LEN), and the password (PWD) itself.
4. When the password is matched, the card is locked and the CARD\_IS\_LOCKED status bit is set in the card status register. When the password sent does not correspond (in size and/or content) to the expected password, the LOCK\_UNLOCK\_FAILED error bit is set in the card status register, and the lock fails.

It is possible to set the password and to lock the card in the same sequence. In this case, the SDMMC card host module performs all the required steps for setting the password (see [Setting the password on page 1258](#)), however it is necessary to set the LOCK\_UNLOCK bit in Step 3 when the new password command is sent.

When the password is previously set (PWD\_LEN is not 0), the card is locked automatically after power on reset. An attempt to lock a locked card or to lock a card that does not have a password fails and the LOCK\_UNLOCK\_FAILED error bit is set in the card status register.

### Unlocking the card

1. Select a card (SELECT/DESELECT\_CARD, CMD7), if none is already selected.
2. Define the block length (SET\_BLOCKLEN, CMD16) to send, given by the 8-bit cardlock/unlock mode (byte 0 in [Table 242](#)), the 8-bit PWD\_LEN, and the number of bytes of the current password.
3. Send LOCK/UNLOCK (CMD42) with the appropriate data block size on the data line including the 16-bit CRC. The data block indicates the mode (LOCK\_UNLOCK = 0), the length (PWD\_LEN), and the password (PWD) itself.
4. When the password is matched, the card is unlocked and the CARD\_IS\_LOCKED status bit is cleared in the card status register. When the password sent is not correct in size and/or content and does not correspond to the expected password, the LOCK\_UNLOCK\_FAILED error bit is set in the card status register, and the card remains locked.

The unlocking function is only valid for the current power session. When the PWD field is not clear, the card is locked automatically on the next power-up.

An attempt to unlock an unlocked card fails and the LOCK\_UNLOCK\_FAILED error bit is set in the card status register.

### Forcing erase

If the user has forgotten the password (PWD content), it is possible to access the card after clearing all the data on the card. This forced erase operation erases all card data and all password data.

1. Select a card (SELECT/DESELECT\_CARD, CMD7), if none is already selected.
2. Set the block length (SET\_BLOCKLEN, CMD16) to 1 byte. Only the 8-bit card lock/unlock byte (byte 0 in [Table 242](#)) is sent.
3. Send LOCK/UNLOCK (CMD42) with the appropriate data byte on the data line including the 16-bit CRC. The data block indicates the mode (ERASE = 1). All other bits must be zero.
4. When the ERASE bit is the only bit set in the data field, all card contents are erased, including the PWD and PWD\_LEN fields, and the card is no longer locked. When any other bits are set, the LOCK\_UNLOCK\_FAILED error bit is set in the card status register and the card retains all of its data, and remains locked.

An attempt to use a force erase on an unlocked card fails and the LOCK\_UNLOCK\_FAILED error bit is set in the card status register.

### 35.4.11 Card status register

The response format R1 contains a 32-bit field named card status. This field is intended to transmit the card status information (which may be stored in a local status register) to the host. If not specified otherwise, the status entries are always related to the previously issued command.

[Table 229](#) defines the different entries of the status. The type and clear condition fields in the table are abbreviated as follows:

Type:

- E: error bit
- S: status bit
- R: detected and set for the actual command response
- X: detected and set during command execution. The SDMMC card host must poll the card by issuing the status command to read these bits.

Clear condition:

- A: according to the card current state
- B: always related to the previous command. Reception of a valid command clears it (with a delay of one command)
- C: clear by read

**Table 229. Card status**

| Bits | Identifier           | Type  | Value                         | Description                                                                                                                                                                                                                                                                                                                                                               | Clear condition |
|------|----------------------|-------|-------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|
| 31   | ADDRESS_OUT_OF_RANGE | E R X | '0' = no error<br>'1' = error | The command address argument was out of the allowed range for this card.<br>A multiple block or stream read/write operation is (although started in a valid address) attempting to read or write beyond the card capacity.                                                                                                                                                | C               |
| 30   | ADDRESS_MISALIGN     | -     | '0' = no error<br>'1' = error | The commands address argument (in accordance with the currently set block length) positions the first data block misaligned to the card physical blocks.<br>A multiple block read/write operation (although started with a valid address/block-length combination) is attempting to read or write a data block which is not aligned with the physical blocks of the card. | C               |

### 35.4.12 SD status register

The SD status contains status bits that are related to the SD memory card proprietary features and may be used for future application-specific usage. The size of the SD Status is one data block of 512 bits. The contents of this register are transmitted to the SDMMC card host if ACMD13 is sent (CMD55 followed with CMD13). ACMD13 can be sent to a card in transfer state only (card is selected).

[Table 230](#) defines the different entries of the SD status register. The type and clear condition fields in the table are abbreviated as follows:

Type:

- E: error bit
- S: status bit
- R: detected and set for the actual command response
- X: detected and set during command execution. The SDMMC card Host must poll the card by issuing the status command to read these bits

Clear condition:

- A: according to the card current state
- B: always related to the previous command. Reception of a valid command clears it (with a delay of one command)
- C: clear by read

**Table 230. SD status**

| Bits     | Identifier             | Type | Value                                                                                                                                                                                    | Description                                                                                                                                                                                                                                       | Clear condition |

### SIZE\_OF\_PROTECTED\_AREA

Setting this field differs between standard- and high-capacity cards. In the case of a standard-capacity card, the capacity of protected area is calculated as follows:

Protected area = SIZE\_OF\_PROTECTED\_AREA \* MULT \* BLOCK\_LEN.

SIZE\_OF\_PROTECTED\_AREA is specified by the unit in MULT\*BLOCK\_LEN.

In the case of a high-capacity card, the capacity of protected area is specified in this field:

Protected area = SIZE\_OF\_PROTECTED\_AREA

SIZE\_OF\_PROTECTED\_AREA is specified by the unit in bytes.

### SPEED\_CLASS

This 8-bit field indicates the speed class and the value can be calculated by  $P_W/2$  (where  $P_W$  is the write performance).

Table 231. Speed class code field

| SPEED_CLASS | Value definition |
|-------------|------------------|
| 00h         | Class 0          |
| 01h         | Class 2          |
| 02h         | Class 4          |
| 03h         | Class 6          |
| 04h – FFh   | Reserved         |

**PERFORMANCE\_MOVE**

This 8-bit field indicates Pm (performance move) and the value can be set by 1 [MB/sec] steps. If the card does not move used RUs (recording units), Pm should be considered as infinity. Setting the field to FFh means infinity.

**Table 232. Performance move field**

| <b>PERFORMANCE_MOVE</b> | <b>Value definition</b> |
|-------------------------|-------------------------|
| 00h                     | Not defined             |
| 01h                     | 1 [MB/sec]              |
| 02h                     | 02h 2 [MB/sec]          |
| -----                   | -----                   |
| FEh                     | 254 [MB/sec]            |
| FFh                     | Infinity                |

**AU\_SIZE**

This 4-bit field indicates the AU size and the value can be selected in the power of 2 base from 16 KB.

**Table 233. AU\_SIZE field**

| <b>AU_SIZE</b> | <b>Value definition</b> |
|----------------|-------------------------|
| 00h            | Not defined             |
| 01h            | 16 KB                   |
| 02h            | 32 KB                   |
| 03h            | 64 KB                   |
| 04h            | 128 KB                  |
| 05h            | 256 KB                  |
| 06h            | 512 KB                  |
| 07h            | 1 MB                    |
| 08h            | 2 MB                    |
| 09h            | 4 MB                    |
| Ah – Fh        | Reserved                |

The maximum AU size, which depends on the card capacity, is defined in [Table 234](#). The card can be set to any AU size between RU size and maximum AU size.

**Table 234. Maximum AU size**

| <b>Capacity</b> | <b>16 MB-64 MB</b> | <b>128 MB-256 MB</b> | <b>512 MB</b> | <b>1 GB-32 GB</b> |
|-----------------|--------------------|----------------------|---------------|-------------------|
| Maximum AU Size | 512 KB             | 1 MB                 | 2 MB          | 4 MB              |

**ERASE\_SIZE**

This 16-bit field indicates  $N_{ERASE}$ . When  $N_{ERASE}$  numbers of AUs are erased, the timeout value is specified by ERASE\_TIMEOUT (Refer to [ERASE\\_TIMEOUT](#)). The host should determine the proper number of AUs to be erased in one operation so that the host can show the progress of the erase operation. If this field is set to 0, the erase timeout calculation is not supported.

**Table 235. Erase size field**

| ERASE_SIZE | Value definition                            |
|------------|---------------------------------------------|
| 0000h      | Erase timeout calculation is not supported. |
| 0001h      | 1 AU                                        |
| 0002h      | 2 AU                                        |

**ERASE\_TIMEOUT**

This 6-bit field indicates  $T_{ERASE}$  and the value indicates the erase timeout from offset when multiple AUs are being erased as specified by ERASE\_SIZE. The range of ERASE\_TIMEOUT can be defined as up to 63 seconds and the card manufacturer can choose any combination of ERASE\_SIZE and ERASE\_TIMEOUT depending on the implementation. Determining ERASE\_TIMEOUT determines the ERASE\_SIZE.

**Table 236. Erase timeout field**

| ERASE_TIMEOUT | Value definition                            |
|---------------|---------------------------------------------|
| 00            | Erase timeout calculation is not supported. |
| 01            | 1 [sec]                                     |
| 02            | 2 [sec]                                     |
| 03            | 3 [sec]                                     |
| -----         | -----                                       |
| 63            | 63 [sec]                                    |

**ERASE\_OFFSET**

This 2-bit field indicates  $T_{OFFSET}$  and one of four values can be selected. This field is meaningless if the ERASE\_SIZE and ERASE\_TIMEOUT fields are set to 0.

**Table 237. Erase offset field**

| ERASE_OFFSET | Value definition |
|--------------|------------------|
| 0h           | 0 [sec]          |
| 1h           | 1 [sec]          |

Table 237. Erase offset field (continued)

| ERASE_OFFSET | Value definition |
|--------------|------------------|
| 2h           | 2 [sec]          |
| 3h           | 3 [sec]          |

### 35.4.13 SD I/O mode

#### SD I/O interrupts

To allow the SD I/O card to interrupt the MultiMediaCard/SD module, an interrupt function is available on a pin on the SD interface. Pin 8, used as SDMMC\_D1 when operating in the 4-bit SD mode, signals the cards interrupt to the MultiMediaCard/SD module. The use of the interrupt is optional for each card or function within a card. The SD I/O interrupt is level-sensitive, which means that the interrupt line must be held active (low) until it is either recognized and acted upon by the MultiMediaCard/SD module or deasserted due to the end of the interrupt period. After the MultiMediaCard/SD module has serviced the interrupt, the interrupt status bit is cleared via an I/O write to the appropriate bit in the SD I/O card's internal registers. The interrupt output of all SD I/O cards is active low and the application must provide pull-up resistors externally on all data lines (SDMMC\_D[3:0]). The MultiMediaCard/SD module samples the level of pin 8 (SDMMC\_D/IRQ) into the interrupt detector only during the interrupt period. At all other times, the MultiMediaCard/SD module ignores this value.

The interrupt period is applicable for both memory and I/O operations. The definition of the interrupt period for operations with single blocks is different from the definition for multiple-block data transfers.

#### SD I/O suspend and resume

Within a multifunction SD I/O or a card with both I/O and memory functions, there are multiple devices (I/O and memory) that share access to the MMC/SD bus. To share access to the MMC/SD module among multiple devices, SD I/O and combo cards optionally implement the concept of suspend/resume. When a card supports suspend/resume, the MMC/SD module can temporarily halt a data transfer operation to one function or memory (suspend) to free the bus for a higher-priority transfer to a different function or memory. After this higher-priority transfer is complete, the original transfer is resumed (restarted) where it left off. Support of suspend/resume is optional on a per-card basis. To perform the suspend/resume operation on the MMC/SD bus, the MMC/SD module performs the following steps:

1. Determines the function currently using the SDMMC\_D [3:0] line(s)
2. Requests the lower-priority or slower transaction to suspend
3. Waits for the transaction suspension to complete
4. Begins the higher-priority transaction
5. Waits for the completion of the higher priority transaction
6. Restores the suspended transaction

#### SD I/O ReadWait

The optional ReadWait (RW) operation is defined only for the SD 1-bit and 4-bit modes. The ReadWait operation allows the MMC/SD module to signal a card that it is reading multiple

registers (IO\_RW\_EXTENDED, CMD53) to temporarily stall the data transfer while allowing the MMC/SD module to send commands to any function within the SD I/O device. To determine when a card supports the ReadWait protocol, the MMC/SD module must test capability bits in the internal card registers. The timing for ReadWait is based on the interrupt period.

### 35.4.14 Commands and responses

#### Application-specific and general commands

The SDMMC card host module system is designed to provide a standard interface for a variety of applications types. In this environment, there is a need for specific customer/application features. To implement these features, two types of generic commands are defined in the standard: application-specific commands (ACMD) and general commands (GEN\_CMD).

When the card receives the APP\_CMD (CMD55) command, the card expects the next command to be an application-specific command. ACMDs have the same structure as regular MultiMediaCard commands and can have the same CMD number. The card recognizes it as ACMD because it appears after APP\_CMD (CMD55). When the command immediately following the APP\_CMD (CMD55) is not a defined application-specific command, the standard command is used. For example, when the card has a definition for SD\_STATUS (ACMD13), and receives CMD13 immediately following APP\_CMD (CMD55), this is interpreted as SD\_STATUS (ACMD13). However, when the card receives CMD7 immediately following APP\_CMD (CMD55) and the card does not have a definition for ACMD7, this is interpreted as the standard (SELECT/DESELECT\_CARD) CMD7.

To use one of the manufacturer-specific ACMDs the SD card Host must perform the following steps:

1. Send APP\_CMD (CMD55)  
The card responds to the MultiMediaCard/SD module, indicating that the APP\_CMD bit is set and an ACMD is now expected.
2. Send the required ACMD  
The card responds to the MultiMediaCard/SD module, indicating that the APP\_CMD bit is set and that the accepted command is interpreted as an ACMD. When a nonACMD is sent, it is handled by the card as a normal MultiMediaCard command and the APP\_CMD bit in the card status register stays clear.

When an invalid command is sent (neither ACMD nor CMD) it is handled as a standard MultiMediaCard illegal command error.

The bus transaction for a GEN\_CMD is the same as the single-block read or write commands (WRITE\_BLOCK, CMD24 or READ\_SINGLE\_BLOCK, CMD17). In this case, the argument denotes the direction of the data transfer rather than the address, and the data block has vendor-specific format and meaning.

The card must be selected (in transfer state) before sending GEN\_CMD (CMD56). The data block size is defined by SET\_BLOCKLEN (CMD16). The response to GEN\_CMD (CMD56) is in R1b format.

## Command types

Both application-specific and general commands are divided into the four following types:

- **broadcast command (BC):** sent to all cards; no responses returned.
- **broadcast command with response (BCR):** sent to all cards; responses received from all cards simultaneously.
- **addressed (point-to-point) command (AC):** sent to the card that is selected; does not include a data transfer on the SDMMC\_D line(s).
- **addressed (point-to-point) data transfer command (ADTC):** sent to the card that is selected; includes a data transfer on the SDMMC\_D line(s).

## Command formats

See [Table 221 on page 1244](#) for command formats.

## Commands for the MultiMediaCard/SD module

**Table 238. Block-oriented write commands**

| CMD index | Type | Argument                                    | Response format | Abbreviation         | Description                                                                                                                                                                                                                            |
|-----------|------|---------------------------------------------|-----------------|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CMD23     | ac   | [31:16] set to 0<br>[15:0] number of blocks | R1              | SET_BLOCK_COUNT      | Defines the number of blocks which are going to be transferred in the multiple-block read or write command that follows.                                                                                                               |
| CMD24     | adtc | [31:0] data address                         | R1              | WRITE_BLOCK          | Writes a block of the size selected by the SET_BLOCKLEN command.                                                                                                                                                                       |
| CMD25     | adtc | [31:0] data address                         | R1              | WRITE_MULTIPLE_BLOCK | Continuously writes blocks of data until a STOP_TRANSMISSION follows or the requested number of blocks has been received.                                                                                                              |
| CMD26     | adtc | [31:0] stuff bits                           | R1              | PROGRAM_CID          | Programming of the card identification register. This command must be issued only once per card. The card contains hardware to prevent this operation after the first programming. Normally this command is reserved for manufacturer. |
| CMD27     | adtc | [31:0] stuff bits                           | R1              | PROGRAM_CSD          | Programming of the programmable bits of the CSD.                                                                                                                                                                                       |

Table 239. Block-oriented write protection commands

| CMD index | Type     | Argument                          | Response format | Abbreviation    | Description                                                                                                                                                                                         |
|-----------|----------|-----------------------------------|-----------------|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CMD28     | ac       | [31:0] data address               | R1b             | SET_WRITE_PROT  | If the card has write protection features, this command sets the write protection bit of the addressed group. The properties of write protection are coded in the card-specific data (WP_GRP_SIZE). |
| CMD29     | ac       | [31:0] data address               | R1b             | CLR_WRITE_PROT  | If the card provides write protection features, this command clears the write protection bit of the addressed group.                                                                                |
| CMD30     | adtc     | [31:0] write protect data address | R1              | SEND_WRITE_PROT | If the card provides write protection features, this command asks the card to send the status of the write protection bits.                                                                         |
| CMD31     | Reserved |                                   |                 |                 |                                                                                                                                                                                                     |

Table 240. Erase commands

| CMD index             | Type                                                                                                                                  | Argument            | Response format | Abbreviation      | Description                                                                                  |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------------------|---------------------|-----------------|-------------------|----------------------------------------------------------------------------------------------|
| CMD32<br>...<br>CMD34 | Reserved. These command indexes cannot be used in order to maintain backward compatibility with older versions of the MultiMediaCard. |                     |                 |                   |                                                                                              |
| CMD35                 | ac                                                                                                                                    | [31:0] data address | R1              | ERASE_GROUP_START | Sets the address of the first erase group within a range to be selected for erase.           |
| CMD36                 | ac                                                                                                                                    | [31:0] data address | R1              | ERASE_GROUP_END   | Sets the address of the last erase group within a continuous range to be selected for erase. |
| CMD37                 | Reserved. This command index cannot be used in order to maintain backward compatibility with older versions of the MultiMediaCards    |                     |                 |                   |                                                                                              |
| CMD38                 | ac                                                                                                                                    | [31:0] stuff bits   | R1              | ERASE             | Erases all previously selected write blocks.                                                 |

Table 241. I/O mode commands

| CMD index | Type | Argument                                                                                     | Response format | Abbreviation | Description                                                                                                                                                                                                                                                                                                                             |
|-----------|------|----------------------------------------------------------------------------------------------|-----------------|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CMD39     | ac   | [31:16] RCA<br>[15:15] register write flag<br>[14:8] register address<br>[7:0] register data | R4              | FAST_IO      | Used to write and read 8-bit (register) data fields. The command addresses a card and a register and provides the data for writing if the write flag is set. The R4 response contains data read from the addressed register. This command accesses application-dependent registers that are not defined in the MultiMediaCard standard. |

Table 241. I/O mode commands (continued)

| CMD index | Type     | Argument          | Response format | Abbreviation | Description                              |
|-----------|----------|-------------------|-----------------|--------------|------------------------------------------|
| CMD40     | bcr      | [31:0] stuff bits | R5              | GO_IRQ_STATE | Places the system in the interrupt mode. |
| CMD41     | Reserved |                   |                 |              |                                          |

Table 242. Lock card

| CMD index             | Type     | Argument          | Response format | Abbreviation | Description                                                                                                         |
|-----------------------|----------|-------------------|-----------------|--------------|---------------------------------------------------------------------------------------------------------------------|
| CMD42                 | adtc     | [31:0] stuff bits | R1b             | LOCK_UNLOCK  | Sets/resets the password or locks/unlocks the card. The size of the data block is set by the SET_BLOCK_LEN command. |
| CMD43<br>...<br>CMD54 | Reserved |                   |                 |              |                                                                                                                     |

Table 243. Application-specific commands

| CMD index             | Type                       | Argument                         | Response format | Abbreviation | Description                                                                                                                                                                                                    |
|-----------------------|----------------------------|----------------------------------|-----------------|--------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CMD55                 | ac                         | [31:16] RCA<br>[15:0] stuff bits | R1              | APP_CMD      | Indicates to the card that the next command bits is an application specific command rather than a standard command                                                                                             |

## 35.5 Response formats

All responses are sent via the SDMMC command line SDMMC\_CMD. The response transmission always starts with the left bit of the bit string corresponding to the response code word. The code length depends on the response type.

A response always starts with a start bit (always 0), followed by the bit indicating the direction of transmission (card = 0). A value denoted by x in the tables below indicates a variable entry. All responses, except for the R3 response type, are protected by a CRC. Every command code word is terminated by the end bit (always 1).

There are five types of responses. Their formats are defined as follows:

### 35.5.1 R1 (normal response command)

Code length = 48 bits. The 45:40 bits indicate the index of the command to be responded to, this value being interpreted as a binary-coded number (between 0 and 63). The status of the card is coded in 32 bits.

**Table 244. R1 response**

| Bit position | Width (bits) | Value | Description      |
|--------------|--------------|-------|------------------|
| 47           | 1            | 0     | Start bit        |
| 46           | 1            | 0     | Transmission bit |
| [45:40]      | 6            | X     | Command index    |
| [39:8]       | 32           | X     | Card status      |
| [7:1]        | 7            | X     | CRC7             |
| 0            | 1            | 1     | End bit          |

### 35.5.2 R1b

It is identical to R1 with an optional busy signal transmitted on the data line. The card may become busy after receiving these commands based on its state prior to the command reception.

### 35.5.3 R2 (CID, CSD register)

Code length = 136 bits. The contents of the CID register are sent as a response to the CMD2 and CMD10 commands. The contents of the CSD register are sent as a response to CMD9. Only the bits [127...1] of the CID and CSD are transferred, the reserved bit [0] of these registers is replaced by the end bit of the response. The card indicates that an erase is in progress by holding SDMMC\_D0 low. The actual erase time may be quite long, and the host may issue CMD7 to deselect the card.

**Table 245. R2 response**

| Bit position | Width (bits) | Value    | Description      |
|--------------|--------------|----------|------------------|
| 135          | 1            | 0        | Start bit        |
| 134          | 1            | 0        | Transmission bit |
| [133:128]    | 6            | '111111' | Command index    |
| [127:1]      | 127          | X        | Card status      |
| 0            | 1            | 1        | End bit          |

### 35.5.4 R3 (OCR register)

Code length: 48 bits. The contents of the OCR register are sent as a response to CMD1. The level coding is as follows: restricted voltage windows = low, card busy = low.

**Table 246. R3 response**

| Bit position | Width (bits) | Value     | Description      |
|--------------|--------------|-----------|------------------|
| 47           | 1            | 0         | Start bit        |
| 46           | 1            | 0         | Transmission bit |
| [45:40]      | 6            | '111111'  | Reserved         |
| [39:8]       | 32           | X         | OCR register     |
| [7:1]        | 7            | '1111111' | Reserved         |
| 0            | 1            | 1         | End bit          |

### 35.5.5 R4 (Fast I/O)

Code length: 48 bits. The argument field contains the RCA of the addressed card, the register address to be read out or written to, and its content.

**Table 247. R4 response**

| Bit position          |         | Width (bits) | Value    | Description            |
|-----------------------|---------|--------------|----------|------------------------|
| 47                    |         | 1            | 0        | Start bit              |
| 46                    |         | 1            | 0        | Transmission bit       |
| [45:40]               |         | 6            | ‘100111’ | CMD39                  |
| [39:8] Argument field | [31:16] | 16           | X        | RCA                    |
|                       | [15:8]  | 8            | X        | register address       |
|                       | [7:0]   | 8            | X        | read register contents |
| [7:1]                 |         | 7            | X        | CRC7                   |
| 0                     |         | 1            | 1        | End bit                |

### 35.5.6 R4b

For SD I/O only: an SDIO card receiving the CMD5 will respond with a unique SDIO response R4. The format is:

**Table 248. R4b response**

| Bit position | Width (bits) | Value | Description      |
|--------------|--------------|-------|------------------|
| 47           | 1            | 0     | Start bit        |
| 46           | 1            | 0     | Transmission bit |
| [45:40]      | 6            | X     | Reserved         |

Table 248. R4b response (continued)

| Bit position          |         | Width (bits) | Value | Description             |
|-----------------------|---------|--------------|-------|-------------------------|
| [39:8] Argument field | 39      | 16           | X     | Card is ready           |
|                       | [38:36] | 3            | X     | Number of I/O functions |
|                       | 35      | 1            | X     | Present memory          |
|                       | [34:32] | 3            | X     | Stuff bits              |
|                       | [31:8]  | 24           | X     | I/O ORC                 |
| [7:1]                 |         | 7            | X     | Reserved                |
| 0                     |         | 1            | 1     | End bit                 |

Once an SD I/O card has received a CMD5, the I/O portion of that card is enabled to respond normally to all further commands. This I/O enable of the function within the I/O card will remain set until a reset, power cycle or CMD52 with write to I/O reset is received by the card. Note that an SD memory-only card may respond to a CMD5. The proper response for a memory-only card would be *Present memory* = 1 and *Number of I/O functions* = 0. A memory-only card built to meet the SD Memory Card specification version 1.0 would detect the CMD5 as an illegal command and not respond. The I/O aware host will send CMD5. If the card responds with response R4, the host determines the card's configuration based on the data contained within the R4 response.

### 35.5.7 R5 (interrupt request)

Only for MultiMediaCard. Code length: 48 bits. If the response is generated by the host, the RCA field in the argument will be 0x0.

Table 249. R5 response

| Bit position          |         | Width (bits) | Value    | Description                                |
|-----------------------|---------|--------------|----------|--------------------------------------------|
| 47                    |         | 1            | 0        | Start bit                                  |
| 46                    |         | 1            | 0        | Transmission bit                           |
| [45:40]               |         | 6            | '101000' | CMD40                                      |
| [39:8] Argument field | [31:16] | 16           | X        | RCA [31:16] of winning card or of the host |
|                       | [15:0]  | 16           | X        | Not defined. May be used for IRQ data      |
| [7:1]                 |         | 7            | X        | CRC7                                       |
| 0                     |         | 1            | 1        | End bit                                    |

### 35.5.8 R6

Only for SD I/O. The normal response to CMD3 by a memory device. It is shown in [Table 250](#).

Table 250. R6 response

| Bit position          |         | Width (bits) | Value    | Description                                |
|-----------------------|---------|--------------|----------|--------------------------------------------|
| 47                    |         | 1            | 0        | Start bit                                  |
| 46                    |         | 1            | 0        | Transmission bit                           |
| [45:40]               |         | 6            | '101000' | CMD40                                      |
| [39:8] Argument field | [31:16] | 16           | X        | RCA [31:16] of winning card or of the host |
|                       | [15:0]  | 16           | X        | Not defined. May be used for IRQ data      |
| [7:1]                 |         | 7            | X        | CRC7                                       |
| 0                     |         | 1            | 1        | End bit                                    |

The card [23:8] status bits are changed when CMD3 is sent to an I/O-only card. In this case, the 16 bits of response are the SD I/O-only values:

- Bit [15] COM\_CRC\_ERROR
- Bit [14] ILLEGAL\_COMMAND
- Bit [13] ERROR
- Bits [12:0] Reserved

## 35.6 SDIO I/O card-specific operations

The following features are SD I/O-specific operations:

- SDIO read wait operation by SDMMC\_D2 signalling
- SDIO read wait operation by stopping the clock
- SDIO suspend/resume operation (write and read suspend)
- SDIO interrupts

The SDMMC supports these operations only if the SDMMC\_DCTRL[11] bit is set, except for read suspend that does not need specific hardware implementation.

### 35.6.1 SDIO I/O read wait operation by SDMMC\_D2 signalling

It is possible to start the readwait interval before the first block is received: when the data path is enabled (SDMMC\_DCTRL[0] bit set), the SDIO-specific operation is enabled (SDMMC\_DCTRL[11] bit set), read wait starts (SDMMC\_DCTRL[10] = 0 and SDMMC\_DCTRL[8] = 1) and data direction is from card to SDMMC (SDMMC\_DCTRL[1] = 1), the DPSM directly moves from Idle to Readwait. In Readwait the DPSM drives SDMMC\_D2 to 0 after 2 SDMMC\_CK clock cycles. In this state, when you set the RWSTOP bit (SDMMC\_DCTRL[9]), the DPSM remains in Wait for two more SDMMC\_CK clock cycles to drive SDMMC\_D2 to 1 for one clock cycle (in accordance with SDIO specification). The DPSM then starts waiting again until it receives data from the card. The DPSM will not start a readwait interval while receiving a block even if read wait start is set: the readwait interval will start after the CRC is received. The RWSTOP bit has to be cleared to start a new read wait operation. During the readwait interval, the SDMMC can detect SDIO interrupts on SDMMC\_D1.

### 35.6.2 SDIO read wait operation by stopping SDMMC\_CLK

If the SDIO card does not support the previous read wait method, the SDMMC can perform a read wait by stopping SDMMC\_CLK (SDMMC\_DCTRL is set just like in the method presented in [Section 35.6.1](#), but SDMMC\_DCTRL[10] = 1): DSPM stops the clock two SDMMC\_CLK cycles after the end bit of the current received block and starts the clock again after the read wait start bit is set.

As SDMMC\_CLK is stopped, any command can be issued to the card. During a read/wait interval, the SDMMC can detect SDIO interrupts on SDMMC\_D1.

### 35.6.3 SDIO suspend/resume operation

While sending data to the card, the SDMMC can suspend the write operation. the SDMMC\_CMD[11] bit is set and indicates to the CPSM that the current command is a suspend command. The CPSM analyzes the response and when the ACK is received from the card (suspend accepted), it acknowledges the DPSM that goes Idle after receiving the CRC token of the current block.

The hardware does not save the number of the remaining block to be sent to complete the suspended operation (resume).

The write operation can be suspended by software, just by disabling the DPSM (SDMMC\_DCTRL[0] = 0) when the ACK of the suspend command is received from the card. The DPSM enters then the Idle state.

To suspend a read: the DPSM waits in the Wait\_r state as the function to be suspended sends a complete packet just before stopping the data transaction. The application continues reading RxFIFO until the FIFO is empty, and the DPSM goes Idle automatically.

### 35.6.4 SDIO interrupts

SDIO interrupts are detected on the SDMMC\_D1 line once the SDMMC\_DCTRL[11] bit is set.

When SDIO interrupt is detected, SDMMC\_STA[22] (SDIOIT) bit is set. This static bit can be cleared with clear bit SDMMC\_ICR[22] (SDIOITC). An interrupt can be generated when SDIOIT status bit is set. Separated interrupt enable SDMMC\_MASK[22] bit (SDIOITE) is available to enable and disable interrupt request.

When SD card interrupt occurs (SDMMC\_STA[22] bit set), host software follows below steps to handle it.

1. Disable SDIOIT interrupt signaling by clearing SDIOITE bit (SDMMC\_MASK[22] = '0'),
2. Serve card interrupt request, and clear the source of interrupt on the SD card,
3. Clear SDIOIT bit by writing '1' to SDIOITC bit (SDMMC\_ICR[22] = '1'),
4. Enable SDIOIT interrupt signaling by writing '1' to SDIOITE bit (SDMMC\_MASK[22] = '1').

*Steps 2 to 4 can be executed out of the SDIO interrupt service routine.*

## 35.7 HW flow control

The HW flow control functionality is used to avoid FIFO underrun (TX mode) and overrun (RX mode) errors.

The behavior is to stop SDMMC\_CLK and freeze SDMMC state machines. The data transfer is stalled while the FIFO is unable to transmit or receive data. Only state machines clocked by SDMMCCLK are frozen, the APB2 interface is still alive. The FIFO can thus be filled or emptied even if flow control is activated.

To enable HW flow control, the SDMMC\_CLKCR[14] register bit must be set to 1. After reset Flow Control is disabled.

## 35.8 SDMMC registers

The device communicates to the system via 32-bit-wide control registers accessible via APB2.

### 35.8.1 SDMMC power control register (SDMMC\_POWER)

Address offset: 0x00

Reset value: 0x0000 0000

|      |      |      |      |      |      |      |      |      |      |      |      |      |      |         |      |
|------|------|------|------|------|------|------|------|------|------|------|------|------|------|---------|------|
| 31   | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21   | 20   | 19   | 18   | 17      | 16   |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res.    | Res. |
|      |      |      |      |      |      |      |      |      |      |      |      |      |      |         |      |
| 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5    | 4    | 3    | 2    | 1       | 0    |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | PWRCTRL |      |
|      |      |      |      |      |      |      |      |      |      |      |      |      |      | rw      | rw   |

Bits 31:2 Reserved, must be kept at reset value.

[1:0] **PWRCTRL**: Power supply control bits.

These bits are used to define the current functional state of the card clock:

00: Power-off: the clock to card is stopped.

01: Reserved

10: Reserved power-up

11: Power-on: the card is clocked.

**Note:** At least seven PCLK2 clock periods are needed between two write accesses to this register.

**Note:** After a data write, data cannot be written to this register for three SDMMCCLK clock periods plus two PCLK2 clock periods.

### 35.8.2 SDMMC clock control register (SDMMC\_CLKCR)

Address offset: 0x04

Reset value: 0x0000 0000

The SDMMC\_CLKCR register controls the SDMMC\_CLK output clock.

|      |             |             |            |      |            |            |       |        |      |      |      |      |      |      |      |
|------|-------------|-------------|------------|------|------------|------------|-------|--------|------|------|------|------|------|------|------|

| 15   | 14          | 13          | 12         | 11   | 10         | 9          | 8     | 7      | 6    | 5    | 4    | 3    | 2    | 1    | 0    |
| Res. | HWFC<br>_EN | NEGE<br>DGE | WID<br>BUS |      | BYPAS<br>S | PWRS<br>AV | CLKEN | CLKDIV |      |      |      |      |      |      |      |
|      | rw          | rw          | rw         | rw   | rw         | rw         | rw    | rw     | rw   | rw   | rw   | rw   | rw   | rw   | rw   |

Bits 31:15 Reserved, must be kept at reset value.

Bit 14 **HWFC\_EN**: HW Flow Control enable

0b: HW Flow Control is disabled

1b: HW Flow Control is enabled

When HW Flow Control is enabled, the meaning of the TXFIFOE and RXFIFOE interrupt signals, see SDMMC Status register definition in [Section 35.8.11](#).

Bit 13 **NEGEDGE**: SDMMC\_CLK dephasing selection bit

0b: Command and Data changed on the SDMMCCLK falling edge succeeding the rising edge of SDMMC\_CLK. (SDMMC\_CLK rising edge occurs on SDMMCCLK rising edge).

1b: Command and Data changed on the SDMMC\_CLK falling edge.

When BYPASS is active, the data and the command change on SDMMCCLK falling edge whatever NEGEDGE value.

Bits 12:11 **WIDBUS**: Wide bus mode enable bit

00: Default bus mode: SDMMC\_D0 used

01: 4-wide bus mode: SDMMC\_D[3:0] used

10: 8-wide bus mode: SDMMC\_D[7:0] used

Bit 10 **BYPASS**: Clock divider bypass enable bit

0: Disable bypass: SDMMCCLK is divided according to the CLKDIV value before driving the SDMMC\_CLK output signal.

1: Enable bypass: SDMMCCLK directly drives the SDMMC\_CLK output signal.

Bit 9 **PWRSAPV**: Power saving configuration bit

For power saving, the SDMMC\_CLK clock output can be disabled when the bus is idle by setting PWRSAPV:

0: SDMMC\_CLK clock is always enabled

1: SDMMC\_CLK is only enabled when the bus is active

Bit 8 **CLKEN**: Clock enable bit

0: SDMMC\_CLK is disabled

1: SDMMC\_CLK is enabled

Bits 7:0 **CLKDIV**: Clock divide factor

This field defines the divide factor between the input clock (SDMMCCLK) and the output clock (SDMMC\_CLK):  $\text{SDMMC\_CK frequency} = \text{SDMMCCLK} / [\text{CLKDIV} + 2]$ .

- Note:**
- 1 While the SD/SDIO card or MultiMediaCard is in identification mode, the SDMMC\_CLK frequency must be less than 400 kHz.
  - 2 The clock frequency can be changed to the maximum card bus frequency when relative card addresses are assigned to all cards.
  - 3 After a data write, data cannot be written to this register for three SDMMCCLK clock periods plus two PCLK2 clock periods. SDMMC\_CLK can also be stopped during the read wait interval for SD I/O cards: in this case the SDMMC\_CLKCR register does not control SDMMC\_CLK.

### 35.8.3 SDMMC argument register (SDMMC\_ARG)

Address offset: 0x08

Reset value: 0x0000 0000

The SDMMC\_ARG register contains a 32-bit command argument, which is sent to a card as part of a command message.

|               |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|---------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31            | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| CMDARG[31:16] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw            | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |
| 15            | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| CMDARG[15:0]  |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw            | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 31:0 **CMDARG**: Command argument

Command argument sent to a card as part of a command message. If a command contains an argument, it must be loaded into this register before writing a command to the command register.

### 35.8.4 SDMMC command register (SDMMC\_CMD)

Address offset: 0x0C

Reset value: 0x0000 0000

The SDMMC\_CMD register contains the command index and command type bits. The command index is sent to a card as part of a command message. The command type bits control the command path state machine (CPSM).

|      |      |      |      |              |         |           |          |          |      |          |      |      |      |      |      |
|------|------|------|------|--------------|---------|-----------|----------|----------|------|----------|------|------|------|------|------|
| 31   | 30   | 29   | 28   | 27           | 26      | 25        | 24       | 23       | 22   | 21       | 20   | 19   | 18   | 17   | 16   |
| Res. | Res. | Res. | Res. | Res.         | Res.    | Res.      | Res.     | Res.     | Res. | Res.     | Res. | Res. | Res. | Res. | Res. |
|      |      |      |      |              |         |           |          |          |      |          |      |      |      |      |      |
| 15   | 14   | 13   | 12   | 11           | 10      | 9         | 8        | 7        | 6    | 5        | 4    | 3    | 2    | 1    | 0    |
| Res. | Res. | Res. | Res. | SDIO Suspend | CPSM EN | WAIT PEND | WAIT INT | WAITRESP |      | CMDINDEX |      |      |      |      |      |
|      |      |      |      | rw           | rw      | rw        | rw       | rw       | rw   | rw       | rw   | rw   | rw   | rw   | rw   |

Bits 31:12 Reserved, must be kept at reset value.

Bit 11 **SDIOSuspend**: SD I/O suspend command

If this bit is set, the command to be sent is a suspend command (to be used only with SDIO card).

Bit 10 **CPSMEN**: Command path state machine (CPSM) Enable bit

If this bit is set, the CPSM is enabled.

Bit 9 **WAITPEND**: CPSM Waits for ends of data transfer (CmdPend internal signal).

If this bit is set, the CPSM waits for the end of data transfer before it starts sending a command. This feature is available only with Stream data transfer mode  
SDMMC\_DCTRL[2] = 1.

Bit 8 **WAITINT**: CPSM waits for interrupt request

If this bit is set, the CPSM disables command timeout and waits for an interrupt request.

Bits 7:6 **WAITRESP**: Wait for response bits

They are used to configure whether the CPSM is to wait for a response, and if yes, which kind of response.

00: No response, expect CMDSENT flag

01: Short response, expect CMDREND or CCRCFAIL flag

10: No response, expect CMDSENT flag

11: Long response, expect CMDREND or CCRCFAIL flag

Bits 5:0 **CMDINDEX**: Command index

The command index is sent to the card as part of a command message.

- Note:**
- 1 After a data write, data cannot be written to this register for three SDMMCCLK clock periods plus two PCLK2 clock periods.
  - 2 MultiMediaCards can send two kinds of response: short responses, 48 bits long, or long responses, 136 bits long. SD card and SD I/O card can send only short responses, the argument can vary according to the type of response: the software will distinguish the type of response according to the sent command.

### 35.8.5 SDMMC command response register (SDMMC\_RESPCMD)

Address offset: 0x10

Reset value: 0x0000 0000

The SDMMC\_RESPCMD register contains the command index field of the last command response received. If the command response transmission does not contain the command index field (long or OCR response), the RESPCMD field is unknown, although it must contain 111111b (the value of the reserved field from the response).

|      |      |      |      |      |      |      |      |      |      |         |      |      |      |      |      |
|------|------|------|------|------|------|------|------|------|------|---------|------|------|------|------|------|
| 31   | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21      | 20   | 19   | 18   | 17   | 16   |

| 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5       | 4    | 3    | 2    | 1    | 0    |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | RESPCMD |      |      |      |      |      |
|      |      |      |      |      |      |      |      |      |      | r       | r    | r    | r    | r    | r    |

Bits 31:6 Reserved, must be kept at reset value.

Bits 5:0 **RESPCMD**: Response command index

Read-only bit field. Contains the command index of the last command response received.

### 35.8.6 SDMMC response 1..4 register (SDMMC\_RESPx)

Address offset: (0x10 + (4 × x)); x = 1..4

Reset value: 0x0000 0000

The SDMMC\_RESP1/2/3/4 registers contain the status of a card, which is part of the received response.

|                    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|--------------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31                 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| CARDSTATUSx[31:16] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| r                  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  |
| 15                 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| CARDSTATUSx[15:0]  |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| r                  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  |

Bits 31:0 **CARDSTATUSx**: see [Table 251](#).

The Card Status size is 32 or 127 bits, depending on the response type.

**Table 251. Response type and SDMMC\_RESPx registers**

| Register    | Short response    | Long response        |
|-------------|-------------------|----------------------|
| SDMMC_RESP1 | Card Status[31:0] | Card Status [127:96] |
| SDMMC_RESP2 | Unused            | Card Status [95:64]  |
| SDMMC_RESP3 | Unused            | Card Status [63:32]  |
| SDMMC_RESP4 | Unused            | Card Status [31:1]0b |

The most significant bit of the card status is received first. The SDMMC\_RESP4 register LSB is always 0b.

### 35.8.7 SDMMC data timer register (SDMMC\_DTIMER)

Address offset: 0x24

Reset value: 0x0000 0000

The SDMMC\_DTIMER register contains the data timeout period, in card bus clock periods.

A counter loads the value from the SDMMC\_DTIMER register, and starts decrementing when the data path state machine (DPSM) enters the Wait\_R or Busy state. If the timer reaches 0 while the DPSM is in either of these states, the timeout status flag is set.

|                 |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|-----------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31              | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| DATETIME[31:16] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rW              | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW |
| 15              | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| DATETIME[15:0]  |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rW              | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW |

Bits 31:0 **DATETIME**: Data timeout period

Data timeout period expressed in card bus clock periods.

**Note:** *A data transfer must be written to the data timer register and the data length register before being written to the data control register.*

### 35.8.8 SDMMC data length register (SDMMC\_DLEN)

Address offset: 0x28

Reset value: 0x0000 0000

The SDMMC\_DLEN register contains the number of data bytes to be transferred. The value is loaded into the data counter when data transfer starts.

|                  |      |      |      |      |      |      |                   |    |    |    |    |    |    |    |    |
|------------------|------|------|------|------|------|------|-------------------|----|----|----|----|----|----|----|----|
| 31               | 30   | 29   | 28   | 27   | 26   | 25   | 24                | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| Res.             | Res. | Res. | Res. | Res. | Res. | Res. | DATALENGTH[24:16] |    |    |    |    |    |    |    |    |
|                  |      |      |      |      |      |      | rw                | rw | rw | rw | rw | rw | rw | rw | rw |
| 15               | 14   | 13   | 12   | 11   | 10   | 9    | 8                 | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| DATALENGTH[15:0] |      |      |      |      |      |      |                   |    |    |    |    |    |    |    |    |
| rw               | rw   | rw   | rw   | rw   | rw   | rw   | rw                | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 31:25 Reserved, must be kept at reset value.

Bits 24:0 **DATALENGTH**: Data length value

Number of data bytes to be transferred.

**Note:** For a block data transfer, the value in the data length register must be a multiple of the block size (see SDMMC\_DCTRL). Before being written to the data control register a timeout must be written to the data timer register and the data length register.

In case of IO\_RW\_EXTENDED (CMD53):

- If the Stream or SDIO multibyte data transfer is selected the value in the data length register must be between 1 and 512.

- If the Block data transfer is selected the value in the data length register must be between 1\*Data block size and 512\*Data block size.

### 35.8.9 SDMMC data control register (SDMMC\_DCTRL)

Address offset: 0x2C

Reset value: 0x0000 0000

The SDMMC\_DCTRL register control the data path state machine (DPSM).

|      |      |      |      |         |        |         |          |            |      |      |      |        |         |       |      |
|------|------|------|------|---------|--------|---------|----------|------------|------|------|------|--------|---------|-------|------|
| 31   | 30   | 29   | 28   | 27      | 26     | 25      | 24       | 23         | 22   | 21   | 20   | 19     | 18      | 17    | 16   |
| Res. | Res. | Res. | Res. | Res.    | Res.   | Res.    | Res.     | Res.       | Res. | Res. | Res. | Res.   | Res.    | Res.  | Res. |
|      |      |      |      |         |        |         |          |            |      |      |      |        |         |       |      |
| 15   | 14   | 13   | 12   | 11      | 10     | 9       | 8        | 7          | 6    | 5    | 4    | 3      | 2       | 1     | 0    |
| Res. | Res. | Res. | Res. | SDIO EN | RW MOD | RW STOP | RW START | DBLOCKSIZE |      |      |      | DMA EN | DT MODE | DTDIR | DTEN |
|      |      |      |      | rw      | rw     | rw      | rw       | rw         | rw   | rw   | rw   | rw     | rw      | rw    | rw   |

Bits 31:12 Reserved, must be kept at reset value.

Bit 11 **SDIOEN**: SD I/O enable functions

If this bit is set, the DPSM performs an SD I/O-card-specific operation.

Bit 10 **RWMOD**: Read wait mode

0: Read Wait control stopping SDMMC\_D2

1: Read Wait control using SDMMC\_CK

Bit 9 **RWSTOP**: Read wait stop

0: Read wait in progress if RWSTART bit is set

1: Enable for read wait stop if RWSTART bit is set

Bit 8 **RWSTART**: Read wait start

If this bit is set, read wait operation starts.

Bits 7:4 **DBLOCKSIZE**: Data block size

Define the data block length when the block data transfer mode is selected:

0000: (0 decimal) lock length =  $2^0$  = 1 byte

0001: (1 decimal) lock length =  $2^1$  = 2 bytes

0010: (2 decimal) lock length =  $2^2$  = 4 bytes

0011: (3 decimal) lock length =  $2^3$  = 8 bytes

0100: (4 decimal) lock length =  $2^4$  = 16 bytes

0101: (5 decimal) lock length =  $2^5$  = 32 bytes

0110: (6 decimal) lock length =  $2^6$  = 64 bytes

0111: (7 decimal) lock length =  $2^7$  = 128 bytes

1000: (8 decimal) lock length =  $2^8$  = 256 bytes

1001: (9 decimal) lock length =  $2^9$  = 512 bytes

1010: (10 decimal) lock length =  $2^{10}$  = 1024 bytes

1011: (11 decimal) lock length =  $2^{11}$  = 2048 bytes

1100: (12 decimal) lock length =  $2^{12}$  = 4096 bytes

1101: (13 decimal) lock length =  $2^{13}$  = 8192 bytes

1110: (14 decimal) lock length =  $2^{14}$  = 16384 bytes

1111: (15 decimal) reserved

Bit 3 **DMAEN**: DMA enable bit

0: DMA disabled.

1: DMA enabled.

Bit 2 **DTMODE**: Data transfer mode selection 1: Stream or SDIO multibyte data transfer.

0: Block data transfer

1: Stream or SDIO multibyte data transfer

Bit 1 **DTDIR**: Data transfer direction selection

0: From controller to card.

1: From card to controller.

[0] **DTEN**: Data transfer enabled bit

Data transfer starts if 1b is written to the DTEN bit. Depending on the direction bit, DTDIR, the DPSM moves to the Wait\_S, Wait\_R state or Readwait if RW Start is set immediately at the beginning of the transfer. It is not necessary to clear the enable bit after the end of a data transfer but the SDMMC\_DCTRL must be updated to enable a new data transfer

*Note: After a data write, data cannot be written to this register for three SDMMCCLK (48 MHz) clock periods plus two PCLK2 clock periods.*

*The meaning of the DTMODE bit changes according to the value of the SDIOEN bit. When SDIOEN=0 and DTMODE=1, the MultiMediaCard stream mode is enabled, and when SDIOEN=1 and DTMODE=1, the peripheral enables an SDIO multibyte transfer.*

### 35.8.10 SDMMC data counter register (SDMMC\_DCOUNT)

Address offset: 0x30

Reset value: 0x0000 0000

The SDMMC\_DCOUNT register loads the value from the data length register (see SDMMC\_DLEN) when the DPSM moves from the Idle state to the Wait\_R or Wait\_S state. As data is transferred, the counter decrements the value until it reaches 0. The DPSM then moves to the Idle state and the data status end flag, DATAEND, is set.

|                 |      |      |      |      |      |      |                  |    |    |    |    |    |    |    |    |

Bits 31:25 Reserved, must be kept at reset value.

Bits 24:0 **DATACOUNT**: Data count value

When this bit is read, the number of remaining data bytes to be transferred is returned. Write has no effect.

*Note:* This register should be read only when the data transfer is complete.

### 35.8.11 SDMMC status register (SDMMC\_STA)

Address offset: 0x34

Reset value: 0x0000 0000

The SDMMC\_STA register is a read-only register. It contains two types of flag:

- Static flags (bits [23:22,10:0]): these bits remain asserted until they are cleared by writing to the SDMMC Interrupt Clear register (see SDMMC\_ICR)
- Dynamic flags (bits [21:11]): these bits change state depending on the state of the underlying logic (for example, FIFO full and empty flags are asserted and deasserted as data while written to the FIFO)

Bits 31:23 Reserved, must be kept at reset value.

Bit 22 **SDIOIT**: SDIO interrupt received

Bit 21 **RXDAVL**: Data available in receive FIFO

- Bit 20 **TXDAVL**: Data available in transmit FIFO
- Bit 19 **RXFIFOE**: Receive FIFO empty
- Bit 18 **TXFIFOE**: Transmit FIFO empty  
When HW Flow Control is enabled, TXFIFOE signals becomes activated when the FIFO contains 2 words.
- Bit 17 **RXFIFO**: Receive FIFO full  
When HW Flow Control is enabled, RXFIFO signals becomes activated 2 words before the FIFO is full.
- Bit 16 **TXFIFO**: Transmit FIFO full
- Bit 15 **RXFIFOH**: Receive FIFO half full: there are at least 8 words in the FIFO
- Bit 14 **TXFIFOH**: Transmit FIFO half empty: at least 8 words can be written into the FIFO
- Bit 13 **RXACT**: Data receive in progress
- Bit 12 **TXACT**: Data transmit in progress
- Bit 11 **CMDACT**: Command transfer in progress
- Bit 10 **DBCKEND**: Data block sent/received (CRC check passed)
- Bit 9 Reserved, must be kept at reset value.
- Bit 8 **DATAEND**: Data end (data counter, SDIDCOUNT, is zero)
- Bit 7 **CMDSENT**: Command sent (no response required)
- Bit 6 **CMDREND**: Command response received (CRC check passed)
- Bit 5 **RXOVERR**: Received FIFO overrun error  
*Note: If DMA is used to read SDMMC FIFO (DMAEN bit is set in SDMMC\_DCTRL register), user software should disable DMA stream, and then write with '0' (to disable DMA request generation).*
- Bit 4 **TXUNDERR**: Transmit FIFO underrun error  
*Note: If DMA is used to fill SDMMC FIFO (DMAEN bit is set in SDMMC\_DCTRL register), user software should disable DMA stream, and then write DMAEN with '0' (to disable DMA request generation).*
- Bit 3 **DTIMEOUT**: Data timeout
- Bit 2 **CTIMEOUT**: Command response timeout  
The Command TimeOut period has a fixed value of 64 SDMMC\_CLK clock periods.
- Bit 1 **DCRCFAIL**: Data block sent/received (CRC check failed)
- Bit 0 **CCRCFAIL**: Command response received (CRC check failed)

### 35.8.12 SDMMC interrupt clear register (SDMMC\_ICR)

Address offset: 0x38

Reset value: 0x0000 0000

The SDMMC\_ICR register is a write-only register. Writing a bit with 1b clears the corresponding bit in the SDMMC\_STA Status register.

|      |      |      |      |      |              |      |              |              |                  |                  |                   |               |               |               |               |

Bits 31:23 Reserved, must be kept at reset value.

Bit 22 **SDIOITC**: SDIOIT flag clear bit

Set by software to clear the SDIOIT flag.

0: SDIOIT not cleared

1: SDIOIT cleared

Bits 21:11 Reserved, must be kept at reset value.

Bit 10 **DBCKENDC**: DBCKEND flag clear bit

Set by software to clear the DBCKEND flag.

0: DBCKEND not cleared

1: DBCKEND cleared

Bit 9 Reserved, must be kept at reset value.

Bit 8 **DATAENDC**: DATAEND flag clear bit

Set by software to clear the DATAEND flag.

0: DATAEND not cleared

1: DATAEND cleared

Bit 7 **CMDSENTC**: CMDSENT flag clear bit

Set by software to clear the CMDSENT flag.

0: CMDSENT not cleared

1: CMDSENT cleared

Bit 6 **CMDREND C**: CMDREND flag clear bit

Set by software to clear the CMDREND flag.

0: CMDREND not cleared

1: CMDREND cleared

Bit 5 **RXOVERRC**: RXOVERR flag clear bit

Set by software to clear the RXOVERR flag.

0: RXOVERR not cleared

1: RXOVERR cleared

Bit 4 **TXUNDERRC**: TXUNDERR flag clear bit

Set by software to clear TXUNDERR flag.

0: TXUNDERR not cleared

1: TXUNDERR cleared

Bit 3 **DTIMEOUTC**: DTIMEOUT flag clear bit

Set by software to clear the DTIMEOUT flag.

0: DTIMEOUT not cleared

1: DTIMEOUT cleared

- Bit 2 **CTIMEOUTC**: CTIMEOUT flag clear bit  
Set by software to clear the CTIMEOUT flag.  
0: CTIMEOUT not cleared  
1: CTIMEOUT cleared
- Bit 1 **DCRCFAILC**: DCRCFAIL flag clear bit  
Set by software to clear the DCRCFAIL flag.  
0: DCRCFAIL not cleared  
1: DCRCFAIL cleared
- Bit 0 **CCRCFAILC**: CCRCFAIL flag clear bit  
Set by software to clear the CCRCFAIL flag.  
0: CCRCFAIL not cleared  
1: CCRCFAIL cleared

### 35.8.13 SDMMC mask register (SDMMC\_MASK)

Address offset: 0x3C

Reset value: 0x0000 0000

The interrupt mask register determines which status flags generate an interrupt request by setting the corresponding bit to 1b.

|                    |                    |             |             |              |               |      |               |                   |                   |                   |                    |                   |                   |                   |                   |

Bits 31:23 Reserved, must be kept at reset value.

- Bit 22 **SDIOITIE**: SDIO mode interrupt received interrupt enable  
Set and cleared by software to enable/disable the interrupt generated when receiving the SDIO mode interrupt.  
0: SDIO Mode Interrupt Received interrupt disabled  
1: SDIO Mode Interrupt Received interrupt enabled
- Bit 21 **RXDAVLIE**: Data available in Rx FIFO interrupt enable  
Set and cleared by software to enable/disable the interrupt generated by the presence of data available in Rx FIFO.  
0: Data available in Rx FIFO interrupt disabled  
1: Data available in Rx FIFO interrupt enabled
- Bit 20 **TXDAVLIE**: Data available in Tx FIFO interrupt enable  
Set and cleared by software to enable/disable the interrupt generated by the presence of data available in Tx FIFO.  
0: Data available in Tx FIFO interrupt disabled  
1: Data available in Tx FIFO interrupt enabled

- Bit 19 **RXFIFOEIE**: Rx FIFO empty interrupt enable  
Set and cleared by software to enable/disable interrupt caused by Rx FIFO empty.  
0: Rx FIFO empty interrupt disabled  
1: Rx FIFO empty interrupt enabled
- Bit 18 **TXFIFOEIE**: Tx FIFO empty interrupt enable  
Set and cleared by software to enable/disable interrupt caused by Tx FIFO empty.  
0: Tx FIFO empty interrupt disabled  
1: Tx FIFO empty interrupt enabled
- Bit 17 **RXFIFOIE**: Rx FIFO full interrupt enable  
Set and cleared by software to enable/disable interrupt caused by Rx FIFO full.  
0: Rx FIFO full interrupt disabled  
1: Rx FIFO full interrupt enabled
- Bit 16 **TXFIFOIE**: Tx FIFO full interrupt enable  
Set and cleared by software to enable/disable interrupt caused by Tx FIFO full.  
0: Tx FIFO full interrupt disabled  
1: Tx FIFO full interrupt enabled
- Bit 15 **RXFIFOHFIE**: Rx FIFO half full interrupt enable  
Set and cleared by software to enable/disable interrupt caused by Rx FIFO half full.  
0: Rx FIFO half full interrupt disabled  
1: Rx FIFO half full interrupt enabled
- Bit 14 **TXFIFOHEIE**: Tx FIFO half empty interrupt enable  
Set and cleared by software to enable/disable interrupt caused by Tx FIFO half empty.  
0: Tx FIFO half empty interrupt disabled  
1: Tx FIFO half empty interrupt enabled
- Bit 13 **RXACTIE**: Data receive acting interrupt enable  
Set and cleared by software to enable/disable interrupt caused by data being received (data receive acting).  
0: Data receive acting interrupt disabled  
1: Data receive acting interrupt enabled
- Bit 12 **TXACTIE**: Data transmit acting interrupt enable  
Set and cleared by software to enable/disable interrupt caused by data being transferred (data transmit acting).  
0: Data transmit acting interrupt disabled  
1: Data transmit acting interrupt enabled
- Bit 11 **CMDACTIE**: Command acting interrupt enable  
Set and cleared by software to enable/disable interrupt caused by a command being transferred (command acting).  
0: Command acting interrupt disabled  
1: Command acting interrupt enabled
- Bit 10 **DBCKENDIE**: Data block end interrupt enable  
Set and cleared by software to enable/disable interrupt caused by data block end.  
0: Data block end interrupt disabled  
1: Data block end interrupt enabled
- Bit 9 Reserved, must be kept at reset value.

- Bit 8 **DATAENDIE**: Data end interrupt enable  
 Set and cleared by software to enable/disable interrupt caused by data end.  
 0: Data end interrupt disabled  
 1: Data end interrupt enabled
- Bit 7 **CMDSENTIE**: Command sent interrupt enable  
 Set and cleared by software to enable/disable interrupt caused by sending command.  
 0: Command sent interrupt disabled  
 1: Command sent interrupt enabled
- Bit 6 **CMDRENDIE**: Command response received interrupt enable  
 Set and cleared by software to enable/disable interrupt caused by receiving command response.  
 0: Command response received interrupt disabled  
 1: command Response Received interrupt enabled
- Bit 5 **RXOVERRIE**: Rx FIFO overrun error interrupt enable  
 Set and cleared by software to enable/disable interrupt caused by Rx FIFO overrun error.  
 0: Rx FIFO overrun error interrupt disabled  
 1: Rx FIFO overrun error interrupt enabled
- Bit 4 **TXUNDERRIE**: Tx FIFO underrun error interrupt enable  
 Set and cleared by software to enable/disable interrupt caused by Tx FIFO underrun error.  
 0: Tx FIFO underrun error interrupt disabled  
 1: Tx FIFO underrun error interrupt enabled
- Bit 3 **DTIMEOUTIE**: Data timeout interrupt enable  
 Set and cleared by software to enable/disable interrupt caused by data timeout.  
 0: Data timeout interrupt disabled  
 1: Data timeout interrupt enabled
- Bit 2 **CTIMEOUTIE**: Command timeout interrupt enable  
 Set and cleared by software to enable/disable interrupt caused by command timeout.  
 0: Command timeout interrupt disabled  
 1: Command timeout interrupt enabled
- Bit 1 **DCRCFAILIE**: Data CRC fail interrupt enable  
 Set and cleared by software to enable/disable interrupt caused by data CRC failure.  
 0: Data CRC fail interrupt disabled  
 1: Data CRC fail interrupt enabled
- Bit 0 **CCRCFAILIE**: Command CRC fail interrupt enable  
 Set and cleared by software to enable/disable interrupt caused by command CRC failure.  
 0: Command CRC fail interrupt disabled  
 1: Command CRC fail interrupt enabled

#### 35.8.14 SDMMC FIFO counter register (SDMMC\_FIFOCNT)

Address offset: 0x48

Reset value: 0x0000 0000

The SDMMC\_FIFOCNT register contains the remaining number of words to be written to or read from the FIFO. The FIFO counter loads the value from the data length register (see SDMMC\_DLEN) when the data transfer enable bit, DTEN, is set in the data control register (SDMMC\_DCTRL register) and the DPSM is at the Idle state. If the data length is not word-aligned (multiple of 4), the remaining 1 to 3 bytes are regarded as a word.

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:0 **FIFOCOUNT**: Remaining number of words to be written to or read from the FIFO.

### 35.8.15 SDMMC data FIFO register (SDMMC\_FIFO)

Address offset: 0x80

Reset value: 0x0000 0000

The receive and transmit FIFOs can be read or written as 32-bit wide registers. The FIFOs contain 32 entries on 32 sequential addresses. This allows the CPU to use its load and store multiple operands to read from/write to the FIFO.

|                 |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

| rw              | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

bits 31:0 **FIFOData**: Receive and transmit FIFO data

The FIFO data occupies 32 entries of 32-bit words, from address:  
SDMMC base + 0x080 to SDMMC base + 0xFC.

### 35.8.16 SDMMC register map

The following table summarizes the SDMMC registers.

**Table 252. SDMMC register map**

## 36 Controller area network (bxCAN)

### 36.1 Introduction

The **Basic Extended CAN** peripheral, named **bxCAN**, interfaces the CAN network. It supports the CAN protocols version 2.0A and B. It has been designed to manage a high number of incoming messages efficiently with a minimum CPU load. It also meets the priority requirements for transmit messages.

For safety-critical applications, the CAN controller provides all hardware functions for supporting the CAN Time Triggered Communication option.

### 36.2 bxCAN main features

- Supports CAN protocol version 2.0 A, B Active
- Bit rates up to 1 Mbit/s
- Supports the Time Triggered Communication option

#### Transmission

- Three transmit mailboxes
- Configurable transmit priority
- Time Stamp on SOF transmission

#### Reception

- Two receive FIFOs with three stages
- Scalable filter banks:
  - 28 filter banks shared between CAN1 and CAN2 for dual CAN
- Identifier list feature
- Configurable FIFO overrun
- Time Stamp on SOF reception

#### Time-triggered communication option

- Disable automatic retransmission mode
- 16-bit free running timer
- Time Stamp sent in last two data bytes

#### Management

- Maskable interrupts
- Software-efficient mailbox mapping at a unique address space

#### Dual CAN peripheral configuration

- CAN1: Master bxCAN for managing the communication between a Slave bxCAN and the 512-byte SRAM memory
- CAN2: Slave bxCAN, with no direct access to the SRAM memory.
- The two bxCAN cells share the 512-byte SRAM memory (see [Figure 442: Dual-CAN block diagram](#))

### 36.3 bxCAN general description

In today CAN applications, the number of nodes in a network is increasing and often several networks are linked together via gateways. Typically the number of messages in the system (to be handled by each node) has significantly increased. In addition to the application messages, Network Management and Diagnostic messages have been introduced.

- An enhanced filtering mechanism is required to handle each type of message.

Furthermore, application tasks require more CPU time, therefore real-time constraints caused by message reception have to be reduced.

- A receive FIFO scheme allows the CPU to be dedicated to application tasks for a long time period without losing messages.

The standard HLP (Higher Layer Protocol) based on standard CAN drivers requires an efficient interface to the CAN controller.

**Figure 441. CAN network topology**

#### 36.3.1 CAN 2.0B active core

The bxCAN module handles the transmission and the reception of CAN messages fully autonomously. Standard identifiers (11-bit) and extended identifiers (29-bit) are fully supported by hardware.

#### 36.3.2 Control, status and configuration registers

The application uses these registers to:

- Configure CAN parameters, e.g. baud rate
- Request transmissions
- Handle receptions
- Manage interrupts
- Get diagnostic information

#### 36.3.3 Tx mailboxes

Three transmit mailboxes are provided to the software for setting up messages. The transmission Scheduler decides which mailbox has to be transmitted first.

### 36.3.4 Acceptance filters

The bxCAN provides up to 28 scalable/configurable identifier filter banks in dual CAN configuration, for selecting the incoming messages, that the software needs and discarding the others.

#### Receive FIFO

Two receive FIFOs are used by hardware to store the incoming messages. Three complete messages can be stored in each FIFO. The FIFOs are managed completely by hardware.

Figure 442. Dual-CAN block diagram

## 36.4 bxCAN operating modes

bxCAN has three main operating modes: **initialization**, **normal** and **Sleep**. After a hardware reset, bxCAN is in Sleep mode to reduce power consumption and an internal pull-up is active on CANTX. The software requests bxCAN to enter **initialization** or **Sleep** mode by setting the INRQ or SLEEP bits in the CAN\_MCR register. Once the mode has been entered, bxCAN confirms it by setting the INAK or SLAK bits in the CAN\_MSR register and the internal pull-up is disabled. When neither INAK nor SLAK are set, bxCAN is in **normal** mode. Before entering **normal** mode bxCAN always has to **synchronize** on the CAN bus. To synchronize, bxCAN waits until the CAN bus is idle, this means 11 consecutive recessive bits have been monitored on CANRX.

### 36.4.1 Initialization mode

The software initialization can be done while the hardware is in Initialization mode. To enter this mode the software sets the INRQ bit in the CAN\_MCR register and waits until the hardware has confirmed the request by setting the INAK bit in the CAN\_MSR register.

To leave Initialization mode, the software clears the INQR bit. bxCAN has left Initialization mode once the INAK bit has been cleared by hardware.

While in Initialization Mode, all message transfers to and from the CAN bus are stopped and the status of the CAN bus output CANTX is recessive (high).

Entering Initialization Mode does not change any of the configuration registers.

To initialize the CAN Controller, software has to set up the Bit Timing (CAN\_BTR) and CAN options (CAN\_MCR) registers.

To initialize the registers associated with the CAN filter banks (mode, scale, FIFO assignment, activation and filter values), software has to set the FINIT bit (CAN\_FMR). Filter initialization also can be done outside the initialization mode.

*Note:* When FINIT=1, CAN reception is deactivated.

*The filter values also can be modified by deactivating the associated filter activation bits (in the CAN\_FA1R register).*

*If a filter bank is not used, it is recommended to leave it non active (leave the corresponding FACT bit cleared).*

### 36.4.2 Normal mode

Once the initialization is complete, the software must request the hardware to enter Normal mode to be able to synchronize on the CAN bus and start reception and transmission.

The request to enter Normal mode is issued by clearing the INRQ bit in the CAN\_MCR register. The bxCAN enters Normal mode and is ready to take part in bus activities when it has synchronized with the data transfer on the CAN bus. This is done by waiting for the occurrence of a sequence of 11 consecutive recessive bits (Bus Idle state). The switch to Normal mode is confirmed by the hardware by clearing the INAK bit in the CAN\_MSR register.

The initialization of the filter values is independent from Initialization Mode but must be done while the filter is not active (corresponding FACTx bit cleared). The filter scale and mode configuration must be configured before entering Normal Mode.

### 36.4.3 Sleep mode (low-power)

To reduce power consumption, bxCAN has a low-power mode called Sleep mode. This mode is entered on software request by setting the SLEEP bit in the CAN\_MCR register. In this mode, the bxCAN clock is stopped, however software can still access the bxCAN mailboxes.

If software requests entry to **initialization** mode by setting the INRQ bit while bxCAN is in **Sleep** mode, it must also clear the SLEEP bit.

bxCAN can be woken up (exit Sleep mode) either by software clearing the SLEEP bit or on detection of CAN bus activity.

On CAN bus activity detection, hardware automatically performs the wakeup sequence by clearing the SLEEP bit if the AWUM bit in the CAN\_MCR register is set. If the AWUM bit is cleared, software has to clear the SLEEP bit when a wakeup interrupt occurs, in order to exit from Sleep mode.

*Note: If the wakeup interrupt is enabled (WKUIE bit set in CAN\_IER register) a wakeup interrupt will be generated on detection of CAN bus activity, even if the bxCAN automatically performs the wakeup sequence.*

After the SLEEP bit has been cleared, Sleep mode is exited once bxCAN has synchronized with the CAN bus, refer to [Figure 443: bxCAN operating modes](#). The Sleep mode is exited once the SLAK bit has been cleared by hardware.

Figure 443. bxCAN operating modes

1. ACK = The wait state during which hardware confirms a request by setting the INAK or SLAK bits in the CAN\_MSR register
2. SYNC = The state during which bxCAN waits until the CAN bus is idle, meaning 11 consecutive recessive bits have been monitored on CANRX

## 36.5 Test mode

Test mode can be selected by the SLM and LBKM bits in the CAN\_BTR register. These bits must be configured while bxCAN is in Initialization mode. Once test mode has been selected, the INRQ bit in the CAN\_MCR register must be reset to enter Normal mode.

### 36.5.1 Silent mode

The bxCAN can be put in Silent mode by setting the SLM bit in the CAN\_BTR register.

In Silent mode, the bxCAN is able to receive valid data frames and valid remote frames, but it sends only recessive bits on the CAN bus and it cannot start a transmission. If the bxCAN has to send a dominant bit (ACK bit, overload flag, active error flag), the bit is rerouted internally so that the CAN Core monitors this dominant bit, although the CAN bus may remain in recessive state. Silent mode can be used to analyze the traffic on a CAN bus without affecting it by the transmission of dominant bits (Acknowledge Bits, Error Frames).

Figure 444. bxCAN in silent mode

### 36.5.2 Loop back mode

The bxCAN can be set in Loop Back Mode by setting the LBKM bit in the CAN\_BTR register. In Loop Back Mode, the bxCAN treats its own transmitted messages as received messages and stores them (if they pass acceptance filtering) in a Receive mailbox.

Figure 445. bxCAN in loop back mode

This mode is provided for self-test functions. To be independent of external events, the CAN Core ignores acknowledge errors (no dominant bit sampled in the acknowledge slot of a data / remote frame) in Loop Back Mode. In this mode, the bxCAN performs an internal feedback from its Tx output to its Rx input. The actual value of the CANRX input pin is disregarded by the bxCAN. The transmitted messages can be monitored on the CANTX pin.

### 36.5.3 Loop back combined with silent mode

It is also possible to combine Loop Back mode and Silent mode by setting the LBKM and SILM bits in the CAN\_BTR register. This mode can be used for a “Hot Selftest”, meaning the bxCAN can be tested like in Loop Back mode but without affecting a running CAN system connected to the CANTX and CANRX pins. In this mode, the CANRX pin is disconnected from the bxCAN and the CANTX pin is held recessive.

Figure 446. bxCAN in combined mode

## 36.6 Behavior in debug mode

When the microcontroller enters the debug mode (Cortex®-M7 core halted), the bxCAN continues to work normally or stops, depending on:

- the DBG\_CAN1\_STOP bit for CAN1 or the DBG\_CAN2\_STOP bit for CAN2 in the DBG module for the dual mode.
- the DBF bit in CAN\_MCR. For more details, refer to [Section 36.9.2: CAN control and status registers](#).

## 36.7 bxCAN functional description

### 36.7.1 Transmission handling

In order to transmit a message, the application must select one **empty** transmit mailbox, set up the identifier, the data length code (DLC) and the data before requesting the transmission by setting the corresponding TXRQ bit in the CAN\_TlRxR register. Once the mailbox has left **empty** state, the software no longer has write access to the mailbox registers. Immediately after the TXRQ bit has been set, the mailbox enters **pending** state and waits to become the highest priority mailbox, see *Transmit Priority*. As soon as the mailbox has the highest priority it will be **scheduled** for transmission. The transmission of the message of the

scheduled mailbox will start (enter **transmit** state) when the CAN bus becomes idle. Once the mailbox has been successfully transmitted, it will become **empty** again. The hardware indicates a successful transmission by setting the RQCP and TXOK bits in the CAN\_TSR register.

If the transmission fails, the cause is indicated by the ALST bit in the CAN\_TSR register in case of an Arbitration Lost, and/or the TERR bit, in case of transmission error detection.

### Transmit priority

By identifier

When more than one transmit mailbox is pending, the transmission order is given by the identifier of the message stored in the mailbox. The message with the lowest identifier value has the highest priority according to the arbitration of the CAN protocol. If the identifier values are equal, the lower mailbox number will be scheduled first.

By transmit request order

The transmit mailboxes can be configured as a transmit FIFO by setting the TXFP bit in the CAN\_MCR register. In this mode the priority order is given by the transmit request order.

This mode is very useful for segmented transmission.

### Abort

A transmission request can be aborted by the user setting the ABRQ bit in the CAN\_TSR register. In **pending** or **scheduled** state, the mailbox is aborted immediately. An abort request while the mailbox is in **transmit** state can have two results. If the mailbox is transmitted successfully the mailbox becomes **empty** with the TXOK bit set in the CAN\_TSR register. If the transmission fails, the mailbox becomes **scheduled**, the transmission is aborted and becomes **empty** with TXOK cleared. In all cases the mailbox will become **empty** again at least at the end of the current transmission.

### Non automatic retransmission mode

This mode has been implemented in order to fulfill the requirement of the Time Triggered Communication option of the CAN standard. To configure the hardware in this mode the NART bit in the CAN\_MCR register must be set.

In this mode, each transmission is started only once. If the first attempt fails, due to an arbitration loss or an error, the hardware will not automatically restart the message transmission.

At the end of the first transmission attempt, the hardware considers the request as completed and sets the RQCP bit in the CAN\_TSR register. The result of the transmission is indicated in the CAN\_TSR register by the TXOK, ALST and TERR bits.

Figure 447. Transmit mailbox states

### 36.7.2 Time triggered communication mode

In this mode, the internal counter of the CAN hardware is activated and used to generate the Time Stamp value stored in the CAN\_RDTxR/CAN\_TDTxR registers, respectively (for Rx and Tx mailboxes). The internal counter is incremented each CAN bit time (refer to [Section 36.7.7: Bit timing](#)). The internal counter is captured on the sample point of the Start Of Frame bit in both reception and transmission.

### 36.7.3 Reception handling

For the reception of CAN messages, three mailboxes organized as a FIFO are provided. In order to save CPU load, simplify the software and guarantee data consistency, the FIFO is managed completely by hardware. The application accesses the messages stored in the FIFO through the FIFO output mailbox.

#### Valid message

A received message is considered as valid **when** it has been received correctly according to the CAN protocol (no error until the last but one bit of the EOF field) **and** It passed through the identifier filtering successfully, see [Section 36.7.4: Identifier filtering](#).

Figure 448. Receive FIFO states

### FIFO management

Starting from the **empty** state, the first valid message received is stored in the FIFO which becomes **pending\_1**. The hardware signals the event setting the FMP[1:0] bits in the CAN\_RFR register to the value 01b. The message is available in the FIFO output mailbox. The software reads out the mailbox content and releases it by setting the RFOM bit in the CAN\_RFR register. The FIFO becomes **empty** again. If a new valid message has been received in the meantime, the FIFO stays in **pending\_1** state and the new message is available in the output mailbox.

If the application does not release the mailbox, the next valid message will be stored in the FIFO which enters **pending\_2** state (FMP[1:0] = 10b). The storage process is repeated for the next valid message putting the FIFO into **pending\_3** state (FMP[1:0] = 11b). At this point, the software must release the output mailbox by setting the RFOM bit, so that a mailbox is free to store the next valid message. Otherwise the next valid message received will cause a loss of message.

Refer also to [Section 36.7.5: Message storage](#)

### Overrun

Once the FIFO is in **pending\_3** state (i.e. the three mailboxes are full) the next valid message reception will lead to an **overrun** and a message will be lost. The hardware signals the overrun condition by setting the FOVR bit in the CAN\_RFR register. Which message is lost depends on the configuration of the FIFO:

- If the FIFO lock function is disabled (RFLM bit in the CAN\_MCR register cleared) the last message stored in the FIFO will be overwritten by the new incoming message. In this case the latest messages will be always available to the application.
- If the FIFO lock function is enabled (RFLM bit in the CAN\_MCR register set) the most recent message will be discarded and the software will have the three oldest messages in the FIFO available.

### Reception related interrupts

Once a message has been stored in the FIFO, the FMP[1:0] bits are updated and an interrupt request is generated if the FMPIE bit in the CAN\_IER register is set.

When the FIFO becomes full (i.e. a third message is stored) the FULL bit in the CAN\_RFR register is set and an interrupt is generated if the FFIE bit in the CAN\_IER register is set.

On overrun condition, the FOVR bit is set and an interrupt is generated if the FOVIE bit in the CAN\_IER register is set.

## 36.7.4 Identifier filtering

In the CAN protocol the identifier of a message is not associated with the address of a node but related to the content of the message. Consequently a transmitter broadcasts its message to all receivers. On message reception a receiver node decides - depending on the identifier value - whether the software needs the message or not. If the message is needed, it is copied into the SRAM. If not, the message must be discarded without intervention by the software.

To fulfill this requirement the bxCAN Controller provides 28 configurable and scalable filter banks (27-0) to the application, in order to receive only the messages the software needs.

This hardware filtering saves CPU resources which would be otherwise needed to perform filtering by software. Each filter bank x consists of two 32-bit registers, CAN\_FxR0 and CAN\_FxR1.

### Scalable width

To optimize and adapt the filters to the application needs, each filter bank can be scaled independently. Depending on the filter scale a filter bank provides:

- One 32-bit filter for the STDID[10:0], EXTID[17:0], IDE and RTR bits.
- Two 16-bit filters for the STDID[10:0], RTR, IDE and EXTID[17:15] bits.

Refer to [Figure 449](#).

Furthermore, the filters can be configured in mask mode or in identifier list mode.

### Mask mode

In **mask** mode the identifier registers are associated with mask registers specifying which bits of the identifier are handled as “must match” or as “don’t care”.

### Identifier list mode

In **identifier list** mode, the mask registers are used as identifier registers. Thus instead of defining an identifier and a mask, two identifiers are specified, doubling the number of single identifiers. All bits of the incoming identifier must match the bits specified in the filter registers.

### Filter bank scale and mode configuration

The filter banks are configured by means of the corresponding CAN\_FMR register. To configure a filter bank it must be deactivated by clearing the FACT bit in the CAN\_FAR register. The filter scale is configured by means of the corresponding FSCx bit in the CAN\_FS1R register, refer to [Figure 449](#). The **identifier list** or **identifier mask** mode for the corresponding Mask/Identifier registers is configured by means of the FBMx bits in the CAN\_FMR register.

To filter a group of identifiers, configure the Mask/Identifier registers in mask mode.

To select single identifiers, configure the Mask/Identifier registers in identifier list mode.

Filters not used by the application should be left deactivated.

Each filter within a filter bank is numbered (called the *Filter Number*) from 0 to a maximum dependent on the mode and the scale of each of the filter banks.

Concerning the filter configuration, refer to [Figure 449](#).

Figure 449. Filter bank scale configuration - register organization

## Filter match index

Once a message has been received in the FIFO it is available to the application. Typically, application data is copied into SRAM locations. To copy the data to the right location the application has to identify the data by means of the identifier. To avoid this, and to ease the access to the SRAM locations, the CAN controller provides a Filter Match Index.

This index is stored in the mailbox together with the message according to the filter priority rules. Thus each received message has its associated filter match index.

The Filter Match index can be used in two ways:

- Compare the Filter Match index with a list of expected values.
- Use the Filter Match Index as an index on an array to access the data destination location.

For non masked filters, the software no longer has to compare the identifier.

If the filter is masked the software reduces the comparison to the masked bits only.

The index value of the filter number does not take into account the activation state of the filter banks. In addition, two independent numbering schemes are used, one for each FIFO.

Refer to [Figure 450](#) for an example.

**Figure 450. Example of filter numbering**

### Filter priority rules

Depending on the filter combination it may occur that an identifier passes successfully through several filters. In this case the filter match value stored in the receive mailbox is chosen according to the following priority rules:

- A 32-bit filter takes priority over a 16-bit filter.
- For filters of equal scale, priority is given to the Identifier List mode over the Identifier Mask mode
- For filters of equal scale and mode, priority is given by the filter number (the lower the number, the higher the priority).

Figure 451. Filtering mechanism - example

The example above shows the filtering principle of the bxCAN. On reception of a message, the identifier is compared first with the filters configured in identifier list mode. If there is a match, the message is stored in the associated FIFO and the index of the matching filter is stored in the Filter Match Index. As shown in the example, the identifier matches with Identifier #2 thus the message content and FMI 2 is stored in the FIFO.

If there is no match, the incoming identifier is then compared with the filters configured in mask mode.

If the identifier does not match any of the identifiers configured in the filters, the message is discarded by hardware without disturbing the software.

### 36.7.5 Message storage

The interface between the software and the hardware for the CAN messages is implemented by means of mailboxes. A mailbox contains all information related to a message; identifier, data, control, status and time stamp information.

#### Transmit mailbox

The software sets up the message to be transmitted in an empty transmit mailbox. The status of the transmission is indicated by hardware in the CAN\_TSR register.

Table 253. Transmit mailbox mapping

| Offset to transmit mailbox base address | Register name |
|-----------------------------------------|---------------|
| 0                                       | CAN_TlRxR     |
| 4                                       | CAN_TDTxR     |
| 8                                       | CAN_TDLxR     |
| 12                                      | CAN_TDHxR     |

### Receive mailbox

When a message has been received, it is available to the software in the FIFO output mailbox. Once the software has handled the message (e.g. read it) the software must release the FIFO output mailbox by means of the RFOM bit in the CAN\_RFR register to make the next incoming message available. The filter match index is stored in the MFMI field of the CAN\_RDTxR register. The 16-bit time stamp value is stored in the TIME[15:0] field of CAN\_RDTxR.

Table 254. Receive mailbox mapping

| Offset to receive mailbox base address (bytes) | Register name |
|------------------------------------------------|---------------|
| 0                                              | CAN_RlRxR     |
| 4                                              | CAN_RDTxR     |
| 8                                              | CAN_RDLxR     |
| 12                                             | CAN_RDHxR     |

Figure 452. CAN error state diagram

### 36.7.6 Error management

The error management as described in the CAN protocol is handled entirely by hardware using a Transmit Error Counter (TEC value, in CAN\_ESR register) and a Receive Error Counter (REC value, in the CAN\_ESR register), which get incremented or decremented according to the error condition. For detailed information about TEC and REC management, refer to the CAN standard.

Both of them may be read by software to determine the stability of the network. Furthermore, the CAN hardware provides detailed information on the current error status in CAN\_ESR register. By means of the CAN\_IER register (ERRIE bit, etc.), the software can configure the interrupt generation on error detection in a very flexible way.

#### Bus-Off recovery

The Bus-Off state is reached when TEC is greater than 255, this state is indicated by BOFF bit in CAN\_ESR register. In Bus-Off state, the bxCAN is no longer able to transmit and receive messages.

Depending on the ABOM bit in the CAN\_MCR register bxCAN will recover from Bus-Off (become error active again) either automatically or on software request. But in both cases the bxCAN has to wait at least for the recovery sequence specified in the CAN standard (128 occurrences of 11 consecutive recessive bits monitored on CANRX).

If ABOM is set, the bxCAN will start the recovering sequence automatically after it has entered Bus-Off state.

If ABOM is cleared, the software must initiate the recovering sequence by requesting bxCAN to enter and to leave initialization mode.

*Note:* In initialization mode, bxCAN does not monitor the CANRX signal, therefore it cannot complete the recovery sequence. **To recover, bxCAN must be in normal mode.**

### 36.7.7 Bit timing

The bit timing logic monitors the serial bus-line and performs sampling and adjustment of the sample point by synchronizing on the start-bit edge and resynchronizing on the following edges.

Its operation may be explained simply by splitting nominal bit time into three segments as follows:

- **Synchronization segment (SYNC\_SEG):** a bit change is expected to occur within this time segment. It has a fixed length of one time quantum ( $1 \times t_q$ ).
- **Bit segment 1 (BS1):** defines the location of the sample point. It includes the PROP\_SEG and PHASE\_SEG1 of the CAN standard. Its duration is programmable between 1 and 16 time quanta but may be automatically lengthened to compensate for positive phase drifts due to differences in the frequency of the various nodes of the network.
- **Bit segment 2 (BS2):** defines the location of the transmit point. It represents the PHASE\_SEG2 of the CAN standard. Its duration is programmable between 1 and 8 time quanta but may also be automatically shortened to compensate for negative phase drifts.

The resynchronization Jump Width (SJW) defines an upper bound to the amount of lengthening or shortening of the bit segments. It is programmable between 1 and 4 time quanta.

A valid edge is defined as the first transition in a bit time from dominant to recessive bus level provided the controller itself does not send a recessive bit.

If a valid edge is detected in BS1 instead of SYNC\_SEG, BS1 is extended by up to SJW so that the sample point is delayed.

Conversely, if a valid edge is detected in BS2 instead of SYNC\_SEG, BS2 is shortened by up to SJW so that the transmit point is moved earlier.

As a safeguard against programming errors, the configuration of the Bit Timing Register (CAN\_BTR) is only possible while the device is in Standby mode.

*Note: For a detailed description of the CAN bit timing and resynchronization mechanism, refer to the ISO 11898 standard.*

**Figure 453. Bit timing**

Figure 454. CAN frames

## 36.8 bxCAN interrupts

Four interrupt vectors are dedicated to bxCAN. Each interrupt source can be independently enabled or disabled by means of the CAN Interrupt Enable Register (CAN\_IER).

**Figure 455. Event flags and interrupt generation**

- The **transmit interrupt** can be generated by the following events:
  - Transmit mailbox 0 becomes empty, RQCP0 bit in the CAN\_TSR register set.
  - Transmit mailbox 1 becomes empty, RQCP1 bit in the CAN\_TSR register set.
  - Transmit mailbox 2 becomes empty, RQCP2 bit in the CAN\_TSR register set.
- The **FIFO 0 interrupt** can be generated by the following events:
  - Reception of a new message, FMP0 bits in the CAN\_RF0R register are not '00'.
  - FIFO0 full condition, FULL0 bit in the CAN\_RF0R register set.
  - FIFO0 overrun condition, FOVR0 bit in the CAN\_RF0R register set.
- The **FIFO 1 interrupt** can be generated by the following events:
  - Reception of a new message, FMP1 bits in the CAN\_RF1R register are not '00'.
  - FIFO1 full condition, FULL1 bit in the CAN\_RF1R register set.
  - FIFO1 overrun condition, FOVR1 bit in the CAN\_RF1R register set.
- The **error and status change interrupt** can be generated by the following events:
  - Error condition, for more details on error conditions refer to the CAN Error Status register (CAN\_ESR).
  - Wakeup condition, SOF monitored on the CAN Rx signal.
  - Entry into Sleep mode.

## 36.9 CAN registers

The peripheral registers have to be accessed by words (32 bits).

### 36.9.1 Register access protection

Erroneous access to certain configuration registers can cause the hardware to temporarily disturb the whole CAN network. Therefore the CAN\_BTR register can be modified by software only while the CAN hardware is in initialization mode.

Although the transmission of incorrect data will not cause problems at the CAN network level, it can severely disturb the application. A transmit mailbox can be only modified by software while it is in empty state, refer to [Figure 447: Transmit mailbox states](#).

The filter values can be modified either deactivating the associated filter banks or by setting the FINIT bit. Moreover, the modification of the filter configuration (scale, mode and FIFO assignment) in CAN\_FMR, CAN\_FSR and CAN\_FFR registers can only be done when the filter initialization mode is set (FINIT=1) in the CAN\_FMR register.

### 36.9.2 CAN control and status registers

Refer to [Section 1.2](#) for a list of abbreviations used in register descriptions.

#### CAN master control register (CAN\_MCR)

Address offset: 0x00

Reset value: 0x0001 0002

|       |      |      |      |      |      |      |      |      |      |      |      |      |      |       |      |

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **DBF**: Debug freeze

0: CAN working during debug

1: CAN reception/transmission frozen during debug. Reception FIFOs can still be accessed/controlled normally.

Bit 15 **RESET**: bxCAN software master reset

0: Normal operation.

1: Force a master reset of the bxCAN -> Sleep mode activated after reset (FMP bits and CAN\_MCR register are initialized to the reset values). This bit is automatically reset to 0.

Bits 14:8 Reserved, must be kept at reset value.

Bit 7 **TTCM**: Time triggered communication mode

0: Time Triggered Communication mode disabled.

1: Time Triggered Communication mode enabled

*Note: For more information on Time Triggered Communication mode, refer to [Section 36.7.2: Time triggered communication mode](#).*

Bit 6 **ABOM**: Automatic bus-off management

This bit controls the behavior of the CAN hardware on leaving the Bus-Off state.

0: The Bus-Off state is left on software request, once 128 occurrences of 11 recessive bits have been monitored and the software has first set and cleared the INRQ bit of the CAN\_MCR register.

1: The Bus-Off state is left automatically by hardware once 128 occurrences of 11 recessive bits have been monitored.

For detailed information on the Bus-Off state refer to [Section 36.7.6: Error management](#).

Bit 5 **AWUM**: Automatic wakeup mode

This bit controls the behavior of the CAN hardware on message reception during Sleep mode.

0: The Sleep mode is left on software request by clearing the SLEEP bit of the CAN\_MCR register.

1: The Sleep mode is left automatically by hardware on CAN message detection.

The SLEEP bit of the CAN\_MCR register and the SLAK bit of the CAN\_MSR register are cleared by hardware.

Bit 4 **NART**: No automatic retransmission

0: The CAN hardware will automatically retransmit the message until it has been successfully transmitted according to the CAN standard.

1: A message will be transmitted only once, independently of the transmission result (successful, error or arbitration lost).

Bit 3 **RFLM**: Receive FIFO locked mode

0: Receive FIFO not locked on overrun. Once a receive FIFO is full the next incoming message will overwrite the previous one.

1: Receive FIFO locked against overrun. Once a receive FIFO is full the next incoming message will be discarded.

Bit 2 **TXFP**: Transmit FIFO priority

This bit controls the transmission order when several mailboxes are pending at the same time.

0: Priority driven by the identifier of the message

1: Priority driven by the request order (chronologically)

Bit 1 **SLEEP**: Sleep mode request

This bit is set by software to request the CAN hardware to enter the Sleep mode. Sleep mode will be entered as soon as the current CAN activity (transmission or reception of a CAN frame) has been completed.

This bit is cleared by software to exit Sleep mode.

This bit is cleared by hardware when the AWUM bit is set and a SOF bit is detected on the CAN Rx signal.

This bit is set after reset - CAN starts in Sleep mode.

Bit 0 **INRQ**: Initialization request

The software clears this bit to switch the hardware into normal mode. Once 11 consecutive recessive bits have been monitored on the Rx signal the CAN hardware is synchronized and ready for transmission and reception. Hardware signals this event by clearing the INAK bit in the CAN\_MSR register.

Software sets this bit to request the CAN hardware to enter initialization mode. Once software has set the INRQ bit, the CAN hardware waits until the current CAN activity (transmission or reception) is completed before entering the initialization mode. Hardware signals this event by setting the INAK bit in the CAN\_MSR register.

**CAN master status register (CAN\_MSR)**

Bits 31:12 Reserved, must be kept at reset value.

Bit 11 **RX**: CAN Rx signal

Monitors the actual value of the **CAN\_RX** Pin.

Bit 10 **SAMP**: Last sample point

The value of RX on the last sample point (current received bit value).

Bit 9 **RXM**: Receive mode

The CAN hardware is currently receiver.

Bit 8 **TXM**: Transmit mode

The CAN hardware is currently transmitter.

Bits 7:5 Reserved, must be kept at reset value.

Bit 4 **SLAKI**: Sleep acknowledge interrupt

When SLKIE=1, this bit is set by hardware to signal that the bxCAN has entered Sleep Mode. When set, this bit generates a status change interrupt if the SLKIE bit in the CAN\_IER register is set.

This bit is cleared by software or by hardware, when SLAK is cleared.

*Note: When SLKIE=0, no polling on SLAKI is possible. In this case the SLAK bit can be polled.*

Bit 3 **WKUI**: Wakeup interrupt

This bit is set by hardware to signal that a SOF bit has been detected while the CAN hardware was in Sleep mode. Setting this bit generates a status change interrupt if the WKUIE bit in the CAN\_IER register is set.

This bit is cleared by software.

Bit 2 **ERRI**: Error interrupt

This bit is set by hardware when a bit of the CAN\_ESR has been set on error detection and the corresponding interrupt in the CAN\_IER is enabled. Setting this bit generates a status change interrupt if the ERRIE bit in the CAN\_IER register is set.

This bit is cleared by software.

Bit 1 **SLAK**: Sleep acknowledge

This bit is set by hardware and indicates to the software that the CAN hardware is now in Sleep mode. This bit acknowledges the Sleep mode request from the software (set SLEEP bit in CAN\_MCR register).

This bit is cleared by hardware when the CAN hardware has left Sleep mode (to be synchronized on the CAN bus). To be synchronized the hardware has to monitor a sequence of 11 consecutive recessive bits on the CAN RX signal.

*Note: The process of leaving Sleep mode is triggered when the SLEEP bit in the CAN\_MCR register is cleared. Refer to the AWUM bit of the CAN\_MCR register description for detailed information for clearing SLEEP bit*

Bit 0 **INAK**: Initialization acknowledge

This bit is set by hardware and indicates to the software that the CAN hardware is now in initialization mode. This bit acknowledges the initialization request from the software (set INRQ bit in CAN\_MCR register).

This bit is cleared by hardware when the CAN hardware has left the initialization mode (to be synchronized on the CAN bus). To be synchronized the hardware has to monitor a sequence of 11 consecutive recessive bits on the CAN RX signal.

- Bit 31 **LOW2**: Lowest priority flag for mailbox 2  
This bit is set by hardware when more than one mailbox are pending for transmission and mailbox 2 has the lowest priority.
- Bit 30 **LOW1**: Lowest priority flag for mailbox 1  
This bit is set by hardware when more than one mailbox are pending for transmission and mailbox 1 has the lowest priority.
- Bit 29 **LOW0**: Lowest priority flag for mailbox 0  
This bit is set by hardware when more than one mailbox are pending for transmission and mailbox 0 has the lowest priority.  
*Note: The LOW[2:0] bits are set to zero when only one mailbox is pending.*
- Bit 28 **TME2**: Transmit mailbox 2 empty  
This bit is set by hardware when no transmit request is pending for mailbox 2.
- Bit 27 **TME1**: Transmit mailbox 1 empty  
This bit is set by hardware when no transmit request is pending for mailbox 1.
- Bit 26 **TME0**: Transmit mailbox 0 empty  
This bit is set by hardware when no transmit request is pending for mailbox 0.
- Bits 25:24 **CODE[1:0]**: Mailbox code  
In case at least one transmit mailbox is free, the code value is equal to the number of the next transmit mailbox free.  
In case all transmit mailboxes are pending, the code value is equal to the number of the transmit mailbox with the lowest priority.
- Bit 23 **ABRQ2**: Abort request for mailbox 2  
Set by software to abort the transmission request for the corresponding mailbox.  
Cleared by hardware when the mailbox becomes empty.  
Setting this bit has no effect when the mailbox is not pending for transmission.
- Bits 22:20 Reserved, must be kept at reset value.
- Bit 19 **TERR2**: Transmission error of mailbox 2  
This bit is set when the previous TX failed due to an error.
- Bit 18 **ALST2**: Arbitration lost for mailbox 2  
This bit is set when the previous TX failed due to an arbitration lost.
- Bit 17 **TXOK2**: Transmission OK of mailbox 2  
The hardware updates this bit after each transmission attempt.  
0: The previous transmission failed  
1: The previous transmission was successful  
This bit is set by hardware when the transmission request on mailbox 2 has been completed successfully. Refer to [Figure 447](#).
- Bit 16 **RQCP2**: Request completed mailbox2  
Set by hardware when the last request (transmit or abort) has been performed.  
Cleared by software writing a "1" or by hardware on transmission request (TXRQ2 set in CAN\_TMD2R register).  
Clearing this bit clears all the status bits (TXOK2, ALST2 and TERR2) for Mailbox 2.
- Bit 15 **ABRQ1**: Abort request for mailbox 1  
Set by software to abort the transmission request for the corresponding mailbox.  
Cleared by hardware when the mailbox becomes empty.  
Setting this bit has no effect when the mailbox is not pending for transmission.
- Bits 14:12 Reserved, must be kept at reset value.

Bit 11 **TERR1**: Transmission error of mailbox1

This bit is set when the previous TX failed due to an error.

Bit 10 **ALST1**: Arbitration lost for mailbox1

This bit is set when the previous TX failed due to an arbitration lost.

Bit 9 **TXOK1**: Transmission OK of mailbox1

The hardware updates this bit after each transmission attempt.

0: The previous transmission failed

1: The previous transmission was successful

This bit is set by hardware when the transmission request on mailbox 1 has been completed successfully. Refer to [Figure 447](#)

Bit 8 **RQCP1**: Request completed mailbox1

Set by hardware when the last request (transmit or abort) has been performed.

Cleared by software writing a "1" or by hardware on transmission request (TXRQ1 set in CAN\_TI1R register).

Clearing this bit clears all the status bits (TXOK1, ALST1 and TERR1) for Mailbox 1.

Bit 7 **ABRQ0**: Abort request for mailbox0

Set by software to abort the transmission request for the corresponding mailbox.

Cleared by hardware when the mailbox becomes empty.

Setting this bit has no effect when the mailbox is not pending for transmission.

Bits 6:4 Reserved, must be kept at reset value.

Bit 3 **TERR0**: Transmission error of mailbox0

This bit is set when the previous TX failed due to an error.

Bit 2 **ALST0**: Arbitration lost for mailbox0

This bit is set when the previous TX failed due to an arbitration lost.

Bit 1 **TXOK0**: Transmission OK of mailbox0

The hardware updates this bit after each transmission attempt.

0: The previous transmission failed

1: The previous transmission was successful

This bit is set by hardware when the transmission request on mailbox 1 has been completed successfully. Refer to [Figure 447](#)

Bit 0 **RQCP0**: Request completed mailbox0

Set by hardware when the last request (transmit or abort) has been performed.

Cleared by software writing a "1" or by hardware on transmission request (TXRQ0 set in CAN\_TI0R register).

Clearing this bit clears all the status bits (TXOK0, ALST0 and TERR0) for Mailbox 0.

Bits 31:6 Reserved, must be kept at reset value.

Bit 5 **RFOM0**: Release FIFO 0 output mailbox

Set by software to release the output mailbox of the FIFO. The output mailbox can only be released when at least one message is pending in the FIFO. Setting this bit when the FIFO is empty has no effect. If at least two messages are pending in the FIFO, the software has to release the output mailbox to access the next message.

Cleared by hardware when the output mailbox has been released.

Bit 4 **FOVR0**: FIFO 0 overrun

This bit is set by hardware when a new message has been received and passed the filter while the FIFO was full.

This bit is cleared by software.

Bit 3 **FULL0**: FIFO 0 full

Set by hardware when three messages are stored in the FIFO.

This bit is cleared by software.

Bit 2 Reserved, must be kept at reset value.

Bits 1:0 **FMP0[1:0]**: FIFO 0 message pending

These bits indicate how many messages are pending in the receive FIFO.

FMP is increased each time the hardware stores a new message in to the FIFO. FMP is decreased each time the software releases the output mailbox by setting the RFOM0 bit.

### CAN receive FIFO 1 register (CAN\_RF1R)

Bits 31:6 Reserved, must be kept at reset value.

Bit 5 **RFOM1**: Release FIFO 1 output mailbox

Set by software to release the output mailbox of the FIFO. The output mailbox can only be released when at least one message is pending in the FIFO. Setting this bit when the FIFO is empty has no effect. If at least two messages are pending in the FIFO, the software has to release the output mailbox to access the next message.

Cleared by hardware when the output mailbox has been released.

Bit 4 **FOVR1**: FIFO 1 overrun

This bit is set by hardware when a new message has been received and passed the filter while the FIFO was full.

This bit is cleared by software.

Bit 3 **FULL1**: FIFO 1 full

Set by hardware when three messages are stored in the FIFO.  
This bit is cleared by software.

Bit 2 Reserved, must be kept at reset value.

Bits 1:0 **FMP1[1:0]**: FIFO 1 message pending

These bits indicate how many messages are pending in the receive FIFO1.  
FMP1 is increased each time the hardware stores a new message in to the FIFO1. FMP is decreased each time the software releases the output mailbox by setting the RFOM1 bit.

### CAN interrupt enable register (CAN\_IER)

Bits 31:18 Reserved, must be kept at reset value.

Bit 17 **SLKIE**: Sleep interrupt enable

0: No interrupt when SLAKI bit is set.  
1: Interrupt generated when SLAKI bit is set.

Bit 16 **WKUIE**: Wakeup interrupt enable

0: No interrupt when WKUI is set.  
1: Interrupt generated when WKUI bit is set.

Bit 15 **ERRIE**: Error interrupt enable

0: No interrupt will be generated when an error condition is pending in the CAN\_ESR.  
1: An interrupt will be generation when an error condition is pending in the CAN\_ESR.

Bits 14:12 Reserved, must be kept at reset value.

Bit 11 **LECIE**: Last error code interrupt enable

0: ERRI bit will not be set when the error code in LEC[2:0] is set by hardware on error detection.  
1: ERRI bit will be set when the error code in LEC[2:0] is set by hardware on error detection.

Bit 10 **BOFIE**: Bus-off interrupt enable

0: ERRI bit will not be set when BOFF is set.  
1: ERRI bit will be set when BOFF is set.

Bit 9 **EPVIE**: Error passive interrupt enable

0: ERRI bit will not be set when EPVF is set.  
1: ERRI bit will be set when EPVF is set.

- Bit 8 **EWGIE**: Error warning interrupt enable  
 0: ERRI bit will not be set when EWGF is set.  
 1: ERRI bit will be set when EWGF is set.
- Bit 7 Reserved, must be kept at reset value.
- Bit 6 **FOVIE1**: FIFO overrun interrupt enable  
 0: No interrupt when FOVR is set.  
 1: Interrupt generation when FOVR is set.
- Bit 5 **FFIE1**: FIFO full interrupt enable  
 0: No interrupt when FULL bit is set.  
 1: Interrupt generated when FULL bit is set.
- Bit 4 **FMPIE1**: FIFO message pending interrupt enable  
 0: No interrupt generated when state of FMP[1:0] bits are not 00b.  
 1: Interrupt generated when state of FMP[1:0] bits are not 00b.
- Bit 3 **FOVIE0**: FIFO overrun interrupt enable  
 0: No interrupt when FOVR bit is set.  
 1: Interrupt generated when FOVR bit is set.
- Bit 2 **FFIE0**: FIFO full interrupt enable  
 0: No interrupt when FULL bit is set.  
 1: Interrupt generated when FULL bit is set.
- Bit 1 **FMPIE0**: FIFO message pending interrupt enable  
 0: No interrupt generated when state of FMP[1:0] bits are not 00b.  
 1: Interrupt generated when state of FMP[1:0] bits are not 00b.
- Bit 0 **TMEIE**: Transmit mailbox empty interrupt enable  
 0: No interrupt when RQCPx bit is set.  
 1: Interrupt generated when RQCPx bit is set.
- Note: Refer to [Section 36.8: bxCAN interrupts](#).*

### CAN error status register (CAN\_ESR)

Address offset: 0x18

Reset value: 0x0000 0000

|          |      |      |      |      |      |      |      |          |          |    |    |      |      |      |      |
|----------|------|------|------|------|------|------|------|----------|----------|----|----|------|------|------|------|
| 31       | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23       | 22       | 21 | 20 | 19   | 18   | 17   | 16   |
| REC[7:0] |      |      |      |      |      |      |      | TEC[7:0] |          |    |    |      |      |      |      |
| r        | r    | r    | r    | r    | r    | r    | r    | r        | r        | r  | r  | r    | r    | r    | r    |
| 15       | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7        | 6        | 5  | 4  | 3    | 2    | 1    | 0    |
| Res.     | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res.     | LEC[2:0] |    |    | Res. | BOFF | EPVF | EWGF |
|          |      |      |      |      |      |      |      |          | rw       | rw | rw |      | r    | r    | r    |

Bits 31:24 **REC[7:0]**: Receive error counter

The implementing part of the fault confinement mechanism of the CAN protocol. In case of an error during reception, this counter is incremented by 1 or by 8 depending on the error condition as defined by the CAN standard. After every successful reception the counter is decremented by 1 or reset to 120 if its value was higher than 128. When the counter value exceeds 127, the CAN controller enters the error passive state.

Bits 23:16 **TEC[7:0]**: Least significant byte of the 9-bit transmit error counter

The implementing part of the fault confinement mechanism of the CAN protocol.

Bits 15:7 Reserved, must be kept at reset value.

Bits 6:4 **LEC[2:0]**: Last error code

This field is set by hardware and holds a code which indicates the error condition of the last error detected on the CAN bus. If a message has been transferred (reception or transmission) without error, this field will be cleared to '0'.

The LEC[2:0] bits can be set to value 0b111 by software. They are updated by hardware to indicate the current communication status.

000: No Error

001: Stuff Error

010: Form Error

011: Acknowledgment Error

100: Bit recessive Error

101: Bit dominant Error

110: CRC Error

111: Set by software

Bit 3 Reserved, must be kept at reset value.

Bit 2 **BOFF**: Bus-off flag

This bit is set by hardware when it enters the bus-off state. The bus-off state is entered on TEC overflow, greater than 255, refer to [Section 36.7.6 on page 1311](#).

Bit 1 **EPVF**: Error passive flag

This bit is set by hardware when the Error Passive limit has been reached (Receive Error Counter or Transmit Error Counter > 127).

Bit 0 **EWGF**: Error warning flag

This bit is set by hardware when the warning limit has been reached (Receive Error Counter or Transmit Error Counter ≥ 96).

### CAN bit timing register (CAN\_BTR)

Address offset: 0x1C

Reset value: 0x0123 0000

This register can only be accessed by the software when the CAN hardware is in initialization mode.

|      |      |      |      |      |      |          |    |      |          |    |    |          |    |    |    |

- Bit 31 **SILM**: Silent mode (debug)  
 0: Normal operation  
 1: Silent Mode
- Bit 30 **LBKM**: Loop back mode (debug)  
 0: Loop Back Mode disabled  
 1: Loop Back Mode enabled
- Bits 29:26 Reserved, must be kept at reset value.
- Bits 25:24 **SJW[1:0]**: Resynchronization jump width  
 These bits define the maximum number of time quanta the CAN hardware is allowed to lengthen or shorten a bit to perform the resynchronization.  
 $t_{RJW} = t_q \times (SJW[1:0] + 1)$
- Bit 23 Reserved, must be kept at reset value.
- Bits 22:20 **TS2[2:0]**: Time segment 2  
 These bits define the number of time quanta in Time Segment 2.  
 $t_{BS2} = t_q \times (TS2[2:0] + 1)$
- Bits 19:16 **TS1[3:0]**: Time segment 1  
 These bits define the number of time quanta in Time Segment 1  
 $t_{BS1} = t_q \times (TS1[3:0] + 1)$   
 For more information on bit timing, refer to [Section 36.7.7: Bit timing on page 1311](#).
- Bits 15:10 Reserved, must be kept at reset value.
- Bits 9:0 **BRP[9:0]**: Baud rate prescaler  
 These bits define the length of a time quanta.  
 $t_q = (BRP[9:0] + 1) \times t_{PCLK}$

### 36.9.3 CAN mailbox registers

This chapter describes the registers of the transmit and receive mailboxes. Refer to [Section 36.7.5: Message storage on page 1309](#) for detailed register mapping.

Transmit and receive mailboxes have the same registers except:

- The FMI field in the CAN\_RDTxR register.
- A receive mailbox is always write protected.
- A transmit mailbox is write-enabled only while empty, corresponding TME bit in the CAN\_TSR register set.

There are 3 TX Mailboxes and 2 RX Mailboxes. Each RX Mailbox allows access to a 3 level depth FIFO, the access being offered only to the oldest received message in the FIFO.

Each mailbox consist of 4 registers.

Figure 456. CAN mailbox registers

**CAN TX mailbox identifier register (CAN\_TlRxR) (x = 0..2)**

Address offsets: 0x180, 0x190, 0x1A0

Reset value: 0xFFFF XXXX (except bit 0, TXRQ = 0)

All TX registers are write protected when the mailbox is pending transmission (TMEx reset).

This register also implements the TX request control (bit 0) - reset value 0.

|                        |    |    |    |    |    |    |    |    |    |    |             |    |     |     |      |
|------------------------|----|----|----|----|----|----|----|----|----|----|-------------|----|-----|-----|------|
| 31                     | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20          | 19 | 18  | 17  | 16   |
| STID[10:0]/EXID[28:18] |    |    |    |    |    |    |    |    |    |    | EXID[17:13] |    |     |     |      |
| rw                     | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw          | rw | rw  | rw  | rw   |
| 15                     | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4           | 3  | 2   | 1   | 0    |
| EXID[12:0]             |    |    |    |    |    |    |    |    |    |    |             |    | IDE | RTR | TXRQ |
| rw                     | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw          | rw | rw  | rw  | rw   |

Bits 31:21 **STID[10:0]/EXID[28:18]**: Standard identifier or extended identifier

The standard identifier or the MSBs of the extended identifier (depending on the IDE bit value).

Bit 20:3 **EXID[17:0]**: Extended identifier

The LSBs of the extended identifier.

Bit 2 **IDE**: Identifier extension

This bit defines the identifier type of message in the mailbox.

0: Standard identifier.

1: Extended identifier.

Bit 1 **RTR**: Remote transmission request

0: Data frame

1: Remote frame

Bit 0 **TXRQ**: Transmit mailbox request

Set by software to request the transmission for the corresponding mailbox.

Cleared by hardware when the mailbox becomes empty.

### CAN mailbox data length control and time stamp register (CAN\_TDTxR) (x = 0..2)

All bits of this register are write protected when the mailbox is not in empty state.

Address offsets: 0x184, 0x194, 0x1A4

Reset value: 0xFFFF XXXX

|            |      |      |      |      |      |      |      |      |      |      |      |          |    |    |    |
|------------|------|------|------|------|------|------|------|------|------|------|------|----------|----|----|----|
| 31         | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21   | 20   | 19       | 18 | 17 | 16 |
| TIME[15:0] |      |      |      |      |      |      |      |      |      |      |      |          |    |    |    |
| rw         | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw       | rw | rw | rw |

| Res.       | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | DLC[3:0] |    |    |    |
|            |      |      |      |      |      |      |      |      |      |      |      | rw       | rw | rw | rw |

Bits 31:16 **TIME[15:0]**: Message time stamp

This field contains the 16-bit timer value captured at the SOF transmission.

Bits 15:9 Reserved, must be kept at reset value.

Bit 8 **TGT**: Transmit global time

This bit is active only when the hardware is in the Time Trigger Communication mode, TTCM bit of the CAN\_MCR register is set.

0: Time stamp TIME[15:0] is not sent.

1: Time stamp TIME[15:0] value is sent in the last two data bytes of the 8-byte message: TIME[7:0] in data byte 7 and TIME[15:8] in data byte 6, replacing the data written in CAN\_TDHxR[31:16] register (DATA6[7:0] and DATA7[7:0]). DLC must be programmed as 8 in order these two bytes to be sent over the CAN bus.

Bits 7:4 Reserved, must be kept at reset value.

Bits 3:0 **DLC[3:0]**: Data length code

This field defines the number of data bytes a data frame contains or a remote frame request. A message can contain from 0 to 8 data bytes, depending on the value in the DLC field.

**CAN mailbox data low register (CAN\_TDLxR) (x = 0..2)**

All bits of this register are write protected when the mailbox is not in empty state.

Address offsets: 0x188, 0x198, 0x1A8

Reset value: 0xFFFF XXXX

|            |    |    |    |    |    |    |    |            |    |    |    |    |    |    |    |

| DATA1[7:0] |    |    |    |    |    |    |    | DATA0[7:0] |    |    |    |    |    |    |    |
| rw         | rw | rw | rw | rw | rw | rw | rw | rw         | rw | rw | rw | rw | rw | rw | rw |

Bits 31:24 **DATA3[7:0]**: Data byte 3

Data byte 3 of the message.

Bits 23:16 **DATA2[7:0]**: Data byte 2

Data byte 2 of the message.

Bits 15:8 **DATA1[7:0]**: Data byte 1

Data byte 1 of the message.

Bits 7:0 **DATA0[7:0]**: Data byte 0

Data byte 0 of the message.

A message can contain from 0 to 8 data bytes and starts with byte 0.

**CAN mailbox data high register (CAN\_TDHxR) (x = 0..2)**

All bits of this register are write protected when the mailbox is not in empty state.

Address offsets: 0x18C, 0x19C, 0x1AC

Reset value: 0xFFFF XXXX

|            |    |    |    |    |    |    |    |            |    |    |    |    |    |    |    |

Bits 31:24 **DATA7[7:0]**: Data byte 7

Data byte 7 of the message.

*Note: If TGT of this message and TTCM are active, DATA7 and DATA6 will be replaced by the TIME stamp value.*

Bits 23:16 **DATA6[7:0]**: Data byte 6

Data byte 6 of the message.

Bits 15:8 **DATA5[7:0]**: Data byte 5

Data byte 5 of the message.

Bits 7:0 **DATA4[7:0]**: Data byte 4

Data byte 4 of the message.

### CAN receive FIFO mailbox identifier register (CAN\_RlRxR) (x = 0..1)

Address offsets: 0x1B0, 0x1C0

Reset value: 0xFFFF XXXX

All RX registers are write protected.

|                        |    |    |    |    |    |    |    |    |    |    |             |    |     |     |     |

| EXID[12:0]             |    |    |    |    |    |    |    |    |    |    |             |    | IDE | RTR | Res |
| r                      | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r           | r  | r   | r   |     |

Bits 31:21 **STID[10:0]/EXID[28:18]**: Standard identifier or extended identifier

The standard identifier or the MSBs of the extended identifier (depending on the IDE bit value).

Bits 20:3 **EXID[17:0]**: Extended identifier

The LSBs of the extended identifier.

Bit 2 **IDE**: Identifier extension

This bit defines the identifier type of message in the mailbox.

0: Standard identifier.

1: Extended identifier.

Bit 1 **RTR**: Remote transmission request

0: Data frame

1: Remote frame

Bit 0 Reserved, must be kept at reset value.

### CAN receive FIFO mailbox data length control and time stamp register (CAN\_RDTxR) (x = 0..1)

Address offsets: 0x1B4, 0x1C4

Reset value: 0xFFFF XXXX

All RX registers are write protected.

|            |    |    |    |    |    |    |    |      |      |      |      |          |    |    |    |
|------------|----|----|----|----|----|----|----|------|------|------|------|----------|----|----|----|
| 31         | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23   | 22   | 21   | 20   | 19       | 18 | 17 | 16 |
| TIME[15:0] |    |    |    |    |    |    |    |      |      |      |      |          |    |    |    |
| r          | r  | r  | r  | r  | r  | r  | r  | r    | r    | r    | r    | r        | r  | r  | r  |
| 15         | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7    | 6    | 5    | 4    | 3        | 2  | 1  | 0  |
| FMI[7:0]   |    |    |    |    |    |    |    | Res. | Res. | Res. | Res. | DLC[3:0] |    |    |    |
| r          | r  | r  | r  | r  | r  | r  | r  |      |      |      |      | r        | r  | r  | r  |

Bits 31:16 **TIME[15:0]**: Message time stamp

This field contains the 16-bit timer value captured at the SOF detection.

Bits 15:8 **FMI[7:0]**: Filter match index

This register contains the index of the filter the message stored in the mailbox passed through. For more details on identifier filtering refer to [Section 36.7.4: Identifier filtering on page 1305](#) - **Filter Match Index** paragraph.

Bits 7:4 Reserved, must be kept at reset value.

Bits 3:0 **DLC[3:0]**: Data length code

This field defines the number of data bytes a data frame contains (0 to 8). It is 0 in the case of a remote frame request.

**CAN receive FIFO mailbox data low register (CAN\_RDLxR) (x = 0..1)**

All bits of this register are write protected when the mailbox is not in empty state.

Address offsets: 0x1B8, 0x1C8

Reset value: 0xFFFF XXXX

All RX registers are write protected.

|            |    |    |    |    |    |    |    |            |    |    |    |    |    |    |    |
|------------|----|----|----|----|----|----|----|------------|----|----|----|----|----|----|----|
| 31         | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23         | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| DATA3[7:0] |    |    |    |    |    |    |    | DATA2[7:0] |    |    |    |    |    |    |    |
| r          | r  | r  | r  | r  | r  | r  | r  | r          | r  | r  | r  | r  | r  | r  | r  |
| 15         | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7          | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| DATA1[7:0] |    |    |    |    |    |    |    | DATA0[7:0] |    |    |    |    |    |    |    |
| r          | r  | r  | r  | r  | r  | r  | r  | r          | r  | r  | r  | r  | r  | r  | r  |

Bits 31:24 **DATA3[7:0]**: Data Byte 3

Data byte 3 of the message.

Bits 23:16 **DATA2[7:0]**: Data Byte 2

Data byte 2 of the message.

Bits 15:8 **DATA1[7:0]**: Data Byte 1

Data byte 1 of the message.

Bits 7:0 **DATA0[7:0]**: Data Byte 0

Data byte 0 of the message.

A message can contain from 0 to 8 data bytes and starts with byte 0.

**CAN receive FIFO mailbox data high register (CAN\_RDHxR) (x = 0..1)**

Address offsets: 0x1BC, 0x1CC

Reset value: 0xFFFF XXXX

All RX registers are write protected.

|            |    |    |    |    |    |    |    |            |    |    |    |    |    |    |    |

| 31         | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23         | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| DATA7[7:0] |    |    |    |    |    |    |    | DATA6[7:0] |    |    |    |    |    |    |    |
| r          | r  | r  | r  | r  | r  | r  | r  | r          | r  | r  | r  | r  | r  | r  | r  |
| 15         | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7          | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| DATA5[7:0] |    |    |    |    |    |    |    | DATA4[7:0] |    |    |    |    |    |    |    |
| r          | r  | r  | r  | r  | r  | r  | r  | r          | r  | r  | r  | r  | r  | r  | r  |

Bits 31:24 **DATA7[7:0]**: Data Byte 7

Data byte 3 of the message.

Bits 23:16 **DATA6[7:0]**: Data Byte 6  
Data byte 2 of the message.

Bits 15:8 **DATA5[7:0]**: Data Byte 5  
Data byte 1 of the message.

Bits 7:0 **DATA4[7:0]**: Data Byte 4  
Data byte 0 of the message.

### 36.9.4 CAN filter registers

#### CAN filter master register (CAN\_FMR)

Address offset: 0x200

Reset value: 0x2A1C 0E01

All bits of this register are set and cleared by software.

|      |      |            |      |      |      |      |      |      |      |      |      |      |      |      |       |
|------|------|------------|------|------|------|------|------|------|------|------|------|------|------|------|-------|
| 31   | 30   | 29         | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21   | 20   | 19   | 18   | 17   | 16    |
| Res. | Res. | Res.       | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res.  |
|      |      |            |      |      |      |      |      |      |      |      |      |      |      |      |       |
| 15   | 14   | 13         | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0     |
| Res. | Res. | CANSB[5:0] |      |      |      |      |      | Res. | Res. | Res. | Res. | Res. | Res. | Res. | FINIT |
|      |      | rw         | rw   | rw   | rw   | rw   | rw   |      |      |      |      |      |      |      | rw    |

Bits 31:14 Reserved, must be kept at reset value.

Bits 13:8 **CANSB[5:0]**: CAN start bank

These bits are set and cleared by software. When both CAN are used, they define the start bank of each CAN interface:

000001 = 1 filter assigned to CAN1 and 27 assigned to CAN2

011011 = 27 filters assigned to CAN1 and 1 filter assigned to CAN2

- to assign all filters to one CAN set CANSB value to zero and deactivate the non used CAN
- to use CAN1 only: stop the clock on CAN2 and/or set the CAN\_MCR.INRQ on CAN2
- to use CAN2 only: set the CAN\_MCR.INRQ on CAN1 or deactivate the interrupt register CAN\_IER on CAN1

Bits 7:1 Reserved, must be kept at reset value.

Bit 0 **FINIT**: Filter initialization mode

Initialization mode for filter banks

0: Active filters mode.

1: Initialization mode for the filters.

#### CAN filter mode register (CAN\_FM1R)

Address offset: 0x204

Reset value: 0x0000 0000

This register can be written only when the filter initialization mode is set (FINIT=1) in the CAN\_FMR register.

|       |       |       |       |       |       |       |       |       |       |       |       |       |       |       |       |
|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|
| 31    | 30    | 29    | 28    | 27    | 26    | 25    | 24    | 23    | 22    | 21    | 20    | 19    | 18    | 17    | 16    |

Note: Refer to [Figure 449: Filter bank scale configuration - register organization on page 1307](#).

Bits 31: Reserved, must be kept at reset value.

Bits 27:0 **FBMx**: Filter mode

Mode of the registers of Filter x.

0: Two 32-bit registers of filter bank x are in Identifier Mask mode.

1: Two 32-bit registers of filter bank x are in Identifier List mode.

### CAN filter scale register (CAN\_FS1R)

Address offset: 0x20C

Reset value: 0x0000 0000

This register can be written only when the filter initialization mode is set (FINIT=1) in the CAN\_FMR register.

|       |       |       |       |       |       |       |       |       |       |       |       |       |       |       |       |

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:0 **FSCx**: Filter scale configuration

These bits define the scale configuration of Filters 27-0.

0: Dual 16-bit scale configuration

1: Single 32-bit scale configuration

Note: Refer to [Figure 449: Filter bank scale configuration - register organization on page 1307](#).

### CAN filter FIFO assignment register (CAN\_FFA1R)

Address offset: 0x214

Reset value: 0x0000 0000

This register can be written only when the filter initialization mode is set (FINIT=1) in the CAN\_FMR register.

|       |       |       |       |       |       |       |       |       |       |       |       |       |       |       |       |

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:0 **FFAx**: Filter FIFO assignment for filter x

The message passing through this filter will be stored in the specified FIFO.

0: Filter assigned to FIFO 0

1: Filter assigned to FIFO 1

### CAN filter activation register (CAN\_FA1R)

Address offset: 0x21C

Reset value: 0x0000 0000

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:0 **FACTx**: Filter active

The software sets this bit to activate Filter x. To modify the Filter x registers (CAN\_FxR[0:7]), the FACTx bit must be cleared or the FINIT bit of the CAN\_FMR register must be set.

0: Filter x is not active

1: Filter x is active

**Filter bank i register x (CAN\_FiRx) (i = 0..27, x = 1, 2)**

Address offsets: 0x240 to 0x31C

Reset value: 0xFFFF XXXX

There are 28 filter banks, i= 0 to 27. Each filter bank i is composed of two 32-bit registers, CAN\_FiR[2:1].

This register can only be modified when the FACTx bit of the CAN\_FAxR register is cleared or when the FINIT bit of the CAN\_FMR register is set.

In all configurations:

Bits 31:0 **FB[31:0]**: Filter bits

**Identifier**

Each bit of the register specifies the level of the corresponding bit of the expected identifier.

0: Dominant bit is expected

1: Recessive bit is expected

**Mask**

Each bit of the register specifies whether the bit of the associated identifier register must match with the corresponding bit of the expected identifier or not.

0: Do not care, the bit is not used for the comparison

1: Must match, the bit of the incoming identifier must have the same level has specified in the corresponding identifier register of the filter.

**Note:** Depending on the scale and mode configuration of the filter the function of each register can differ. For the filter mapping, functions description and mask registers association, refer to [Section 36.7.4: Identifier filtering on page 1305](#).

A Mask/Identifier register in **mask mode** has the same bit mapping as in **identifier list mode**.

For the register mapping/addresses of the filter banks refer to [Table 255 on page 1336](#).

### 36.9.5 bxCAN register map

Refer to [Section 2.2.2 on page 69](#) for the register boundary addresses. The registers from offset 0x200 to 0x31C are present only in CAN1.

**Table 255. bxCAN register map and reset values**

| Offset      | Register    | 31                     | 30   | 29  | 28       | 27  | 26  | 25        | 24  | 23       | 22    | 21       | 20  | 19         | 18       | 17    | 16    | 15    | 14  | 13    | 12  | 11  | 10    | 9        | 8     | 7     | 6    | 5     | 4        | 3     | 2         | 1     | 0      |       |      |

## 37 USB on-the-go full-speed/high-speed (OTG\_FS/OTG\_HS)

### 37.1 Introduction

Portions Copyright (c) Synopsys, Inc. All rights reserved. Used with permission.

This section presents the architecture and the programming model of the OTG\_FS/OTG\_HS controller.

The following acronyms are used throughout the section:

|      |                                                |
|------|------------------------------------------------|
| FS   | Full-speed                                     |
| LS   | Low-speed                                      |
| HS   | High-speed                                     |
| MAC  | Media access controller                        |
| OTG  | On-the-go                                      |
| PFC  | Packet FIFO controller                         |
| PHY  | Physical layer                                 |
| USB  | Universal serial bus                           |
| UTMI | USB 2.0 Transceiver Macrocell interface (UTMI) |
| ULPI | UTMI+ Low Pin Interface                        |
| LPM  | Link power management                          |
| HNP  | Host negotiation protocol                      |
| SRP  | Session request protocol                       |

References are made to the following documents:

- USB On-The-Go Supplement, Revision 2.0
- Universal Serial Bus Revision 2.0 Specification
- USB 2.0 Link Power Management Addendum Engineering Change Notice to the USB 2.0 specification, July 16, 2007
- Errata for USB 2.0 ECN: Link Power Management (LPM) - 7/2007

The USB OTG is a dual-role device (DRD) controller that supports both device and host functions and is fully compliant with the *On-The-Go Supplement to the USB 2.0 Specification*. It can also be configured as a host-only or device-only controller, fully compliant with the *USB 2.0 Specification*. OTG\_HS supports the speeds defined in the [Table 256: OTG\\_HS speeds supported](#) below. OTG\_FS supports the speeds defined in the [Table 257: OTG\\_FS speeds supported](#) below. The USB OTG supports both HNP and SRP. The only external device required is a charge pump for V<sub>BUS</sub> in OTG mode.

**Table 256. OTG\_HS speeds supported**

| -           | HS (480 Mb/s) | FS (12 Mb/s) | LS (1.5 Mb/s) |
|-------------|---------------|--------------|---------------|
| Host mode   | X             | X            | X             |
| Device mode | X             | X            | -             |

**Table 257. OTG\_FS speeds supported**

| -           | HS (480 Mb/s) | FS (12 Mb/s) | LS (1.5 Mb/s) |
|-------------|---------------|--------------|---------------|
| Host mode   | -             | X            | X             |
| Device mode | -             | X            | -             |

## 37.2 OTG main features

The main features can be divided into three categories: general, host-mode and device-mode features.

### 37.2.1 General features

The OTG\_FS/OTG\_HS interface general features are the following:

- It is USB-IF certified to the Universal Serial Bus Specification Rev 2.0
- OTG\_HS supports the following PHY interfaces:
  - An on-chip full-speed PHY
  - An ULPI interface for external high-speed PHY
- It includes full support (PHY) for the optional On-The-Go (OTG) protocol detailed in the On-The-Go Supplement Rev 2.0 specification
  - Integrated support for A-B device identification (ID line)
  - Integrated support for host Negotiation protocol (HNP) and session request protocol (SRP)
  - It allows host to turn  $V_{BUS}$  off to conserve battery power in OTG applications
  - It supports OTG monitoring of  $V_{BUS}$  levels with internal comparators
  - It supports dynamic host-peripheral switch of role
- It is software-configurable to operate as:
  - SRP capable USB FS/HS Peripheral (B-device)
  - SRP capable USB FS/HS/LS host (A-device)
  - USB On-The-Go Full-Speed Dual Role device
- It supports FS/HS SOF and LS Keep-alives with
  - SOF pulse PAD connectivity
  - SOF pulse internal connection to timer (TIMx)
  - Configurable framing period
  - Configurable end of frame interrupt
- OTG\_HS embeds an internal DMA with shareholding support and software selectable AHB burst type in DMA mode.
- It includes power saving features such as system stop during USB suspend, switch-off of clock domains internal to the digital core, PHY and DFIFO power management.
- It features a dedicated RAM of 1.25[FS] / 4[HS] Kbytes with advanced FIFO control:
  - Configurable partitioning of RAM space into different FIFOs for flexible and efficient use of RAM
  - Each FIFO can hold multiple packets
  - Dynamic memory allocation
  - Configurable FIFO sizes that are not powers of 2 to allow the use of contiguous memory locations
- It guarantees max USB bandwidth for up to one frame (1 ms) without system intervention.

### 37.2.2 Host-mode features

The OTG\_FS/OTG\_HS interface main features and requirements in host-mode are the following:

- External charge pump for  $V_{BUS}$  voltage generation.
- Up to 12[FS] / 16[HS] host channels (pipes): each channel is dynamically reconfigurable to allocate any type of USB transfer.
- Built-in hardware scheduler holding:
  - Up to 12[FS] / 16[HS] interrupt plus isochronous transfer requests in the periodic hardware queue
  - Up to 12[FS] / 16[HS] control plus bulk transfer requests in the non-periodic hardware queue
- Management of a shared Rx FIFO, a periodic Tx FIFO and a nonperiodic Tx FIFO for efficient usage of the USB data RAM.

### 37.2.3 Peripheral-mode features

The OTG\_FS/OTG\_HS interface main features in peripheral-mode are the following:

- 1 bidirectional control endpoint0
- 5[FS] / 8[HS] IN endpoints (EPs) configurable to support bulk, interrupt or isochronous transfers
- 5[FS] / 8[HS] OUT endpoints configurable to support bulk, interrupt or isochronous transfers
- Management of a shared Rx FIFO and a Tx-OUT FIFO for efficient usage of the USB data RAM
- Management of up to 6[FS] / 9[HS] dedicated Tx-IN FIFOs (one for each active IN EP) to put less load on the application
- Support for the soft disconnect feature.

## 37.3 OTG implementation

**Table 258. OTG implementation<sup>(1)</sup>**

| USB features                                   | OTG_FS | OTG_HS |
|------------------------------------------------|--------|--------|
| Device bidirectional endpoints (including EP0) | 6      | 9      |
| Host mode channels                             | 12     | 16     |
| Size of dedicated SRAM                         | 1.2 KB | 4 KB   |
| USB 2.0 link power management (LPM) support    | X      |        |
| OTG revision supported                         | 2.0    |        |
| Attach detection protocol (ADP) support        | -      |        |
| Battery charging detection (BCD) support       | -      |        |

1. "X" = supported, "-" = not supported

### 37.4.3 OTG core

The USB OTG receives the 48 MHz clock from the reset and clock controller (RCC). The USB clock is used for driving the 48 MHz domain at full-speed (12 Mbit/s) and must be enabled prior to configuring the OTG core.

The CPU reads and writes from/to the OTG core registers through the AHB peripheral bus. It is informed of USB events through the single USB OTG interrupt line described in [Section 37.13: OTG\\_FS/OTG\\_HS interrupts](#).

The CPU submits data over the USB by writing 32-bit words to dedicated OTG locations (push registers). The data are then automatically stored into Tx-data FIFOs configured within the USB data RAM. There is one Tx FIFO push register for each in-endpoint (peripheral mode) or out-channel (host mode).

The CPU receives the data from the USB by reading 32-bit words from dedicated OTG addresses (pop registers). The data are then automatically retrieved from a shared Rx FIFO configured within the 1.25[FS] / 4[HS]-Kbyte USB data RAM. There is one Rx FIFO pop register for each out-endpoint or in-channel.

The USB protocol layer is driven by the serial interface engine (SIE) and serialized over the USB by the transceiver module within the on-chip physical layer (PHY) or external HS PHY.

### 37.4.4 Full-speed OTG PHY<sup>(a)</sup>

The embedded full-speed OTG PHY is controlled by the OTG FS core and conveys USB control & data signals through the full-speed subset of the UTMI+ Bus (UTMIFS). It provides

a. The content of this section applies only to USB OTG FS.

the physical support to USB connectivity.

The full-speed OTG PHY includes the following components:

- FS/LS transceiver module used by both host and device. It directly drives transmission and reception on the single-ended USB lines.
- Integrated ID pull-up resistor used to sample the ID line for A/B device identification.
- DP/DM integrated pull-up and pull-down resistors controlled by the OTG\_FS core depending on the current role of the device. As a peripheral, it enables the DP pull-up resistor to signal full-speed peripheral connections as soon as  $V_{BUS}$  is sensed to be at a valid level (B-session valid). In host mode, pull-down resistors are enabled on both DP/DM. Pull-up and pull-down resistors are dynamically switched when the role of the device is changed via the host negotiation protocol (HNP).
- Pull-up/pull-down resistor ECN circuit. The DP pull-up consists of two resistors controlled separately from the OTG\_FS as per the resistor Engineering Change Notice applied to USB Rev2.0. The dynamic trimming of the DP pull-up strength allows for better noise rejection and Tx/Rx signal quality.
- $V_{BUS}$  sensing comparators with hysteresis used to detect  $V_{BUS}$  valid, A-B session valid and session-end voltage thresholds. They are used to drive the session request protocol (SRP), detect valid startup and end-of-session conditions, and constantly monitor the  $V_{BUS}$  supply during USB operations.
- $V_{BUS}$  pulsing method circuit used to charge/discharge  $V_{BUS}$  through resistors during the SRP (weak drive).

**Caution:** To guarantee a correct operation for the USB OTG FS peripheral, the AHB frequency should be higher than 14.2 MHz.

### 37.4.5 Embedded full speed OTG PHY<sup>(a)</sup>

The full-speed OTG PHY includes the following components:

- FS/LS transceiver module used by both host and device. It directly drives transmission and reception on the single-ended USB lines.
- integrated ID pull-up resistor used to sample the ID line for A/B device identification.
- DP/DM integrated pull-up and pull-down resistors controlled by the OTG\_HS core depending on the current role of the device. As a peripheral, it enables the DP pull-up resistor to signal full-speed peripheral connections as soon as  $V_{BUS}$  is sensed to be at a valid level (B-session valid). In host mode, pull-down resistors are enabled on both DP/DM. Pull-up and pull-down resistors are dynamically switched when the peripheral role is changed via the host negotiation protocol (HNP).
- Pull-up/pull-down resistor ECN circuit. The DP pull-up consists of 2 resistors controlled separately from the OTG\_HS as per the resistor Engineering Change Notice applied to USB Rev2.0. The dynamic trimming of the DP pull-up strength allows to achieve a better noise rejection and Tx/Rx signal quality.
- $V_{BUS}$  sensing comparators with hysteresis used to detect  $V_{BUS}$  valid, A-B session valid and session-end voltage thresholds. They are used to drive the session request protocol (SRP), detect valid startup and end-of-session conditions, and constantly monitor the  $V_{BUS}$  supply during USB operations.

---

a. The content of this section applies only to USB OTG HS.

To guarantee a correct operation for the USB OTG\_HS peripheral, the AHB frequency should be higher than 30 MHz.

### 37.4.6 High-speed OTG PHY<sup>(a)</sup>

The USB OTG\_HS core includes an ULPI interface to connect an external HS PHY.

## 37.5 OTG dual role device (DRD)

Figure 459. OTG\_FS A-B device connection

1. External voltage regulator only needed when building a VBUS powered device.
2. STMP2141STR needed only if the application has to support a VBUS powered device. A basic power switch can be used if 5 V are available on the application board.

### 37.5.1 ID line detection

The host or peripheral (the default) role is assumed depending on the ID input pin. The ID line status is determined on plugging in the USB cable, depending on whether a MicroA or MicroB plug is connected to the micro-AB receptacle.

- If the B-side of the USB cable is connected with a floating ID wire, the integrated pull-up resistor detects a high ID level and the default peripheral role is confirmed. In this configuration the OTG\_FS/OTG\_HS complies with the standard FSM described in section 4.2.4: ID pin of the On-the-Go specification Rev2.0, supplement to the USB2.0.
- If the A-side of the USB cable is connected with a grounded ID, the OTG\_FS/OTG\_HS issues an ID line status change interrupt (CIDSCHG bit in OTG\_GINTSTS) for host software initialization, and automatically switches to the host role. In this configuration the OTG\_FS/OTG\_HS complies with the standard FSM described by section 4.2.4: ID pin of the On-the-Go specification Rev2.0, supplement to the USB2.0.

a. The content of this section applies only to USB OTG HS.

### 37.5.2 HNP dual role device

The HNP capable bit in the Global USB configuration register (HNPCAP bit in OTG\_GUSBCFG) enables the OTG\_FS/OTG\_HS core to dynamically change its role from A-host to A-peripheral and vice-versa, or from B-Peripheral to B-host and vice-versa according to the host negotiation protocol (HNP). The current device status can be read by the combined values of the connector ID status bit in the Global OTG control and status register (CIDSTS bit in OTG\_GOTGCTL) and the current mode of operation bit in the global interrupt and status register (CMOD bit in OTG\_GINTSTS).

The HNP program model is described in detail in [Section 37.16: OTG\\_FS/OTG\\_HS programming model](#).

### 37.5.3 SRP dual role device

The SRP capable bit in the global USB configuration register (SRPCAP bit in OTG\_GUSBCFG) enables the OTG\_FS/OTG\_HS core to switch off the generation of  $V_{BUS}$  for the A-device to save power. Note that the A-device is always in charge of driving  $V_{BUS}$  regardless of the host or peripheral role of the OTG\_FS/OTG\_HS.

The SRP A/B-device program model is described in detail in [Section 37.16: OTG\\_FS/OTG\\_HS programming model](#).

## 37.6 USB peripheral

This section gives the functional description of the OTG\_FS/OTG\_HS in the USB peripheral mode. The OTG\_FS/OTG\_HS works as an USB peripheral in the following circumstances:

- OTG B-Peripheral
  - OTG B-device default state if B-side of USB cable is plugged in
- OTG A-Peripheral
  - OTG A-device state after the HNP switches the OTG\_FS/OTG\_HS to its peripheral role
- B-device
  - If the ID line is present, functional and connected to the B-side of the USB cable, and the HNP-capable bit in the Global USB Configuration register (HNPCAP bit in OTG\_GUSBCFG) is cleared.
- Peripheral only (see [Figure 460: USB\\_FS peripheral-only connection](#))
  - The force device mode bit (FDMOD) in the [Section 37.15.4: OTG USB configuration register \(OTG\\_GUSBCFG\)](#) is set to 1, forcing the OTG\_FS/OTG\_HS core to work as an USB peripheral-only. In this case, the ID line is ignored even if it is present on the USB connector.

**Note:** *To build a bus-powered device implementation in case of the B-device or peripheral-only configuration, an external regulator has to be added, that generates the necessary power-supply from  $V_{BUS}$ .*

Figure 460. USB\_FS peripheral-only connection

1. Use a regulator to build a bus-powered device.

### 37.6.1 SRP-capable peripheral

The SRP capable bit in the Global USB configuration register (SRPCAP bit in OTG\_GUSBCFG) enables the OTG\_FS/OTG\_HS to support the session request protocol (SRP). In this way, it allows the remote A-device to save power by switching off  $V_{BUS}$  while the USB session is suspended.

The SRP peripheral mode program model is described in detail in the [B-device session request protocol](#) section.

### 37.6.2 Peripheral states

#### Powered state

The  $V_{BUS}$  input detects the B-session valid voltage by which the USB peripheral is allowed to enter the powered state (see USB2.0 section 9.1). The OTG\_FS/OTG\_HS then automatically connects the DP pull-up resistor to signal full-speed device connection to the host and generates the session request interrupt (SRQINT bit in OTG\_GINTSTS) to notify the powered state.

The  $V_{BUS}$  input also ensures that valid  $V_{BUS}$  levels are supplied by the host during USB operations. If a drop in  $V_{BUS}$  below B-session valid happens to be detected (for instance because of a power disturbance or if the host port has been switched off), the OTG\_FS/OTG\_HS automatically disconnects and the session end detected (SEDET bit in OTG\_GOTGINT) interrupt is generated to notify that the OTG\_FS/OTG\_HS has exited the powered state.

In the powered state, the OTG\_FS/OTG\_HS expects to receive some reset signaling from the host. No other USB operation is possible. When a reset signaling is received the reset detected interrupt (USBRST in OTG\_GINTSTS) is generated. When the reset signaling is complete, the enumeration done interrupt (ENUMDNE bit in OTG\_GINTSTS) is generated and the OTG\_FS/OTG\_HS enters the Default state.

### Soft disconnect

The powered state can be exited by software with the soft disconnect feature. The DP pull-up resistor is removed by setting the soft disconnect bit in the device control register (SDIS bit in OTG\_DCTL), causing a device disconnect detection interrupt on the host side even though the USB cable was not really removed from the host port.

### Default state

In the Default state the OTG\_FS/OTG\_HS expects to receive a SET\_ADDRESS command from the host. No other USB operation is possible. When a valid SET\_ADDRESS command is decoded on the USB, the application writes the corresponding number into the device address field in the device configuration register (DAD bit in OTG\_DCFG). The OTG\_FS/OTG\_HS then enters the address state and is ready to answer host transactions at the configured USB address.

### Suspended state

The OTG\_FS/OTG\_HS peripheral constantly monitors the USB activity. After counting 3 ms of USB idleness, the early suspend interrupt (ESUSP bit in OTG\_GINTSTS) is issued, and confirmed 3 ms later, if appropriate, by the suspend interrupt (USBSUSP bit in OTG\_GINTSTS). The device suspend bit is then automatically set in the device status register (SUSPSTS bit in OTG\_DSTS) and the OTG\_FS/OTG\_HS enters the suspended state.

The suspended state may optionally be exited by the device itself. In this case the application sets the remote wakeup signaling bit in the device control register (RWUSIG bit in OTG\_DCTL) and clears it after 1 to 15 ms.

When a resume signaling is detected from the host, the resume interrupt (WKUPINT bit in OTG\_GINTSTS) is generated and the device suspend bit is automatically cleared.

## 37.6.3 Peripheral endpoints

The OTG\_FS/OTG\_HS core instantiates the following USB endpoints:

- Control endpoint 0:
  - Bidirectional and handles control messages only
  - Separate set of registers to handle in and out transactions
  - Proper control (OTG\_DIEPCTL0/OTG\_DOEPCTL0), transfer configuration (OTG\_DIEPTSIZ0/OTG\_DOEPSIZ0), and status-interrupt (OTG\_DIEPINT0/OTG\_DOEPINT0) registers. The available set of bits inside the control and transfer size registers slightly differs from that of other endpoints
- 5[FS] / 8[HS] IN endpoints
  - Each of them can be configured to support the isochronous, bulk or interrupt transfer type
  - Each of them has proper control (OTG\_DIEPCTLx), transfer configuration (OTG\_DIEPTSIZx), and status-interrupt (OTG\_DIEPINTx) registers
  - The device IN endpoints common interrupt mask register (OTG\_DIEPMSK) is available to enable/disable a single kind of endpoint interrupt source on all of the IN endpoints (EP0 included)
  - Support for incomplete isochronous IN transfer interrupt (IISOIXFR bit in OTG\_GINTSTS), asserted when there is at least one isochronous IN endpoint on

which the transfer is not completed in the current frame. This interrupt is asserted along with the end of periodic frame interrupt (OTG\_GINTSTS/EOPF).

- 5[FS] / 8[HS] OUT endpoints
  - Each of them can be configured to support the isochronous, bulk or interrupt transfer type
  - Each of them has a proper control (OTG\_DOEPCTLx), transfer configuration (OTG\_DOEPTSIZx) and status-interrupt (OTG\_DOEPINTx) register
  - Device OUT endpoints common interrupt mask register (OTG\_DOEPMSK) is available to enable/disable a single kind of endpoint interrupt source on all of the OUT endpoints (EP0 included)
  - Support for incomplete isochronous OUT transfer interrupt (INCOMPISOOUT bit in OTG\_GINTSTS), asserted when there is at least one isochronous OUT endpoint on which the transfer is not completed in the current frame. This interrupt is asserted along with the end of periodic frame interrupt (OTG\_GINTSTS/EOPF).

### Endpoint control

- The following endpoint controls are available to the application through the device endpoint-x IN/OUT control register (OTG\_DIEPCTLx/OTG\_DOEPCTLx):
  - Endpoint enable/disable
  - Endpoint activate in current configuration
  - Program USB transfer type (isochronous, bulk, interrupt)
  - Program supported packet size
  - Program Tx FIFO number associated with the IN endpoint
  - Program the expected or transmitted data0/data1 PID (bulk/interrupt only)
  - Program the even/odd frame during which the transaction is received or transmitted (isochronous only)
  - Optionally program the NAK bit to always negative-acknowledge the host regardless of the FIFO status
  - Optionally program the STALL bit to always stall host tokens to that endpoint
  - Optionally program the SNOOP mode for OUT endpoint not to check the CRC field of received data

### Endpoint transfer

The device endpoint-x transfer size registers (OTG\_DIEPTSIZx/OTG\_DOEPTSIZx) allow the application to program the transfer size parameters and read the transfer status. Programming must be done before setting the endpoint enable bit in the endpoint control register. Once the endpoint is enabled, these fields are read-only as the OTG\_FS/OTG\_HS core updates them with the current transfer status.

The following transfer parameters can be programmed:

- Transfer size in bytes
- Number of packets that constitute the overall transfer size

### Endpoint status/interrupt

The device endpoint-x interrupt registers (OTG\_DIEPINTx/OTG\_DOEPINTx) indicate the status of an endpoint with respect to USB- and AHB-related events. The application must read these registers when the OUT endpoint interrupt bit or the IN endpoint interrupt bit in

the core interrupt register (OEPINT bit in OTG\_GINTSTS or IEPINT bit in OTG\_GINTSTS, respectively) is set. Before the application can read these registers, it must first read the device all endpoints interrupt (OTG\_DAINTE) register to get the exact endpoint number for the device endpoint-x interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the OTG\_DAINTE and OTG\_GINTSTS registers

The peripheral core provides the following status checks and interrupt generation:

- Transfer completed interrupt, indicating that data transfer was completed on both the application (AHB) and USB sides
- Setup stage has been done (control-out only)
- Associated transmit FIFO is half or completely empty (in endpoints)
- NAK acknowledge has been transmitted to the host (isochronous-in only)
- IN token received when Tx FIFO was empty (bulk-in/interrupt-in only)
- Out token received when endpoint was not yet enabled
- Babble error condition has been detected
- Endpoint disable by application is effective
- Endpoint NAK by application is effective (isochronous-in only)
- More than 3 back-to-back setup packets were received (control-out only)
- Timeout condition detected (control-in only)
- Isochronous out packet has been dropped, without generating an interrupt

## 37.7 USB host

This section gives the functional description of the OTG\_FS/OTG\_HS in the USB host mode. The OTG\_FS/OTG\_HS works as a USB host in the following circumstances:

- OTG A-host
  - OTG A-device default state when the A-side of the USB cable is plugged in
- OTG B-host
  - OTG B-device after HNP switching to the host role
- A-device
  - If the ID line is present, functional and connected to the A-side of the USB cable, and the HNP-capable bit is cleared in the Global USB Configuration register (HNPCAP bit in OTG\_GUSBCFG). Integrated pull-down resistors are automatically set on the DP/DM lines.
- Host only
  - The force host mode bit (FHMOD) in the [OTG USB configuration register \(OTG\\_GUSBCFG\)](#) forces the OTG\_FS/OTG\_HS core to work as a USB host-only. In this case, the ID line is ignored even if present on the USB connector. Integrated pull-down resistors are automatically set on the DP/DM lines.

*Note:* On-chip 5 V  $V_{BUS}$  generation is not supported. For this reason, a charge pump or, if 5 V are available on the application board, a basic power switch must be added externally to drive the 5 V  $V_{BUS}$  line. The external charge pump can be driven by any GPIO output. This is required for the OTG A-host, A-device and host-only configurations.

Figure 461. USB\_FS host-only connection

MSv36915V2

1.  $V_{DD}$  range is between 2 V and 3.6 V.

### 37.7.1 SRP-capable host

SRP support is available through the SRP capable bit in the global USB configuration register (SRPCAP bit in OTG\_GUSBCFG). With the SRP feature enabled, the host can save power by switching off the  $V_{BUS}$  power while the USB session is suspended.

The SRP host mode program model is described in detail in the [A-device session request protocol](#) section.

### 37.7.2 USB host states

#### Host port power

On-chip 5 V  $V_{BUS}$  generation is not supported. For this reason, a charge pump or, if 5 V are available on the application board, a basic power switch, must be added externally to drive the 5 V  $V_{BUS}$  line. The external charge pump can be driven by any GPIO output or via an I<sup>2</sup>C interface connected to an external PMIC (power management IC). When the application decides to power on  $V_{BUS}$ , it must also set the port power bit in the host port control and status register (PPWR bit in OTG\_HPRT).

#### $V_{BUS}$ valid

When HNP or SRP is enabled the VBUS sensing pin should be connected to  $V_{BUS}$ . The  $V_{BUS}$  input ensures that valid  $V_{BUS}$  levels are supplied by the charge pump during USB operations. Any unforeseen  $V_{BUS}$  voltage drop below the  $V_{BUS}$  valid threshold (4.4 V) leads to an OTG interrupt triggered by the session end detected bit (SEDET bit in OTG\_GOTGINT). The application is then required to remove the  $V_{BUS}$  power and clear the port power bit.

When HNP and SRP are both disabled, the VBUS sensing pin does not need to be connected to  $V_{BUS}$ .

The charge pump overcurrent flag can also be used to prevent electrical damage. Connect the overcurrent flag output from the charge pump to any GPIO input and configure it to generate a port interrupt on the active level. The overcurrent ISR must promptly disable the  $V_{BUS}$  generation and clear the port power bit.

### Host detection of a peripheral connection

If SRP or HNP are enabled, even if USB peripherals or B-devices can be attached at any time, the OTG\_FS/OTG\_HS will not detect any bus connection until  $V_{BUS}$  is no longer sensed at a valid level (5 V). When  $V_{BUS}$  is at a valid level and a remote B-device is attached, the OTG\_FS/OTG\_HS core issues a host port interrupt triggered by the device connected bit in the host port control and status register (PCDET bit in OTG\_HPRT).

When HNP and SRP are both disabled, USB peripherals or B-device are detected as soon as they are connected. The OTG\_FS/OTG\_HS core issues a host port interrupt triggered by the device connected bit in the host port control and status (PCDET bit in OTG\_HPRT).

### Host detection of peripheral a disconnection

The peripheral disconnection event triggers the disconnect detected interrupt (DISCINT bit in OTG\_GINTSTS).

### Host enumeration

After detecting a peripheral connection the host must start the enumeration process by sending USB reset and configuration commands to the new peripheral.

Before starting to drive a USB reset, the application waits for the OTG interrupt triggered by the debounce done bit (DBCDNE bit in OTG\_GOTGINT), which indicates that the bus is stable again after the electrical debounce caused by the attachment of a pull-up resistor on DP (FS) or DM (LS).

The application drives a USB reset signaling (single-ended zero) over the USB by keeping the port reset bit set in the host port control and status register (PRST bit in OTG\_HPRT) for a minimum of 10 ms and a maximum of 20 ms. The application takes care of the timing count and then of clearing the port reset bit.

Once the USB reset sequence has completed, the host port interrupt is triggered by the port enable/disable change bit (PENCHNG bit in OTG\_HPRT). This informs the application that the speed of the enumerated peripheral can be read from the port speed field in the host port control and status register (PSPD bit in OTG\_HPRT) and that the host is starting to drive SOFs (FS) or Keep alives (LS). The host is now ready to complete the peripheral enumeration by sending peripheral configuration commands.

### Host suspend

The application decides to suspend the USB activity by setting the port suspend bit in the host port control and status register (PSUSP bit in OTG\_HPRT). The OTG\_FS/OTG\_HS core stops sending SOFs and enters the suspended state.

The suspended state can be optionally exited on the remote device's initiative (remote wakeup). In this case the remote wakeup interrupt (WKUPINT bit in OTG\_GINTSTS) is generated upon detection of a remote wakeup signaling, the port resume bit in the host port control and status register (PRES bit in OTG\_HPRT) self-sets, and resume signaling is automatically driven over the USB. The application must time the resume window and then clear the port resume bit to exit the suspended state and restart the SOF.

If the suspended state is exited on the host initiative, the application must set the port resume bit to start resume signaling on the host port, time the resume window and finally clear the port resume bit.

### 37.7.3 Host channels

The OTG\_FS/OTG\_HS core instantiates 12[FS] / 16[HS] host channels. Each host channel supports an USB host transfer (USB pipe). The host is not able to support more than 12[FS] / 16[HS] transfer requests at the same time. If more than 12[FS] / 16[HS] transfer requests are pending from the application, the host controller driver (HCD) must re-allocate channels when they become available from previous duty, that is, after receiving the transfer completed and channel halted interrupts.

Each host channel can be configured to support in/out and any type of periodic/nonperiodic transaction. Each host channel makes use of proper control (OTG\_HCCHARx), transfer configuration (OTG\_HCTSIZx) and status/interrupt (OTG\_HCINTx) registers with associated mask (OTG\_HCINTMSKx) registers.

#### Host channel control

- The following host channel controls are available to the application through the host channel-x characteristics register (OTG\_HCCHARx):
  - Channel enable/disable
  - Program the HS/FS/LS speed of target USB peripheral
  - Program the address of target USB peripheral
  - Program the endpoint number of target USB peripheral
  - Program the transfer IN/OUT direction
  - Program the USB transfer type (control, bulk, interrupt, isochronous)
  - Program the maximum packet size (MPS)
  - Program the periodic transfer to be executed during odd/even frames

#### Host channel transfer

The host channel transfer size registers (OTG\_HCTSIZx) allow the application to program the transfer size parameters, and read the transfer status. Programming must be done before setting the channel enable bit in the host channel characteristics register. Once the endpoint is enabled the packet count field is read-only as the OTG\_FS/OTG\_HS core updates it according to the current transfer status.

- The following transfer parameters can be programmed:
  - transfer size in bytes
  - number of packets making up the overall transfer size
  - initial data PID

#### Host channel status/interrupt

The host channel-x interrupt register (OTG\_HCINTx) indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read these register when the host channels interrupt bit in the core interrupt register (HCINT bit in OTG\_GINTSTS) is set. Before the application can read these registers, it must first read the host all channels interrupt (OTG\_HAINT) register to get the exact channel number for the host channel-x interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the OTG\_HAINT and OTG\_GINTSTS registers.

The mask bits for each interrupt source of each channel are also available in the OTG\_HCINTMSKx register.

- The host core provides the following status checks and interrupt generation:
  - Transfer completed interrupt, indicating that the data transfer is complete on both the application (AHB) and USB sides
  - Channel has stopped due to transfer completed, USB transaction error or disable command from the application
  - Associated transmit FIFO is half or completely empty (IN endpoints)
  - ACK response received
  - NAK response received
  - STALL response received
  - USB transaction error due to CRC failure, timeout, bit stuff error, false EOP
  - Babble error
  - frame overrun
  - data toggle error

#### 37.7.4 Host scheduler

The host core features a built-in hardware scheduler which is able to autonomously re-order and manage the USB transaction requests posted by the application. At the beginning of each frame the host executes the periodic (isochronous and interrupt) transactions first, followed by the nonperiodic (control and bulk) transactions to achieve the higher level of priority granted to the isochronous and interrupt transfer types by the USB specification.

The host processes the USB transactions through request queues (one for periodic and one for nonperiodic). Each request queue can hold up to 8 entries. Each entry represents a pending transaction request from the application, and holds the IN or OUT channel number along with other information to perform a transaction on the USB. The order in which the requests are written to the queue determines the sequence of the transactions on the USB interface.

At the beginning of each frame, the host processes the periodic request queue first, followed by the nonperiodic request queue. The host issues an incomplete periodic transfer interrupt (IPXFR bit in OTG\_GINTSTS) if an isochronous or interrupt transaction scheduled for the current frame is still pending at the end of the current frame. The OTG\_FS/OTG\_HS core is fully responsible for the management of the periodic and nonperiodic request queues. The periodic transmit FIFO and queue status register (OTG\_HPTXSTS) and nonperiodic transmit FIFO and queue status register (OTG\_HNPTXSTS) are read-only registers which can be used by the application to read the status of each request queue. They contain:

- The number of free entries currently available in the periodic (nonperiodic) request queue (8 max)
- Free space currently available in the periodic (nonperiodic) Tx FIFO (out-transactions)
- IN/OUT token, host channel number and other status information.

As request queues can hold a maximum of 8 entries each, the application can push to schedule host transactions in advance with respect to the moment they physically reach the SB for a maximum of 8 pending periodic transactions plus 8 pending non-periodic transactions.

To post a transaction request to the host scheduler (queue) the application must check that there is at least 1 entry available in the periodic (nonperiodic) request queue by reading the

PTXQSAV bits in the OTG\_HNPTXSTS register or NPTQXSAV bits in the OTG\_HNPTXSTS register.

## 37.8 SOF trigger

**Figure 462. SOF connectivity (SOF trigger output to TIM and ITR1 connection)**

The OTG\_FS/OTG\_HS core provides means to monitor, track and configure SOF framing in the host and peripheral, as well as an SOF pulse output connectivity feature.

Such utilities are especially useful for adaptive audio clock generation techniques, where the audio peripheral needs to synchronize to the isochronous stream provided by the PC, or the host needs to trim its framing rate according to the requirements of the audio peripheral.

### 37.8.1 Host SOFs

In host mode the number of PHY clocks occurring between the generation of two consecutive SOF (HS/FS) or Keep-alive (LS) tokens is programmable in the host frame interval register (HFIR), thus providing application control over the SOF framing period. An interrupt is generated at any start of frame (SOF bit in OTG\_GINTSTS). The current frame number and the time remaining until the next SOF are tracked in the host frame number register (HFNUM).

A SOF pulse signal, is generated at any SOF starting token and with a width of 20 HCLK cycles. The SOF pulse is also internally connected to the input trigger of the timer, so that the input capture feature, the output compare feature and the timer can be triggered by the SOF pulse.

### 37.8.2 Peripheral SOFs

In device mode, the start of frame interrupt is generated each time an SOF token is received on the USB (SOF bit in OTG\_GINTSTS). The corresponding frame number can be read from the device status register (FNSOF bit in OTG\_DSTS). A SOF pulse signal with a width of 20 HCLK cycles is also generated. The SOF pulse signal is also internally connected to the TIM input trigger, so that the input capture feature, the output compare feature and the timer can be triggered by the SOF pulse.

The end of periodic frame interrupt (OTG\_GINTSTS/EOPF) is used to notify the application when 80%, 85%, 90% or 95% of the time frame interval elapsed depending on the periodic frame interval field in the device configuration register (PFIVL bit in OTG\_DCFG). This feature can be used to determine if all of the isochronous traffic for that frame is complete.

## 37.9 OTG low-power modes

[Table 262](#) below defines the STM32 low power modes and their compatibility with the OTG.

**Table 262. Compatibility of STM32 low power modes with the OTG**

| Mode    | Description                                                                                                 | USB compatibility                        |
|---------|-------------------------------------------------------------------------------------------------------------|------------------------------------------|
| Run     | MCU fully active                                                                                            | Required when USB not in suspend state.  |
| Sleep   | USB suspend exit causes the device to exit Sleep mode. Peripheral registers content is kept.                | Available while USB is in suspend state. |
| Stop    | USB suspend exit causes the device to exit Stop mode. Peripheral registers content is kept <sup>(1)</sup> . | Available while USB is in suspend state. |
| Standby | Powered-down. The peripheral must be reinitialized after exiting Standby mode.                              | Not compatible with USB applications.    |

1. Within Stop mode there are different possible settings. Some restrictions may also exist, please refer to [Section 4: Power controller \(PWR\)](#) to understand which (if any) restrictions apply when using OTG.

The following bits and procedures reduce power consumption.

The power consumption of the OTG PHY is controlled by two or three bits in the general core configuration register, depending on OTG revision supported.

- PHY power down (OTG\_GCCFG/PWRDWN)  
It switches on/off the full-speed transceiver module of the PHY. It must be preliminarily set to allow any USB operation
- V<sub>BUS</sub> detection enable (OTG\_GCCFG/VBDEN)  
It switches on/off the V<sub>BUS</sub> sensing comparators associated with OTG operations

Power reduction techniques are available while in the USB suspended state, when the USB session is not yet valid or the device is disconnected.

- Stop PHY clock (STPPCLK bit in OTG\_PCGCCTL)  
When setting the stop PHY clock bit in the clock gating control register, most of the 48 MHz clock domain internal to the OTG full-speed core is switched off by clock gating. The dynamic power consumption due to the USB clock switching activity is cut even if the 48 MHz clock input is kept running by the application  
Most of the transceiver is also disabled, and only the part in charge of detecting the asynchronous resume or remote wakeup event is kept alive.
- Gate HCLK (GATEHCLK bit in OTG\_PCGCCTL)  
When setting the Gate HCLK bit in the clock gating control register, most of the system clock domain internal to the OTG\_FS/OTG\_HS core is switched off by clock gating. Only the register read and write interface is kept alive. The dynamic power

consumption due to the USB clock switching activity is cut even if the system clock is kept running by the application for other purposes.

- USB system stop

When the OTG\_FS/OTG\_HS is in the USB suspended state, the application may decide to drastically reduce the overall power consumption by a complete shut down of all the clock sources in the system. USB System Stop is activated by first setting the Stop PHY clock bit and then configuring the system deep sleep mode in the power control system module (PWR).

The OTG\_FS/OTG\_HS core automatically reactivates both system and USB clocks by asynchronous detection of remote wakeup (as an host) or resume (as a device) signaling on the USB.

To save dynamic power, the USB data FIFO is clocked only when accessed by the OTG\_FS/OTG\_HS core.

### 37.10 Dynamic update of the OTG\_HFIR register

The USB core embeds a dynamic trimming capability of micro-SOF[HS] / SOF[FS] framing period in host mode allowing to synchronize an external device with the micro-SOF[HS] / SOF[FS] frames.

When the OTG\_HFIR register is changed within a current micro-SOF[HS] / SOF[FS] frame, the SOF period correction is applied in the next frame as described in [Figure 463](#).

For a dynamic update, it is required to set RLDCTRL=0.

**Figure 463. Updating OTG\_HFIR dynamically (RLDCTRL = 0)**

### 37.11 USB data FIFOs

The USB system features 1.25[FS] / 4[HS] Kbytes of dedicated RAM with a sophisticated FIFO control mechanism. The packet FIFO controller module in the OTG\_FS/OTG\_HS core organizes RAM space into Tx FIFOs into which the application pushes the data to be temporarily stored before the USB transmission, and into a single Rx FIFO where the data received from the USB are temporarily stored before retrieval (popped) by the application. The number of instructed FIFOs and how these are organized inside the RAM depends on

the device's role. In peripheral mode an additional Tx FIFO is instructed for each active IN endpoint. Any FIFO size is software configured to better meet the application requirements.

### 37.11.1 Peripheral FIFO architecture

**Figure 464. Device-mode FIFO address mapping and AHB FIFO access mapping**

#### Peripheral Rx FIFO

The OTG peripheral uses a single receive FIFO that receives the data directed to all OUT endpoints. Received packets are stacked back-to-back until free space is available in the Rx FIFO. The status of the received packet (which contains the OUT endpoint destination number, the byte count, the data PID and the validity of the received data) is also stored by the core on top of the data payload. When no more space is available, host transactions are NACKed and an interrupt is received on the addressed endpoint. The size of the receive FIFO is configured in the receive FIFO size register (OTG\_GRXFSIZ).

The single receive FIFO architecture makes it more efficient for the USB peripheral to fill in the receive RAM buffer:

- All OUT endpoints share the same RAM buffer (shared FIFO)
- The OTG\_FS/OTG\_HS core can fill in the receive FIFO up to the limit for any host sequence of OUT tokens

The application keeps receiving the Rx FIFO non-empty interrupt (RXFLVL bit in OTG\_GINTSTS) as long as there is at least one packet available for download. It reads the packet information from the receive status read and pop register (OTG\_GRXSTSP) and finally pops data off the receive FIFO by reading from the endpoint-related pop address.

## Peripheral Tx FIFOs

The core has a dedicated FIFO for each IN endpoint. The application configures FIFO sizes by writing the endpoint 0 transmit FIFO size register (OTG\_DIEPTXF0) for IN endpoint0 and the device IN endpoint transmit FIFOx registers (OTG\_DIEPTXFx) for IN endpoint-x.

### 37.11.2 Host FIFO architecture

**Figure 465. Host-mode FIFO address mapping and AHB FIFO access mapping**

## Host Rx FIFO

The host uses one receiver FIFO for all periodic and nonperiodic transactions. The FIFO is used as a receive buffer to hold the received data (payload of the received packet) from the USB until it is transferred to the system memory. Packets received from any remote IN endpoint are stacked back-to-back until free space is available. The status of each received packet with the host channel destination, byte count, data PID and validity of the received data are also stored into the FIFO. The size of the receive FIFO is configured in the receive FIFO size register (OTG\_GRXF0SIZ).

The single receive FIFO architecture makes it highly efficient for the USB host to fill in the receive data buffer:

- All IN configured host channels share the same RAM buffer (shared FIFO)
- The OTG\_FS/OTG\_HS core can fill in the receive FIFO up to the limit for any sequence of IN tokens driven by the host software

The application receives the Rx FIFO not-empty interrupt as long as there is at least one packet available for download. It reads the packet information from the receive status read and pop register and finally pops the data off the receive FIFO.

## Host Tx FIFOs

The host uses one transmit FIFO for all non-periodic (control and bulk) OUT transactions and one transmit FIFO for all periodic (isochronous and interrupt) OUT transactions. FIFOs are used as transmit buffers to hold the data (payload of the transmit packet) to be transmitted over the USB. The size of the periodic (nonperiodic) Tx FIFO is configured in the host periodic (nonperiodic) transmit FIFO size OTG\_HPTXFSIZ / OTG\_HNPTXFSIZ register.

The two Tx FIFO implementation derives from the higher priority granted to the periodic type of traffic over the USB frame. At the beginning of each frame, the built-in host scheduler processes the periodic request queue first, followed by the nonperiodic request queue.

The two transmit FIFO architecture provides the USB host with separate optimization for periodic and nonperiodic transmit data buffer management:

- All host channels configured to support periodic (nonperiodic) transactions in the OUT direction share the same RAM buffer (shared FIFOs)
- The OTG\_FS/OTG\_HS core can fill in the periodic (nonperiodic) transmit FIFO up to the limit for any sequence of OUT tokens driven by the host software

The OTG\_FS/OTG\_HS core issues the periodic Tx FIFO empty interrupt (PTXFE bit in OTG\_GINTSTS) as long as the periodic Tx FIFO is half or completely empty, depending on the value of the periodic Tx FIFO empty level bit in the AHB configuration register (PTXFELVL bit in OTG\_GAHBCFG). The application can push the transmission data in advance as long as free space is available in both the periodic Tx FIFO and the periodic request queue. The host periodic transmit FIFO and queue status register (OTG\_HPTXSTS) can be read to know how much space is available in both.

OTG\_FS/OTG\_HS core issues the non periodic Tx FIFO empty interrupt (NPTXFE bit in OTG\_GINTSTS) as long as the nonperiodic Tx FIFO is half or completely empty depending on the non periodic Tx FIFO empty level bit in the AHB configuration register (TXFELVL bit in OTG\_GAHBCFG). The application can push the transmission data as long as free space is available in both the nonperiodic Tx FIFO and nonperiodic request queue. The host nonperiodic transmit FIFO and queue status register (OTG\_HNPTXSTS) can be read to know how much space is available in both.

## 37.11.3 FIFO RAM allocation

### Device mode

**Receive FIFO RAM allocation:** the application should allocate RAM for SETUP packets:

- 10 locations must be reserved in the receive FIFO to receive SETUP packets on control endpoint. The core does not use these locations, which are reserved for SETUP packets, to write any other data.
- One location is to be allocated for Global OUT NAK.
- Status information is written to the FIFO along with each received packet. Therefore, a minimum space of  $(\text{largest packet size} / 4) + 1$  must be allocated to receive packets. If multiple isochronous endpoints are enabled, then at least two  $(\text{largest packet size} / 4) + 1$  spaces must be allocated to receive back-to-back packets. Typically, two  $(\text{largest packet size} / 4) + 1$  spaces are recommended so that when the previous packet is being transferred to the CPU, the USB can receive the subsequent packet.
- Along with the last packet for each endpoint, transfer complete status information is also pushed to the FIFO. One location for each OUT endpoint is recommended.

Device RxFIFO =

$(5 * \text{number of control endpoints} + 8) + ((\text{largest USB packet used} / 4) + 1 \text{ for status information}) + (2 * \text{number of OUT endpoints}) + 1 \text{ for Global NAK}$

Example: The MPS is 1,024 bytes for a periodic USB packet and 512 bytes for a non-periodic USB packet. There are three OUT endpoints, three IN endpoints, one control endpoint, and three host channels.

Device RxFIFO =  $(5 * 1 + 8) + ((1,024 / 4) + 1) + (2 * 4) + 1 = 279$

**Transmit FIFO RAM allocation:** the minimum RAM space required for each IN endpoint Transmit FIFO is the maximum packet size for that particular IN endpoint.

*Note: More space allocated in the transmit IN endpoint FIFO results in better performance on the USB.*

## Host mode

Receive FIFO RAM allocation:

Status information is written to the FIFO along with each received packet. Therefore, a minimum space of  $(\text{largest packet size} / 4) + 1$  must be allocated to receive packets. If multiple isochronous channels are enabled, then at least two  $(\text{largest packet size} / 4) + 1$  spaces must be allocated to receive back-to-back packets. Typically, two  $(\text{largest packet size} / 4) + 1$  spaces are recommended so that when the previous packet is being transferred to the CPU, the USB can receive the subsequent packet.

Along with the last packet in the host channel, transfer complete status information is also pushed to the FIFO. So one location must be allocated for this.

Host RxFIFO =  $(\text{largest USB packet used} / 4) + 1 \text{ for status information} + 1 \text{ transfer complete}$

Example: Host RxFIFO =  $((1,024 / 4) + 1) + 1 = 258$

Transmit FIFO RAM allocation:

The minimum amount of RAM required for the host Non-periodic Transmit FIFO is the largest maximum packet size among all supported non-periodic OUT channels.

Typically, two largest packet sizes worth of space is recommended, so that when the current packet is under transfer to the USB, the CPU can get the next packet.

Non-Periodic TxFIFO =  $\text{largest non-periodic USB packet used} / 4$

Example: Non-Periodic TxFIFO =  $(512 / 4) = 128$

The minimum amount of RAM required for host periodic Transmit FIFO is the largest maximum packet size out of all the supported periodic OUT channels. If there is at least one isochronous OUT endpoint, then the space must be at least two times the maximum packet size of that channel.

Host Periodic TxFIFO =  $\text{largest periodic USB packet used} / 4$

Example: Host Periodic TxFIFO =  $(1,024 / 4) = 256$

*Note: More space allocated in the Transmit Non-periodic FIFO results in better performance on the USB.*

## 37.12 OTG\_FS system performance

Best USB and system performance is achieved owing to the large RAM buffers, the highly configurable FIFO sizes, the quick 32-bit FIFO access through AHB push/pop registers and, especially, the advanced FIFO control mechanism. Indeed, this mechanism allows the OTG\_FS to fill in the available RAM space at best regardless of the current USB sequence. With these features:

- The application gains good margins to calibrate its intervention in order to optimize the CPU bandwidth usage:
  - It can accumulate large amounts of transmission data in advance compared to when they are effectively sent over the USB
  - It benefits of a large time margin to download data from the single receive FIFO
- The USB core is able to maintain its full operating rate, that is to provide maximum full-speed bandwidth with a great margin of autonomy versus application intervention:
  - It has a large reserve of transmission data at its disposal to autonomously manage the sending of data over the USB
  - It has a lot of empty space available in the receive buffer to autonomously fill it in with the data coming from the USB

As the OTG\_FS core is able to fill in the 1.25-Kbyte RAM buffer very efficiently, and as 1.25-Kbyte of transmit/receive data is more than enough to cover a full speed frame, the USB system is able to withstand the maximum full-speed data rate for up to one USB frame (1 ms) without any CPU intervention.

## 37.13 OTG\_FS/OTG\_HS interrupts

When the OTG\_FS/OTG\_HS controller is operating in one mode, either device or host, the application must not access registers from the other mode. If an illegal access occurs, a mode mismatch interrupt is generated and reflected in the core interrupt register (MMIS bit in the OTG\_GINTSTS register). When the core switches from one mode to the other, the registers in the new mode of operation must be reprogrammed as they would be after a power-on reset.

*Figure 466* shows the interrupt hierarchy.

Figure 466. Interrupt hierarchy

MSv47471V3

1. OTG\_FS\_WKUP / OTG\_HS\_WKUP become active (high state) when resume condition occurs during L1 SLEEP or L2 SUSPEND states.

## 37.14 OTG\_FS/OTG\_HS control and status registers

By reading from and writing to the control and status registers (CSRs) through the AHB slave interface, the application controls the OTG\_FS/OTG\_HS controller. These registers are 32 bits wide, and the addresses are 32-bit block aligned. The OTG\_FS/OTG\_HS registers must be accessed by words (32 bits).

CSRs are classified as follows:

- Core global registers
- Host-mode registers
- Host global registers
- Host port CSRs
- Host channel-specific registers
- Device-mode registers
- Device global registers
- Device endpoint-specific registers
- Power and clock-gating registers
- Data FIFO (DFIFO) access registers

Only the core global, power and clock-gating, data FIFO access, and host port control and status registers can be accessed in both host and device modes. When the OTG\_FS/OTG\_HS controller is operating in one mode, either device or host, the application must not access registers from the other mode. If an illegal access occurs, a mode mismatch interrupt is generated and reflected in the core interrupt register (MMIS bit in the OTG\_GINTSTS register). When the core switches from one mode to the other, the registers in the new mode of operation must be reprogrammed as they would be after a power-on reset.

### 37.14.1 CSR memory map

The host and device mode registers occupy different addresses. All registers are implemented in the AHB clock domain.

#### Global CSR map

These registers are available in both host and device modes.

**Table 263. Core global control and status registers (CSRs)**

| Acronym     | Address offset | Register name                                                                  |

1. The general rule is to use OTG\_HNPTXFSIZ for host mode and OTG\_DIEPTXF0 for device mode.

### Host-mode CSR map

These registers must be programmed every time the core changes to host mode.

Table 264. Host-mode control and status registers (CSRs)

### Data FIFO (DFIFO) access register map

These registers, available in both host and device modes, are used to read or write the FIFO space for a specific endpoint or a channel, in a given direction. If a host channel is of type IN, the FIFO can only be read on the channel. Similarly, if a host channel is of type OUT, the FIFO can only be written on the channel.

Table 266. Data FIFO (DFIFO) access register map

| FIFO access register section                                                                                              | Offset address | Access |
|---------------------------------------------------------------------------------------------------------------------------|----------------|--------|

1. Where x is 5[FS] / 8[HS] in device mode and 11[FS] / 15[HS] in host mode.

### Power and clock gating CSR map

There is a single register for power and clock gating. It is available in both host and device modes.

Table 267. Power and clock gating control and status registers

| Acronym     | Offset address | Register name                                                                               |

## 37.15 OTG\_FS/OTG\_HS registers

These registers are available in both host and device modes, and do not need to be reprogrammed when switching between these modes.

Bit values in the register descriptions are expressed in binary unless otherwise specified.

### 37.15.1 OTG control and status register (OTG\_GOTGCTL)

Address offset: 0x000

Reset value: 0x0001 0000

The OTG\_GOTGCTL register controls the behavior and reflects the status of the OTG function of the core.

|      |      |      |      |         |          |        |         |           |          |           |          |            |           |      |         |

Bits 31:22 Reserved, must be kept at reset value.

Bit 21 **CURMOD**: Current mode of operation

Indicates the current mode (host or device).

0: Device mode

1: Host mode

Bit 20 **OTGVER**: OTG version

Selects the OTG revision.

0: OTG Version 1.3. OTG1.3 is obsolete for new product development.

1: OTG Version 2.0. In this version the core supports only data line pulsing for SRP.

Bit 19 **BSVLD**: B-session valid

Indicates the device mode transceiver status.

0: B-session is not valid.

1: B-session is valid.

In OTG mode, the user can use this bit to determine if the device is connected or disconnected.

*Note: Only accessible in device mode.*

Bit 18 **ASVLD**: A-session valid

Indicates the host mode transceiver status.

0: A-session is not valid

1: A-session is valid

*Note: Only accessible in host mode.*

Bit 17 **DBCT**: Long/short debounce time

Indicates the debounce time of a detected connection.

0: Long debounce time, used for physical connections (100 ms + 2.5  $\mu$ s)

1: Short debounce time, used for soft connections (2.5  $\mu$ s)

*Note: Only accessible in host mode.*

Bit 16 **CIDSTS**: Connector ID status

Indicates the connector ID status on a connect event.

0: The OTG\_FS/OTG\_HS controller is in A-device mode

1: The OTG\_FS/OTG\_HS controller is in B-device mode

*Note: Accessible in both device and host modes.*

Bits 15:13 Reserved, must be kept at reset value.

Bit 12 **EHEN**: Embedded host enable

It is used to select between OTG A device state machine and embedded host state machine.

0: OTG A device state machine is selected

1: Embedded host state machine is selected

Bit 11 **DHNPEN**: Device HNP enabled

The application sets this bit when it successfully receives a SetFeature.SetHNPEnable command from the connected USB host.

0: HNP is not enabled in the application

1: HNP is enabled in the application

*Note: Only accessible in device mode.*

**Bit 10 HSHNPEN:** host set HNP enable

The application sets this bit when it has successfully enabled HNP (using the SetFeature.SetHNPEnable command) on the connected device.

0: Host Set HNP is not enabled

1: Host Set HNP is enabled

*Note:* Only accessible in host mode.

**Bit 9 HNPRQ:** HNP request

The application sets this bit to initiate an HNP request to the connected USB host. The application can clear this bit by writing a 0 when the host negotiation success status change bit in the OTG\_GOTGINT register (HNSSCHG bit in OTG\_GOTGINT) is set. The core clears this bit when the HNSSCHG bit is cleared.

0: No HNP request

1: HNP request

*Note:* Only accessible in device mode.

**Bit 8 HNGSCS:** Host negotiation success

The core sets this bit when host negotiation is successful. The core clears this bit when the HNP request (HNPRQ) bit in this register is set.

0: Host negotiation failure

1: Host negotiation success

*Note:* Only accessible in device mode.

**Bit 7 BVALOVAL:** B-peripheral session valid override value.

This bit is used to set override value for Bvalid signal when BVALOEN bit is set.

0: Bvalid value is '0' when BVALOEN = 1

1: Bvalid value is '1' when BVALOEN = 1

*Note:* Only accessible in device mode.

**Bit 6 BVALOEN:** B-peripheral session valid override enable.

This bit is used to enable/disable the software to override the Bvalid signal using the BVALOVAL bit.

0: Override is disabled and Bvalid signal from the respective PHY selected is used internally by the core

1: Internally Bvalid received from the PHY is overridden with BVALOVAL bit value

*Note:* Only accessible in device mode.

**Bit 5 AVALOVAL:** A-peripheral session valid override value.

This bit is used to set override value for Avalid signal when AVALOEN bit is set.

0: Avalid value is '0' when AVALOEN = 1

1: Avalid value is '1' when AVALOEN = 1

*Note:* Only accessible in host mode.

**Bit 4 AVALOEN:** A-peripheral session valid override enable.

This bit is used to enable/disable the software to override the Avalid signal using the AVALOVAL bit.

0: Override is disabled and Avalid signal from the respective PHY selected is used internally by the core

1: Internally Avalid received from the PHY is overridden with AVALOVAL bit value

*Note:* Only accessible in host mode.

Bit 3 **VBVALOVAL**:  $V_{BUS}$  valid override value.

This bit is used to set override value for vbusvalid signal when VBVALOEN bit is set.

0: vbusvalid value is '0' when VBVALOEN = 1

1: vbusvalid value is '1' when VBVALOEN = 1

*Note:* Only accessible in host mode.

Bit 2 **VBVALOEN**:  $V_{BUS}$  valid override enable.

This bit is used to enable/disable the software to override the vbusvalid signal using the VBVALOVAL bit.

0: Override is disabled and vbusvalid signal from the respective PHY selected is used internally by the core

1: Internally vbusvalid received from the PHY is overridden with VBVALOVAL bit value

*Note:* Only accessible in host mode.

Bit 1 **SRQ**: Session request

The application sets this bit to initiate a session request on the USB. The application can clear this bit by writing a 0 when the host negotiation success status change bit in the OTG\_GOTGINT register (HNSSCHG bit in OTG\_GOTGINT) is set. The core clears this bit when the HNSSCHG bit is cleared.

If the user uses the USB 1.1 full-speed serial transceiver interface to initiate the session request, the application must wait until  $V_{BUS}$  discharges to 0.2 V, after the B-session valid bit in this register (BSVLD bit in OTG\_GOTGCTL) is cleared.

0: No session request

1: Session request

*Note:* Only accessible in device mode.

Bit 0 **SRQSCS**: Session request success

The core sets this bit when a session request initiation is successful.

0: Session request failure

1: Session request success

*Note:* Only accessible in device mode.

### 37.15.2 OTG interrupt register (OTG\_GOTGINT)

Address offset: 0x04

Reset value: 0x0000 0000

The application reads this register whenever there is an OTG interrupt and clears the bits in this register to clear the OTG interrupt.

|      |      |      |      |      |      |             |             |      |      |      |            |            |             |            |      |

Bits 31:21 Reserved, must be kept at reset value.

Bit 20 **IDCHNG**:

This bit when set indicates that there is a change in the value of the ID input pin.

Bit 19 **DBCONE**: Debounce done

The core sets this bit when the debounce is completed after the device connect. The application can start driving USB reset after seeing this interrupt. This bit is only valid when the HNP Capable or SRP Capable bit is set in the OTG\_GUSBCFG register (HNPCAP bit or SRPCAP bit in OTG\_GUSBCFG, respectively).

*Note: Only accessible in host mode.*

Bit 18 **ADTOCHG**: A-device timeout change

The core sets this bit to indicate that the A-device has timed out while waiting for the B-device to connect.

*Note: Accessible in both device and host modes.*

Bit 17 **HNGDET**: Host negotiation detected

The core sets this bit when it detects a host negotiation request on the USB.

*Note: Accessible in both device and host modes.*

Bits 16:10 Reserved, must be kept at reset value.

Bit 9 **HNSSCHG**: Host negotiation success status change

The core sets this bit on the success or failure of a USB host negotiation request. The application must read the host negotiation success bit of the OTG\_GOTGCTL register (HNGSCS bit in OTG\_GOTGCTL) to check for success or failure.

*Note: Accessible in both device and host modes.*

Bits 7:3 Reserved, must be kept at reset value.

Bit 8 **SRSSCHG**: Session request success status change

The core sets this bit on the success or failure of a session request. The application must read the session request success bit in the OTG\_GOTGCTL register (SRQSCS bit in OTG\_GOTGCTL) to check for success or failure.

*Note: Accessible in both device and host modes.*

Bit 2 **SEDET**: Session end detected

The core sets this bit to indicate that the level of the voltage on  $V_{BUS}$  is no longer valid for a B-Peripheral session when  $V_{BUS} < 0.8$  V.

*Note: Accessible in both device and host modes.*

Bits 1:0 Reserved, must be kept at reset value.

### 37.15.3 OTG AHB configuration register (OTG\_GAHBCFG)

Address offset: 0x008

Reset value: 0x0000 0000

This register can be used to configure the core after power-on or a change in mode. This register mainly contains AHB system-related configuration parameters. Do not change this register after the initial programming. The application must program this register before starting any transactions on either the AHB or the USB.

**Note:** Configuration register for USB OTG HS

Bits 31:9 Reserved, must be kept at reset value.

Bit 8 **PTXFELVL**: Periodic Tx FIFO empty level

Indicates when the periodic Tx FIFO empty interrupt bit in the OTG\_GINTSTS register (PTXFE bit in OTG\_GINTSTS) is triggered.

0: PTXFE (in OTG\_GINTSTS) interrupt indicates that the Periodic Tx FIFO is half empty

1: PTXFE (in OTG\_GINTSTS) interrupt indicates that the Periodic Tx FIFO is completely empty

*Note: Only accessible in host mode.*

Bit 7 **TXFELVL**: Tx FIFO empty level

In device mode, this bit indicates when IN endpoint Transmit FIFO empty interrupt (TXFE in OTG\_DIEPINTx) is triggered:

0: The TXFE (in OTG\_DIEPINTx) interrupt indicates that the IN endpoint Tx FIFO is half empty

1: The TXFE (in OTG\_DIEPINTx) interrupt indicates that the IN endpoint Tx FIFO is completely empty

In host mode, this bit indicates when the nonperiodic Tx FIFO empty interrupt (NPTXFE bit in OTG\_GINTSTS) is triggered:

0: The NPTXFE (in OTG\_GINTSTS) interrupt indicates that the nonperiodic Tx FIFO is half empty

1: The NPTXFE (in OTG\_GINTSTS) interrupt indicates that the nonperiodic Tx FIFO is completely empty

Bits 6:1 Reserved, must be kept at reset value for USB OTG FS.

Bit 6 Reserved, must be kept at reset value for USB OTG HS.

Bit 5 **DMAEN**: DMA enabled for USB OTG HS

0: The core operates in slave mode

1: The core operates in DMA mode

Bits 4:1 **HBSTLEN[3:0]**: Burst length/type for USB OTG HS

0000 Single: Bus transactions use single 32 bit accesses (not recommended)

0001 INCR: Bus transactions use unspecified length accesses (not recommended, uses the INCR AHB bus command)

0011 INCR4: Bus transactions target 4x 32 bit accesses

0101 INCR8: Bus transactions target 8x 32 bit accesses

0111 INCR16: Bus transactions based on 16x 32 bit accesses

Others: Reserved

Bit 0 **GINTMSK**: Global interrupt mask

The application uses this bit to mask or unmask the interrupt line assertion to itself.

Irrespective of this bit's setting, the interrupt status registers are updated by the core.

0: Mask the interrupt assertion to the application.

1: Unmask the interrupt assertion to the application.

*Note: Accessible in both device and host modes.*

### 37.15.4 OTG USB configuration register (OTG\_GUSBCFG)

Address offset: 0x00C

Reset value: 0x0000 1440 for USB OTG FS

Reset value: 0x0000 1400 for USB OTG HS

This register can be used to configure the core after power-on or a changing to host mode or device mode. It contains USB and USB-PHY related configuration parameters. The application must program this register before starting any transactions on either the AHB or the USB. Do not make changes to this register after the initial programming.

**Note:** Configuration register for USB OTG HS

Bit 31 Reserved, must be kept at reset value.

Bit 30 **FDMOD**: Force device mode

Writing a 1 to this bit, forces the core to device mode irrespective of the OTG\_ID input pin.

0: Normal mode

1: Force device mode

After setting the force bit, the application must wait at least 25 ms before the change takes effect.

**Note:** Accessible in both device and host modes.

Bit 29 **FHMOD**: Force host mode

Writing a 1 to this bit, forces the core to host mode irrespective of the OTG\_ID input pin.

0: Normal mode

1: Force host mode

After setting the force bit, the application must wait at least 25 ms before the change takes effect.

**Note:** Accessible in both device and host modes.

Bits 28:26 Reserved, must be kept at reset value.

- Bit 25 **ULPIPD**: ULPI interface protect disable for USB OTG HS  
 This bit controls the circuitry built in the PHY to protect the ULPI interface when the link tri-states stp and data. Any pull-up or pull-down resistors employed by this feature can be disabled. Refer to the ULPI specification for more details.  
 0: Enables the interface protection circuit  
 1: Disables the interface protection circuit
- Bit 24 **PTCI**: Indicator pass through for USB OTG HS  
 This bit controls whether the complement output is qualified with the internal  $V_{BUS}$  valid comparator before being used in the  $V_{BUS}$  state in the RX CMD. Refer to the ULPI specification for more details.  
 0: Complement Output signal is qualified with the Internal  $V_{BUS}$  valid comparator  
 1: Complement Output signal is not qualified with the Internal  $V_{BUS}$  valid comparator
- Bit 23 **PCCI**: Indicator complement for USB OTG HS  
 This bit controls the PHY to invert the ExternalVbusIndicator input signal, and generate the complement output. Refer to the ULPI specification for more details.  
 0: PHY does not invert the ExternalVbusIndicator signal  
 1: PHY inverts ExternalVbusIndicator signal
- Bit 22 **TSDPS**: TermSel DLine pulsing selection for USB OTG HS  
 This bit selects utmi\_termselect to drive the data line pulse during SRP (session request protocol).  
 0: Data line pulsing using utmi\_txvalid (default)  
 1: Data line pulsing using utmi\_termsel
- Bit 21 **ULPIVBUSI**: ULPI external  $V_{BUS}$  indicator for USB OTG HS  
 This bit indicates to the ULPI PHY to use an external  $V_{BUS}$  overcurrent indicator.  
 0: PHY uses an internal  $V_{BUS}$  valid comparator  
 1: PHY uses an external  $V_{BUS}$  valid comparator
- Bit 20 **ULPIVBUSD**: ULPI External  $V_{BUS}$  Drive for USB OTG HS  
 This bit selects between internal or external supply to drive 5 V on  $V_{BUS}$ , in the ULPI PHY.  
 0: PHY drives  $V_{BUS}$  using internal charge pump (default)  
 1: PHY drives  $V_{BUS}$  using external supply.
- Bit 19 **ULPICSM**: ULPI clock SuspendM for USB OTG HS  
 This bit sets the ClockSuspendM bit in the interface control register on the ULPI PHY. This bit applies only in the serial and carkit modes.  
 0: PHY powers down the internal clock during suspend  
 1: PHY does not power down the internal clock
- Bit 18 **ULPIAR**: ULPI Auto-resume for USB OTG HS  
 This bit sets the AutoResume bit in the interface control register on the ULPI PHY.  
 0: PHY does not use AutoResume feature  
 1: PHY uses AutoResume feature
- Bit 17 **ULPIFSL**: ULPI FS/LS select for USB OTG HS  
 The application uses this bit to select the FS/LS serial interface for the ULPI PHY. This bit is valid only when the FS serial transceiver is selected on the ULPI PHY.  
 0: ULPI interface  
 1: ULPI FS/LS serial interface
- Bit 16 Reserved, must be kept at reset value.

Bit 15 **PHYLPC**: PHY Low-power clock select for USB OTG HS

This bit selects either 480 MHz or 48 MHz (low-power) PHY mode. In FS and LS modes, the PHY can usually operate on a 48 MHz clock to save power.

0: 480 MHz internal PLL clock

1: 48 MHz external clock

In 480 MHz mode, the UTMI interface operates at either 60 or 30 MHz, depending on whether the 8- or 16-bit data width is selected. In 48 MHz mode, the UTMI interface operates at 48 MHz in FS and LS modes.

Bit 14 Reserved, must be kept at reset value.

Bits 13:10 **TRDT[3:0]**: USB turnaround time

These bits allow to set the turnaround time in PHY clocks. They must be configured according to [Table 268: TRDT values \(FS\)](#) or [Table 269: TRDT values \(HS\)](#), depending on the application AHB frequency. Higher TRDT values allow stretching the USB response time to IN tokens in order to compensate for longer AHB read access latency to the data FIFO.

*Note: Only accessible in device mode.*

Bit 9 **HNPcap**: HNP-capable

The application uses this bit to control the OTG\_FS/OTG\_HS controller's HNP capabilities.

0: HNP capability is not enabled.

1: HNP capability is enabled.

*Note: Accessible in both device and host modes.*

Bit 8 **SRPcap**: SRP-capable

The application uses this bit to control the OTG\_FS/OTG\_HS controller's SRP capabilities. If the core operates as a non-SRP-capable

B-device, it cannot request the connected A-device (host) to activate  $V_{BUS}$  and start a session.

0: SRP capability is not enabled.

1: SRP capability is enabled.

*Note: Accessible in both device and host modes.*

Bit 7 Reserved, must be kept at reset value.

Bit 6 **PHYSEL**: Full Speed serial transceiver select for USB OTG FS

This bit is always 1 with read-only access.

Bit 6 **PHYSEL**: Full speed serial transceiver select for USB OTG HS

0: USB 2.0 external ULPI high-speed PHY.

1: USB 1.1 full-speed serial transceiver.

Bit 5 Reserved, must be kept at reset value.

Bit 4 Reserved, must be kept at reset value.

Bit 3 Reserved, must be kept at reset value.

Bits 2:0 **TOCAL[2:0]**: FS timeout calibration

The number of PHY clocks that the application programs in this field is added to the full-speed interpacket timeout duration in the core to account for any additional delays introduced by the PHY. This can be required, because the delay introduced by the PHY in generating the line state condition can vary from one PHY to another.

The USB standard timeout value for full-speed operation is 16 to 18 (inclusive) bit times. The application must program this field based on the speed of enumeration. The number of bit times added per PHY clock is 0.25 bit times.

Table 268. TRDT values (FS)

| AHB frequency range (MHz) |      | TRDT minimum value |
|---------------------------|------|--------------------|
| Min                       | Max  |                    |
| 14.2                      | 15   | 0xF                |
| 15                        | 16   | 0xE                |
| 16                        | 17.2 | 0xD                |
| 17.2                      | 18.5 | 0xC                |
| 18.5                      | 20   | 0xB                |
| 20                        | 21.8 | 0xA                |
| 21.8                      | 24   | 0x9                |
| 24                        | 27.5 | 0x8                |
| 27.5                      | 32   | 0x7                |
| 32                        | -    | 0x6                |

Table 269. TRDT values (HS)

| AHB frequency range (MHz) |     | TRDT minimum value |
|---------------------------|-----|--------------------|
| Min                       | Max |                    |
| 30                        | -   | 0x9                |

### 37.15.5 OTG reset register (OTG\_GRSTCTL)

Address offset: 0x10

Reset value: 0x8000 0000

The application uses this register to reset various hardware features inside the core.

|         |      |      |      |      |        |      |      |      |      |          |          |      |       |       |       |

**Note:** Configuration register for USB OTG HS

**Bit 31 AHBIDL:** AHB master idle

Indicates that the AHB master state machine is in the Idle condition.

*Note:* Accessible in both device and host modes.

Bits 30:11 Reserved, must be kept at reset value for USB OTG FS.

**Bit 30 DMAREQ:** DMA request signal enabled for USB OTG HS

This bit indicates that the DMA request is in progress. Used for debug.

Bits 29:11 Reserved, must be kept at reset value for USB OTG HS.

**Bits 10:6 TXFNUM[4:0]:** Tx FIFO number

This is the FIFO number that must be flushed using the Tx FIFO Flush bit. This field must not be changed until the core clears the Tx FIFO Flush bit.

00000:

- Non-periodic Tx FIFO flush in host mode
- Tx FIFO 0 flush in device mode

00001:

- Periodic Tx FIFO flush in host mode
- Tx FIFO 1 flush in device mode

00010: Tx FIFO 2 flush in device mode

...

01111: Tx FIFO 15 flush in device mode

10000: Flush all the transmit FIFOs in device or host mode.

*Note:* Accessible in both device and host modes.

**Bit 5 TXFFLSH:** Tx FIFO flush

This bit selectively flushes a single or all transmit FIFOs, but cannot do so if the core is in the midst of a transaction.

The application must write this bit only after checking that the core is neither writing to the Tx FIFO nor reading from the Tx FIFO. Verify using these registers:

Read—NAK Effective interrupt ensures the core is not reading from the FIFO

Write—AHBIDL bit in OTG\_GRSTCTL ensures the core is not writing anything to the FIFO.

Flushing is normally recommended when FIFOs are reconfigured. FIFO flushing is also recommended during device endpoint disable. The application must wait until the core clears this bit before performing any operations. This bit takes eight clocks to clear, using the slower clock of phy\_clk or hclk.

*Note:* Accessible in both device and host modes.

Bit 4 **RXFFLSH**: Rx FIFO flush

The application can flush the entire Rx FIFO using this bit, but must first ensure that the core is not in the middle of a transaction.

The application must only write to this bit after checking that the core is neither reading from the Rx FIFO nor writing to the Rx FIFO.

The application must wait until the bit is cleared before performing any other operations. This bit requires 8 clocks (slowest of PHY or AHB clock) to clear.

*Note: Accessible in both device and host modes.*

## Bit 3 Reserved, must be kept at reset value.

Bit 2 **FCRST**: Host frame counter reset for USB OTG FS

The application writes this bit to reset the frame number counter inside the core. When the frame counter is reset, the subsequent SOF sent out by the core has a frame number of 0.

When application writes '1' to the bit, it might not be able to read back the value as it will get cleared by the core in a few clock cycles.

*Note: Only accessible in host mode.*

## Bit 2 Reserved, must be kept at reset value for USB OTG HS.

Bit 1 **PSRST**: Partial soft reset

Resets the internal state machines but keeps the enumeration info. Could be used to recover some specific PHY errors.

*Note: Accessible in both device and host modes.*

Bit 0 **CSRST**: Core soft reset

Resets the HCLK and PHY clock domains as follows:

Clears the interrupts and all the CSR register bits except for the following bits:

- GATEHCLK bit in OTG\_PCGCCTL
- STPPCLK bit in OTG\_PCGCCTL
- FSLSPCS bits in OTG\_HCFG
- DSPD bit in OTG\_DCFG
- SDIS bit in OTG\_DCTL
- OTG\_GCCFG register

All module state machines (except for the AHB slave unit) are reset to the Idle state, and all the transmit FIFOs and the receive FIFO are flushed.

Any transactions on the AHB Master are terminated as soon as possible, after completing the last data phase of an AHB transfer. Any transactions on the USB are terminated immediately.

The application can write to this bit any time it wants to reset the core. This is a self-clearing bit and the core clears this bit after all the necessary logic is reset in the core, which can take several clocks, depending on the current state of the core. Once this bit has been cleared, the software must wait at least 3 PHY clocks before accessing the PHY domain (synchronization delay). The software must also check that bit 31 in this register is set to 1 (AHB Master is Idle) before starting any operation.

Typically, the software reset is used during software development and also when the user dynamically changes the PHY selection bits in the above listed USB configuration registers. When you change the PHY, the corresponding clock for the PHY is selected and used in the PHY domain. Once a new clock is selected, the PHY domain has to be reset for proper operation.

*Note: Accessible in both device and host modes.*

### 37.15.6 OTG core interrupt register (OTG\_GINTSTS)

Address offset: 0x014

Reset value: 0x1400 0020

This register interrupts the application for system-level events in the current mode (device mode or host mode).

Some of the bits in this register are valid only in host mode, while others are valid in device mode only. This register also indicates the current mode. To clear the interrupt status bits of the rc\_w1 type, the application must write 1 into the bit.

The FIFO status interrupts are read-only; once software reads from or writes to the FIFO while servicing these interrupts, FIFO interrupt conditions are cleared automatically.

The application must clear the OTG\_GINTSTS register at initialization before unmasking the interrupt bit to avoid any interrupts generated prior to initialization.

**Note:** Configuration register for USB OTG HS

- Bit 31 **WKUPINT**: Resume/remote wakeup detected interrupt  
 Wakeup interrupt during suspend(L2) or LPM(L1) state.  
 – During suspend(L2):  
 In device mode, this interrupt is asserted when a resume is detected on the USB. In host mode, this interrupt is asserted when a remote wakeup is detected on the USB.  
 – During LPM(L1):  
 This interrupt is asserted for either host initiated resume or device initiated remote wakeup on USB.  
*Note: Accessible in both device and host modes.*
- Bit 30 **SRQINT**: Session request/new session detected interrupt  
 In host mode, this interrupt is asserted when a session request is detected from the device.  
 In device mode, this interrupt is asserted when  $V_{BUS}$  is in the valid range for a B-peripheral device. Accessible in both device and host modes.
- Bit 29 **DISCINT**: Disconnect detected interrupt  
 Asserted when a device disconnect is detected.  
*Note: Only accessible in host mode.*
- Bit 28 **CIDSCHG**: Connector ID status change  
 The core sets this bit when there is a change in connector ID status.  
*Note: Accessible in both device and host modes.*
- Bit 27 **LPMINT**: LPM interrupt  
 In device mode, this interrupt is asserted when the device receives an LPM transaction and responds with a non-ERRORed response.  
 In host mode, this interrupt is asserted when the device responds to an LPM transaction with a non-ERRORed response or when the host core has completed LPM transactions for the programmed number of times (RETRYCNT bit in OTG\_GLPMCFG).  
 This field is valid only if the LPMEN bit in OTG\_GLPMCFG is set to 1.
- Bit 27 Reserved, must be kept at reset value for USB OTG FS.
- Bit 26 **PTXFE**: Periodic Tx FIFO empty  
 Asserted when the periodic transmit FIFO is either half or completely empty and there is space for at least one entry to be written in the periodic request queue. The half or completely empty status is determined by the periodic Tx FIFO empty level bit in the OTG\_GAHBCFG register (PTXFELVL bit in OTG\_GAHBCFG).  
*Note: Only accessible in host mode.*
- Bit 25 **HCINT**: Host channels interrupt  
 The core sets this bit to indicate that an interrupt is pending on one of the channels of the core (in host mode). The application must read the OTG\_HAINT register to determine the exact number of the channel on which the interrupt occurred, and then read the corresponding OTG\_HCINTx register to determine the exact cause of the interrupt. The application must clear the appropriate status bit in the OTG\_HCINTx register to clear this bit.  
*Note: Only accessible in host mode.*
- Bit 24 **HPRTINT**: Host port interrupt  
 The core sets this bit to indicate a change in port status of one of the OTG\_FS/OTG\_HS controller ports in host mode. The application must read the OTG\_HPRT register to determine the exact event that caused this interrupt. The application must clear the appropriate status bit in the OTG\_HPRT register to clear this bit.  
*Note: Only accessible in host mode.*

Bit 23 **RSTDET**: Reset detected interrupt

In device mode, this interrupt is asserted when a reset is detected on the USB in partial power-down mode when the device is in suspend.

*Note: Only accessible in device mode.*

Bit 23 Reserved, must be kept at reset value for USB OTG HS.

Bit 22 Reserved, must be kept at reset value for USB OTG FS.

Bit 22 **DATAFSUSP**: Data fetch suspended for USB OTG HS

This interrupt is valid only in DMA mode. This interrupt indicates that the core has stopped fetching data for IN endpoints due to the unavailability of TxFIFO space or request queue space. This interrupt is used by the application for an endpoint mismatch algorithm. For example, after detecting an endpoint mismatch, the application:

- Sets a global nonperiodic IN NAK handshake
- Disables IN endpoints
- Flushes the FIFO
- Determines the token sequence from the IN token sequence learning queue
- Re-enables the endpoints

Clears the global nonperiodic IN NAK handshake If the global nonperiodic IN NAK is cleared, the core has not yet fetched data for the IN endpoint, and the IN token is received: the core generates an “IN token received when FIFO empty” interrupt. The OTG then sends a NAK response to the host. To avoid this scenario, the application can check the FetSusp interrupt in OTG\_GINTSTS, which ensures that the FIFO is full before clearing a global NAK handshake. Alternatively, the application can mask the “IN token received when FIFO empty” interrupt when clearing a global IN NAK handshake.

Bit 21 **IPXFR**: Incomplete periodic transfer

In host mode, the core sets this interrupt bit when there are incomplete periodic transactions still pending, which are scheduled for the current frame.

**INCOMPISOOUT**: Incomplete isochronous OUT transfer

In device mode, the core sets this interrupt to indicate that there is at least one isochronous OUT endpoint on which the transfer is not completed in the current frame. This interrupt is asserted along with the End of periodic frame interrupt (EOPF) bit in this register.

Bit 20 **IISOIXFR**: Incomplete isochronous IN transfer

The core sets this interrupt to indicate that there is at least one isochronous IN endpoint on which the transfer is not completed in the current frame. This interrupt is asserted along with the End of periodic frame interrupt (EOPF) bit in this register.

*Note: Only accessible in device mode.*

Bit 19 **OEPINT**: OUT endpoint interrupt

The core sets this bit to indicate that an interrupt is pending on one of the OUT endpoints of the core (in device mode). The application must read the OTG\_DAIN register to determine the exact number of the OUT endpoint on which the interrupt occurred, and then read the corresponding OTG\_DOEPINTx register to determine the exact cause of the interrupt. The application must clear the appropriate status bit in the corresponding OTG\_DOEPINTx register to clear this bit.

*Note: Only accessible in device mode.*

**Bit 18 IEPINT:** IN endpoint interrupt

The core sets this bit to indicate that an interrupt is pending on one of the IN endpoints of the core (in device mode). The application must read the OTG\_DAIN register to determine the exact number of the IN endpoint on which the interrupt occurred, and then read the corresponding OTG\_DIEPINTx register to determine the exact cause of the interrupt. The application must clear the appropriate status bit in the corresponding OTG\_DIEPINTx register to clear this bit.

*Note: Only accessible in device mode.*

Bits 17:16 Reserved, must be kept at reset value.

**Bit 15 EOPF:** End of periodic frame interrupt

Indicates that the period specified in the periodic frame interval field of the OTG\_DCFG register (PFIVL bit in OTG\_DCFG) has been reached in the current frame.

*Note: Only accessible in device mode.*

**Bit 14 ISOODRP:** Isochronous OUT packet dropped interrupt

The core sets this bit when it fails to write an isochronous OUT packet into the Rx FIFO because the Rx FIFO does not have enough space to accommodate a maximum size packet for the isochronous OUT endpoint.

*Note: Only accessible in device mode.*

**Bit 13 ENUMDNE:** Enumeration done

The core sets this bit to indicate that speed enumeration is complete. The application must read the OTG\_DSTS register to obtain the enumerated speed.

*Note: Only accessible in device mode.*

**Bit 12 USBRST:** USB reset

The core sets this bit to indicate that a reset is detected on the USB.

*Note: Only accessible in device mode.*

**Bit 11 USBSUSP:** USB suspend

The core sets this bit to indicate that a suspend was detected on the USB. The core enters the suspended state when there is no activity on the data lines for an extended period of time.

*Note: Only accessible in device mode.*

**Bit 10 ESUSP:** Early suspend

The core sets this bit to indicate that an Idle state has been detected on the USB for 3 ms.

*Note: Only accessible in device mode.*

Bits 9:8 Reserved, must be kept at reset value.

**Bit 7 GONAKEFF:** Global OUT NAK effective

Indicates that the Set global OUT NAK bit in the OTG\_DCTL register (SGONAK bit in OTG\_DCTL), set by the application, has taken effect in the core. This bit can be cleared by writing the Clear global OUT NAK bit in the OTG\_DCTL register (CGONAK bit in OTG\_DCTL).

*Note: Only accessible in device mode.*

Bit 6 **GINAKEFF**: Global IN non-periodic NAK effective

Indicates that the Set global non-periodic IN NAK bit in the OTG\_DCTL register (SGINAK bit in OTG\_DCTL), set by the application, has taken effect in the core. That is, the core has sampled the Global IN NAK bit set by the application. This bit can be cleared by clearing the Clear global non-periodic IN NAK bit in the OTG\_DCTL register (CGINAK bit in OTG\_DCTL).

This interrupt does not necessarily mean that a NAK handshake is sent out on the USB. The STALL bit takes precedence over the NAK bit.

*Note: Only accessible in device mode.*

Bit 5 **NPTXFE**: Non-periodic Tx FIFO empty

This interrupt is asserted when the non-periodic Tx FIFO is either half or completely empty, and there is space for at least one entry to be written to the non-periodic transmit request queue. The half or completely empty status is determined by the non-periodic Tx FIFO empty level bit in the OTG\_GAHBCFG register (TXFELVL bit in OTG\_GAHBCFG).

*Note: Accessible in host mode only.*

Bit 4 **RXFLVL**: Rx FIFO non-empty

Indicates that there is at least one packet pending to be read from the Rx FIFO.

*Note: Accessible in both host and device modes.*

Bit 3 **SOF**: Start of frame

In host mode, the core sets this bit to indicate that an SOF (FS), or Keep-Alive (LS) is transmitted on the USB. The application must write a 1 to this bit to clear the interrupt.

In device mode, the core sets this bit to indicate that an SOF token has been received on the USB. The application can read the OTG\_DSTS register to get the current frame number. This interrupt is seen only when the core is operating in FS.

*Note: This register may return '1' if read immediately after power on reset. If the register bit reads '1' immediately after power on reset it does not indicate that an SOF has been sent (in case of host mode) or SOF has been received (in case of device mode). The read value of this interrupt is valid only after a valid connection between host and device is established. If the bit is set after power on reset the application can clear the bit.*

*Note: Accessible in both host and device modes.*

Bit 2 **OTGINT**: OTG interrupt

The core sets this bit to indicate an OTG protocol event. The application must read the OTG interrupt status (OTG\_GOTGINT) register to determine the exact event that caused this interrupt. The application must clear the appropriate status bit in the OTG\_GOTGINT register to clear this bit.

*Note: Accessible in both host and device modes.*

Bit 1 **MMIS**: Mode mismatch interrupt

The core sets this bit when the application is trying to access:

- A host mode register, when the core is operating in device mode
- A device mode register, when the core is operating in host mode

The register access is completed on the AHB with an OKAY response, but is ignored by the core internally and does not affect the operation of the core.

*Note: Accessible in both host and device modes.*

Bit 0 **CMOD**: Current mode of operation

Indicates the current mode.

0: Device mode

1: Host mode

*Note: Accessible in both host and device modes.*

### 37.15.7 OTG interrupt mask register (OTG\_GINTMSK)

Address offset: 0x018

Reset value: 0x0000 0000

This register works with the core interrupt register to interrupt the application. When an interrupt bit is masked, the interrupt associated with that bit is not generated. However, the core interrupt (OTG\_GINTSTS) register bit corresponding to that interrupt is still set.

1: Unmasked interrupt

*Note: Only accessible in device mode.*

Bits 9:8 Reserved, must be kept at reset value.

Bit 7 **GONAKEFFM**: Global OUT NAK effective mask

0: Masked interrupt

1: Unmasked interrupt

*Note: Only accessible in device mode.*

Bit 6 **GINAKEFFM**: Global non-periodic IN NAK effective mask

0: Masked interrupt

1: Unmasked interrupt

*Note: Only accessible in device mode.*

Bit 5 **NPTXFEM**: Non-periodic Tx FIFO empty mask

0: Masked interrupt

1: Unmasked interrupt

*Note: Only accessible in host mode.*

Bit 4 **RXFLVLM**: Receive FIFO non-empty mask

0: Masked interrupt

1: Unmasked interrupt

*Note: Accessible in both device and host modes.*

Bit 3 **SOFM**: Start of frame mask

- 0: Masked interrupt
- 1: Unmasked interrupt

*Note: Accessible in both device and host modes.*

Bit 2 **OTGINT**: OTG interrupt mask

- 0: Masked interrupt
- 1: Unmasked interrupt

*Note: Accessible in both device and host modes.*

Bit 1 **MMISM**: Mode mismatch interrupt mask

- 0: Masked interrupt
- 1: Unmasked interrupt

*Note: Accessible in both device and host modes.*

Bit 0 Reserved, must be kept at reset value.

### 37.15.8 OTG receive status debug read/OTG status read and pop registers (OTG\_GRXSTSR/OTG\_GRXSTSP)

Address offset for read: 0x01C

Address offset for pop: 0x020

Reset value: 0x0000 0000

A read to the receive status debug read register returns the contents of the top of the receive FIFO. A read to the receive status read and pop register additionally pops the top data entry out of the Rx FIFO.

The receive status contents must be interpreted differently in host and device modes. The core ignores the receive status pop/read when the receive FIFO is empty and returns a value of 0x0000 0000. The application must only pop the receive status FIFO when the receive FIFO non-empty bit of the core interrupt register (RXFLVL bit in OTG\_GINTSTS) is asserted.

#### Host mode:

Bits 31:21 Reserved, must be kept at reset value.

Bits 20:17 **PKTSTS[3:0]**: Packet status

Indicates the status of the received packet

0010: IN data packet received

0011: IN transfer completed (triggers an interrupt)

0101: Data toggle error (triggers an interrupt)

0111: Channel halted (triggers an interrupt)

Others: Reserved

Bits 16:15 **DPID**: Data PID

Indicates the data PID of the received packet

00: DATA0

10: DATA1

01: DATA2

11: MDATA

Bits 14:4 **BCNT[10:0]**: Byte count

Indicates the byte count of the received IN data packet.

Bits 3:0 **CHNUM[3:0]**: Channel number

Indicates the channel number to which the current received packet belongs.

**Device mode:**

Bits 31:28 Reserved, must be kept at reset value.

Bit 27 **STSPHST**: Status phase start

Indicates the start of the status phase for a control write transfer. This bit is set along with the OUT transfer completed PKTSTS pattern.

Bits 26:25 Reserved, must be kept at reset value.

Bits 24:21 **FRMNUM[3:0]**: Frame number

This is the least significant 4 bits of the frame number in which the packet is received on the USB. This field is supported only when isochronous OUT endpoints are supported.

Bits 20:17 **PKTSTS[3:0]**: Packet status

Indicates the status of the received packet

0001: Global OUT NAK (triggers an interrupt)

0010: OUT data packet received

0011: OUT transfer completed (triggers an interrupt)

0100: SETUP transaction completed (triggers an interrupt)

0110: SETUP data packet received

Others: Reserved

Bits 16:15 **DPID[1:0]**: Data PID

Indicates the data PID of the received OUT data packet

00: DATA0

10: DATA1

01: DATA2

11: MDATA

Bits 14:4 **BCNT[10:0]**: Byte count

Indicates the byte count of the received data packet.

Bits 3:0 **EPNUM[3:0]**: Endpoint number

Indicates the endpoint number to which the current received packet belongs.

### 37.15.9 OTG receive FIFO size register (OTG\_GRXFSIZ)

Address offset: 0x024

Reset value: 0x0000 0200 for USB OTG FS

Reset value: 0x0000 0400 for USB OTG HS

The application can program the RAM size that must be allocated to the Rx FIFO.

|            |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **RXFD[15:0]**: Rx FIFO depth

This value is in terms of 32-bit words.

Minimum value is 16

Maximum value is 1024

Programmed values must respect the available FIFO memory allocation and must not exceed the power-on value.

### 37.15.10 OTG host non-periodic transmit FIFO size register (OTG\_HNPTXFSIZ)/Endpoint 0 Transmit FIFO size (OTG\_DIEPTXF0)

Address offset: 0x028

Reset value: 0x0200 0200

|                      |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

| NPTXFSA/TX0FSA[15:0] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw                   | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

#### Host mode

Bits 31:16 **NPTXFD[15:0]**: Non-periodic Tx FIFO depth

This value is in terms of 32-bit words.

Minimum value is 16

Programmed values must respect the available FIFO memory allocation and must not exceed the power-on value.

Bits 15:0 **NPTXFSA[15:0]**: Non-periodic transmit RAM start address

This field configures the memory start address for non-periodic transmit FIFO RAM.

## Device mode

Bits 31:16 **TX0FD**: Endpoint 0 Tx FIFO depth

This value is in terms of 32-bit words.

Minimum value is 16

Programmed values must respect the available FIFO memory allocation and must not exceed the power-on value.

Bits 15:0 **TX0FSA**: Endpoint 0 transmit RAM start address

This field configures the memory start address for the endpoint 0 transmit FIFO RAM.

### 37.15.11 OTG non-periodic transmit FIFO/queue status register (OTG\_HNPTXSTS)

Address offset: 0x02C

Reset value: 0x0008 0200 for USB OTG FS

Reset value: 0x0008 0400 for USB OTG HS

**Note:** *In device mode, this register is not valid.*

This read-only register contains the free space information for the non-periodic Tx FIFO and the non-periodic transmit request queue.

| 31             | 30            | 29 | 28 | 27 | 26 | 25 | 24 | 23            | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

Bit 31 Reserved, must be kept at reset value.

Bits 30:24 **NPTXQTOP[6:0]**: Top of the non-periodic transmit request queue

Entry in the non-periodic Tx request queue that is currently being processed by the MAC.

Bits 30:27: Channel/endpoint number

Bits 26:25:

00: IN/OUT token

01: Zero-length transmit packet (device IN/host OUT)

11: Channel halt command

Bit 24: Terminate (last entry for selected channel/endpoint)

Bits 23:16 **NPTQXSAV[7:0]**: Non-periodic transmit request queue space available

Indicates the amount of free space available in the non-periodic transmit request queue.

This queue holds both IN and OUT requests.

0: Non-periodic transmit request queue is full

1: 1 location available

2: locations available

n: n locations available ( $0 \leq n \leq 8$ )

Others: Reserved

Bits 15:0 **NPTXFSAV[15:0]**: Non-periodic Tx FIFO space available

Indicates the amount of free space available in the non-periodic Tx FIFO.

Values are in terms of 32-bit words.

0: Non-periodic Tx FIFO is full

1: 1 word available

2: 2 words available

n: n words available (where  $0 \leq n \leq 512$ )

Others: Reserved

### 37.15.12 OTG general core configuration register (OTG\_GCCFG)

Address offset: 0x038

Reset value: 0x0000 XXXX

|      |      |      |      |      |      |      |      |      |      |       |      |      |           |      |            |

|      |      |      |      |      |      |      |      |      |      |       |      |      |           |      | r          |

Bits 31:22 Reserved, must be kept at reset value.

Bit 21 **VBDEN**: USB  $V_{BUS}$  detection enable

Enables  $V_{BUS}$  sensing comparators to detect  $V_{BUS}$  valid levels on the  $V_{BUS}$  PAD for USB host and device operation. If HNP and/or SRP support is enabled,  $V_{BUS}$  comparators are automatically enabled independently of VBDEN value.

0 =  $V_{BUS}$  detection disabled

1 =  $V_{BUS}$  detection enabled

Bits 20:19 Reserved, must be kept at reset value.

Bit 18 **DCDEN**: Data contact detection (DCD) mode enable

This bit is set by the software to put the BCD into DCD mode. Only one detection mode (DCD, PD, SD or OFF) should be selected to work correctly.

Bit 17 Reserved, must be kept at reset value.

Bit 16 **PWRDWN**: Power down control

Used to activate the transceiver in transmission/reception. When reset, the transceiver is kept in power-down. 0 = USB FS transceiver disabled

1 = USB FS transceiver enabled

Bits 15:4 Reserved, must be kept at reset value.

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **DCDET**: Data contact detection (DCD) status

This bit gives the result of DCD.

0: data lines contact not detected

1: data lines contact detected

### 37.15.13 OTG core ID register (OTG\_CID)

Address offset: 0x03C

Reset value: 0x0000 2000 for USB OTG FS

Reset value: 0x0000 2100 for USB OTG HS

This is a register containing the Product ID as reset value.

|                   |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

| 15         | 14          | 13   | 12         | 11              | 10 | 9  | 8          | 7            | 6           | 5         | 4             | 3    | 2    | 1           | 0         |
| SLP<br>STS | LPMRSP[1:0] |      | L1DS<br>EN | BESLTHRS[3:0]   |    |    |            | L1SS<br>EN   | REM<br>WAKE | BESL[3:0] |               |      |      | LPM<br>ACK  | LPM<br>EN |
| r          | r           | r    | rw         | rw              | rw | rw | rw         | rw           | rw/r        | rw/r      | rw/r          | rw/r | rw/r | rw          | rw        |

Bits 31:29 Reserved, must be kept at reset value.

Bit 28 **ENBESL**: Enable best effort service latency

This bit enables the BESL feature as defined in the LPM errata:

0: The core works as described in the following document:

*USB 2.0 Link Power Management Addendum Engineering Change Notice to the USB 2.0 specification, July 16, 2007*

1: The core works as described in the LPM Errata:

*Errata for USB 2.0 ECN: Link Power Management (LPM) - 7/2007*

*Note: Only the updated behavior (described in LPM Errata) is considered in this document and so the ENBESL bit should be set to '1' by application SW.*

Bits 27:25 **LPMRCNTSTS[2:0]**: LPM retry count status

Number of LPM host retries still remaining to be transmitted for the current LPM sequence.

*Note: Accessible only in host mode.*

Bit 24 **SNDLPM**: Send LPM transaction

When the application software sets this bit, an LPM transaction containing two tokens, EXT and LPM is sent. The hardware clears this bit once a valid response (STALL, NYET, or ACK) is received from the device or the core has finished transmitting the programmed number of LPM retries.

*Note: This bit must be set only when the host is connected to a local port.*

*Note: Accessible only in host mode.*

Bits 23:21 **LPMRCNT[2:0]**: LPM retry count

When the device gives an ERROR response, this is the number of additional LPM retries that the host performs until a valid device response (STALL, NYET, or ACK) is received.

*Note: Accessible only in host mode.*

Bits 20:17 **LPMCHIDX[3:0]**: LPM Channel Index

The channel number on which the LPM transaction has to be applied while sending an LPM transaction to the local device. Based on the LPM channel index, the core automatically inserts the device address and endpoint number programmed in the corresponding channel into the LPM transaction.

*Note: Accessible only in host mode.*

Bit 16 **L1RSMOK**: Sleep state resume OK

Indicates that the device or host can start resume from Sleep state. This bit is valid in LPM sleep (L1) state. It is set in sleep mode after a delay of 50  $\mu$ s ( $T_{L1Residency}$ ).

This bit is reset when SLPSTS is 0.

1: The application or host can start resume from Sleep state

0: The application or host cannot start resume from Sleep state

Bit 15 **SLPSTS**: Port sleep status**Device mode:**

This bit is set as long as a Sleep condition is present on the USB bus. The core enters the Sleep state when an ACK response is sent to an LPM transaction and the  $T_{L1TokenRetry}$  timer has expired. To stop the PHY clock, the application must set the STPPCLK bit in OTG\_PCGCCTL, which asserts the PHY suspend input signal.

The application must rely on SLPSTS and not ACK in LPMRSP to confirm transition into sleep.

The core comes out of sleep:

- When there is any activity on the USB linestate
- When the application writes to the RWUSIG bit in OTG\_DCTL or when the application resets or soft-disconnects the device.

**Host mode:**

The host transitions to Sleep (L1) state as a side-effect of a successful LPM transaction by the core to the local port with ACK response from the device. The read value of this bit reflects the current Sleep status of the port.

The core clears this bit after:

- The core detects a remote L1 wakeup signal,
- The application sets the PRST bit or the PRES bit in the OTG\_HPRT register, or
- The application sets the L1Resume/ remote wakeup detected interrupt bit or disconnect detected interrupt bit in the core interrupt register (WKUPINT or DISCINT bit in OTG\_GINTSTS, respectively).

0: Core not in L1

1: Core in L1

Bits 14:13 **LPMRST[1:0]**: LPM response**Device mode:**

The response of the core to LPM transaction received is reflected in these two bits.

**Host mode:**

Handshake response received from local device for LPM transaction

11: ACK

10: NYET

01: STALL

00: ERROR (No handshake response)

Bit 12 **L1DSEN**: L1 deep sleep enable

Enables suspending the PHY in L1 Sleep mode. For maximum power saving during L1 Sleep mode, this bit should be set to '1' by application SW in all the cases.

Bits11:8 **BESLTHRS[3:0]**: BESL threshold

**Device mode:**

The core puts the PHY into deep low power mode in L1 when BESL value is greater than or equal to the value defined in this field BESL\_Thres[3:0].

**Host mode:**

The core puts the PHY into deep low power mode in L1. BESLTHRS[3:0] specifies the time for which resume signaling is to be reflected by host ( $T_{L1HubDrvResume2}$ ) on the USB bus when it detects device initiated resume.

BESLTHRS must not be programmed with a value greater than 1100b in host mode, because this exceeds maximum  $T_{L1HubDrvResume2}$ .

Thres[3:0] host mode resume signaling time ( $\mu$ s):

0000: 75

0001: 100

0010: 150

0011: 250

0100: 350

0101: 450

0110: 950

All other values: reserved

Bit 7 **L1SSEN**: L1 Shallow Sleep enable

Enables suspending the PHY in L1 Sleep mode. For maximum power saving during L1 Sleep mode, this bit should be set to '1' by application SW in all the cases.

Bit 6 **REMWAKE**: bRemoteWake value

**Host mode:**

The value of remote wake up to be sent in the wIndex field of LPM transaction.

**Device mode (read-only):**

This field is updated with the received LPM token bRemoteWake bmAttribute when an ACK, NYET, or STALL response is sent to an LPM transaction.

Bits 5:2 **BESL[3:0]**: Best effort service latency

**Host mode:**

The value of BESL to be sent in an LPM transaction. This value is also used to initiate resume for a duration  $T_{L1HubDrvResume1}$  for host initiated resume.

**Device mode (read-only):**

This field is updated with the received LPM token BESL bmAttribute when an ACK, NYET, or STALL response is sent to an LPM transaction.

BESL[3:0] $T_{BESL}$  ( $\mu$ s)

0000: 125  
 0001: 150  
 0010: 200  
 0011: 300  
 0100: 400  
 0101: 500  
 0110: 1000  
 0111: 2000  
 1000: 3000  
 1001: 4000  
 1010: 5000  
 1011: 6000  
 1100: 7000  
 1101: 8000  
 1110: 9000  
 1111: 10000

Bit 1 **LPMACK**: LPM token acknowledge enable

Handshake response to LPM token preprogrammed by device application software.

1: ACK

Even though ACK is preprogrammed, the core device responds with ACK only on successful LPM transaction. The LPM transaction is successful if:

- No PID/CRC5 errors in either EXT token or LPM token (else ERROR)
- Valid bLinkState = 0001B (L1) received in LPM transaction (else STALL)
- No data pending in transmit queue (else NYET).

0: NYET

The preprogrammed software bit is over-ridden for response to LPM token when:

- The received bLinkState is not L1 (STALL response), or
- An error is detected in either of the LPM token packets because of corruption (ERROR response).

*Note: Accessible only in device mode.*

Bit 0 **LPMEN**: LPM support enable

The application uses this bit to control the OTG\_FS/OTG\_HS core LPM capabilities.

If the core operates as a non-LPM-capable host, it cannot request the connected device or hub to activate LPM mode.

If the core operates as a non-LPM-capable device, it cannot respond to any LPM transactions.

0: LPM capability is not enabled

1: LPM capability is enabled

### 37.15.15 OTG host periodic transmit FIFO size register (OTG\_HPTXFSIZ)

Address offset: 0x100

Reset value: 0x0200 0400

|               |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|---------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31            | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| PTXFSIZ[15:0] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw            | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |
| 15            | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| PTXSA[15:0]   |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw            | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 31:16 **PTXFSIZ[15:0]**: Host periodic Tx FIFO depth

This value is in terms of 32-bit words.

Minimum value is 16

Bits 15:0 **PTXSA[15:0]**: Host periodic Tx FIFO start address

This field configures the memory start address for periodic transmit FIFO RAM.

### 37.15.16 OTG device IN endpoint transmit FIFO size register (OTG\_DIEPTXF<sub>x</sub>) (x = 1..5[FS] /8[HS], where x is the FIFO number)

Address offset: 0x104 + (x – 1) \* 0x04

Reset value: 0x0200 0200 + (x \* 0x200)

|                |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|----------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31             | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| INEPTXFD[15:0] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw             | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |
| 15             | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| INEPTXSA[15:0] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw             | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 31:16 **INEPTXFD[15:0]**: IN endpoint Tx FIFO depth

This value is in terms of 32-bit words.

Minimum value is 16

Bits 15:0 **INEPTXSA[15:0]**: IN endpoint FIFO<sub>x</sub> transmit RAM start address

This field contains the memory start address for IN endpoint transmit FIFO<sub>x</sub>. The address must be aligned with a 32-bit memory location.

### 37.15.17 Host-mode registers

Bit values in the register descriptions are expressed in binary unless otherwise specified.

Host-mode registers affect the operation of the core in the host mode. Host mode registers must not be accessed in device mode, as the results are undefined. Host mode registers can be categorized as follows:

### 37.15.18 OTG host configuration register (OTG\_HCFG)

Address offset: 0x400

Reset value: 0x0000 0000

This register configures the core after power-on. Do not make changes to this register after initializing the host.

|      |      |      |      |      |      |      |      |      |      |      |      |      |       |              |      |
|------|------|------|------|------|------|------|------|------|------|------|------|------|-------|--------------|------|
| 31   | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21   | 20   | 19   | 18    | 17           | 16   |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. |      | Res. | Res. | Res. | Res. | Res. | Res.  | Res.         | Res. |
|      |      |      |      |      |      |      |      |      |      |      |      |      |       |              |      |
| 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5    | 4    | 3    | 2     | 1            | 0    |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | FSLSS | FSLSPCS[1:0] |      |
|      |      |      |      |      |      |      |      |      |      |      |      |      | r     | rw           | rw   |

Bits 31:3 Reserved, must be kept at reset value.

Bit 2 **FSLSS**: FS- and LS-only support

The application uses this bit to control the core's enumeration speed. Using this bit, the application can make the core enumerate as an FS host, even if the connected device supports HS traffic. Do not make changes to this field after initial programming.

1: FS/LS-only, even if the connected device can support HS (read-only).

Bits 1:0 **FSLSPCS[1:0]**: FS/LS PHY clock select

When the core is in FS host mode

01: PHY clock is running at 48 MHz

Others: Reserved

When the core is in LS host mode

00: Reserved

01: Select 48 MHz PHY clock frequency

10: Select 6 MHz PHY clock frequency

11: Reserved

*Note: The FSLSPCS must be set on a connection event according to the speed of the connected device (after changing this bit, a software reset must be performed).*

### 37.15.19 OTG host frame interval register (OTG\_HFIR)

Address offset: 0x404

Reset value: 0x0000 EA60

This register stores the frame interval information for the current speed to which the OTG\_FS/OTG\_HS controller has enumerated.

|             |      |      |      |      |      |      |      |      |      |      |      |      |      |      |          |
|-------------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|----------|
| 31          | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21   | 20   | 19   | 18   | 17   | 16       |
| Res.        | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | RLD CTRL |
|             |      |      |      |      |      |      |      |      |      |      |      |      |      |      | rw       |
| 15          | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0        |
| FRIVL[15:0] |      |      |      |      |      |      |      |      |      |      |      |      |      |      |          |
| rw          | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw       |

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **RLDCTRL**: Reload control

This bit allows dynamic reloading of the HFIR register during run time.

0: The HFIR can be dynamically reloaded during run time.

1: The HFIR cannot be reloaded dynamically

This bit needs to be programmed during initial configuration and its value must not be changed during run time.

**Caution:** RLDCTRL = 1 is not recommended.

Bits 15:0 **FRIVL[15:0]**: Frame interval for USB OTG FS

The value that the application programs to this field, specifies the interval between two consecutive SOFs (FS) or Keep-Alive tokens (LS). This field contains the number of PHY clocks that constitute the required frame interval. The application can write a value to this register only after the port enable bit of the host port control and status register (PENA bit in OTG\_HPRT) has been set. If no value is programmed, the core calculates the value based on the PHY clock specified in the FS/LS PHY clock select field of the host configuration register (FSLSPCS in OTG\_HCFG). Do not change the value of this field after the initial configuration, unless the RLDCTRL bit is set. In such case, the FRIVL is reloaded with each SOF event.

– Frame interval = 1 ms × (FRIVL - 1)

Bits 15:0 **FRIVL[15:0]**: Frame interval for USB OTG HS

The value that the application programs to this field, specifies the interval between two consecutive micro-SOFs (HS) or Keep-Alive tokens (LS). This field contains the number of PHY clocks that constitute the required frame interval. The application can write a value to this register only after the port enable bit of the host port control and status register (PENA bit in OTG\_HPRT) has been set. If no value is programmed, the core calculates the value based on the PHY clock specified in the FS/LS PHY clock select field of the host configuration register (FSLSPCS in OTG\_HCFG). Do not change the value of this field after the initial configuration, unless the RLDCTRL bit is set. In such case, the FRIVL is reloaded with each SOF event.

– Frame interval = 125 μs × (FRIVL - 1)

in high speed operation (PHYSEL = 0)

– Frame interval = 1 ms × (FRIVL - 1)

in low/full speed operation (PHYSEL = 1)

### 37.15.20 OTG host frame number/frame time remaining register (OTG\_HFNUM)

Address offset: 0x408

Reset value: 0x0000 3FFF

This register indicates the current frame number. It also indicates the time remaining (in terms of the number of PHY clocks) in the current frame.

|             |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|-------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31          | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| FTREM[15:0] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| r           | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  |
| 15          | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| FRNUM[15:0] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| r           | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  |

Bits 31:16 **FTREM[15:0]**: Frame time remaining

Indicates the amount of time remaining in the current frame, in terms of PHY clocks. This field decrements on each PHY clock. When it reaches zero, this field is reloaded with the value in the Frame interval register and a new SOF is transmitted on the USB.

Bits 15:0 **FRNUM[15:0]**: Frame number

This field increments when a new SOF is transmitted on the USB, and is cleared to 0 when it reaches 0x3FFF.

### 37.15.21 OTG\_Host periodic transmit FIFO/queue status register (OTG\_HPTXSTS)

Address offset: 0x410

Reset value: 0x0008 0100

This read-only register contains the free space information for the periodic Tx FIFO and the periodic transmit request queue.

|                |    |    |    |    |    |    |    |              |    |    |    |    |    |    |    |
|----------------|----|----|----|----|----|----|----|--------------|----|----|----|----|----|----|----|
| 31             | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23           | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| PTXQTOP[7:0]   |    |    |    |    |    |    |    | PTXQSAV[7:0] |    |    |    |    |    |    |    |
| r              | r  | r  | r  | r  | r  | r  | r  | r            | r  | r  | r  | r  | r  | r  | r  |
| 15             | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7            | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| PTXFSAVL[15:0] |    |    |    |    |    |    |    |              |    |    |    |    |    |    |    |
| r              | r  | r  | r  | r  | r  | r  | r  | r            | r  | r  | r  | r  | r  | r  | r  |

Bits 31:24 **PTXQTOP[7:0]**: Top of the periodic transmit request queue

This indicates the entry in the periodic Tx request queue that is currently being processed by the MAC.

This register is used for debugging.

Bit 31: Odd/Even frame

0: send in even frame

1: send in odd frame

Bits 30:27: Channel/endpoint number

Bits 26:25: Type

00: IN/OUT

01: Zero-length packet

11: Disable channel command

Bit 24: Terminate (last entry for the selected channel/endpoint)

Bits 23:16 **PTXQSAV[7:0]**: Periodic transmit request queue space available

Indicates the number of free locations available to be written in the periodic transmit request queue. This queue holds both IN and OUT requests.

00: Periodic transmit request queue is full

01: 1 location available

10: 2 locations available

bxn: n locations available ( $0 \leq n \leq 8$ )

Others: Reserved

Bits 15:0 **PTXFSAVL[15:0]**: Periodic transmit data FIFO space available

Indicates the number of free locations available to be written to in the periodic Tx FIFO.

Values are in terms of 32-bit words

0000: Periodic Tx FIFO is full

0001: 1 word available

0010: 2 words available

bxn: n words available (where  $0 \leq n \leq \text{PTXFD}$ )

Others: Reserved

### 37.15.22 OTG host all channels interrupt register (OTG\_HAINT)

Address offset: 0x414

Reset value: 0x0000 0000

When a significant event occurs on a channel, the host all channels interrupt register interrupts the application using the host channels interrupt bit of the core interrupt register (HCINT bit in OTG\_GINTSTS). This is shown in [Figure 466](#). There is one interrupt bit per channel, up to a maximum of 16 bits. Bits in this register are set and cleared when the application sets and clears bits in the corresponding host channel-x interrupt register.

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **HAINT[15:0]**: Channel interrupts

One bit per channel: Bit 0 for Channel 0, bit 15 for Channel 15

### 37.15.23 OTG host all channels interrupt mask register (OTG\_HAINTMSK)

Address offset: 0x418

Reset value: 0x0000 0000

The host all channel interrupt mask register works with the host all channel interrupt register to interrupt the application when an event occurs on a channel. There is one interrupt mask bit per channel, up to a maximum of 16 bits.

|              |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **HAINTM[15:0]**: Channel interrupt mask

0: Masked interrupt

1: Unmasked interrupt

One bit per channel: Bit 0 for channel 0, bit 15 for channel 15

### 37.15.24 OTG host port control and status register (OTG\_HPRT)

Address offset: 0x440

Reset value: 0x0000 0000

This register is available only in host mode. Currently, the OTG host supports only one port.

A single register holds USB port-related information such as USB reset, enable, suspend, resume, connect status, and test mode for each port. It is shown in [Figure 466](#). The rc\_w1 bits in this register can trigger an interrupt to the application through the host port interrupt bit of the core interrupt register (HPRTINT bit in OTG\_GINTSTS). On a port interrupt, the application must read this register and clear the bit that caused the interrupt. For the rc\_w1 bits, the application must write a 1 to the bit to clear the interrupt.

|            |      |      |      |            |      |      |      |       |      |          |      |          |           |       |          |

Bits 31:19 Reserved, must be kept at reset value.

Bits 18:17 **PSPD[1:0]**: Port speed

Indicates the speed of the device attached to this port.

01: Full speed

10: Low speed

11: Reserved

00: High speed

Bits 16:13 **PTCTL[3:0]**: Port test control

The application writes a nonzero value to this field to put the port into a Test mode, and the corresponding pattern is signaled on the port.

0000: Test mode disabled

0001: Test\_J mode

0010: Test\_K mode

0011: Test\_SE0\_NAK mode

0100: Test\_Packet mode

0101: Test\_Force\_Enable

Others: Reserved

Bit 12 **PPWR**: Port power

The application uses this field to control power to this port, and the core clears this bit on an overcurrent condition.

0: Power off

1: Power on

Bits 11:10 **PLSTS[1:0]**: Port line status

Indicates the current logic level USB data lines

Bit 10: Logic level of OTG\_DP

Bit 11: Logic level of OTG\_DM

Bit 9 Reserved, must be kept at reset value.

**Bit 8 PRST:** Port reset

When the application sets this bit, a reset sequence is started on this port. The application must time the reset period and clear this bit after the reset sequence is complete.

0: Port not in reset

1: Port in reset

The application must leave this bit set for a minimum duration of at least 10 ms to start a reset on the port. The application can leave it set for another 10 ms in addition to the required minimum duration, before clearing the bit, even though there is no maximum limit set by the USB standard.

High speed: 50 ms

Full speed/Low speed: 10 ms

**Bit 7 PSUSP:** Port suspend

The application sets this bit to put this port in suspend mode. The core only stops sending SOFs when this is set. To stop the PHY clock, the application must set the port clock stop bit, which asserts the suspend input pin of the PHY.

The read value of this bit reflects the current suspend status of the port. This bit is cleared by the core after a remote wakeup signal is detected or the application sets the port reset bit or port resume bit in this register or the resume/remote wakeup detected interrupt bit or disconnect detected interrupt bit in the core interrupt register (WKUPINT or DISCINT in OTG\_GINTSTS, respectively).

0: Port not in suspend mode

1: Port in suspend mode

**Bit 6 PRES:** Port resume

The application sets this bit to drive resume signaling on the port. The core continues to drive the resume signal until the application clears this bit.

If the core detects a USB remote wakeup sequence, as indicated by the port resume/remote wakeup detected interrupt bit of the core interrupt register (WKUPINT bit in OTG\_GINTSTS), the core starts driving resume signaling without application intervention and clears this bit when it detects a disconnect condition. The read value of this bit indicates whether the core is currently driving resume signaling.

0: No resume driven

1: Resume driven

When LPM is enabled and the core is in L1 state, the behavior of this bit is as follow:

1. The application sets this bit to drive resume signaling on the port.
2. The core continues to drive the resume signal until a predetermined time specified in BESLTHRS[3:0] field of OTG\_GLPMCFG register.
3. If the core detects a USB remote wakeup sequence, as indicated by the port L1Resume/Remote L1Wakeup detected interrupt bit of the core interrupt register (WKUPINT in OTG\_GINTSTS), the core starts driving resume signaling without application intervention and clears this bit at the end of resume. This bit can be set or cleared by both the core and the application. This bit is cleared by the core even if there is no device connected to the host.

**Bit 5 POCCHNG:** Port overcurrent change

The core sets this bit when the status of the port overcurrent active bit (bit 4) in this register changes.

**Bit 4 POCA:** Port overcurrent active

Indicates the overcurrent condition of the port.

0: No overcurrent condition

1: Overcurrent condition

**Bit 3 PENCHNG:** Port enable/disable change

The core sets this bit when the status of the port enable bit 2 in this register changes.

Bit 2 **PENA**: Port enable

A port is enabled only by the core after a reset sequence, and is disabled by an overcurrent condition, a disconnect condition, or by the application clearing this bit. The application cannot set this bit by a register write. It can only clear it to disable the port. This bit does not trigger any interrupt to the application.

0: Port disabled

1: Port enabled

Bit 1 **PCDET**: Port connect detected

The core sets this bit when a device connection is detected to trigger an interrupt to the application using the host port interrupt bit in the core interrupt register (HPRTINT bit in OTG\_GINTSTS). The application must write a 1 to this bit to clear the interrupt.

Bit 0 **PCSTS**: Port connect status

0: No device is attached to the port

1: A device is attached to the port

### 37.15.25 OTG host channel x characteristics register (OTG\_HCCHARx) (x = 0..15[HS] / 11[FS], where x = Channel number)

Address offset: 0x500 + (x \* 0x20)

Reset value: 0x0000 0000

|       |            |         |          |    |             |    |    |    |    |           |    |            |    |       |      |

| rw    | rw         | rw      | rw       | rw | rw          | rw | rw | rw | rw | rw        | rw | rw         | rw | rw    | rw   |

Bit 31 **CHENA**: Channel enable

This field is set by the application and cleared by the OTG host.

0: Channel disabled

1: Channel enabled

Bit 30 **CHDIS**: Channel disable

The application sets this bit to stop transmitting/receiving data on a channel, even before the transfer for that channel is complete. The application must wait for the Channel disabled interrupt before treating the channel as disabled.

Bit 29 **ODDFRM**: Odd frame

This field is set (reset) by the application to indicate that the OTG host must perform a transfer in an odd frame. This field is applicable for only periodic (isochronous and interrupt) transactions.

0: Even frame

1: Odd frame

Bits 28:22 **DAD[6:0]**: Device address

This field selects the specific device serving as the data source or sink.

Bits 21:20 **MCNT[1:0]**: Multicount

This field indicates to the host the number of transactions that must be executed per frame for this periodic endpoint. For non-periodic transfers, this field is not used

00: Reserved. This field yields undefined results

01: 1 transaction

10: 2 transactions per frame to be issued for this endpoint

11: 3 transactions per frame to be issued for this endpoint

*Note: This field must be set to at least 01.*

Bits 19:18 **EPTYP[1:0]**: Endpoint type

Indicates the transfer type selected.

00: Control

01: Isochronous

10: Bulk

11: Interrupt

Bit 17 **LSDEV**: Low-speed device

This field is set by the application to indicate that this channel is communicating to a low-speed device.

Bit 16 Reserved, must be kept at reset value.

Bit 15 **EPDIR**: Endpoint direction

Indicates whether the transaction is IN or OUT.

0: OUT

1: IN

Bits 14:11 **EPNUM[3:0]**: Endpoint number

Indicates the endpoint number on the device serving as the data source or sink.

Bits 10:0 **MPSIZ[10:0]**: Maximum packet size

Indicates the maximum packet size of the associated endpoint.

### 37.15.26 OTG host channel x split control register (OTG\_HCSPLTx) (x = 0..15, where x = Channel number)

Address offset:  $0x504 + (x * 0x20)$

Reset value: 0x0000 0000

*Note: Configuration register applies only to USB OTG HS.*

Bit 31 **SPLITEN**: Split enable

The application sets this bit to indicate that this channel is enabled to perform split transactions.

Bits 30:17 Reserved, must be kept at reset value.

Bit 16 **COMPLSPLT**: Do complete split

The application sets this bit to request the OTG host to perform a complete split transaction.

Bits 15:14 **XACTPOS[1:0]**: Transaction position

This field is used to determine whether to send all, first, middle, or last payloads with each OUT transaction.

11: All. This is the entire data payload of this transaction (which is less than or equal to 188 bytes)

10: Begin. This is the first data payload of this transaction (which is larger than 188 bytes)

00: Mid. This is the middle payload of this transaction (which is larger than 188 bytes)

01: End. This is the last payload of this transaction (which is larger than 188 bytes)

Bits 13:7 **HUBADDR[6:0]**: Hub address

This field holds the device address of the transaction translator's hub.

Bits 6:0 **PRTADDR[6:0]**: Port address

This field is the port number of the recipient transaction translator.

### 37.15.27 OTG host channel x interrupt register (OTG\_HCINTx) (x = 0..15[HS] / 11[FS], where x = Channel number)

Address offset:  $0x508 + (x * 0x20)$

Reset value: 0x0000 0000

This register indicates the status of a channel with respect to USB- and AHB-related events. It is shown in [Figure 466](#). The application must read this register when the host channels interrupt bit in the core interrupt register (HCINT bit in OTG\_GINTSTS) is set. Before the application can read this register, it must first read the host all channels interrupt (OTG\_HAINT) register to get the exact channel number for the host channel-x interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the OTG\_HAINT and OTG\_GINTSTS registers.

**Note:** Configuration register for USB OTG HS.

Bits 31:11 Reserved, must be kept at reset value.

Bit 10 **DTERR**: Data toggle error.

Bit 9 **FRMOR**: Frame overrun.

Bit 8 **BBERR**: Babble error.

Bit 7 **TXERR**: Transaction error.

Indicates one of the following errors occurred on the USB.

- CRC check failure
- Timeout
- Bit stuff error
- False EOP

Bit 6 Reserved, must be kept at reset value for USB OTG FS.

Bit 6 **NYET**: Not yet ready response received interrupt for USB OTG HS.

Bit 5 **ACK**: ACK response received/transmitted interrupt.

Bit 4 **NAK**: NAK response received interrupt.

Bit 3 **STALL**: STALL response received interrupt.

Bit 2 Reserved, must be kept at reset value for USB OTG FS.

Bit 2 **AHBERR**: AHB error for USB OTG HS

This error is generated only in Internal DMA mode when an AHB error occurs during an AHB read/write operation. The application can read the corresponding DMA channel address register to get the error address.

Bit 1 **CHH**: Channel halted.

Indicates the transfer completed abnormally either because of any USB transaction error or in response to disable request by the application.

Bit 0 **XFRC**: Transfer completed.

Transfer completed normally without any errors.

### 37.15.28 OTG host channel x interrupt mask register (OTG\_HCINTMSKx) (x = 0..15[HS] / 11[FS], where x = Channel number)

Address offset: 0x50C + (x \* 0x20)

Reset value: 0x0000 0000

This register reflects the mask for each channel status described in the previous section.

| XFRSIZ[15:0] |           |    |             |    |    |    |    |    |    |    |    |    |               |    |    |
| rW           | rW        | rW | rW          | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW            | rW | rW |

Bit 31 Reserved, must be kept at reset value.

Bits 30:29 **DPID[1:0]**: Data PID

The application programs this field with the type of PID to use for the initial transaction. The host maintains this field for the rest of the transfer.

00: DATA0

01: DATA2

10: DATA1

11: SETUP (control) / reserved[FS]MDATA[HS] (non-control)

Bits 28:19 **PKTCNT[9:0]**: Packet count

This field is programmed by the application with the expected number of packets to be transmitted (OUT) or received (IN).

The host decrements this count on every successful transmission or reception of an OUT/IN packet. Once this count reaches zero, the application is interrupted to indicate normal completion.

Bits 18:0 **XFRSIZ[18:0]**: Transfer size

For an OUT, this field is the number of data bytes the host sends during the transfer.

For an IN, this field is the buffer size that the application has reserved for the transfer. The application is expected to program this field as an integer multiple of the maximum packet size for IN transactions (periodic and non-periodic).

### 37.15.30 OTG host channel x DMA address register (OTG\_HCDMAx) (x = 0..15, where x = Channel number)

Address offset:  $0x514 + (x * 0x20)$

Reset value: 0x0000 0000

|                |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|----------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|

| DMAADDR[31:16] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw             | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |
| 15             | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| DMAADDR[15:0]  |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw             | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 31:0 **DMAADDR[31:0]**: DMA address

This field holds the start address in the external memory from which the data for the endpoint must be fetched or to which it must be stored. This register is incremented on every AHB transaction.

### 37.15.31 Device-mode registers

These registers must be programmed every time the core changes to device mode

### 37.15.32 OTG device configuration register (OTG\_DCFG)

Address offset: 0x800

Reset value: 0x0220 0000

This register configures the core in device mode after power-on or after certain control commands or enumeration. Do not make changes to this register after initial programming.

*Note:* Configuration register for USB OTG HS

Bits 31:16 Reserved, must be kept at reset value for USB OTG FS.

Bits 31:26 Reserved, must be kept at reset value for USB OTG HS.

Bits 25:24 **PERSCHIVL[1:0]**: Periodic schedule interval for USB OTG HS

This field specifies the amount of time the Internal DMA engine must allocate for fetching periodic IN endpoint data. Based on the number of periodic endpoints, this value must be specified as 25, 50 or 75% of the (micro) frame.

- When any periodic endpoints are active, the internal DMA engine allocates the specified amount of time in fetching periodic IN endpoint data
- When no periodic endpoint is active, then the internal DMA engine services nonperiodic endpoints, ignoring this field
- After the specified time within a (micro) frame, the DMA switches to fetching nonperiodic endpoints

00: 25% of (micro)frame

01: 50% of (micro)frame

10: 75% of (micro)frame

11: Reserved

Bits 23:16 Reserved, must be kept at reset value for USB OTG HS.

Bit 15 **ERRATIM**: Erratic error interrupt mask

1: Mask early suspend interrupt on erratic error

0: Early suspend interrupt is generated on erratic error

- Bit 14 **XCVRDLY**: Transceiver delay  
 Enables or disables delay in ULPI timing during device chirp.  
 0: Disable delay (use default timing)  
 1: Enable delay to default timing, necessary for some ULPI PHYs
- Bit 13 Reserved, must be kept at reset value.
- Bits 12:11 **PFIVL[1:0]**: Periodic frame interval  
 Indicates the time within a frame at which the application must be notified using the end of periodic frame interrupt. This can be used to determine if all the isochronous traffic for that frame is complete.  
 00: 80% of the frame interval  
 01: 85% of the frame interval  
 10: 90% of the frame interval  
 11: 95% of the frame interval
- Bits 10:4 **DAD[6:0]**: Device address  
 The application must program this field after every SetAddress control command.
- Bit 3 Reserved, must be kept at reset value.
- Bit 2 **NZLSOHSK**: Non-zero-length status OUT handshake  
 The application can use this field to select the handshake the core sends on receiving a nonzero-length data packet during the OUT transaction of a control transfer's status stage.  
 1: Send a STALL handshake on a nonzero-length status OUT transaction and do not send the received OUT packet to the application.  
 0: Send the received OUT packet to the application (zero-length or nonzero-length) and send a handshake based on the NAK and STALL bits for the endpoint in the device endpoint control register.
- Bits 1:0 **DSPD[1:0]**: Device speed  
 Indicates the speed at which the application requires the core to enumerate, or the maximum speed the application can support. However, the actual bus speed is determined only after the chirp sequence is completed, and is based on the speed of the USB host to which the core is connected.  
 00: Reserved  
 01: Reserved  
 10: Reserved  
 11: Full speed (USB 1.1 transceiver clock is 48 MHz)
- Bits 1:0 **DSPD[1:0]**: Device speed  
 Indicates the speed at which the application requires the core to enumerate, or the maximum speed the application can support. However, the actual bus speed is determined only after the chirp sequence is completed, and is based on the speed of the USB host to which the core is connected.  
 00: High speed  
 01: Full speed using HS  
 10: Reserved  
 11: Full speed using internal FS PHY

**37.15.33 OTG device control register (OTG\_DCTL)**

Address offset: 0x804

Reset value: 0x0000 0002

Bits 31:19 Reserved, must be kept at reset value.

Bit 18 **DSBESLRJCT**: Deep sleep BESL reject

Core rejects LPM request with BESL value greater than BESL threshold programmed.  
 NYET response is sent for LPM tokens with BESL value greater than BESL threshold. By default, the deep sleep BESL reject feature is disabled.

Bits 17:12 Reserved, must be kept at reset value.

Bit 11 **POPRGDNE**: Power-on programming done

The application uses this bit to indicate that register programming is completed after a wakeup from power down mode.

Bit 10 **CGONAK**: Clear global OUT NAK

Writing 1 to this field clears the Global OUT NAK.

Bit 9 **SGONAK**: Set global OUT NAK

Writing 1 to this field sets the Global OUT NAK.  
 The application uses this bit to send a NAK handshake on all OUT endpoints.  
 The application must set this bit only after making sure that the Global OUT NAK effective bit in the core interrupt register (GONAKEFF bit in OTG\_GINTSTS) is cleared.

Bit 8 **CGINAK**: Clear global IN NAK

Writing 1 to this field clears the Global IN NAK.

Bit 7 **SGINAK**: Set global IN NAK

Writing 1 to this field sets the Global non-periodic IN NAK. The application uses this bit to send a NAK handshake on all non-periodic IN endpoints.  
 The application must set this bit only after making sure that the Global IN NAK effective bit in the core interrupt register (GINAKEFF bit in OTG\_GINTSTS) is cleared.

Bits 6:4 **TCTL[2:0]**: Test control

000: Test mode disabled  
 001: Test\_J mode  
 010: Test\_K mode  
 011: Test\_SE0\_NAK mode  
 100: Test\_Packet mode  
 101: Test\_Force\_Enable  
 Others: Reserved

Bit 3 **GONSTS**: Global OUT NAK status

0: A handshake is sent based on the FIFO status and the NAK and STALL bit settings.

1: No data is written to the Rx FIFO, irrespective of space availability. Sends a NAK handshake on all packets, except on SETUP transactions. All isochronous OUT packets are dropped.

Bit 2 **GINSTS**: Global IN NAK status

0: A handshake is sent out based on the data availability in the transmit FIFO.

1: A NAK handshake is sent out on all non-periodic IN endpoints, irrespective of the data availability in the transmit FIFO.

Bit 1 **SDIS**: Soft disconnect

The application uses this bit to signal the USB OTG core to perform a soft disconnect. As long as this bit is set, the host does not see that the device is connected, and the device does not receive signals on the USB. The core stays in the disconnected state until the application clears this bit.

0: Normal operation. When this bit is cleared after a soft disconnect, the core generates a device connect event to the USB host. When the device is reconnected, the USB host restarts device enumeration.

1: The core generates a device disconnect event to the USB host.

Bit 0 **RWUSIG**: Remote wakeup signaling

When the application sets this bit, the core initiates remote signaling to wake up the USB host. The application must set this bit to instruct the core to exit the suspend state. As specified in the USB 2.0 specification, the application must clear this bit 1 ms to 15 ms after setting it.

If LPM is enabled and the core is in the L1 (sleep) state, when the application sets this bit, the core initiates L1 remote signaling to wake up the USB host. The application must set this bit to instruct the core to exit the sleep state. As specified in the LPM specification, the hardware automatically clears this bit 50  $\mu$ s ( $T_{L1DevDrvResume}$ ) after being set by the application. The application must not set this bit when bRemoteWake from the previous LPM transaction is zero (refer to REMWAKE bit in GLPMCFG register).

[Table 270](#) contains the minimum duration (according to device state) for which the Soft disconnect (SDIS) bit must be set for the USB host to detect a device disconnect. To accommodate clock jitter, it is recommended that the application add some extra delay to the specified minimum duration.

**Table 270. Minimum duration for soft disconnect**

| Operating speed | Device state                                    | Minimum duration   |
|-----------------|-------------------------------------------------|--------------------|
| Full speed      | Suspended                                       | 1 ms + 2.5 $\mu$ s |
| Full speed      | Idle                                            | 2.5 $\mu$ s        |
| Full speed      | Not Idle or suspended (Performing transactions) | 2.5 $\mu$ s        |
| High speed      | Not Idle or suspended (Performing transactions) | 125 $\mu$ s        |

### 37.15.34 OTG device status register (OTG\_DSTS)

Address offset: 0x808

Reset value: 0x0000 0010

This register indicates the status of the core with respect to USB-related events. It must be read on interrupts from the device all interrupts (OTG\_DAINTE) register.

|            |      |      |      |      |      |      |      |               |      |             |      |      |              |    |         |

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:22 **DEVLNSTS[1:0]**: Device line status

Indicates the current logic level USB data lines.

Bit [23]: Logic level of D+

Bit [22]: Logic level of D-

Bits 21:8 **FNSOF[13:0]**: Frame number of the received SOF

Bits 7:4 Reserved, must be kept at reset value.

Bit 3 **EERR**: Erratic error

The core sets this bit to report any erratic errors.

Due to erratic errors, the OTG\_FS/OTG\_HS controller goes into suspended state and an interrupt is generated to the application with Early suspend bit of the OTG\_GINTSTS register (ESUSP bit in OTG\_GINTSTS). If the early suspend is asserted due to an erratic error, the application can only perform a soft disconnect recover.

Bits 2:1 **ENUMSPD[1:0]**: Enumerated speed

Indicates the speed at which the OTG\_FS/OTG\_HS controller has come up after speed detection through a chirp sequence.

01: Reserved

10: Reserved

11: Full speed (PHY clock is running at 48 MHz)

Others: reserved

Bit 0 **SUSPSTS**: Suspend status

In device mode, this bit is set as long as a suspend condition is detected on the USB. The core enters the suspended state when there is no activity on the USB data lines for a period of 3 ms. The core comes out of the suspend:

- When there is an activity on the USB data lines
- When the application writes to the remote wakeup signaling bit in the OTG\_DCTL register (RWUSIG bit in OTG\_DCTL).

### 37.15.35 OTG device IN endpoint common interrupt mask register (OTG\_DIEPMSK)

Address offset: 0x810

Reset value: 0x0000 0000

This register works with each of the OTG\_DIEPINTx registers for all endpoints to generate an interrupt per IN endpoint. The IN endpoint interrupt for a specific status in the OTG\_DIEPINTx register can be masked by writing to the corresponding bit in this register. Status bits are masked by default.

### 37.15.36 OTG device OUT endpoint common interrupt mask register (OTG\_DOEPMSK)

Address offset: 0x814

Reset value: 0x0000 0000

This register works with each of the OTG\_DOEPINTx registers for all endpoints to generate an interrupt per OUT endpoint. The OUT endpoint interrupt for a specific status in the OTG\_DOEPINTx register can be masked by writing into the corresponding bit in this register. Status bits are masked by default.

### 37.15.37 OTG device all endpoints interrupt register (OTG\_DAINR)

Address offset: 0x818

Reset value: 0x0000 0000

When a significant event occurs on an endpoint, a OTG\_DAINR register interrupts the application using the device OUT endpoints interrupt bit or device IN endpoints interrupt bit of the OTG\_GINTSTS register (OEPINT or IEPINT in OTG\_GINTSTS, respectively). There is one interrupt bit per endpoint, up to a maximum of 16 bits for OUT endpoints and 16 bits for IN endpoints. For a bidirectional endpoint, the corresponding IN and OUT interrupt bits are used. Bits in this register are set and cleared when the application sets and clears bits in the corresponding device endpoint-x interrupt register (OTG\_DIEPINTx/OTG\_DOEPINTx).

|              |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|--------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31           | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| OEPINT[15:0] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| r            | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  |
| 15           | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| IEPINT[15:0] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| r            | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  |

Bits 31:16 **OEPINT[15:0]**: OUT endpoint interrupt bits

One bit per OUT endpoint:

Bit 16 for OUT endpoint 0, bit 19 for OUT endpoint 3.

Bits 15:0 **IEPINT[15:0]**: IN endpoint interrupt bits

One bit per IN endpoint:

Bit 0 for IN endpoint 0, bit 3 for endpoint 3.

### 37.15.38 OTG all endpoints interrupt mask register (OTG\_DAINMSK)

Address offset: 0x81C

Reset value: 0x0000 0000

The OTG\_DAINMSK register works with the device endpoint interrupt register to interrupt the application when an event occurs on a device endpoint. However, the OTG\_DAINR register bit corresponding to that interrupt is still set.

|              |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |

Bits 31:16 **OEPM[15:0]**: OUT EP interrupt mask bits

One per OUT endpoint:

Bit 16 for OUT EP 0, bit 19 for OUT EP 3

0: Masked interrupt

1: Unmasked interrupt

Bits 15:0 **IEPM[15:0]**: IN EP interrupt mask bits

One bit per IN endpoint:

Bit 0 for IN EP 0, bit 3 for IN EP 3

0: Masked interrupt

1: Unmasked interrupt

### 37.15.39 OTG device $V_{BUS}$ discharge time register (OTG\_DVBUSDIS)

Address offset: 0x0828

Reset value: 0x0000 17D7

This register specifies the  $V_{BUS}$  discharge time after  $V_{BUS}$  pulsing during SRP.

|              |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
|--------------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|
| 31           | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21   | 20   | 19   | 18   | 17   | 16   |
| Res.         | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. |
|              |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
| 15           | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0    |
| VBUSDT[15:0] |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
| rW           | rW   | rW   | rW   | rW   | rW   | rW   | rW   | rW   | rW   | rW   | rW   | rW   | rW   | rW   | rW   |

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **VBUSDT[15:0]**: Device  $V_{BUS}$  discharge time

Specifies the  $V_{BUS}$  discharge time after  $V_{BUS}$  pulsing during SRP. This value equals:

$V_{BUS}$  discharge time in PHY clocks / 1 024

Depending on your  $V_{BUS}$  load, this value may need adjusting.

### 37.15.40 OTG device $V_{BUS}$ pulsing time register (OTG\_DVBUSPULSE)

Address offset: 0x082C

Reset value: 0x0000 05B8

This register specifies the  $V_{BUS}$  pulsing time during SRP.

|              |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
|--------------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|

| 15           | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0    |
| DVBUSP[15:0] |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
| rW           | rW   | rW   | rW   | rW   | rW   | rW   | rW   | rW   | rW   | rW   | rW   | rW   | rW   | rW   | rW   |

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **DVBUSP[15:0]**: Device  $V_{BUS}$  pulsing time. This feature is only relevant to OTG1.3.

Specifies the  $V_{BUS}$  pulsing time during SRP. This value equals:

$V_{BUS}$  pulsing time in PHY clocks / 1 024

### 37.15.41 OTG device threshold control register (OTG\_DTHRCTL)

Address offset: 0x0830

Reset value: 0x0000 0000

*Note: Configuration register applies only to USB OTG HS*

|      |      |      |      |       |                |                |    |    |    |    |    |    |          |             |    |
|------|------|------|------|-------|----------------|----------------|----|----|----|----|----|----|----------|-------------|----|
| 31   | 30   | 29   | 28   | 27    | 26             | 25             | 24 | 23 | 22 | 21 | 20 | 19 | 18       | 17          | 16 |

|      |      |      |      | rw    |                | rw             | rw | rw | rw | rw | rw | rw | rw       | rw          | rw |
| 15   | 14   | 13   | 12   | 11    | 10             | 9              | 8  | 7  | 6  | 5  | 4  | 3  | 2        | 1           | 0  |
| Res. | Res. | Res. | Res. | Res.  | TXTHRLLEN[8:0] |                |    |    |    |    |    |    | ISOTHREN | NONISOTHREN |    |
|      |      |      |      |       | rw             | rw             | rw | rw | rw | rw | rw | rw | rw       | rw          | rw |

Bits 31:28 Reserved, must be kept at reset value.

Bit 27 **ARPEN**: Arbiter parking enable

This bit controls internal DMA arbiter parking for IN endpoints. When thresholding is enabled and this bit is set to one, then the arbiter parks on the IN endpoint for which there is a token received on the USB. This is done to avoid getting into underrun conditions. By default parking is enabled.

Bit 26 Reserved, must be kept at reset value.

Bits 25:17 **RXTHRLLEN[8:0]**: Receive threshold length

This field specifies the receive thresholding size in 32-bit words. This field also specifies the amount of data received on the USB before the core can start transmitting on the AHB. The threshold length has to be at least eight 32-bit words. The recommended value for RXTHRLLEN is to be the same as the programmed AHB burst length (HBSTLEN bit in OTG\_GAHBCFG).

Bit 16 **RXTHREN**: Receive threshold enable

When this bit is set, the core enables thresholding in the receive direction.

Bits 15:11 Reserved, must be kept at reset value.

Bits 10:2 **TXTHRLEN[8:0]**: Transmit threshold length

This field specifies the transmit thresholding size in 32-bit words. This field specifies the amount of data in bytes to be in the corresponding endpoint transmit FIFO, before the core can start transmitting on the USB. The threshold length has to be at least eight 32-bit words. This field controls both isochronous and nonisochronous IN endpoint thresholds. The recommended value for TXTHRLEN is to be the same as the programmed AHB burst length (HBSTLEN bit in OTG\_GAHBCFG).

Bit 1 **ISOTHREN**: ISO IN endpoint threshold enable

When this bit is set, the core enables thresholding for isochronous IN endpoints.

Bit 0 **NONISOTHREN**: Nonisochronous IN endpoints threshold enable

When this bit is set, the core enables thresholding for nonisochronous IN endpoints.

### 37.15.42 OTG device IN endpoint FIFO empty interrupt mask register (OTG\_DIEPEMPMSK)

Address offset: 0x834

Reset value: 0x0000 0000

This register is used to control the IN endpoint FIFO empty interrupt generation (TXFE\_OTG\_DIEPINTx).

|                 |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
|-----------------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|
| 31              | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21   | 20   | 19   | 18   | 17   | 16   |

| 15              | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0    |
| INEPTXFEM[15:0] |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
| rw              | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   |

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **INEPTXFEM[15:0]**: IN EP Tx FIFO empty interrupt mask bits

These bits act as mask bits for OTG\_DIEPINTx.

TXFE interrupt one bit per IN endpoint:

Bit 0 for IN endpoint 0, bit 3 for IN endpoint 3

0: Masked interrupt

1: Unmasked interrupt

**37.15.43 OTG device each endpoint interrupt register (OTG\_DEACHINT)**

Address offset: 0x0838

Reset value: 0x0000 0000

*Note: Configuration register applies only to USB OTG HS.*

Bits 16:2 Reserved, must be kept at reset value.

Bit 1 **IEP1INTM**: IN endpoint 1 interrupt mask bit

Bit 0 Reserved, must be kept at reset value.

*Note: Configuration register applies only to USB OTG HS*

### 37.15.45 OTG device each IN endpoint-1 interrupt mask register (OTG\_HS\_DIEPEACHMSK1)

Address offset: 0x844

Reset value: 0x0000 0000

This register works with the OTG\_DIEPINT1 register to generate a dedicated interrupt OTG\_HS\_EP1\_IN for endpoint #1. The IN endpoint interrupt for a specific status in the OTG\_DOEPINT1 register can be masked by writing into the corresponding bit in this register. Status bits are masked by default.

|      |      |      |      |      |      |      |        |      |         |      |           |      |         |      |        |

Bit 1 **EPDM**: Endpoint disabled interrupt mask

0: Masked interrupt

1: Unmasked interrupt

Bit 0 **XFRCM**: Transfer completed interrupt mask

0: Masked interrupt

1: Unmasked interrupt

### 37.15.46 OTG device each OUT endpoint-1 interrupt mask register (OTG\_HS\_DOEPEACHMSK1)

Address offset: 0x884

Reset value: 0x0000 0000

This register works with the OTG\_DOEPINT1 register to generate a dedicated interrupt OTG\_HS\_EP1\_OUT for endpoint #1. The OUT endpoint interrupt for a specific status in the OTG\_DOEPINT1 register can be masked by writing into the corresponding bit in this register. Status bits are masked by default.

|      |             |            |           |      |      |      |                    |      |              |      |            |       |             |      |           |

### 37.15.47 OTG device control IN endpoint 0 control register (OTG\_DIEPCTL0)

Address offset: 0x900

Reset value: 0x0000 0000

This section describes the OTG\_DIEPCTL0 register for USB\_OTG FS. Nonzero control endpoints use registers for endpoints 1–3.

|        |       |      |      |      |      |             |      |      |      |       |      |       |      |            |      |

- Bit 31 **EPENA**: Endpoint enable  
The application sets this bit to start transmitting data on the endpoint 0.  
The core clears this bit before setting any of the following interrupts on this endpoint:
- Endpoint disabled
  - Transfer completed
- Bit 30 **EPDIS**: Endpoint disable  
The application sets this bit to stop transmitting data on an endpoint, even before the transfer for that endpoint is complete. The application must wait for the endpoint disabled interrupt before treating the endpoint as disabled. The core clears this bit before setting the endpoint disabled interrupt. The application must set this bit only if endpoint enable is already set for this endpoint.
- Bits 29:28 Reserved, must be kept at reset value.
- Bit 27 **SNAK**: Set NAK  
A write to this bit sets the NAK bit for the endpoint.  
Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also set this bit for an endpoint after a SETUP packet is received on that endpoint.
- Bit 26 **CNAK**: Clear NAK  
A write to this bit clears the NAK bit for the endpoint.
- Bits 25:22 **TXFNUM[3:0]**: Tx FIFO number  
This value is set to the FIFO number that is assigned to IN endpoint 0.
- Bit 21 **STALL**: STALL handshake  
The application can only set this bit, and the core clears it when a SETUP token is received for this endpoint. If a NAK bit, a Global IN NAK or Global OUT NAK is set along with this bit, the STALL bit takes priority.
- Bit 20 Reserved, must be kept at reset value.
- Bits 19:18 **EPTYP**: Endpoint type  
Hardcoded to '00' for control.
- Bit 17 **NAKSTS**: NAK status  
Indicates the following:
- 0: The core is transmitting non-NAK handshakes based on the FIFO status
  - 1: The core is transmitting NAK handshakes on this endpoint.
- When this bit is set, either by the application or core, the core stops transmitting data, even if there are data available in the Tx FIFO. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake.
- Bit 16 Reserved, must be kept at reset value.

Bit 15 **USBAEP**: USB active endpoint

This bit is always set to 1, indicating that control endpoint 0 is always active in all configurations and interfaces.

Bits 14:2 Reserved, must be kept at reset value.

Bits 1:0 **MPSIZ[1:0]**: Maximum packet size

The application must program this field with the maximum packet size for the current logical endpoint.

00: 64 bytes

01: 32 bytes

10: 16 bytes

11: 8 bytes

*Note:* Configuration register applies only to USB OTG FS

### 37.15.48 OTG device IN endpoint x control register (OTG\_DIEPCTLx) (x = 1..5[FS] / 0..8[HS], where x = endpoint number)

Address offset: 0x900 + (x \* 0x20)

Reset value: 0x0000 0000

The application uses this register to control the behavior of each logical endpoint other than endpoint 0.

Bit 31 **EPENA**: Endpoint enable

The application sets this bit to start transmitting data on an endpoint.

The core clears this bit before setting any of the following interrupts on this endpoint:

- SETUP phase done
- Endpoint disabled
- Transfer completed

Bit 30 **EPDIS**: Endpoint disable

The application sets this bit to stop transmitting/receiving data on an endpoint, even before the transfer for that endpoint is complete. The application must wait for the endpoint disabled interrupt before treating the endpoint as disabled. The core clears this bit before setting the endpoint disabled interrupt. The application must set this bit only if endpoint enable is already set for this endpoint.

Bit 29 **SODDFRM**: Set odd frame

Applies to isochronous IN and OUT endpoints only.

Writing to this field sets the Even/Odd frame (EONUM) field to odd frame.

- Bit 28 **SD0PID**: Set DATA0 PID  
 Applies to interrupt/bulk IN endpoints only.  
 Writing to this field sets the endpoint data PID (DPID) field in this register to DATA0.
- SEVNFRM**: Set even frame  
 Applies to isochronous IN endpoints only.  
 Writing to this field sets the Even/Odd frame (EONUM) field to even frame.
- Bit 27 **SNAK**: Set NAK  
 A write to this bit sets the NAK bit for the endpoint.  
 Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also set this bit for OUT endpoints on a transfer completed interrupt, or after a SETUP is received on the endpoint.
- Bit 26 **CNAK**: Clear NAK  
 A write to this bit clears the NAK bit for the endpoint.
- Bits 25:22 **TXFNUM**: Tx FIFO number  
 These bits specify the FIFO number associated with this endpoint. Each active IN endpoint must be programmed to a separate FIFO number.  
 This field is valid only for IN endpoints.
- Bit 21 **STALL**: STALL handshake  
 Applies to non-control, non-isochronous IN endpoints only (access type is rw).  
 The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK bit, Global IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Only the application can clear this bit, never the core.  
 Applies to control endpoints only (access type is rs).  
 The application can only set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit, Global IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake.
- Bit 20 Reserved, must be kept at reset value.
- Bits 19:18 **EPTYP[1:0]**: Endpoint type  
 This is the transfer type supported by this logical endpoint.  
 00: Control  
 01: Isochronous  
 10: Bulk  
 11: Interrupt
- Bit 17 **NAKSTS**: NAK status  
 It indicates the following:  
 0: The core is transmitting non-NAK handshakes based on the FIFO status.  
 1: The core is transmitting NAK handshakes on this endpoint.  
 When either the application or the core sets this bit:  
 For non-isochronous IN endpoints: The core stops transmitting any data on an IN endpoint, even if there are data available in the Tx FIFO.  
 For isochronous IN endpoints: The core sends out a zero-length data packet, even if there are data available in the Tx FIFO.  
 Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake.

**Bit 16 EONUM:** Even/odd frame

Applies to isochronous IN endpoints only.

Indicates the frame number in which the core transmits/receives isochronous data for this endpoint. The application must program the even/odd frame number in which it intends to transmit/receive isochronous data for this endpoint using the SEVNFRM and SODDFRM fields in this register.

0: Even frame

1: Odd frame

**DPID:** Endpoint data PID

Applies to interrupt/bulk IN endpoints only.

Contains the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The application uses the SD0PID register field to program either DATA0 or DATA1 PID.

0: DATA0

1: DATA1

**Bit 15 USBAEP:** USB active endpoint

Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit.

Bits 14:11 Reserved, must be kept at reset value.

**Bits 10:0 MPSIZ[10:0]:** Maximum packet size

The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.

### 37.15.49 OTG device IN endpoint x interrupt register (OTG\_DIEPINTx) (x = 0..5[FS] / 8[HS], where x = Endpoint number)

Address offset:  $0x908 + (x * 0x20)$

Reset value: 0x0000 0080

This register indicates the status of an endpoint with respect to USB- and AHB-related events. It is shown in [Figure 466](#). The application must read this register when the IN endpoints interrupt bit of the core interrupt register (IEPINT in OTG\_GINTSTS) is set. Before the application can read this register, it must first read the device all endpoints interrupt (OTG\_DAINTE) register to get the exact endpoint number for the device endpoint-x interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the OTG\_DAINTE and OTG\_GINTSTS registers.

**Note:** Configuration register for USB OTG HS

Bits 31:14 Reserved, must be kept at reset value.

Bit 13 **NAK**: NAK input

The core generates this interrupt when a NAK is transmitted or received by the device. In case of isochronous IN endpoints the interrupt gets generated when a zero length packet is transmitted due to unavailability of data in the Tx FIFO.

Bit 12 Reserved, must be kept at reset value.

Bit 11 **PKTDRPSTS**: Packet dropped status

This bit indicates to the application that an ISOC OUT packet has been dropped. This bit does not have an associated mask bit and does not generate an interrupt.

Bit 10 Reserved, must be kept at reset value.

Bit 9 Reserved, must be kept at reset value.

Bit 8 **TXFIFOUDRN**: Transmit Fifo Underrun (TxfifoUndrn)

The core generates this interrupt when it detects a transmit FIFO underrun condition for this endpoint. Dependency: This interrupt is valid only when Thresholding is enabled

Bit 7 **TXFE**: Transmit FIFO empty

This interrupt is asserted when the Tx FIFO for this endpoint is either half or completely empty. The half or completely empty status is determined by the Tx FIFO Empty Level bit in the OTG\_GAHBCFG register (TXFELVL bit in OTG\_GAHBCFG).

Bit 6 **INEPNE**: IN endpoint NAK effective

This bit can be cleared when the application clears the IN endpoint NAK by writing to the CNAK bit in OTG\_DIEPCTLx.

This interrupt indicates that the core has sampled the NAK bit set (either by the application or by the core). The interrupt indicates that the IN endpoint NAK bit set by the application has taken effect in the core.

This interrupt does not guarantee that a NAK handshake is sent on the USB. A STALL bit takes priority over a NAK bit.

Bit 5 **INEPNM**: IN token received with EP mismatch

Indicates that the data in the top of the non-periodic TxFIFO belongs to an endpoint other than the one for which the IN token was received. This interrupt is asserted on the endpoint for which the IN token was received.

Bit 4 **ITTXFE**: IN token received when Tx FIFO is empty

Indicates that an IN token was received when the associated Tx FIFO (periodic/non-periodic) was empty. This interrupt is asserted on the endpoint for which the IN token was received.

Bit 3 **TOC**: Timeout condition

Indicates that the core has detected a timeout condition on the USB for the last IN token on this endpoint.

Bit 2 **AHBERR**: AHB error for USB OTG HS

This is generated only in internal DMA mode when there is an AHB error during an AHB read/write. The application can read the corresponding endpoint DMA address register to get the error address.

Bit 1 **EPDISD**: Endpoint disabled interrupt

This bit indicates that the endpoint is disabled per the application's request.

Bit 0 **XFRC**: Transfer completed interrupt

This field indicates that the programmed transfer is complete on the AHB as well as on the USB, for this endpoint.

### 37.15.50 OTG device IN endpoint 0 transfer size register (OTG\_DIEPTSIZ0)

Address offset: 0x910

Reset value: 0x0000 0000

The application must modify this register before enabling endpoint 0. Once endpoint 0 is enabled using the endpoint enable bit in the device control endpoint 0 control registers (EPENA in OTG\_DIEPCTL0), the core modifies this register. The application can only read this register once the core has cleared the endpoint enable bit.

Nonzero endpoints use the registers for endpoints 1–3.

Bits 31:21 Reserved, must be kept at reset value.

Bits 20:19 **PKTCNT[1:0]**: Packet count

Indicates the total number of USB packets that constitute the transfer size amount of data for endpoint 0.

This field is decremented every time a packet (maximum size or short packet) is read from the Tx FIFO.

Bits 18:7 Reserved, must be kept at reset value.

Bits 6:0 **XFRSIZ[6:0]**: Transfer size

Indicates the transfer size in bytes for endpoint 0. The core interrupts the application only after it has exhausted the transfer size amount of data. The transfer size can be set to the maximum packet size of the endpoint, to be interrupted at the end of each packet.

The core decrements this field every time a packet from the external memory is written to the Tx FIFO.

### 37.15.51 OTG device IN endpoint x DMA address register (OTG\_DIEPDMAx) (x = 0..8, where x = endpoint number)

Address offset: 0x914 + (x \* 0x20)

Reset value: 0x0000 0000

*Note:* Configuration register applies only to USB OTG HS

|                |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

Bits 31:0 **DMAADDR[31:0]**: DMA Address

This field holds the start address in the external memory from which the data for the endpoint must be fetched. This register is incremented on every AHB transaction.

### 37.15.52 OTG device IN endpoint transmit FIFO status register (OTG\_DTXFSTSx) (x = 0..5[FS] /8[HS], where x = endpoint number)

Address offset for IN endpoints: 0x918 + (x \* 0x20) This read-only register contains the free space information for the device IN endpoint Tx FIFO.

|                 |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |

| INEPTFSAV[15:0] |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
| r               | r    | r    | r    | r    | r    | r    | r    | r    | r    | r    | r    | r    | r    | r    | r    |

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **INEPTFSAV[15:0]**: IN endpoint Tx FIFO space available

Indicates the amount of free space available in the endpoint Tx FIFO.

Values are in terms of 32-bit words:

0x0: Endpoint Tx FIFO is full

0x1: 1 word available

0x2: 2 words available

0xn: n words available

Others: Reserved

### 37.15.53 OTG device IN endpoint x transfer size register (OTG\_DIEPTSIZx) ( $x = 1..5[FS] / 8[HS]$ , where $x$ = endpoint number)

Address offset:  $0x910 + (x * 0x20)$

Reset value: 0x0000 0000

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using the endpoint enable bit in the OTG\_DIEPCTLx registers (EPENA bit in OTG\_DIEPCTLx), the core modifies this register. The application can only read this register once the core has cleared the endpoint enable bit.

Bit 31 Reserved, must be kept at reset value.

Bits 30:29 **MCNT[1:0]**: Multi count

For periodic IN endpoints, this field indicates the number of packets that must be transmitted per frame on the USB. The core uses this field to calculate the data PID for isochronous IN endpoints.

01: 1 packet

10: 2 packets

11: 3 packets

Bits 28:19 **PKTCNT[9:0]**: Packet count

Indicates the total number of USB packets that constitute the transfer size amount of data for this endpoint.

This field is decremented every time a packet (maximum size or short packet) is read from the Tx FIFO.

Bits 18:0 **XFRSIZ[18:0]**: Transfer size

This field contains the transfer size in bytes for the current endpoint. The core only interrupts the application after it has exhausted the transfer size amount of data. The transfer size can be set to the maximum packet size of the endpoint, to be interrupted at the end of each packet.

The core decrements this field every time a packet from the external memory is written to the Tx FIFO.

### 37.15.54 OTG device control OUT endpoint 0 control register (OTG\_DOEPCTL0)

Address offset: 0xB00

Reset value: 0x0000 8000

This section describes the OTG\_DOEPCTL0 register. Nonzero control endpoints use registers for endpoints 1–3.

| 31      | 30    | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21    | 20   | 19         | 18   | 17         | 16   |

| EPENA   | EPDIS | Res. | Res. | SNAK | CNAK | Res. | Res. | Res. | Res. | STALL | SNPM | EPTYP[1:0] |      | NAK STS    | Res. |
| w       | r     |      |      | w    | w    |      |      |      |      | rs    | rw   | r          | r    | r          |      |
| 15      | 14    | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5     | 4    | 3          | 2    | 1          | 0    |
| USBA EP | Res.  | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res.  | Res. | Res.       | Res. | MPSIZ[1:0] |      |
| r       |       |      |      |      |      |      |      |      |      |       |      |            |      | r          | r    |

Bit 31 **EPENA**: Endpoint enable

The application sets this bit to start transmitting data on endpoint 0.

The core clears this bit before setting any of the following interrupts on this endpoint:

- SETUP phase done
- Endpoint disabled
- Transfer completed

Bit 30 **EPDIS**: Endpoint disable

The application cannot disable control OUT endpoint 0.

Bits 29:28 Reserved, must be kept at reset value.

Bit 27 **SNAK**: Set NAK

A write to this bit sets the NAK bit for the endpoint.

Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also set this bit on a transfer completed interrupt, or after a SETUP is received on the endpoint.

Bit 26 **CNAK**: Clear NAK

A write to this bit clears the NAK bit for the endpoint.

Bits 25:22 Reserved, must be kept at reset value.

Bit 21 **STALL**: STALL handshake

The application can only set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit or Global OUT NAK is set along with this bit, the STALL bit takes priority. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake.

Bit 20 **SNPM**: Snoop mode

This bit configures the endpoint to Snoop mode. In Snoop mode, the core does not check the correctness of OUT packets before transferring them to application memory.

Bits 19:18 **EPTYP[1:0]**: Endpoint type

Hardcoded to 2'b00 for control.

Bit 17 **NAKSTS**: NAK status

Indicates the following:

0: The core is transmitting non-NAK handshakes based on the FIFO status.

1: The core is transmitting NAK handshakes on this endpoint.

When either the application or the core sets this bit, the core stops receiving data, even if there is space in the Rx FIFO to accommodate the incoming packet. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake.

Bit 16 Reserved, must be kept at reset value.

Bit 15 **USBAEP**: USB active endpoint

This bit is always set to 1, indicating that a control endpoint 0 is always active in all configurations and interfaces.

Bits 14:2 Reserved, must be kept at reset value.

Bits 1:0 **MPSIZ[1:0]**: Maximum packet size

The maximum packet size for control OUT endpoint 0 is the same as what is programmed in control IN endpoint 0.

00: 64 bytes

01: 32 bytes

10: 16 bytes

11: 8 bytes

### 37.15.55 OTG device OUT endpoint x interrupt register (OTG\_DOEPINTx) (x = 0..5[FS] / 8[HS], where x = Endpoint number)

Address offset: 0xB08 + (x \* 0x20)

Reset value: 0x0000 0080

This register indicates the status of an endpoint with respect to USB- and AHB-related events. It is shown in [Figure 466](#). The application must read this register when the OUT endpoints interrupt bit of the OTG\_GINTSTS register (OEPINT bit in OTG\_GINTSTS) is set. Before the application can read this register, it must first read the OTG\_DAIN register to get the exact endpoint number for the OTG\_DOEPINTx register. The application must clear the appropriate bit in this register to clear the corresponding bits in the OTG\_DAIN and OTG\_GINTSTS registers.

**Note:** Configuration register for USB OTG HS.

Bits 31:16 Reserved, must be kept at reset value.

Bit 15 **STPKTRX**: Setup packet received.

Applicable for control OUT endpoints in only in the Buffer DMA Mode. Set by the OTG\_HS, this bit indicates that this buffer holds 8 bytes of setup data. There is only one setup packet per buffer. On receiving a setup packet, the OTG\_HS closes the buffer and disables the corresponding endpoint after SETUP\_COMPLETE status is seen in the Rx FIFO. OTG\_HS puts a SETUP\_COMPLETE status into the Rx FIFO when it sees the first IN or OUT token after the SETUP packet for that particular endpoint. The application must then re-enable the endpoint to receive any OUT data for the control transfer and reprogram the buffer start address. Because of the above behavior, OTG\_HS can receive any number of back to back setup packets and one buffer for every setup packet is used.

Bit 14 **NYET**: NYET interrupt

This interrupt is generated when a NYET response is transmitted for a non isochronous OUT endpoint.

Bit 13 **NAK**: NAK input

The core generates this interrupt when a NAK is transmitted or received by the device. In case of isochronous IN endpoints the interrupt gets generated when a zero length packet is transmitted due to unavailability of data in the Tx FIFO.

Bit 12 **BERR**: Babble error interrupt

The core generates this interrupt when babble is received for the endpoint.

Bits 11:10 Reserved, must be kept at reset value.

Bit 9 Reserved, must be kept at reset value.

Bit 8 **OUTPKTERR**: OUT packet error

This interrupt is asserted when the core detects an overflow or a CRC error for an OUT packet. This interrupt is valid only when thresholding is enabled.

Bit 7 Reserved, must be kept at reset value.

Bit 6 **B2BSTUP**: Back-to-back SETUP packets received for USB OTG HS

Applies to control OUT endpoint only.

This bit indicates that the core has received more than three back-to-back SETUP packets for this particular endpoint.

Bit 5 **STSPHSRX**: Status phase received for control write

This interrupt is valid only for control OUT endpoints. This interrupt is generated only after OTG\_FS/OTG\_HS has transferred all the data that the host has sent during the data phase of a control write transfer, to the system memory buffer. The interrupt indicates to the application that the host has switched from data phase to the status phase of a control write transfer. The application can use this interrupt to ACK or STALL the status phase, after it has decoded the data phase.

Bit 4 **OTEPDIS**: OUT token received when endpoint disabled

Applies only to control OUT endpoints.

Indicates that an OUT token was received when the endpoint was not yet enabled. This interrupt is asserted on the endpoint for which the OUT token was received.

Bit 3 **STUP**: SETUP phase done

Applies to control OUT endpoint only.

Indicates that the SETUP phase for the control endpoint is complete and no more back-to-back SETUP packets were received for the current control transfer. On this interrupt, the application can decode the received SETUP data packet.

Bit 2 **AHBERR**: AHB error for USB OTG HS

This is generated only in internal DMA mode when there is an AHB error during an AHB read/write. The application can read the corresponding endpoint DMA address register to get the error address.

Bit 1 **EPDISD**: Endpoint disabled interrupt

This bit indicates that the endpoint is disabled per the application's request.

Bit 0 **XFRC**: Transfer completed interrupt

This field indicates that the programmed transfer is complete on the AHB as well as on the USB, for this endpoint.

### 37.15.56 OTG device OUT endpoint 0 transfer size register (OTG\_DOEPTSIZE0)

Address offset: 0xB10

Reset value: 0x0000 0000

The application must modify this register before enabling endpoint 0. Once endpoint 0 is enabled using the endpoint enable bit in the OTG\_DOEPCTL0 registers (EPENA bit in OTG\_DOEPCTL0), the core modifies this register. The application can only read this register once the core has cleared the endpoint enable bit.

Nonzero endpoints use the registers for endpoints 1–5[FS] /8[HS].

Bit 31 Reserved, must be kept at reset value.

Bits 30:29 **STUPCNT[1:0]**: SETUP packet count

This field specifies the number of back-to-back SETUP data packets the endpoint can receive.

01: 1 packet

10: 2 packets

11: 3 packets

Bits 28:20 Reserved, must be kept at reset value.

Bit 19 **PKTCNT**: Packet count

This field is decremented to zero after a packet is written into the Rx FIFO.

Bits 18:7 Reserved, must be kept at reset value.

Bits 6:0 **XFRSIZ[6:0]**: Transfer size

Indicates the transfer size in bytes for endpoint 0. The core interrupts the application only after it has exhausted the transfer size amount of data. The transfer size can be set to the maximum packet size of the endpoint, to be interrupted at the end of each packet.

The core decrements this field every time a packet is read from the Rx FIFO and written to the external memory.

### 37.15.57 OTG device OUT endpoint x DMA address register (OTG\_DOEPDMAx) (x = 0..8, where x = endpoint number)

Address offset:  $0xB14 + (x * 0x20)$

Reset value: 0x0000 0000

*Note:* Configuration register applies only to USB OTG HS

|                |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

| rw             | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 31:0 **DMAADDR[31:0]**: DMA Address

This field holds the start address in the external memory from which the data for the endpoint must be fetched. This register is incremented on every AHB transaction.

### 37.15.58 OTG device OUT endpoint x control register (OTG\_DOEPTCTLx) ( $x = 1..5[FS] / 8[HS]$ , where $x$ = endpoint number)

Address offset for OUT endpoints:  $0xB00 + (x * 0x20)$

Reset value: 0x0000 0000

The application uses this register to control the behavior of each logical endpoint other than endpoint 0.

| 31         | 30    | 29                         | 28                         | 27   | 26          | 25   | 24   | 23   | 22   | 21    | 20   | 19         | 18 | 17         | 16                 |

**Bit 31 EPENA:** Endpoint enable

Applies to IN and OUT endpoints.

The application sets this bit to start transmitting data on an endpoint.

The core clears this bit before setting any of the following interrupts on this endpoint:

- SETUP phase done
- Endpoint disabled
- Transfer completed

**Bit 30 EPDIS:** Endpoint disable

The application sets this bit to stop transmitting/receiving data on an endpoint, even before the transfer for that endpoint is complete. The application must wait for the endpoint disabled interrupt before treating the endpoint as disabled. The core clears this bit before setting the endpoint disabled interrupt. The application must set this bit only if endpoint enable is already set for this endpoint.

**Bit 29 SD1PID:** Set DATA1 PID

Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the endpoint data PID (DPID) field in this register to DATA1.

**SODDFRM:** Set odd frame

Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd frame (EONUM) field to odd frame.

**Bit 28 SD0PID:** Set DATA0 PID

Applies to interrupt/bulk OUT endpoints only.

Writing to this field sets the endpoint data PID (DPID) field in this register to DATA0.

**SEVNFRM:** Set even frame

Applies to isochronous OUT endpoints only.

Writing to this field sets the Even/Odd frame (EONUM) field to even frame.

**Bit 27 SNAK:** Set NAK

A write to this bit sets the NAK bit for the endpoint.

Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also set this bit for OUT endpoints on a transfer completed interrupt, or after a SETUP is received on the endpoint.

**Bit 26 CNAK:** Clear NAK

A write to this bit clears the NAK bit for the endpoint.

Bits 25:22 Reserved, must be kept at reset value.

**Bit 21 STALL:** STALL handshake

Applies to non-control, non-isochronous OUT endpoints only (access type is rw).

The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK bit, Global IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Only the application can clear this bit, never the core.

Applies to control endpoints only (access type is rs).

The application can only set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit, Global IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake.

**Bit 20 SNPM:** Snoop mode

This bit configures the endpoint to Snoop mode. In Snoop mode, the core does not check the correctness of OUT packets before transferring them to application memory.

**Bits 19:18 EPTYP[1:0]:** Endpoint type

This is the transfer type supported by this logical endpoint.

00: Control

01: Isochronous

10: Bulk

11: Interrupt

**Bit 17 NAKSTS:** NAK status

Indicates the following:

0: The core is transmitting non-NAK handshakes based on the FIFO status.

1: The core is transmitting NAK handshakes on this endpoint.

When either the application or the core sets this bit:

The core stops receiving any data on an OUT endpoint, even if there is space in the Rx FIFO to accommodate the incoming packet.

Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake.

**Bit 16 EONUM:** Even/odd frame

Applies to isochronous IN and OUT endpoints only.

Indicates the frame number in which the core transmits/receives isochronous data for this endpoint. The application must program the even/odd frame number in which it intends to transmit/receive isochronous data for this endpoint using the SEVNFRM and SODDFRM fields in this register.

0: Even frame

1: Odd frame

**DPID:** Endpoint data PID

Applies to interrupt/bulk OUT endpoints only.

Contains the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The application uses the SD0PID register field to program either DATA0 or DATA1 PID.

0: DATA0

1: DATA1

Bit 15 **USBAEP**: USB active endpoint

Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit.

Bits 14:11 Reserved, must be kept at reset value.

Bits 10:0 **MPSIZ[10:0]**: Maximum packet size

The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.

### 37.15.59 OTG device OUT endpoint x transfer size register (OTG\_DOEPTSIZE<sub>x</sub>) (x = 1..5[FS] / 8[HS], where x = Endpoint number)

Address offset: 0xB10 + (x \* 0x20)

Reset value: 0x0000 0000

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using endpoint enable bit of the OTG\_DOEPCTL<sub>x</sub> registers (EPENA bit in OTG\_DOEPCTL<sub>x</sub>), the core modifies this register. The application can only read this register once the core has cleared the endpoint enable bit.

Bit 31 Reserved, must be kept at reset value.

Bits 30:29 **RXDPID[1:0]**: Received data PID

Applies to isochronous OUT endpoints only.

This is the data PID received in the last packet for this endpoint.

00: DATA0

01: DATA2

10: DATA1

11: MDATA

**STUPCNT[1:0]: SETUP packet count**

Applies to control OUT endpoints only.

This field specifies the number of back-to-back SETUP data packets the endpoint can receive.

01: 1 packet

10: 2 packets

11: 3 packets

**Bits 28:19 PKTCNT[9:0]: Packet count**

Indicates the total number of USB packets that constitute the transfer size amount of data for this endpoint.

This field is decremented every time a packet (maximum size or short packet) is written to the Rx FIFO.

**Bits 18:0 XFRSIZ: Transfer size**

This field contains the transfer size in bytes for the current endpoint. The core only interrupts the application after it has exhausted the transfer size amount of data. The transfer size can be set to the maximum packet size of the endpoint, to be interrupted at the end of each packet.

The core decrements this field every time a packet is read from the Rx FIFO and written to the external memory.

**37.15.60 OTG power and clock gating control register (OTG\_PCGCCTL)**

Address offset: 0xE00

Reset value: 0x200B 8000

This register is available in host and device modes.

| 31   | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22        | 21       | 20       | 19   | 18   | 17        | 16       |

Bits 31:8 Reserved, must be kept at reset value.

**Bit 7 SUSP: Deep Sleep**

This bit indicates that the PHY is in Deep Sleep when in L1 state.

**Bit 6 PHYSLEEP: PHY in Sleep**

This bit indicates that the PHY is in the Sleep state.

**Bit 5 ENL1GTG: Enable sleep clock gating**

When this bit is set, core internal clock gating is enabled in Sleep state if the core cannot assert utmi\_l1\_suspend\_n. When this bit is not set, the PHY clock is not gated in Sleep state.

**Bit 4 PHYSUSP: PHY suspended**

Indicates that the PHY has been suspended. This bit is updated once the PHY is suspended after the application has set the STPPCLK bit.

Bits 3:2 Reserved, must be kept at reset value.

Bit 1 **GATEHCLK**: Gate HCLK

The application sets this bit to gate HCLK to modules other than the AHB Slave and Master and wakeup logic when the USB is suspended or the session is not valid. The application clears this bit when the USB is resumed or a new session starts.

Bit 0 **STPPCLK**: Stop PHY clock

The application sets this bit to stop the PHY clock when the USB is suspended, the session is not valid, or the device is disconnected. The application clears this bit when the USB is resumed or a new session starts.

### 37.15.61 OTG\_FS/OTG\_HS register map

The table below gives the USB OTG register map and reset values.

**Table 271. OTG\_FS/OTG\_HS register map and reset values**

| Offset | Register name | 31   | 30    | 29    | 28   | 27   | 26   | 25      | 24   | 23   | 22    | 21        | 20        | 19      | 18     | 17      | 16     | 15     | 14   | 13   | 12   | 11     | 10      | 9        | 8       | 7        | 6       | 5        | 4       | 3         | 2        | 1       | 0       |  |

Refer to [Section 2.2.2 on page 69](#) for the register boundary addresses.

## 37.16 OTG\_FS/OTG\_HS programming model

### 37.16.1 Core initialization

The application must perform the core initialization sequence. If the cable is connected during power-up, the current mode of operation bit in the OTG\_GINTSTS (CMOD bit in OTG\_GINTSTS) reflects the mode. The OTG\_FS/OTG\_HS controller enters host mode when an "A" plug is connected or device mode when a "B" plug is connected.

This section explains the initialization of the OTG\_FS/OTG\_HS controller after power-on. The application must follow the initialization sequence irrespective of host or device mode operation. All core global registers are initialized according to the core's configuration:

1. Program the following fields in the OTG\_GAHBCFG register:
  - Global interrupt mask bit GINTMSK = 1
  - Rx FIFO non-empty (RXFLVL bit in OTG\_GINTSTS)
  - Periodic Tx FIFO empty level
2. Program the following fields in the OTG\_GUSBCFG register:
  - HNP capable bit
  - SRP capable bit
  - OTG\_FS/OTG\_HS timeout calibration field
  - USB turnaround time field
3. The software must unmask the following bits in the OTG\_GINTMSK register:
  - OTG interrupt mask
  - Mode mismatch interrupt mask
4. The software can read the CMOD bit in OTG\_GINTSTS to determine whether the OTG\_FS/OTG\_HS controller is operating in host or device mode.

### 37.16.2 Host initialization

To initialize the core as host, the application must perform the following steps:

1. Program the HPRTINT in the OTG\_GINTMSK register to unmask
2. Program the OTG\_HCFG register to select full-speed host
3. Program the PPWR bit in OTG\_HPRT to 1. This drives  $V_{BUS}$  on the USB.
4. Wait for the PCDET interrupt in OTG\_HPRT0. This indicates that a device is connecting to the port.
5. Program the PRST bit in OTG\_HPRT to 1. This starts the reset process.
6. Wait at least 10 ms for the reset process to complete.
7. Program the PRST bit in OTG\_HPRT to 0.
8. Wait for the PENCHNG interrupt in OTG\_HPRT.
9. Read the PSPD bit in OTG\_HPRT to get the enumerated speed.
10. Program the HFIR register with a value corresponding to the selected PHY clock 1
11. Program the FSLSPCS field in the OTG\_HCFG register following the speed of the device detected in step 9. If FSLSPCS has been changed a port reset must be performed.
12. Program the OTG\_GRXFSIZ register to select the size of the receive FIFO.
13. Program the OTG\_HNPTXFSIZ register to select the size and the start address of the Non-periodic transmit FIFO for non-periodic transactions.
14. Program the OTG\_HPTXFSIZ register to select the size and start address of the periodic transmit FIFO for periodic transactions.

To communicate with devices, the system software must initialize and enable at least one channel.

### 37.16.3 Device initialization

The application must perform the following steps to initialize the core as a device on power-up or after a mode change from host to device.

1. Program the following fields in the OTG\_DCFG register:
  - Device speed
  - Non-zero-length status OUT handshake
2. Program the OTG\_GINTMSK register to unmask the following interrupts:
  - USB reset
  - Enumeration done
  - Early suspend
  - USB suspend
  - SOF
3. Wait for the USBRST interrupt in OTG\_GINTSTS. It indicates that a reset has been detected on the USB that lasts for about 10 ms on receiving this interrupt.

Wait for the ENUMDNE interrupt in OTG\_GINTSTS. This interrupt indicates the end of reset on the USB. On receiving this interrupt, the application must read the OTG\_DSTS register to determine the enumeration speed and perform the steps listed in [Endpoint initialization on enumeration completion on page 1501](#).

At this point, the device is ready to accept SOF packets and perform control transfers on control endpoint 0.

### 37.16.4 DMA mode

The OTG host uses the AHB master interface to fetch the transmit packet data (AHB to USB) and receive the data update (USB to AHB). The AHB master uses the programmed DMA address (OTG\_HCDMAx register in host mode and OTG\_DIEPDMAx/OTG\_DOEPDMAx register in peripheral mode) to access the data buffers.

### 37.16.5 Host programming model

#### Channel initialization

The application must initialize one or more channels before it can communicate with connected devices. To initialize and enable a channel, the application must perform the following steps:

1. Program the OTG\_GINTMSK register to unmask the following:
2. Channel interrupt
  - Non-periodic transmit FIFO empty for OUT transactions (applicable when operating in pipelined transaction-level with the packet count field programmed with more than one).
  - Non-periodic transmit FIFO half-empty for OUT transactions (applicable when operating in pipelined transaction-level with the packet count field programmed with more than one).
3. Program the OTG\_HAINTMSK register to unmask the selected channels' interrupts.
4. Program the OTG\_HCINTMSK register to unmask the transaction-related interrupts of interest given in the host channel interrupt register.
5. Program the selected channel's OTG\_HCTSIZx register with the total transfer size, in bytes, and the expected number of packets, including short packets. The application must program the PID field with the initial data PID (to be used on the first OUT transaction or to be expected from the first IN transaction).
6. Program the OTG\_HCCHARx register of the selected channel with the device's endpoint characteristics, such as type, speed, direction, and so forth. (The channel can be enabled by setting the channel enable bit to 1 only when the application is ready to transmit or receive any packet).
7. Program the selected channels in the OTG\_HCSPLTx register(s) with the hub and port addresses (split transactions only).
8. Program the selected channels in the OTG\_HCDMAx register(s) with the buffer start address (DMA transactions only).

#### Halting a channel

The application can disable any channel by programming the OTG\_HCCHARx register with the CHDIS and CHENA bits set to 1. This enables the OTG\_FS/OTG\_HS host to flush the posted requests (if any) and generates a channel halted interrupt. The application must wait for the CHH interrupt in OTG\_HCINTx before reallocating the channel for other transactions. The OTG\_FS/OTG\_HS host does not interrupt the transaction that has already been started on the USB.

To disable a channel in DMA mode operation, the application does not need to check for space in the request queue. The OTG\_HS host checks for space to write the disable

request on the disabled channel's turn during arbitration. Meanwhile, all posted requests are dropped from the request queue when the CHDIS bit in OTG\_HCCHARx is set to 1.

Before disabling a channel, the application must ensure that there is at least one free space available in the non-periodic request queue (when disabling a non-periodic channel) or the periodic request queue (when disabling a periodic channel). The application can simply flush the posted requests when the request queue is full (before disabling the channel), by programming the OTG\_HCCHARx register with the CHDIS bit set to 1, and the CHENA bit cleared to 0.

The application is expected to disable a channel on any of the following conditions:

1. When an STALL, TXERR, BBERR or DTERR interrupt in OTG\_HCINTx is received for an IN or OUT channel. The application must be able to receive other interrupts (DTERR, Nak, data, TXERR) for the same channel before receiving the halt.
2. When an XFRC interrupt in OTG\_HCINTx is received during a non periodic IN transfer or high-bandwidth interrupt IN transfer
3. When a DISCINT (disconnect device) interrupt in OTG\_GINTSTS is received. (The application is expected to disable all enabled channels).
4. When the application aborts a transfer before normal completion.

### Ping protocol

When the OTG\_HS host operates in high speed, the application must initiate the ping protocol when communicating with high-speed bulk or control (data and status stage) OUT endpoints. The application must initiate the ping protocol when it receives a NAK/NYET/TXERR interrupt. When the OTG\_HS host receives one of the above responses, it does not continue any transaction for a specific endpoint, drops all posted or fetched OUT requests (from the request queue), and flushes the corresponding data (from the transmit FIFO). This is valid in slave mode only. In Slave mode, the application can send a ping token either by setting the DOPING bit in OTG\_HCTSIZx before enabling the channel or by just writing the OTG\_HCTSIZx register with the DOPING bit set when the channel is already enabled. This enables the OTG\_HS host to write a ping request entry to the request queue. The application must wait for the response to the ping token (a NAK, ACK, or TXERR interrupt) before continuing the transaction or sending another ping token. The application can continue the data transaction only after receiving an ACK from the OUT endpoint for the requested ping. In DMA mode operation, the application does not need to set the DOPING bit in OTG\_HCTSIZx for a NAK/NYET response in case of bulk/control OUT. The OTG\_HS host automatically sets the DOPING bit in OTG\_HCTSIZx, and issues the ping tokens for bulk/control OUT. The OTG\_HS host continues sending ping tokens until it receives an ACK, and then switches automatically to the data transaction.

### Operational model

The application must initialize a channel before communicating to the connected device. This section explains the sequence of operation to be performed for different types of USB transactions.

- **Writing the transmit FIFO**

The OTG\_FS/OTG\_HS host automatically writes an entry (OUT request) to the periodic/non-periodic request queue, along with the last 32-bit word write of a packet. The application must ensure that at least one free space is available in the periodic/non-periodic request queue before starting to write to the transmit FIFO. The application must always write to the transmit FIFO in 32-bit words. If the packet size is non-32-bit word aligned, the application must use padding. The OTG\_FS/OTG\_HS

host determines the actual packet size based on the programmed maximum packet size and transfer size.

**Figure 467. Transmit FIFO write task**

- **Reading the receive FIFO**

The application must ignore all packet statuses other than IN data packet (bx0010).

Figure 468. Receive FIFO read task

- Bulk and control OUT/SETUP transactions**

A typical bulk or control OUT/SETUP pipelined transaction-level operation is shown in [Figure 469](#). See channel 1 (ch\_1). Two bulk OUT packets are transmitted. A control SETUP transaction operates in the same way but has only one packet. The assumptions are:

- The application is attempting to send two maximum-packet-size packets (transfer size = 1,024 bytes).
- The non-periodic transmit FIFO can hold two packets (1 KB for HS/128 bytes for FS).
- The non-periodic request queue depth = 4.

- Normal bulk and control OUT/SETUP operations**

The sequence of operations in (channel 1) is as follows:

1. Initialize channel 1
2. Write the first packet for channel 1
3. Along with the last word write, the core writes an entry to the non-periodic request queue
4. As soon as the non-periodic queue becomes non-empty, the core attempts to send an OUT token in the current frame
5. Write the second (last) packet for channel 1
6. The core generates the XFRC interrupt as soon as the last transaction is completed successfully
7. In response to the XFRC interrupt, de-allocate the channel for other transfers
8. Handling non-ACK responses

Figure 469. Normal bulk/control OUT/SETUP

MSv36018V1

1. The grayed elements are not relevant in the context of this figure.

The channel-specific interrupt service routine for bulk and control OUT/SETUP transactions is shown in the following code samples.

- **Interrupt service routine for bulk/control OUT/SETUP and bulk/control IN transactions**

- a) Bulk/control OUT/SETUP

```
Unmask (NAK/TXERR/STALL/XFRC)
if (XFRC)
{
    Reset Error Count
    Mask ACK
    De-allocate Channel
}
else if (STALL)
{
    Transfer Done = 1
    Unmask CHH
    Disable Channel
}
else if (NAK or TXERR )
{
    Rewind Buffer Pointers
    Unmask CHH
    Disable Channel
    if (TXERR)
    {
        Increment Error Count
        Unmask ACK
    }
    else
    {
        Reset Error Count
    }
}
else if (CHH)
{
    Mask CHH
    if (Transfer Done or (Error_count == 3))
    {
        De-allocate Channel
    }
    else
    {
        Re-initialize Channel
    }
}
```

```

else if (ACK)
{
    Reset Error Count
    Mask ACK
}

```

The application is expected to write the data packets into the transmit FIFO when the space is available in the transmit FIFO and the request queue. The application can make use of the NPTXFE interrupt in OTG\_GINTSTS to find the transmit FIFO space.

#### b) Bulk/control IN

```

Unmask (TXERR/XFRC/BBERR/STALL/DTERR)
if (XFRC)
{
    Reset Error Count
    Unmask CHH
    Disable Channel
    Reset Error Count
    Mask ACK
}
else if (TXERR or BBERR or STALL)
{
    Unmask CHH
    Disable Channel
    if (TXERR)
    {
        Increment Error Count
        Unmask ACK
    }
}
else if (CHH)
{
    Mask CHH
    if (Transfer Done or (Error_count == 3))
    {
        De-allocate Channel
    }
    else
    {
        Re-initialize Channel
    }
}
else if (ACK)
{
    Reset Error Count
    Mask ACK
}

```

```
else if (DTERR)
{
    Reset Error Count
}
```

The application is expected to write the requests as and when the request queue space is available and until the XFRC interrupt is received.

- **Bulk and control IN transactions**

A typical bulk or control IN pipelined transaction-level operation is shown in [Figure 470](#). See channel 2 (ch\_2). The assumptions are:

- The application is attempting to receive two maximum-packet-size packets (transfer size = 1 024 bytes).
- The receive FIFO can contain at least one maximum-packet-size packet and two status words per packet (72 bytes for FS/520 bytes for HS).
- The non-periodic request queue depth = 4.

Figure 470. Bulk/control IN transactions

1. The grayed elements are not relevant in the context of this figure.

The sequence of operations is as follows:

1. Initialize channel 2.
2. Set the CHENA bit in OTG\_HCCHAR2 to write an IN request to the non-periodic request queue.
3. The core attempts to send an IN token after completing the current OUT transaction.
4. The core generates an RXFLVL interrupt as soon as the received packet is written to the receive FIFO.
5. In response to the RXFLVL interrupt, mask the RXFLVL interrupt and read the received packet status to determine the number of bytes received, then read the receive FIFO accordingly. Following this, unmask the RXFLVL interrupt.
6. The core generates the RXFLVL interrupt for the transfer completion status entry in the receive FIFO.
7. The application must read and ignore the receive packet status when the receive packet status is not an IN data packet (PKTSTS in OTG\_GRXSTSR  $\neq$  0b0010).
8. The core generates the XFRC interrupt as soon as the receive packet status is read.
9. In response to the XFRC interrupt, disable the channel and stop writing the OTG\_HCCHAR2 register for further requests. The core writes a channel disable request to the non-periodic request queue as soon as the OTG\_HCCHAR2 register is written.
10. The core generates the RXFLVL interrupt as soon as the halt status is written to the receive FIFO.
11. Read and ignore the receive packet status.
12. The core generates a CHH interrupt as soon as the halt status is popped from the receive FIFO.
13. In response to the CHH interrupt, de-allocate the channel for other transfers.
14. Handling non-ACK responses

- **Control transactions**

Setup, data, and status stages of a control transfer must be performed as three separate transfers. setup-, data- or status-stage OUT transactions are performed similarly to the bulk OUT transactions explained previously. Data- or status-stage IN transactions are performed similarly to the bulk IN transactions explained previously. For all three stages, the application is expected to set the EPTYP field in OTG\_HCCHAR1 to control. During the setup stage, the application is expected to set the PID field in OTG\_HCTSIZ1 to SETUP.

- **Interrupt OUT transactions**

A typical interrupt OUT operation is shown in [Figure 471](#). The assumptions are:

- The application is attempting to send one packet in every frame (up to 1 maximum packet size), starting with the odd frame (transfer size = 1 024 bytes)
- The periodic transmit FIFO can hold one packet (1 KB)
- Periodic request queue depth = 4

The sequence of operations is as follows:

1. Initialize and enable channel 1. The application must set the ODDFRM bit in OTG\_HCCHAR1.
2. Write the first packet for channel 1.
3. Along with the last word write of each packet, the OTG\_FS/OTG\_HS host writes an entry to the periodic request queue.
4. The OTG\_FS/OTG\_HS host attempts to send an OUT token in the next (odd) frame.
5. The OTG\_FS/OTG\_HS host generates an XFRC interrupt as soon as the last packet is transmitted successfully.
6. In response to the XFRC interrupt, reinitialize the channel for the next transfer.

Figure 471. Normal interrupt OUT

Unmask (NAK/TXERR/STALL/XFRC/FRMOR)

```
if (XFRC)
{
    Reset Error Count
    Mask ACK
    De-allocate Channel
}
else
    if (STALL or FRMOR)
    {
        Mask ACK
        Unmask CHH
        Disable Channel
        if (STALL)
        {
            Transfer Done = 1
        }
    }
else
    if (NAK or TXERR)
    {
        Rewind Buffer Pointers
        Reset Error Count
        Mask ACK
        Unmask CHH
        Disable Channel
    }
else
    if (CHH)
    {
        Mask CHH
        if (Transfer Done or (Error_count == 3))
        {
            De-allocate Channel
        }
        else
        {
            Re-initialize Channel (in next b_interval - 1 Frame)
        }
    }
else
    if (ACK)
    {
        Reset Error Count
        Mask ACK
    }
```

The application uses the NPTXFE interrupt in OTG\_GINTSTS to find the transmit FIFO space.

Interrupt IN

Unmask (NAK/TXERR/XFRC/BBERR/STALL/FRMOR/DTERR)

```
if (XFRC)
{
    Reset Error Count
    Mask ACK
    if (OTG_HCTSIZx.PKTCNT == 0)
    {
        De-allocate Channel
    }
    else
    {
        Transfer Done = 1
        Unmask CHH
        Disable Channel
    }
}
else
    if (STALL or FRMOR or NAK or DTERR or BBERR)
    {
        Mask ACK
        Unmask CHH
        Disable Channel
        if (STALL or BBERR)
        {
            Reset Error Count
            Transfer Done = 1
        }
        else
            if (!FRMOR)
            {
                Reset Error Count
            }
    }
else
    if (TXERR)
    {
        Increment Error Count
        Unmask ACK
        Unmask CHH
        Disable Channel
    }
else
```

```

if (CHH)
{
    Mask CHH
    if (Transfer Done or (Error_count == 3))
    {
        De-allocate Channel
    }
    else
        Re-initialize Channel (in next b_interval - 1 /Frame)
}
}
else
    if (ACK)
    {
        Reset Error Count
        Mask ACK
    }
}

```

- **Interrupt IN transactions**

The assumptions are:

- The application is attempting to receive one packet (up to 1 maximum packet size) in every frame, starting with odd (transfer size = 1 024 bytes).
- The receive FIFO can hold at least one maximum-packet-size packet and two status words per packet (1 031 bytes).
- Periodic request queue depth = 4.

- **Normal interrupt IN operation**

The sequence of operations is as follows:

1. Initialize channel 2. The application must set the ODDFRM bit in OTG\_HCCHAR2.
2. Set the CHENA bit in OTG\_HCCHAR2 to write an IN request to the periodic request queue.
3. The OTG\_FS/OTG\_HS host writes an IN request to the periodic request queue for each OTG\_HCCHAR2 register write with the CHENA bit set.
4. The OTG\_FS/OTG\_HS host attempts to send an IN token in the next (odd) frame.
5. As soon as the IN packet is received and written to the receive FIFO, the OTG\_FS/OTG\_HS host generates an RXFLVL interrupt.
6. In response to the RXFLVL interrupt, read the received packet status to determine the number of bytes received, then read the receive FIFO accordingly. The application must mask the RXFLVL interrupt before reading the receive FIFO, and unmask after reading the entire packet.
7. The core generates the RXFLVL interrupt for the transfer completion status entry in the receive FIFO. The application must read and ignore the receive packet status when the receive packet status is not an IN data packet (PKTSTS in GRXSTSR ≠ 0b0010).
8. The core generates an XFRC interrupt as soon as the receive packet status is read.
9. In response to the XFRC interrupt, read the PKTCNT field in OTG\_HCTSIZ2. If the PKTCNT bit in OTG\_HCTSIZ2 is not equal to 0, disable the channel before re-

initializing the channel for the next transfer, if any). If PKTCNT bit in OTG\_HCTSIZ2 = 0, reinitialize the channel for the next transfer. This time, the application must reset the ODDFRM bit in OTG\_HCCHAR2.

Figure 472. Normal interrupt IN

1. The grayed elements are not relevant in the context of this figure.

- **Isochronous OUT transactions**

A typical isochronous OUT operation is shown in [Figure 472](#). The assumptions are:

- The application is attempting to send one packet every frame (up to 1 maximum)

packet size), starting with an odd frame. (transfer size = 1 024 bytes).

- The periodic transmit FIFO can hold one packet (1 KB).
- Periodic request queue depth = 4.

The sequence of operations is as follows:

1. Initialize and enable channel 1. The application must set the ODDFRM bit in OTG\_HCCHAR1.
2. Write the first packet for channel 1.
3. Along with the last word write of each packet, the OTG\_FS/OTG\_HS host writes an entry to the periodic request queue.
4. The OTG\_FS/OTG\_HS host attempts to send the OUT token in the next frame (odd).
5. The OTG\_FS/OTG\_HS host generates the XFRC interrupt as soon as the last packet is transmitted successfully.
6. In response to the XFRC interrupt, reinitialize the channel for the next transfer.
7. Handling non-ACK responses

- **Isochronous IN transactions**

The assumptions are:

- The application is attempting to receive one packet (up to 1 maximum packet size) in every frame starting with the next odd frame (transfer size = 1 024 bytes).
- The receive FIFO can hold at least one maximum-packet-size packet and two status word per packet (1 031 bytes).
- Periodic request queue depth = 4.

The sequence of operations is as follows:

1. Initialize channel 2. The application must set the ODDFRM bit in OTG\_HCCHAR2.
2. Set the CHENA bit in OTG\_HCCHAR2 to write an IN request to the periodic request queue.
3. The OTG\_FS/OTG\_HS host writes an IN request to the periodic request queue for each OTG\_HCCHAR2 register write with the CHENA bit set.
4. The OTG\_FS/OTG\_HS host attempts to send an IN token in the next odd frame.
5. As soon as the IN packet is received and written to the receive FIFO, the OTG\_FS/OTG\_HS host generates an RXFLVL interrupt.
6. In response to the RXFLVL interrupt, read the received packet status to determine the number of bytes received, then read the receive FIFO accordingly. The application must mask the RXFLVL interrupt before reading the receive FIFO, and unmask it after reading the entire packet.
7. The core generates an RXFLVL interrupt for the transfer completion status entry in the receive FIFO. This time, the application must read and ignore the receive packet status when the receive packet status is not an IN data packet (PKTSTS bit in OTG\_GRXSTSR ≠ 0b0010).
8. The core generates an XFRC interrupt as soon as the receive packet status is read.
9. In response to the XFRC interrupt, read the PKTCNT field in OTG\_HCTSIZ2. If PKTCNT ≠ 0 in OTG\_HCTSIZ2, disable the channel before re-initializing the channel for the next transfer, if any. If PKTCNT = 0 in OTG\_HCTSIZ2, reinitialize the channel for the next transfer. This time, the application must reset the ODDFRM bit in OTG\_HCCHAR2.

Figure 474. Isochronous IN transactions

1. The grayed elements are not relevant in the context of this figure.

- **Selecting the queue depth**

Choose the periodic and non-periodic request queue depths carefully to match the number of periodic/non-periodic endpoints accessed.

The non-periodic request queue depth affects the performance of non-periodic

transfers. The deeper the queue (along with sufficient FIFO size), the more often the core is able to pipeline non-periodic transfers. If the queue size is small, the core is able to put in new requests only when the queue space is freed up.

The core's periodic request queue depth is critical to perform periodic transfers as scheduled. Select the periodic queue depth, based on the number of periodic transfers scheduled in a microframe. If the periodic request queue depth is smaller than the periodic transfers scheduled in a microframe, a frame overrun condition occurs.

- **Handling babble conditions**

OTG\_FS/OTG\_HS controller handles two cases of babble: packet babble and port babble. Packet babble occurs if the device sends more data than the maximum packet size for the channel. Port babble occurs if the core continues to receive data from the device at EOF2 (the end of frame 2, which is very close to SOF).

When OTG\_FS/OTG\_HS controller detects a packet babble, it stops writing data into the Rx buffer and waits for the end of packet (EOP). When it detects an EOP, it flushes already written data in the Rx buffer and generates a Babble interrupt to the application.

When OTG\_FS/OTG\_HS controller detects a port babble, it flushes the Rx FIFO and disables the port. The core then generates a port disabled interrupt (HPRTINT in OTG\_GINTSTS, PENCHNG in OTG\_HPRT). On receiving this interrupt, the application must determine that this is not due to an overcurrent condition (another cause of the port disabled interrupt) by checking POCA in OTG\_HPRT, then perform a soft reset. The core does not send any more tokens after it has detected a port babble condition.

*Note: The following paragraphs, ranging from here to the beginning of [Section 37.16](#), and covering DMA configurations, apply only to USB OTG HS.*

- **Bulk and control OUT/SETUP transactions in DMA mode**

The sequence of operations is as follows:

1. Initialize and enable channel 1 as explained in [Section : Channel initialization](#).
2. The OTG\_HS host starts fetching the first packet as soon as the channel is enabled. For internal DMA mode, the OTG\_HS host uses the programmed DMA address to fetch the packet.
3. After fetching the last 32-bit word of the second (last) packet, the OTG\_HS host masks channel 1 internally for further arbitration.
4. The OTG\_HS host generates a CHH interrupt as soon as the last packet is sent.
5. In response to the CHH interrupt, de-allocate the channel for other transfers.

Figure 475. Normal bulk/control OUT/SETUP transactions - DMA

- **NAK and NYET handling with internal DMA:**

1. The OTG\_HS host sends a bulk OUT transaction.
2. The device responds with NAK or NYET.
3. If the application has unmasked NAK or NYET, the core generates the corresponding interrupt(s) to the application. The application is not required to service these interrupts, since the core takes care of rewinding the buffer pointers and re-initializing the Channel without application intervention.
4. The core automatically issues a ping token.
5. When the device returns an ACK, the core continues with the transfer. Optionally, the application can utilize these interrupts, in which case the NAK or NYET interrupt is masked by the application.

The core does not generate a separate interrupt when NAK or NYET is received by the host functionality.

- **Bulk and control IN transactions in DMA mode**

The sequence of operations is as follows:

1. Initialize and enable the used channel (channel x) as explained in [Section : Channel initialization](#).
2. The OTG\_HS host writes an IN request to the request queue as soon as the channel receives the grant from the arbiter (arbitration is performed in a round-robin fashion).
3. The OTG\_HS host starts writing the received data to the system memory as soon as the last byte is received with no errors.
4. When the last packet is received, the OTG\_HS host sets an internal flag to remove any extra IN requests from the request queue.
5. The OTG\_HS host flushes the extra requests.
6. The final request to disable channel x is written to the request queue. At this point, channel 2 is internally masked for further arbitration.
7. The OTG\_HS host generates the CHH interrupt as soon as the disable request comes to the top of the queue.
8. In response to the CHH interrupt, de-allocate the channel for other transfers.

**Figure 476. Normal bulk/control IN transaction - DMA**

- **Interrupt OUT transactions in DMA mode**

1. Initialize and enable channel x as explained in [Section : Channel initialization](#).
2. The OTG\_HS host starts fetching the first packet as soon the channel is enabled and writes the OUT request along with the last 32-bit word fetch. In high-bandwidth transfers, the OTG\_HS host continues fetching the next packet (up to the value specified in the MC field) before switching to the next channel.
3. The OTG\_HS host attempts to send the OUT token at the beginning of the next odd frame/micro-frame.

4. After successfully transmitting the packet, the OTG\_HS host generates a CHH interrupt.
5. In response to the CHH interrupt, reinitialize the channel for the next transfer.

**Figure 477. Normal interrupt OUT transactions - DMA mode**

- **Interrupt IN transactions in DMA mode**

The sequence of operations (channelx) is as follows:

1. Initialize and enable channel x as explained in [Section : Channel initialization](#).
2. The OTG\_HS host writes an IN request to the request queue as soon as the channel x gets the grant from the arbiter (round-robin with fairness). In high-bandwidth transfers, the OTG\_HS host writes consecutive writes up to MC times.

3. The OTG\_HS host attempts to send an IN token at the beginning of the next (odd) frame/micro-frame.
4. As soon the packet is received and written to the receive FIFO, the OTG\_HS host generates a CHH interrupt.
5. In response to the CHH interrupt, reinitialize the channel for the next transfer.

**Figure 478. Normal interrupt IN transactions - DMA mode**

- **Isochronous OUT transactions in DMA mode**

1. Initialize and enable channel x as explained in [Section : Channel initialization](#).
2. The OTG\_HS host starts fetching the first packet as soon as the channel is enabled, and writes the OUT request along with the last 32-bit word fetch. In high-bandwidth

- transfers, the OTG\_HS host continues fetching the next packet (up to the value specified in the MC field) before switching to the next channel.
3. The OTG\_HS host attempts to send an OUT token at the beginning of the next (odd) frame/micro-frame.
  4. After successfully transmitting the packet, the OTG\_HS host generates a CHH interrupt.
  5. In response to the CHH interrupt, reinitialize the channel for the next transfer.

**Figure 479. Normal isochronous OUT transaction - DMA mode**

- **Isochronous IN transactions in DMA mode**

The sequence of operations ((channel x) is as follows:

1. Initialize and enable channel x as explained in [Section : Channel initialization](#).
2. The OTG\_HS host writes an IN request to the request queue as soon as the channel x gets the grant from the arbiter (round-robin with fairness). In high-bandwidth transfers, the OTG\_HS host performs consecutive write operations up to MC times.

3. The OTG\_HS host attempts to send an IN token at the beginning of the next (odd) frame/micro-frame.
4. As soon the packet is received and written to the receive FIFO, the OTG\_HS host generates a CHH interrupt.
5. In response to the CHH interrupt, reinitialize the channel for the next transfer.

**Figure 480. Normal isochronous IN transactions - DMA mode**

- Bulk and control OUT/SETUP split transactions in DMA mode**

The sequence of operations in (channel x) is as follows:

1. Initialize and enable channel x for start split as explained in [Section : Channel initialization](#).
2. The OTG\_HS host starts fetching the first packet as soon the channel is enabled and writes the OUT request along with the last 32-bit word fetch.
3. After successfully transmitting start split, the OTG\_HS host generates the CHH interrupt.
4. In response to the CHH interrupt, set the COMPLSPLT bit in OTG\_HCSPLT1 to send the complete split.

5. After successfully transmitting complete split, the OTG\_HS host generates the CHH interrupt.
6. In response to the CHH interrupt, de-allocate the channel.
- **Bulk/control IN split transactions in DMA mode**  
The sequence of operations (channel x) is as follows:
  1. Initialize and enable channel x as explained in [Section : Channel initialization](#).
  2. The OTG\_HS host writes the start split request to the nonperiodic request after getting the grant from the arbiter. The OTG\_HS host masks the channel x internally for the arbitration after writing the request.
  3. As soon as the IN token is transmitted, the OTG\_HS host generates the CHH interrupt.
  4. In response to the CHH interrupt, set the COMPLSPLT bit in OTG\_HCSPLT2 and re-enable the channel to send the complete split token. This unmask channel x for arbitration.
  5. The OTG\_HS host writes the complete split request to the nonperiodic request after receiving the grant from the arbiter.
  6. The OTG\_HS host starts writing the packet to the system memory after receiving the packet successfully.
  7. As soon as the received packet is written to the system memory, the OTG\_HS host generates a CHH interrupt.
  8. In response to the CHH interrupt, de-allocate the channel.
- **Interrupt OUT split transactions in DMA mode**  
The sequence of operations in (channel x) is as follows:
  1. Initialize and enable channel 1 for start split as explained in [Section : Channel initialization](#). The application must set the ODDFRM bit in OTG\_HCCHAR1.
  2. The OTG\_HS host starts reading the packet.
  3. The OTG\_HS host attempts to send the start split transaction.
  4. After successfully transmitting the start split, the OTG\_HS host generates the CHH interrupt.
  5. In response to the CHH interrupt, set the COMPLSPLT bit in OTG\_HCSPLT1 to send the complete split.
  6. After successfully completing the complete split transaction, the OTG\_HS host generates the CHH interrupt.
  7. In response to CHH interrupt, de-allocate the channel.
- **Interrupt IN split transactions in DMA mode**  
The sequence of operations in (channel x) is as follows:
  1. Initialize and enable channel x for start split as explained in [Section : Channel initialization](#).
  2. The OTG\_HS host writes an IN request to the request queue as soon as channel x receives the grant from the arbiter.
  3. The OTG\_HS host attempts to send the start split IN token at the beginning of the next odd micro-frame.
  4. The OTG\_HS host generates the CHH interrupt after successfully transmitting the start split IN token.
  5. In response to the CHH interrupt, set the COMPLSPLT bit in OTG\_HCSPLT2 to send the complete split.

6. As soon as the packet is received successfully, the OTG\_HS host starts writing the data to the system memory.
7. The OTG\_HS host generates the CHH interrupt after transferring the received data to the system memory.
8. In response to the CHH interrupt, de-allocate or reinitialize the channel for the next start split.

- **Isochronous OUT split transactions in DMA mode**

The sequence of operations (channel x) is as follows:

1. Initialize and enable channel x for start split (begin) as explained in [Section : Channel initialization](#). The application must set the ODDFRM bit in OTG\_HCCHAR1. Program the MPS field.
2. The OTG\_HS host starts reading the packet.
3. After successfully transmitting the start split (begin), the OTG\_HS host generates the CHH interrupt.
4. In response to the CHH interrupt, reinitialize the registers to send the start split (end).
5. After successfully transmitting the start split (end), the OTG\_HS host generates a CHH interrupt.
6. In response to the CHH interrupt, de-allocate the channel.

- **Isochronous IN split transactions in DMA mode**

The sequence of operations (channel x) is as follows:

1. Initialize and enable channel x for start split as explained in [Section : Channel initialization](#).
2. The OTG\_HS host writes an IN request to the request queue as soon as channel x receives the grant from the arbiter.
3. The OTG\_HS host attempts to send the start split IN token at the beginning of the next odd micro-frame.
4. The OTG\_HS host generates the CHH interrupt after successfully transmitting the start split IN token.
5. In response to the CHH interrupt, set the COMPLSPLT bit in OTG\_HCSPLT2 to send the complete split.
6. As soon as the packet is received successfully, the OTG\_HS host starts writing the data to the system memory.

The OTG\_HS host generates the CHH interrupt after transferring the received data to the system memory. In response to the CHH interrupt, de-allocate the channel or reinitialize the channel for the next start split.

### 37.16.6 Device programming model

#### Endpoint initialization on USB reset

1. Set the NAK bit for all OUT endpoints
  - SNAK = 1 in OTG\_DOEPCTLx (for all OUT endpoints)
2. Unmask the following interrupt bits
  - INEP0 = 1 in OTG\_DAINMSK (control 0 IN endpoint)
  - OUTEP0 = 1 in OTG\_DAINMSK (control 0 OUT endpoint)
  - STUPM = 1 in OTG\_DOEPMSK
  - XFRCM = 1 in OTG\_DOEPMSK
  - XFRCM = 1 in OTG\_DIEPMSK
  - TOM = 1 in OTG\_DIEPMSK
3. Set up the data FIFO RAM for each of the FIFOs
  - Program the OTG\_GRXFSIZ register, to be able to receive control OUT data and setup data. If thresholding is not enabled, at a minimum, this must be equal to 1 max packet size of control endpoint 0 + 2 words (for the status of the control OUT data packet) + 10 words (for setup packets).
  - Program the OTG\_DIEPTXF0 register (depending on the FIFO number chosen) to be able to transmit control IN data. At a minimum, this must be equal to 1 max packet size of control endpoint 0.
4. Program the following fields in the endpoint-specific registers for control OUT endpoint 0 to receive a SETUP packet
  - STUPCNT = 3 in OTG\_DOEPTSIZ0 (to receive up to 3 back-to-back SETUP packets)
5. For USB OTG\_HS in DMA mode, the OTG\_DOEPDMA0 register should have a valid memory address to store any SETUP packets received.

At this point, all initialization required to receive SETUP packets is done.

#### Endpoint initialization on enumeration completion

1. On the Enumeration Done interrupt (ENUMDNE in OTG\_GINTSTS), read the OTG\_DSTS register to determine the enumeration speed.
2. Program the MPSIZ field in OTG\_DIEPCTL0 to set the maximum packet size. This step configures control endpoint 0. The maximum packet size for a control endpoint depends on the enumeration speed.
3. For USB OTG\_HS in DMA mode, program the OTG\_DOEPCTL0 register to enable control OUT endpoint 0, to receive a SETUP packet.

At this point, the device is ready to receive SOF packets and is configured to perform control transfers on control endpoint 0.

#### Endpoint initialization on SetAddress command

This section describes what the application must do when it receives a SetAddress command in a SETUP packet.

1. Program the OTG\_DCFG register with the device address received in the SetAddress command
2. Program the core to send out a status IN packet

### Endpoint initialization on SetConfiguration/SetInterface command

This section describes what the application must do when it receives a SetConfiguration or SetInterface command in a SETUP packet.

1. When a SetConfiguration command is received, the application must program the endpoint registers to configure them with the characteristics of the valid endpoints in the new configuration.
2. When a SetInterface command is received, the application must program the endpoint registers of the endpoints affected by this command.
3. Some endpoints that were active in the prior configuration or alternate setting are not valid in the new configuration or alternate setting. These invalid endpoints must be deactivated.
4. Unmask the interrupt for each active endpoint and mask the interrupts for all inactive endpoints in the OTG\_DAINMSK register.
5. Set up the data FIFO RAM for each FIFO.
6. After all required endpoints are configured; the application must program the core to send a status IN packet.

At this point, the device core is configured to receive and transmit any type of data packet.

### Endpoint activation

This section describes the steps required to activate a device endpoint or to configure an existing device endpoint to a new type.

1. Program the characteristics of the required endpoint into the following fields of the OTG\_DIEPCTLx register (for IN or bidirectional endpoints) or the OTG\_DOEPCTLx register (for OUT or bidirectional endpoints).
  - Maximum packet size
  - USB active endpoint = 1
  - Endpoint start data toggle (for interrupt and bulk endpoints)
  - Endpoint type
  - Tx FIFO number
2. Once the endpoint is activated, the core starts decoding the tokens addressed to that endpoint and sends out a valid handshake for each valid token received for the endpoint.

### Endpoint deactivation

This section describes the steps required to deactivate an existing endpoint.

1. In the endpoint to be deactivated, clear the USB active endpoint bit in the OTG\_DIEPCTLx register (for IN or bidirectional endpoints) or the OTG\_DOEPCTLx register (for OUT or bidirectional endpoints).
2. Once the endpoint is deactivated, the core ignores tokens addressed to that endpoint, which results in a timeout on the USB.

*Note:* The application must meet the following conditions to set up the device core to handle traffic:

*NPTXFEM and RXFLVLM in the OTG\_GINTMSK register must be cleared.*

## Operational model

SETUP and OUT data transfers:

This section describes the internal data flow and application-level operations during data OUT transfers and SETUP transactions.

### • Packet read

This section describes how to read packets (OUT data and SETUP packets) from the receive FIFO.

1. On catching an RXFLVL interrupt (OTG\_GINTSTS register), the application must read the receive status pop register (OTG\_GRXSTSP).
2. The application can mask the RXFLVL interrupt (in OTG\_GINTSTS) by writing to RXFLVLM = 0 (in OTG\_GINTMSK), until it has read the packet from the receive FIFO.
3. If the received packet's byte count is not 0, the byte count amount of data is popped from the receive data FIFO and stored in memory. If the received packet byte count is 0, no data is popped from the receive data FIFO.
4. The receive status readout of the packet of FIFO indicates one of the following:
  - a) Global OUT NAK pattern:  
 PKTSTS = Global OUT NAK, BCNT = 0x000, EPNUM = (0x0),  
 DPID = (0b00).  
 These data indicate that the global OUT NAK bit has taken effect.
  - b) SETUP packet pattern:  
 PKTSTS = SETUP, BCNT = 0x008, EPNUM = Control EP Num,  
 DPID = DATA0. These data indicate that a SETUP packet for the specified endpoint is now available for reading from the receive FIFO.
  - c) Setup stage done pattern:  
 PKTSTS = Setup Stage Done, BCNT = 0x0, EPNUM = Control EP Num,  
 DPID = (0b00).  
 These data indicate that the setup stage for the specified endpoint has completed and the data stage has started. After this entry is popped from the receive FIFO, the core asserts a setup interrupt on the specified control OUT endpoint.
  - d) Data OUT packet pattern:  
 PKTSTS = DataOUT, BCNT = size of the received data OUT packet ( $0 \leq \text{BCNT} \leq 1024$ ), EPNUM = EPNUM on which the packet was received, DPID = Actual Data PID.
  - e) Data transfer completed pattern:  
 PKTSTS = Data OUT transfer done, BCNT = 0x0, EPNUM = OUT EP Num on which the data transfer is complete, DPID = (0b00).  
 These data indicate that an OUT data transfer for the specified OUT endpoint has completed. After this entry is popped from the receive FIFO, the core asserts a transfer completed interrupt on the specified OUT endpoint.
5. After the data payload is popped from the receive FIFO, the RXFLVL interrupt (OTG\_GINTSTS) must be unmasked.
6. Steps 1–5 are repeated every time the application detects assertion of the interrupt line due to RXFLVL in OTG\_GINTSTS. Reading an empty receive FIFO can result in undefined core behavior.

*Figure 481* provides a flowchart of the above procedure.

Figure 481. Receive FIFO packet read

### SETUP transactions

This section describes how the core handles SETUP packets and the application's sequence for handling SETUP transactions.

- **Application requirements**

1. To receive a SETUP packet, the STUPCNT field (OTG\_DOEPTSIZE<sub>x</sub>) in a control OUT endpoint must be programmed to a non-zero value. When the application programs the STUPCNT field to a non-zero value, the core receives SETUP packets and writes them to the receive FIFO, irrespective of the NAK status and EPENA bit setting in OTG\_DOEPTCTL<sub>x</sub>. The STUPCNT field is decremented every time the control endpoint receives a SETUP packet. If the STUPCNT field is not programmed to a proper value before receiving a SETUP packet, the core still receives the SETUP packet and decrements the STUPCNT field, but the application may not be able to determine the correct number of SETUP packets received in the setup stage of a control transfer.
  - STUPCNT = 3 in OTG\_DOEPTSIZE<sub>x</sub>
2. The application must always allocate some extra space in the receive data FIFO, to be able to receive up to three SETUP packets on a control endpoint.
  - The space to be reserved is 10 words. Three words are required for the first SETUP packet, 1 word is required for the setup stage done word and 6 words are required to store two extra SETUP packets among all control endpoints.
  - 3 words per SETUP packet are required to store 8 bytes of SETUP data and 4 bytes of SETUP status (setup packet pattern). The core reserves this space in the

receive data FIFO to write SETUP data only, and never uses this space for data packets.

3. The application must read the 2 words of the SETUP packet from the receive FIFO.
4. The application must read and discard the setup stage done word from the receive FIFO.

- **Internal data flow**

1. When a SETUP packet is received, the core writes the received data to the receive FIFO, without checking for available space in the receive FIFO and irrespective of the endpoint's NAK and STALL bit settings.
  - The core internally sets the IN NAK and OUT NAK bits for the control IN/OUT endpoints on which the SETUP packet was received.
2. For every SETUP packet received on the USB, 3 words of data are written to the receive FIFO, and the STUPCNT field is decremented by 1.
  - The first word contains control information used internally by the core
  - The second word contains the first 4 bytes of the SETUP command
  - The third word contains the last 4 bytes of the SETUP command
3. When the setup stage changes to a data IN/OUT stage, the core writes an entry (setup stage done word) to the receive FIFO, indicating the completion of the setup stage.
4. On the AHB side, SETUP packets are emptied by the application.
5. When the application pops the setup stage done word from the receive FIFO, the core interrupts the application with an STUP interrupt (OTG\_DOEPINTx), indicating it can process the received SETUP packet.
6. The core clears the endpoint enable bit for control OUT endpoints.

- **Application programming sequence**

1. Program the OTG\_DOEPSIZx register.
  - STUPCNT = 3
2. Wait for the RXFLVL interrupt (OTG\_GINTSTS) and empty the data packets from the receive FIFO.
3. Assertion of the STUP interrupt (OTG\_DOEPINTx) marks a successful completion of the SETUP data transfer.
  - On this interrupt, the application must read the OTG\_DOEPSIZx register to determine the number of SETUP packets received and process the last received SETUP packet.

Figure 482. Processing a SETUP packet

- **Handling more than three back-to-back SETUP packets**

Per the USB 2.0 specification, normally, during a SETUP packet error, a host does not send more than three back-to-back SETUP packets to the same endpoint. However, the USB 2.0 specification does not limit the number of back-to-back SETUP packets a host can send to the same endpoint. When this condition occurs, the OTG\_FS/OTG\_HS controller generates an interrupt (B2BSTUP in OTG\_DOEPINTx).

- **Setting the global OUT NAK**

Internal data flow:

1. When the application sets the Global OUT NAK (SGONAK bit in OTG\_DCTL), the core stops writing data, except SETUP packets, to the receive FIFO. Irrespective of the space availability in the receive FIFO, non-isochronous OUT tokens receive a NAK handshake response, and the core ignores isochronous OUT data packets
2. The core writes the Global OUT NAK pattern to the receive FIFO. The application must reserve enough receive FIFO space to write this data pattern.
3. When the application pops the Global OUT NAK pattern word from the receive FIFO, the core sets the GONAKEFF interrupt (OTG\_GINTSTS).
4. Once the application detects this interrupt, it can assume that the core is in Global OUT NAK mode. The application can clear this interrupt by clearing the SGONAK bit in OTG\_DCTL.

Application programming sequence:

1. To stop receiving any kind of data in the receive FIFO, the application must set the Global OUT NAK bit by programming the following field:
  - SGONAK = 1 in OTG\_DCTL
2. Wait for the assertion of the GONAKEFF interrupt in OTG\_GINTSTS. When asserted, this interrupt indicates that the core has stopped receiving any type of data except SETUP packets.
3. The application can receive valid OUT packets after it has set SGONAK in OTG\_DCTL and before the core asserts the GONAKEFF interrupt (OTG\_GINTSTS).
4. The application can temporarily mask this interrupt by writing to the GONAKEFFM bit in the OTG\_GINTMSK register.
  - GONAKEFFM = 0 in the OTG\_GINTMSK register
5. Whenever the application is ready to exit the Global OUT NAK mode, it must clear the SGONAK bit in OTG\_DCTL. This also clears the GONAKEFF interrupt (OTG\_GINTSTS).
  - CGONAK = 1 in OTG\_DCTL
6. If the application has masked this interrupt earlier, it must be unmasked as follows:
  - GONAKEFFM = 1 in OTG\_GINTMSK

- **Disabling an OUT endpoint**

The application must use this sequence to disable an OUT endpoint that it has enabled.

Application programming sequence:

1. Before disabling any OUT endpoint, the application must enable Global OUT NAK mode in the core.
  - SGONAK = 1 in OTG\_DCTL
2. Wait for the GONAKEFF interrupt (OTG\_GINTSTS)
3. Disable the required OUT endpoint by programming the following fields:
  - EPDIS = 1 in OTG\_DOEPCTLx
  - SNAK = 1 in OTG\_DOEPCTLx
4. Wait for the EPDISD interrupt (OTG\_DOEPINTx), which indicates that the OUT endpoint is completely disabled. When the EPDISD interrupt is asserted, the core also clears the following bits:
  - EPDIS = 0 in OTG\_DOEPCTLx
  - EPENA = 0 in OTG\_DOEPCTLx
5. The application must clear the Global OUT NAK bit to start receiving data from other non-disabled OUT endpoints.
  - SGONAK = 0 in OTG\_DCTL

- **Generic non-isochronous OUT data transfers**

This section describes a regular non-isochronous OUT data transfer (control, bulk, or interrupt).

Application requirements:

1. Before setting up an OUT transfer, the application must allocate a buffer in the memory to accommodate all data to be received as part of the OUT transfer.
2. For OUT transfers, the transfer size field in the endpoint's transfer size register must be a multiple of the maximum packet size of the endpoint, adjusted to the word boundary.
  - $\text{transfer size}[\text{EPNUM}] = n \times (\text{MPSIZ}[\text{EPNUM}] + 4 - (\text{MPSIZ}[\text{EPNUM}] \bmod 4))$
  - $\text{packet count}[\text{EPNUM}] = n$
  - $n > 0$
3. On any OUT endpoint interrupt, the application must read the endpoint's transfer size register to calculate the size of the payload in the memory. The received payload size can be less than the programmed transfer size.
  - $\text{Payload size in memory} = \text{application programmed initial transfer size} - \text{core updated final transfer size}$
  - $\text{Number of USB packets in which this payload was received} = \text{application programmed initial packet count} - \text{core updated final packet count}$

Internal data flow:

1. The application must set the transfer size and packet count fields in the endpoint-specific registers, clear the NAK bit, and enable the endpoint to receive the data.
2. Once the NAK bit is cleared, the core starts receiving data and writes it to the receive FIFO, as long as there is space in the receive FIFO. For every data packet received on the USB, the data packet and its status are written to the receive FIFO. Every packet (maximum packet size or short packet) written to the receive FIFO decrements the packet count field for that endpoint by 1.
  - OUT data packets received with bad data CRC are flushed from the receive FIFO automatically.
  - After sending an ACK for the packet on the USB, the core discards non-isochronous OUT data packets that the host, which cannot detect the ACK, re-sends. The application does not detect multiple back-to-back data OUT packets on the same endpoint with the same data PID. In this case the packet count is not decremented.
  - If there is no space in the receive FIFO, isochronous or non-isochronous data packets are ignored and not written to the receive FIFO. Additionally, non-isochronous OUT tokens receive a NAK handshake reply.
  - In all the above three cases, the packet count is not decremented because no data are written to the receive FIFO.
3. When the packet count becomes 0 or when a short packet is received on the endpoint, the NAK bit for that endpoint is set. Once the NAK bit is set, the isochronous or non-isochronous data packets are ignored and not written to the receive FIFO, and non-isochronous OUT tokens receive a NAK handshake reply.
4. After the data are written to the receive FIFO, the application reads the data from the receive FIFO and writes it to external memory, one packet at a time per endpoint.
5. At the end of every packet write on the AHB to external memory, the transfer size for the endpoint is decremented by the size of the written packet.
6. The OUT data transfer completed pattern for an OUT endpoint is written to the receive FIFO on one of the following conditions:
  - The transfer size is 0 and the packet count is 0
  - The last OUT data packet written to the receive FIFO is a short packet ( $0 \leq \text{packet size} < \text{maximum packet size}$ )

7. When either the application pops this entry (OUT data transfer completed), a transfer completed interrupt is generated for the endpoint and the endpoint enable is cleared.

Application programming sequence:

1. Program the OTG\_DOEPTSIZx register for the transfer size and the corresponding packet count.
2. Program the OTG\_DOEPCTLx register with the endpoint characteristics, and set the EPENA and CNAK bits.
  - EPENA = 1 in OTG\_DOEPCTLx
  - CNAK = 1 in OTG\_DOEPCTLx
3. Wait for the RXFLVL interrupt (in OTG\_GINTSTS) and empty the data packets from the receive FIFO.
  - This step can be repeated many times, depending on the transfer size.
4. Asserting the XFRC interrupt (OTG\_DOEPINTx) marks a successful completion of the non-isochronous OUT data transfer.
5. Read the OTG\_DOEPTSIZx register to determine the size of the received data payload.

#### • Generic isochronous OUT data transfer

This section describes a regular isochronous OUT data transfer.

Application requirements:

1. All the application requirements for non-isochronous OUT data transfers also apply to isochronous OUT data transfers.
2. For isochronous OUT data transfers, the transfer size and packet count fields must always be set to the number of maximum-packet-size packets that can be received in a single frame and no more. Isochronous OUT data transfers cannot span more than 1 frame.
3. The application must read all isochronous OUT data packets from the receive FIFO (data and status) before the end of the periodic frame (EOPF interrupt in OTG\_GINTSTS).
4. To receive data in the following frame, an isochronous OUT endpoint must be enabled after the EOPF (OTG\_GINTSTS) and before the SOF (OTG\_GINTSTS).

Internal data flow:

1. The internal data flow for isochronous OUT endpoints is the same as that for non-isochronous OUT endpoints, but for a few differences.
2. When an isochronous OUT endpoint is enabled by setting the endpoint enable and clearing the NAK bits, the Even/Odd frame bit must also be set appropriately. The core receives data on an isochronous OUT endpoint in a particular frame only if the following condition is met:
  - EONUM (in OTG\_DOEPCTLx) = FNSOF[0] (in OTG\_DSTS)
3. When the application completely reads an isochronous OUT data packet (data and status) from the receive FIFO, the core updates the RXDPID field in OTG\_DOEPTSIZx with the data PID of the last isochronous OUT data packet read from the receive FIFO.

Application programming sequence:

1. Program the OTG\_DOEPTSLZx register for the transfer size and the corresponding packet count
2. Program the OTG\_DOEPCTLx register with the endpoint characteristics and set the endpoint enable, ClearNAK, and Even/Odd frame bits.
  - EPENA = 1
  - CNAK = 1
  - EONUM = (0: Even/1: Odd)
3. Wait for the RXFLVL interrupt (in OTG\_GINTSTS) and empty the data packets from the receive FIFO
  - This step can be repeated many times, depending on the transfer size.
4. The assertion of the XFRC interrupt (in OTG\_DOEPINTx) marks the completion of the isochronous OUT data transfer. This interrupt does not necessarily mean that the data in memory are good.
5. This interrupt cannot always be detected for isochronous OUT transfers. Instead, the application can detect the INCOMPISOOUT interrupt in OTG\_GINTSTS.
6. Read the OTG\_DOEPTSLZx register to determine the size of the received transfer and to determine the validity of the data received in the frame. The application must treat the data received in memory as valid only if one of the following conditions is met:
  - RXDPID = DATA0 (in OTG\_DOEPTSLZx) and the number of USB packets in which this payload was received = 1
  - RXDPID = DATA1 (in OTG\_DOEPTSLZx) and the number of USB packets in which this payload was received = 2
  - RXDPID = D2 (in OTG\_DOEPTSLZx) and the number of USB packets in which this payload was received = 3[HS]

The number of USB packets in which this payload was received =  
Application programmed initial packet count – core updated final packet count

The application can discard invalid data packets.

#### • Incomplete isochronous OUT data transfers

This section describes the application programming sequence when isochronous OUT data packets are dropped inside the core.

Internal data flow:

1. For isochronous OUT endpoints, the XFRC interrupt (in OTG\_DOEPINTx) may not always be asserted. If the core drops isochronous OUT data packets, the application could fail to detect the XFRC interrupt (OTG\_DOEPINTx) under the following circumstances:
  - When the receive FIFO cannot accommodate the complete ISO OUT data packet, the core drops the received ISO OUT data
  - When the isochronous OUT data packet is received with CRC errors
  - When the isochronous OUT token received by the core is corrupted
  - When the application is very slow in reading the data from the receive FIFO
2. When the core detects an end of periodic frame before transfer completion to all isochronous OUT endpoints, it asserts the incomplete isochronous OUT data interrupt (INCOMPISOOUT in OTG\_GINTSTS), indicating that an XFRC interrupt (in OTG\_DOEPINTx) is not asserted on at least one of the isochronous OUT endpoints. At

this point, the endpoint with the incomplete transfer remains enabled, but no active transfers remain in progress on this endpoint on the USB.

Application programming sequence:

1. Asserting the INCOMPISOOUT interrupt (OTG\_GINTSTS) indicates that in the current frame, at least one isochronous OUT endpoint has an incomplete transfer.
2. If this occurs because isochronous OUT data is not completely emptied from the endpoint, the application must ensure that the application empties all isochronous OUT data (data and status) from the receive FIFO before proceeding.
  - When all data are emptied from the receive FIFO, the application can detect the XFRC interrupt (OTG\_DOEPINTx). In this case, the application must re-enable the endpoint to receive isochronous OUT data in the next frame.
3. When it receives an INCOMPISOOUT interrupt (in OTG\_GINTSTS), the application must read the control registers of all isochronous OUT endpoints (OTG\_DOEPCTLx) to determine which endpoints had an incomplete transfer in the current microframe. An endpoint transfer is incomplete if both the following conditions are met:
  - EONUM bit (in OTG\_DOEPCTLx) = FNSOF[0] (in OTG\_DSTS)
  - EPENA = 1 (in OTG\_DOEPCTLx)
4. The previous step must be performed before the SOF interrupt (in OTG\_GINTSTS) is detected, to ensure that the current frame number is not changed.
5. For isochronous OUT endpoints with incomplete transfers, the application must discard the data in the memory and disable the endpoint by setting the EPDIS bit in OTG\_DOEPCTLx.
6. Wait for the EPDISD interrupt (in OTG\_DOEPINTx) and enable the endpoint to receive new data in the next frame.
  - Because the core can take some time to disable the endpoint, the application may not be able to receive the data in the next frame after receiving bad isochronous data.

#### • Stalling a non-isochronous OUT endpoint

This section describes how the application can stall a non-isochronous endpoint.

1. Put the core in the Global OUT NAK mode.
2. Disable the required endpoint
  - When disabling the endpoint, instead of setting the SNAK bit in OTG\_DOEPCTL, set STALL = 1 (in OTG\_DOEPCTL).

The STALL bit always takes precedence over the NAK bit.
3. When the application is ready to end the STALL handshake for the endpoint, the STALL bit (in OTG\_DOEPCTLx) must be cleared.
4. If the application is setting or clearing a STALL for an endpoint due to a SetFeature.Endpoint Halt or ClearFeature.Endpoint Halt command, the STALL bit must be set or cleared before the application sets up the status stage transfer on the control endpoint.

### Examples

This section describes and depicts some fundamental transfer types and scenarios.

- Bulk OUT transaction

Figure 483 depicts the reception of a single Bulk OUT data packet from the USB to the AHB and describes the events involved in the process.

**Figure 483. Bulk OUT transaction**

After a SetConfiguration/SetInterface command, the application initializes all OUT endpoints by setting CNAK = 1 and EPENA = 1 (in OTG\_DOEPTCTLx), and setting a suitable XFRSIZ and PKTCNT in the OTG\_DOEPTSLX register.

1. host attempts to send data (OUT token) to an endpoint.
2. When the core receives the OUT token on the USB, it stores the packet in the Rx FIFO because space is available there.
3. After writing the complete packet in the Rx FIFO, the core then asserts the RXFLVL interrupt (in OTG\_GINTSTS).
4. On receiving the PKTCNT number of USB packets, the core internally sets the NAK bit for this endpoint to prevent it from receiving any more packets.
5. The application processes the interrupt and reads the data from the Rx FIFO.
6. When the application has read all the data (equivalent to XFRSIZ), the core generates an XFRSIZ interrupt (in OTG\_DOEPINTx).
7. The application processes the interrupt and uses the setting of the XFRSIZ interrupt bit (in OTG\_DOEPINTx) to determine that the intended transfer is complete.

## IN data transfers

### • Packet write

This section describes how the application writes data packets to the endpoint FIFO when dedicated transmit FIFOs are enabled.

1. The application can either choose the polling or the interrupt mode.
  - In polling mode, the application monitors the status of the endpoint transmit data FIFO by reading the OTG\_DTXFSTSx register, to determine if there is enough space in the data FIFO.
  - In interrupt mode, the application waits for the TXFE interrupt (in OTG\_DIEPINTx) and then reads the OTG\_DTXFSTSx register, to determine if there is enough space in the data FIFO.
  - To write a single non-zero length data packet, there must be space to write the entire packet in the data FIFO.
  - To write zero length packet, the application must not look at the FIFO space.
2. Using one of the above mentioned methods, when the application determines that there is enough space to write a transmit packet, the application must first write into the endpoint control register, before writing the data into the data FIFO. Typically, the application, must do a read modify write on the OTG\_DIEPCTLx register to avoid modifying the contents of the register, except for setting the endpoint enable bit.

The application can write multiple packets for the same endpoint into the transmit FIFO, if space is available. For periodic IN endpoints, the application must write packets only for one microframe. It can write packets for the next periodic transaction only after getting transfer complete for the previous transaction.

#### • Setting IN endpoint NAK

Internal data flow:

1. When the application sets the IN NAK for a particular endpoint, the core stops transmitting data on the endpoint, irrespective of data availability in the endpoint's transmit FIFO.
2. Non-isochronous IN tokens receive a NAK handshake reply
  - Isochronous IN tokens receive a zero-data-length packet reply
3. The core asserts the INEPNE (IN endpoint NAK effective) interrupt in OTG\_DIEPINTx in response to the SNAK bit in OTG\_DIEPCTLx.
4. Once this interrupt is seen by the application, the application can assume that the endpoint is in IN NAK mode. This interrupt can be cleared by the application by setting the CNAK bit in OTG\_DIEPCTLx.

Application programming sequence:

1. To stop transmitting any data on a particular IN endpoint, the application must set the IN NAK bit. To set this bit, the following field must be programmed.
  - SNAK = 1 in OTG\_DIEPCTLx
2. Wait for assertion of the INEPNE interrupt in OTG\_DIEPINTx. This interrupt indicates that the core has stopped transmitting data on the endpoint.
3. The core can transmit valid IN data on the endpoint after the application has set the NAK bit, but before the assertion of the NAK Effective interrupt.
4. The application can mask this interrupt temporarily by writing to the INEPNEM bit in OTG\_DIEPMSK.
  - INEPNEM = 0 in OTG\_DIEPMSK
5. To exit endpoint NAK mode, the application must clear the NAK status bit (NAKSTS) in OTG\_DIEPCTLx. This also clears the INEPNE interrupt (in OTG\_DIEPINTx).

- CNAK = 1 in OTG\_DIEPCTLx
- 6. If the application masked this interrupt earlier, it must be unmasked as follows:
  - INEPNEM = 1 in OTG\_DIEPMSK

- **IN endpoint disable**

Use the following sequence to disable a specific IN endpoint that has been previously enabled.

Application programming sequence:

1. The application must stop writing data on the AHB for the IN endpoint to be disabled.
2. The application must set the endpoint in NAK mode.
  - SNAK = 1 in OTG\_DIEPCTLx
3. Wait for the INEPNE interrupt in OTG\_DIEPINTx.
4. Set the following bits in the OTG\_DIEPCTLx register for the endpoint that must be disabled.
  - EPDIS = 1 in OTG\_DIEPCTLx
  - SNAK = 1 in OTG\_DIEPCTLx
5. Assertion of the EPDISD interrupt in OTG\_DIEPINTx indicates that the core has completely disabled the specified endpoint. Along with the assertion of the interrupt, the core also clears the following bits:
  - EPENA = 0 in OTG\_DIEPCTLx
  - EPDIS = 0 in OTG\_DIEPCTLx
6. The application must read the OTG\_DIEPTSIZx register for the periodic IN EP, to calculate how much data on the endpoint were transmitted on the USB.
7. The application must flush the data in the endpoint transmit FIFO, by setting the following fields in the OTG\_GRSTCTL register:
  - TXFNUM (in OTG\_GRSTCTL) = Endpoint transmit FIFO number
  - TXFFLSH in (OTG\_GRSTCTL) = 1

The application must poll the OTG\_GRSTCTL register, until the TXFFLSH bit is cleared by the core, which indicates the end of flush operation. To transmit new data on this endpoint, the application can re-enable the endpoint at a later point.

- **Generic non-periodic IN data transfers**

Application requirements:

1. Before setting up an IN transfer, the application must ensure that all data to be transmitted as part of the IN transfer are part of a single buffer.
2. For IN transfers, the transfer size field in the endpoint transfer size register denotes a payload that constitutes multiple maximum-packet-size packets and a single short packet. This short packet is transmitted at the end of the transfer.
  - To transmit a few maximum-packet-size packets and a short packet at the end of the transfer:
 
$$\text{Transfer size}[\text{EPNUM}] = x \times \text{MPSIZ}[\text{EPNUM}] + \text{sp}$$
 If (sp > 0), then packet count[EPNUM] = x + 1.  
 Otherwise, packet count[EPNUM] = x
  - To transmit a single zero-length data packet:

Transfer size[EPNUM] = 0

Packet count[EPNUM] = 1

- To transmit a few maximum-packet-size packets and a zero-length data packet at the end of the transfer, the application must split the transfer into two parts. The first sends maximum-packet-size data packets and the second sends the zero-length data packet alone.  
First transfer: transfer size[EPNUM] =  $x \times \text{MPSIZ}[\text{epnum}]$ ; packet count =  $n$ ;  
Second transfer: transfer size[EPNUM] = 0; packet count = 1;
- 3. Once an endpoint is enabled for data transfers, the core updates the transfer size register. At the end of the IN transfer, the application must read the transfer size register to determine how much data posted in the transmit FIFO have already been sent on the USB.
- 4. Data fetched into transmit FIFO = Application-programmed initial transfer size – core-updated final transfer size
  - Data transmitted on USB = (application-programmed initial packet count – core updated final packet count)  $\times$  MPSIZ[EPNUM]
  - Data yet to be transmitted on USB = (Application-programmed initial transfer size – data transmitted on USB)

Internal data flow:

1. The application must set the transfer size and packet count fields in the endpoint-specific registers and enable the endpoint to transmit the data.
2. The application must also write the required data to the transmit FIFO for the endpoint.
3. Every time a packet is written into the transmit FIFO by the application, the transfer size for that endpoint is decremented by the packet size. The data is fetched from the memory by the application, until the transfer size for the endpoint becomes 0. After writing the data into the FIFO, the “number of packets in FIFO” count is incremented (this is a 3-bit count, internally maintained by the core for each IN endpoint transmit FIFO. The maximum number of packets maintained by the core at any time in an IN endpoint FIFO is eight). For zero-length packets, a separate flag is set for each FIFO, without any data in the FIFO.
4. Once the data are written to the transmit FIFO, the core reads them out upon receiving an IN token. For every non-isochronous IN data packet transmitted with an ACK handshake, the packet count for the endpoint is decremented by one, until the packet count is zero. The packet count is not decremented on a timeout.
5. For zero length packets (indicated by an internal zero length flag), the core sends out a zero-length packet for the IN token and decrements the packet count field.
6. If there are no data in the FIFO for a received IN token and the packet count field for that endpoint is zero, the core generates an “IN token received when Tx FIFO is empty” (ITTXFE) interrupt for the endpoint, provided that the endpoint NAK bit is not set. The core responds with a NAK handshake for non-isochronous endpoints on the USB.
7. The core internally rewinds the FIFO pointers and no timeout interrupt is generated.
8. When the transfer size is 0 and the packet count is 0, the transfer complete (XFRC) interrupt for the endpoint is generated and the endpoint enable is cleared.

Application programming sequence:

1. Program the OTG\_DIEPTISIZx register with the transfer size and corresponding packet count.
2. Program the OTG\_DIEPCTLx register with the endpoint characteristics and set the CNAK and EPENA (endpoint enable) bits.
3. When transmitting non-zero length data packet, the application must poll the OTG\_DTXFSTSx register (where x is the FIFO number associated with that endpoint) to determine whether there is enough space in the data FIFO. The application can optionally use TXFE (in OTG\_DIEPINTx) before writing the data.

#### • Generic periodic IN data transfers

This section describes a typical periodic IN data transfer.

Application requirements:

1. Application requirements 1, 2, 3, and 4 of [Generic non-periodic IN data transfers on page 1514](#) also apply to periodic IN data transfers, except for a slight modification of requirement 2.
  - The application can only transmit multiples of maximum-packet-size data packets or multiples of maximum-packet-size packets, plus a short packet at the end. To transmit a few maximum-packet-size packets and a short packet at the end of the transfer, the following conditions must be met:  

$$\text{transfer size}[\text{EPNUM}] = x \times \text{MPSIZ}[\text{EPNUM}] + \text{sp}$$
 (where x is an integer  $\geq 0$ , and  $0 \leq \text{sp} < \text{MPSIZ}[\text{EPNUM}]$ )  
 If ( $\text{sp} > 0$ ),  $\text{packet count}[\text{EPNUM}] = x + 1$   
 Otherwise,  $\text{packet count}[\text{EPNUM}] = x$ ;  
 $\text{MCNT}[\text{EPNUM}] = \text{packet count}[\text{EPNUM}]$
  - The application cannot transmit a zero-length data packet at the end of a transfer. It can transmit a single zero-length data packet by itself. To transmit a single zero-length data packet:  
 $\text{transfer size}[\text{EPNUM}] = 0$   
 $\text{packet count}[\text{EPNUM}] = 1$   
 $\text{MCNT}[\text{EPNUM}] = \text{packet count}[\text{EPNUM}]$
2. The application can only schedule data transfers one frame at a time.
  - $(\text{MCNT} - 1) \times \text{MPSIZ} \leq \text{XFERSIZ} \leq \text{MCNT} \times \text{MPSIZ}$
  - $\text{PKTCNT} = \text{MCNT}$  (in OTG\_DIEPTISIZx)
  - If  $\text{XFERSIZ} < \text{MCNT} \times \text{MPSIZ}$ , the last data packet of the transfer is a short packet.
  - Note that: MCNT is in OTG\_DIEPTISIZx, MPSIZ is in OTG\_DIEPCTLx, PKTCNT is in OTG\_DIEPTISIZx and XFERSIZ is in OTG\_DIEPTISIZx
3. The complete data to be transmitted in the frame must be written into the transmit FIFO by the application, before the IN token is received. Even when 1 word of the data to be transmitted per frame is missing in the transmit FIFO when the IN token is received, the core behaves as when the FIFO is empty. When the transmit FIFO is empty:
  - A zero data length packet would be transmitted on the USB for isochronous IN endpoints
  - A NAK handshake would be transmitted on the USB for interrupt IN endpoints

Internal data flow:

1. The application must set the transfer size and packet count fields in the endpoint-specific registers and enable the endpoint to transmit the data.
2. The application must also write the required data to the associated transmit FIFO for the endpoint.
3. Every time the application writes a packet to the transmit FIFO, the transfer size for that endpoint is decremented by the packet size. The data are fetched from application memory until the transfer size for the endpoint becomes 0.
4. When an IN token is received for a periodic endpoint, the core transmits the data in the FIFO, if available. If the complete data payload (complete packet, in dedicated FIFO mode) for the frame is not present in the FIFO, then the core generates an IN token received when Tx FIFO empty interrupt for the endpoint.
  - A zero-length data packet is transmitted on the USB for isochronous IN endpoints
  - A NAK handshake is transmitted on the USB for interrupt IN endpoints
5. The packet count for the endpoint is decremented by 1 under the following conditions:
  - For isochronous endpoints, when a zero- or non-zero-length data packet is transmitted
  - For interrupt endpoints, when an ACK handshake is transmitted
  - When the transfer size and packet count are both 0, the transfer completed interrupt for the endpoint is generated and the endpoint enable is cleared.
6. At the “Periodic frame Interval” (controlled by PFIVL in OTG\_DCFG), when the core finds non-empty any of the isochronous IN endpoint FIFOs scheduled for the current frame non-empty, the core generates an IISOIXFR interrupt in OTG\_GINTSTS.

Application programming sequence:

1. Program the OTG\_DIEPCTLx register with the endpoint characteristics and set the CNAK and EPENA bits.
2. Write the data to be transmitted in the next frame to the transmit FIFO.
3. Asserting the ITTXFE interrupt (in OTG\_DIEPINTx) indicates that the application has not yet written all data to be transmitted to the transmit FIFO.
4. If the interrupt endpoint is already enabled when this interrupt is detected, ignore the interrupt. If it is not enabled, enable the endpoint so that the data can be transmitted on the next IN token attempt.
5. Asserting the XFRC interrupt (in OTG\_DIEPINTx) with no ITTXFE interrupt in OTG\_DIEPINTx indicates the successful completion of an isochronous IN transfer. A read to the OTG\_DIEPTSIZx register must give transfer size = 0 and packet count = 0, indicating all data were transmitted on the USB.
6. Asserting the XFRC interrupt (in OTG\_DIEPINTx), with or without the ITTXFE interrupt (in OTG\_DIEPINTx), indicates the successful completion of an interrupt IN transfer. A read to the OTG\_DIEPTSIZx register must give transfer size = 0 and packet count = 0, indicating all data were transmitted on the USB.
7. Asserting the incomplete isochronous IN transfer (IISOIXFR) interrupt in OTG\_GINTSTS with none of the aforementioned interrupts indicates the core did not receive at least 1 periodic IN token in the current frame.

- **Incomplete isochronous IN data transfers**

This section describes what the application must do on an incomplete isochronous IN data transfer.

Internal data flow:

1. An isochronous IN transfer is treated as incomplete in one of the following conditions:
  - a) The core receives a corrupted isochronous IN token on at least one isochronous IN endpoint. In this case, the application detects an incomplete isochronous IN transfer interrupt (IISOIXFR in OTG\_GINTSTS).
  - b) The application is slow to write the complete data payload to the transmit FIFO and an IN token is received before the complete data payload is written to the FIFO. In this case, the application detects an IN token received when Tx FIFO empty interrupt in OTG\_DIEPINTx. The application can ignore this interrupt, as it eventually results in an incomplete isochronous IN transfer interrupt (IISOIXFR in OTG\_GINTSTS) at the end of periodic frame.  
The core transmits a zero-length data packet on the USB in response to the received IN token.
2. The application must stop writing the data payload to the transmit FIFO as soon as possible.
3. The application must set the NAK bit and the disable bit for the endpoint.
4. The core disables the endpoint, clears the disable bit, and asserts the endpoint disable interrupt for the endpoint.

Application programming sequence:

1. The application can ignore the IN token received when Tx FIFO empty interrupt in OTG\_DIEPINTx on any isochronous IN endpoint, as it eventually results in an incomplete isochronous IN transfer interrupt (in OTG\_GINTSTS).
2. Assertion of the incomplete isochronous IN transfer interrupt (in OTG\_GINTSTS) indicates an incomplete isochronous IN transfer on at least one of the isochronous IN endpoints.
3. The application must read the endpoint control register for all isochronous IN endpoints to detect endpoints with incomplete IN data transfers.
4. The application must stop writing data to the Periodic Transmit FIFOs associated with these endpoints on the AHB.
5. Program the following fields in the OTG\_DIEPCTLx register to disable the endpoint:
  - SNAK = 1 in OTG\_DIEPCTLx
  - EPDIS = 1 in OTG\_DIEPCTLx
6. The assertion of the endpoint disabled interrupt in OTG\_DIEPINTx indicates that the core has disabled the endpoint.
  - At this point, the application must flush the data in the associated transmit FIFO or overwrite the existing data in the FIFO by enabling the endpoint for a new transfer in the next microframe. To flush the data, the application must use the OTG\_GRSTCTL register.

#### • Stalling non-isochronous IN endpoints

This section describes how the application can stall a non-isochronous endpoint.

Application programming sequence:

1. Disable the IN endpoint to be stalled. Set the STALL bit as well.
2. EPDIS = 1 in OTG\_DIEPCTLx, when the endpoint is already enabled
  - STALL = 1 in OTG\_DIEPCTLx
  - The STALL bit always takes precedence over the NAK bit
3. Assertion of the endpoint disabled interrupt (in OTG\_DIEPINTx) indicates to the application that the core has disabled the specified endpoint.
4. The application must flush the non-periodic or periodic transmit FIFO, depending on the endpoint type. In case of a non-periodic endpoint, the application must re-enable the other non-periodic endpoints that do not need to be stalled, to transmit data.
5. Whenever the application is ready to end the STALL handshake for the endpoint, the STALL bit must be cleared in OTG\_DIEPCTLx.
6. If the application sets or clears a STALL bit for an endpoint due to a SetFeature.Endpoint Halt command or ClearFeature.Endpoint Halt command, the STALL bit must be set or cleared before the application sets up the status stage transfer on the control endpoint.

Special case: stalling the control OUT endpoint

The core must stall IN/OUT tokens if, during the data stage of a control transfer, the host sends more IN/OUT tokens than are specified in the SETUP packet. In this case, the application must enable the ITTXFE interrupt in OTG\_DIEPINTx and the OTEPDIS interrupt in OTG\_DOEPINTx during the data stage of the control transfer, after the core has transferred the amount of data specified in the SETUP packet. Then, when the application receives this interrupt, it must set the STALL bit in the corresponding endpoint control register, and clear this interrupt.

### 37.16.7 Worst case response time

When the OTG\_FS/OTG\_HS controller acts as a device, there is a worst case response time for any tokens that follow an isochronous OUT. This worst case response time depends on the AHB clock frequency.

The core registers are in the AHB domain, and the core does not accept another token before updating these register values. The worst case is for any token following an isochronous OUT, because for an isochronous transaction, there is no handshake and the next token could come sooner. This worst case value is 7 PHY clocks when the AHB clock is the same as the PHY clock. When the AHB clock is faster, this value is smaller.

If this worst case condition occurs, the core responds to bulk/interrupt tokens with a NAK and drops isochronous and SETUP tokens. The host interprets this as a timeout condition for SETUP and retries the SETUP packet. For isochronous transfers, the Incomplete isochronous IN transfer interrupt (IISOIXFR) and Incomplete isochronous OUT transfer interrupt (IISOOXFR) inform the application that isochronous IN/OUT packets were dropped.

#### Choosing the value of TRDT in OTG\_GUSBCFG

The value in TRDT (OTG\_GUSBCFG) is the time it takes for the MAC, in terms of PHY clocks after it has received an IN token, to get the FIFO status, and thus the first data from the PFC block. This time involves the synchronization delay between the PHY and AHB clocks. The worst case delay for this is when the AHB clock is the same as the PHY clock. In this case, the delay is 5 clocks.

Once the MAC receives an IN token, this information (token received) is synchronized to the AHB clock by the PFC (the PFC runs on the AHB clock). The PFC then reads the data from the SPRAM and writes them into the dual clock source buffer. The MAC then reads the data out of the source buffer (4 deep).

If the AHB is running at a higher frequency than the PHY, the application can use a smaller value for TRDT (in OTG\_GUSBCFG).

[Figure 484](#) has the following signals:

- `tkn_rcvd`: Token received information from MAC to PFC
- `dynced_tkn_rcvd`: Doubled sync `tkn_rcvd`, from PCLK to HCLK domain
- `spr_read`: Read to SPRAM
- `spr_addr`: Address to SPRAM
- `spr_rdata`: Read data from SPRAM
- `srcbuf_push`: Push to the source buffer
- `srcbuf_rdata`: Read data from the source buffer. Data seen by MAC

To calculate the value of TRDT, refer to [Table 268: TRDT values \(FS\)](#) or [Table 269: TRDT values \(HS\)](#).

Figure 484. TRDT max timing case

### 37.16.8 OTG programming model

The OTG\_FS/OTG\_HS controller is an OTG device supporting HNP and SRP. When the core is connected to an “A” plug, it is referred to as an A-device. When the core is connected to a “B” plug it is referred to as a B-device. In host mode, the OTG\_FS/OTG\_HS controller turns off  $V_{BUS}$  to conserve power. SRP is a method by which the B-device signals the A-device to turn on  $V_{BUS}$  power. A device must perform both data-line pulsing and  $V_{BUS}$  pulsing, but a host can detect either data-line pulsing or  $V_{BUS}$  pulsing for SRP. HNP is a method by which the B-device negotiates and switches to host role. In Negotiated mode after HNP, the B-device suspends the bus and reverts to the device role.

#### A-device session request protocol

The application must set the SRP-capable bit in the core USB configuration register. This enables the OTG\_FS/OTG\_HS controller to detect SRP as an A-device.

Figure 485. A-device SRP

1. DRV\_VBUS =  $V_{BUS}$  drive signal to the PHY  
VBUS\_VALID =  $V_{BUS}$  valid signal from PHY  
A\_VALID = A-peripheral  $V_{BUS}$  level signal to PHY  
D+ = Data plus line  
D- = Data minus line

The following points refer and describe the signal numeration shown in the [Figure 485](#):

1. To save power, the application suspends and turns off port power when the bus is idle by writing the port suspend and port power bits in the host port control and status register.
2. PHY indicates port power off by deasserting the VBUS\_VALID signal.
3. The device must detect SE0 for at least 2 ms to start SRP when  $V_{BUS}$  power is off.
4. To initiate SRP, the device turns on its data line pull-up resistor for 5 to 10 ms. The OTG\_FS/OTG\_HS controller detects data-line pulsing.
5. The device drives  $V_{BUS}$  above the A-device session valid (2.0 V minimum) for  $V_{BUS}$  pulsing.  
The OTG\_FS/OTG\_HS controller interrupts the application on detecting SRP. The session request detected bit is set in Global interrupt status register (SRQINT set in OTG\_GINTSTS).
6. The application must service the session request detected interrupt and turn on the port power bit by writing the port power bit in the host port control and status register. The PHY indicates port power-on by asserting the VBUS\_VALID signal.
7. When the USB is powered, the device connects, completing the SRP process.

### B-device session request protocol

The application must set the SRP-capable bit in the core USB configuration register. This enables the OTG\_FS/OTG\_HS controller to initiate SRP as a B-device. SRP is a means by which the OTG\_FS/OTG\_HS controller can request a new session from the host.

Figure 486. B-device SRP

1.  $V_{BUS\_VALID} = V_{BUS}$  valid signal from PHY
- $B\_VALID$  = B-peripheral valid session to PHY
- $DISCHRG\_VBUS$  = discharge signal to PHY
- $SESS\_END$  = session end signal to PHY
- $CHRG\_VBUS$  = charge  $V_{BUS}$  signal to PHY
- DP = Data plus line
- DM = Data minus line

The following points refer and describe the signal numeration shown in the [Figure 486](#):

1. To save power, the host suspends and turns off port power when the bus is idle. The OTG\_FS/OTG\_HS controller sets the early suspend bit in the core interrupt register after 3 ms of bus idleness. Following this, the OTG\_FS/OTG\_HS controller sets the USB suspend bit in the core interrupt register. The OTG\_FS/OTG\_HS controller informs the PHY to discharge  $V_{BUS}$ .
2. The PHY indicates the session's end to the device. This is the initial condition for SRP. The OTG\_FS/OTG\_HS controller requires 2 ms of SE0 before initiating SRP. For a USB 1.1 full-speed serial transceiver, the application must wait until  $V_{BUS}$  discharges to 0.2 V after BSVLD (in OTG\_GOTGCTL) is deasserted. This discharge time can be obtained from the transceiver vendor and varies from one transceiver to another.
3. The OTG\_FS/OTG\_HS core informs the PHY to speed up  $V_{BUS}$  discharge.
4. The application initiates SRP by writing the session request bit in the OTG control and status register. The OTG\_FS/OTG\_HS controller performs data-line pulsing followed by  $V_{BUS}$  pulsing.
5. The host detects SRP from either the data-line or  $V_{BUS}$  pulsing, and turns on  $V_{BUS}$ . The PHY indicates  $V_{BUS}$  power-on to the device.
6. The OTG\_FS/OTG\_HS controller performs  $V_{BUS}$  pulsing. The host starts a new session by turning on  $V_{BUS}$ , indicating SRP success. The OTG\_FS/OTG\_HS controller interrupts the application by setting the session request

success status change bit in the OTG interrupt status register. The application reads the session request success bit in the OTG control and status register.

- When the USB is powered, the OTG\_FS/OTG\_HS controller connects, completing the SRP process.

### A-device host negotiation protocol

HNP switches the USB host role from the A-device to the B-device. The application must set the HNP-capable bit in the core USB configuration register to enable the OTG\_FS/OTG\_HS controller to perform HNP as an A-device.

**Figure 487. A-device HNP**

1. DPPULLDOWN = signal from core to PHY to enable/disable the pull-down on the DP line inside the PHY.  
DMPULLDOWN = signal from core to PHY to enable/disable the pull-down on the DM line inside the PHY.

The following points refer and describe the signal numeration shown in the [Figure 487](#):

1. The OTG\_FS/OTG\_HS controller sends the B-device a SetFeature b\_hnp\_enable descriptor to enable HNP support. The B-device's ACK response indicates that the B-device supports HNP. The application must set host Set HNP enable bit in the OTG

control and status register to indicate to the OTG\_FS/OTG\_HS controller that the B-device supports HNP.

2. When it has finished using the bus, the application suspends by writing the port suspend bit in the host port control and status register.
3. When the B-device observes a USB suspend, it disconnects, indicating the initial condition for HNP. The B-device initiates HNP only when it must switch to the host role; otherwise, the bus continues to be suspended.

The OTG\_FS/OTG\_HS controller sets the host negotiation detected interrupt in the OTG interrupt status register, indicating the start of HNP.

The OTG\_FS/OTG\_HS controller deasserts the DM pull down and DM pull down in the PHY to indicate a device role. The PHY enables the OTG\_DP pull-up resistor to indicate a connect for B-device.

The application must read the current mode bit in the OTG control and status register to determine device mode operation.

4. The B-device detects the connection, issues a USB reset, and enumerates the OTG\_FS/OTG\_HS controller for data traffic.
5. The B-device continues the host role, initiating traffic, and suspends the bus when done.

The OTG\_FS/OTG\_HS controller sets the early suspend bit in the core interrupt register after 3 ms of bus idleness. Following this, the OTG\_FS/OTG\_HS controller sets the USB suspend bit in the core interrupt register.

6. In Negotiated mode, the OTG\_FS/OTG\_HS controller detects the suspend, disconnects, and switches back to the host role. The OTG\_FS/OTG\_HS controller asserts the DM pull down and DM pull down in the PHY to indicate its assumption of the host role.
7. The OTG\_FS/OTG\_HS controller sets the connector ID status change interrupt in the OTG interrupt status register. The application must read the connector ID status in the OTG control and status register to determine the OTG\_FS/OTG\_HS controller operation as an A-device. This indicates the completion of HNP to the application. The application must read the Current mode bit in the OTG control and status register to determine host mode operation.
8. The B-device connects, completing the HNP process.

### **B-device host negotiation protocol**

HNP switches the USB host role from B-device to A-device. The application must set the HNP-capable bit in the core USB configuration register to enable the OTG\_FS/OTG\_HS controller to perform HNP as a B-device.

Figure 488. B-device HNP

1. DPPULLDOWN = signal from core to PHY to enable/disable the pull-down on the DP line inside the PHY.  
DMPULLDOWN = signal from core to PHY to enable/disable the pull-down on the DM line inside the PHY.

The following points refer and describe the signal numeration shown in the [Figure 488](#):

1. The A-device sends the SetFeature b\_hnp\_enable descriptor to enable HNP support. The OTG\_FS/OTG\_HS controller's ACK response indicates that it supports HNP. The application must set the device HNP enable bit in the OTG control and status register to indicate HNP support.  
  
The application sets the HNP request bit in the OTG control and status register to indicate to the OTG\_FS/OTG\_HS controller to initiate HNP.
2. When it has finished using the bus, the A-device suspends by writing the port suspend bit in the host port control and status register.  
  
The OTG\_FS/OTG\_HS controller sets the Early suspend bit in the core interrupt register after 3 ms of bus idleness. Following this, the OTG\_FS/OTG\_HS controller sets the USB suspend bit in the core interrupt register.  
  
The OTG\_FS/OTG\_HS controller disconnects and the A-device detects SE0 on the bus, indicating HNP. The OTG\_FS/OTG\_HS controller asserts the DP pull down and DM pull down in the PHY to indicate its assumption of the host role.  
  
The A-device responds by activating its OTG\_DP pull-up resistor within 3 ms of detecting SE0. The OTG\_FS/OTG\_HS controller detects this as a connect.  
  
The OTG\_FS/OTG\_HS controller sets the host negotiation success status change interrupt in the OTG interrupt status register, indicating the HNP status. The application must read the host negotiation success bit in the OTG control and status register to

determine host negotiation success. The application must read the current Mode bit in the core interrupt register (OTG\_GINTSTS) to determine host mode operation.

3. The application sets the reset bit (PRST in OTG\_HPRT) and the OTG\_FS/OTG\_HS controller issues a USB reset and enumerates the A-device for data traffic.
4. The OTG\_FS/OTG\_HS controller continues the host role of initiating traffic, and when done, suspends the bus by writing the port suspend bit in the host port control and status register.
5. In Negotiated mode, when the A-device detects a suspend, it disconnects and switches back to the host role. The OTG\_FS/OTG\_HS controller deasserts the DP pull down and DM pull down in the PHY to indicate the assumption of the device role.
6. The application must read the current mode bit in the core interrupt (OTG\_GINTSTS) register to determine the host mode operation.
7. The OTG\_FS/OTG\_HS controller connects, completing the HNP process.

## **38 Ethernet (ETH): media access control (MAC) with DMA controller**

### **38.1 Ethernet introduction**

Portions Copyright (c) 2004, 2005 Synopsys, Inc. All rights reserved. Used with permission.

The Ethernet peripheral enables the STM32F75xxx and STM32F74xxx to transmit and receive data over Ethernet in compliance with the IEEE 802.3-2002 standard.

The Ethernet provides a configurable, flexible peripheral to meet the needs of various applications and customers. It supports two industry standard interfaces to the external physical layer (PHY): the default media independent interface (MII) defined in the IEEE 802.3 specifications and the reduced media independent interface (RMII). It can be used in number of applications such as switches, network interface cards, etc.

The Ethernet is compliant with the following standards:

- IEEE 802.3-2002 for Ethernet MAC
- IEEE 1588-2008 standard for precision networked clock synchronization
- AMBA 2.0 for AHB Master/Slave ports
- RMII specification from RMII consortium

### **38.2 Ethernet main features**

The Ethernet (ETH) peripheral includes the following features, listed by category:

### 38.2.1 MAC core features

- Supports 10/100 Mbit/s data transfer rates with external PHY interfaces
- IEEE 802.3-compliant MII interface to communicate with an external Fast Ethernet PHY
- Supports both full-duplex and half-duplex operations
  - Supports CSMA/CD Protocol for half-duplex operation
  - Supports IEEE 802.3x flow control for full-duplex operation
  - Optional forwarding of received pause control frames to the user application in full-duplex operation
  - Back-pressure support for half-duplex operation
  - Automatic transmission of zero-quanta pause frame on deassertion of flow control input in full-duplex operation
- Preamble and start-of-frame data (SFD) insertion in Transmit, and deletion in Receive paths
- Automatic CRC and pad generation controllable on a per-frame basis
- Options for automatic pad/CRC stripping on receive frames
- Programmable frame length to support Standard frames with sizes up to 16 KB
- Programmable interframe gap (40-96 bit times in steps of 8)
- Supports a variety of flexible address filtering modes:
  - Up to four 48-bit perfect (DA) address filters with masks for each byte
  - Up to three 48-bit SA address comparison check with masks for each byte
  - 64-bit Hash filter (optional) for multicast and unicast (DA) addresses
  - Option to pass all multicast addressed frames
  - Promiscuous mode support to pass all frames without any filtering for network monitoring
  - Passes all incoming packets (as per filter) with a status report
- Separate 32-bit status returned for transmission and reception packets
- Supports IEEE 802.1Q VLAN tag detection for reception frames
- Separate transmission, reception, and control interfaces to the Application
- Supports mandatory network statistics with RMON/MIB counters (RFC2819/RFC2665)
- MDIO interface for PHY device configuration and management
- Detection of LAN wakeup frames and AMD Magic Packet™ frames
- Receive feature for checksum off-load for received IPv4 and TCP packets encapsulated by the Ethernet frame
- Enhanced receive feature for checking IPv4 header checksum and TCP, UDP, or ICMP checksum encapsulated in IPv4 or IPv6 datagrams
- Support Ethernet frame time stamping as described in IEEE 1588-2008. Sixty-four-bit time stamps are given in each frame's transmit or receive status
- Two sets of FIFOs: a 2-KB Transmit FIFO with programmable threshold capability, and a 2-KB Receive FIFO with a configurable threshold (default of 64 bytes)
- Receive Status vectors inserted into the Receive FIFO after the EOF transfer enables multiple-frame storage in the Receive FIFO without requiring another FIFO to store those frames' Receive Status
- Option to filter all error frames on reception and not forward them to the application in

## Store-and-Forward mode

- Option to forward under-sized good frames
- Supports statistics by generating pulses for frames dropped or corrupted (due to overflow) in the Receive FIFO
- Supports Store and Forward mechanism for transmission to the MAC core
- Automatic generation of PAUSE frame control or back pressure signal to the MAC core based on Receive FIFO-fill (threshold configurable) level
- Handles automatic retransmission of Collision frames for transmission
- Discards frames on late collision, excessive collisions, excessive deferral and underrun conditions
- Software control to flush Tx FIFO
- Calculates and inserts IPv4 header checksum and TCP, UDP, or ICMP checksum in frames transmitted in Store-and-Forward mode
- Supports internal loopback on the MII for debugging

### 38.2.2 DMA features

- Supports all AHB burst types in the AHB Slave Interface
- Software can select the type of AHB burst (fixed or indefinite burst) in the AHB Master interface.
- Option to select address-aligned bursts from AHB master port
- Optimization for packet-oriented DMA transfers with frame delimiters
- Byte-aligned addressing for data buffer support
- Dual-buffer (ring) or linked-list (chained) descriptor chaining
- Descriptor architecture, allowing large blocks of data transfer with minimum CPU intervention;
- each descriptor can transfer up to 8 KB of data
- Comprehensive status reporting for normal operation and transfers with errors
- Individual programmable burst size for Transmit and Receive DMA Engines for optimal host bus utilization
- Programmable interrupt options for different operational conditions
- Per-frame Transmit/Receive complete interrupt control
- Round-robin or fixed-priority arbitration between Receive and Transmit engines
- Start/Stop modes
- Current Tx/Rx Buffer pointer as status registers
- Current Tx/Rx Descriptor pointer as status registers

### 38.2.3 PTP features

- Received and transmitted frames time stamping
- Coarse and fine correction methods
- Trigger interrupt when system time becomes greater than target time
- Pulse per second output (product alternate function output)

### 38.3 Ethernet pins

[Table 272](#) shows the MAC signals and the corresponding MII/RMII signal mapping. All MAC signals are mapped onto AF11, some signals are mapped onto different I/O pins, and should be configured in Alternate function mode (for more details, refer to [Section 6.3.2: I/O pin alternate function multiplexer and mapping](#) and the corresponding datasheet).

**Table 272. Alternate function mapping**

| AF11                              |
|-----------------------------------|
| ETH                               |
| ETH_MII_CRS                       |
| ETH_MII_RX_CLK / ETH_RMII_REF_CLK |
| ETH_MDIO                          |
| ETH_MII_COL                       |
| ETH_MII_RX_DV / ETH_RMII_CRS_DV   |
| ETH_MII_RXD2                      |
| ETH_MII_RXD3                      |
| ETH_PPS_OUT                       |
| ETH_MII_TXD3                      |
| ETH_MII_RX_ER                     |
| ETH_MII_TX_EN / ETH_RMII_TX_EN    |
| ETH_MII_TXD0 / ETH_RMII_TXD0      |
| ETH_MII_TXD1 / ETH_RMII_TXD1      |
| ETH_MDC                           |
| ETH_MII_TXD2                      |
| ETH_MII_TX_CLK                    |
| ETH_MII_RXD0 / ETH_RMII_RXD0      |
| ETH_MII_RXD1 / ETH_RMII_RXD1      |
| ETH_MII_TXD3                      |
| ETH_PPS_OUT                       |
| ETH_MII_TX_EN / ETH_RMII_TX_EN    |
| ETH_MII_TXD0 / ETH_RMII_TXD0      |
| ETH_MII_TXD1 / ETH_RMII_TXD1      |
| ETH_MII_CRS                       |
| ETH_MII_COL                       |
| ETH_MII_RXD2                      |
| ETH_MII_RXD3                      |
| ETH_MII_RX_ER                     |

## 38.4 Ethernet functional description: SMI, MII and RMII

The Ethernet peripheral consists of a MAC 802.3 (media access control) with a dedicated DMA controller. It supports both default media-independent interface (MII) and reduced media-independent interface (RMII) through one selection bit (refer to SYSCFG\_PMC register).

The DMA controller interfaces with the Core and memories through the AHB Master and Slave interfaces. The AHB Master Interface controls data transfers while the AHB Slave interface accesses Control and Status Registers (CSR) space.

The Transmit FIFO (Tx FIFO) buffers data read from system memory by the DMA before transmission by the MAC Core. Similarly, the Receive FIFO (Rx FIFO) stores the Ethernet frames received from the line until they are transferred to system memory by the DMA.

The Ethernet peripheral also includes an SMI to communicate with external PHY. A set of configuration registers permit the user to select the desired mode and features for the MAC and the DMA controller.

**Note:** The AHB clock frequency must be at least 25 MHz when the Ethernet is used.

**Figure 489. ETH block diagram**

1. For AHB connections refer to [Figure 1: System architecture](#).

### 38.4.1 Station management interface: SMI

The station management interface (SMI) allows the application to access any PHY registers through a 2-wire clock and data lines. The interface supports accessing up to 32 PHYs.

The application can select one of the 32 PHYs and one of the 32 registers within any PHY and send control data or receive status information. Only one register in one PHY can be addressed at any given time.

Both the MDC clock line and the MDIO data line are implemented as alternate function I/O in the microcontroller:

- MDC: a periodic clock that provides the timing reference for the data transfer at the maximum frequency of 2.5 MHz. The minimum high and low times for MDC must be

160 ns each, and the minimum period for MDC must be 400 ns. In idle state the SMI management interface drives the MDC clock signal low.

- MDIO: data input/output bitstream to transfer status information to/from the PHY device synchronously with the MDC clock signal

Figure 490. SMI interface signals

### SMI frame format

The frame structure related to a read or write operation is shown in [Table 273](#), the order of bit transmission must be from left to right.

Table 273. Management frame format

|       | Management frame fields |       |           |       |       |    |                 |      |
|-------|-------------------------|-------|-----------|-------|-------|----|-----------------|------|
|       | Preamble (32 bits)      | Start | Operation | PADDR | RADDR | TA | Data (16 bits)  | Idle |
| Read  | 1... 1                  | 01    | 10        | ppppp | rrrrr | Z0 | ddddddddddddddd | Z    |
| Write | 1... 1                  | 01    | 01        | ppppp | rrrrr | 10 | ddddddddddddddd | Z    |

The management frame consists of eight fields:

- **Preamble:** each transaction (read or write) can be initiated with the preamble field that corresponds to 32 contiguous logic one bits on the MDIO line with 32 corresponding cycles on MDC. This field is used to establish synchronization with the PHY device.
- **Start:** the start of frame is defined by a <01> pattern to verify transitions on the line from the default logic one state to zero and back to one.
- **Operation:** defines the type of transaction (read or write) in progress.
- **PADDR:** the PHY address is 5 bits, allowing 32 unique PHY addresses. The MSB bit of the address is the first transmitted and received.
- **RADDR:** the register address is 5 bits, allowing 32 individual registers to be addressed within the selected PHY device. The MSB bit of the address is the first transmitted and received.
- **TA:** the turn-around field defines a 2-bit pattern between the RADDR and DATA fields to avoid contention during a read transaction. For a read transaction the MAC controller drives high-impedance on the MDIO line for the 2 bits of TA. The PHY device must drive a high-impedance state on the first bit of TA, a zero bit on the second one.

For a write transaction, the MAC controller drives a <10> pattern during the TA field. The PHY device must drive a high-impedance state for the 2 bits of TA.

- **Data:** the data field is 16-bit. The first bit transmitted and received must be bit 15 of the ETH\_MIID register.
- **Idle:** the MDIO line is driven in high-impedance state. All three-state drivers must be disabled and the PHY's pull-up resistor keeps the line at logic one.

### SMI write operation

When the application sets the MII Write and Busy bits (in *Ethernet MAC MII address register (ETH\_MACMIAR)*), the SMI initiates a write operation into the PHY registers by transferring the PHY address, the register address in PHY, and the write data (in *Ethernet MAC MII data register (ETH\_MACMIIDR)*). The application should not change the MII Address register contents or the MII Data register while the transaction is ongoing. Write operations to the MII Address register or the MII Data Register during this period are ignored (the Busy bit is high), and the transaction is completed without any error. After the Write operation has completed, the SMI indicates this by resetting the Busy bit.

Figure 491 shows the frame format for the write operation.

**Figure 491. MDIO timing and frame structure - Write cycle**

### SMI read operation

When the user sets the MII Busy bit in the Ethernet MAC MII address register (ETH\_MACMIAR) with the MII Write bit at 0, the SMI initiates a read operation in the PHY registers by transferring the PHY address and the register address in PHY. The application should not change the MII Address register contents or the MII Data register while the transaction is ongoing. Write operations to the MII Address register or MII Data Register during this period are ignored (the Busy bit is high) and the transaction is completed without any error. After the read operation has completed, the SMI resets the Busy bit and then updates the MII Data register with the data read from the PHY.

Figure 492 shows the frame format for the read operation.

Figure 492. MDIO timing and frame structure - Read cycle

### SMI clock selection

The MAC initiates the Management Write/Read operation. The SMI clock is a divided clock whose source is the application clock (AHB clock). The divide factor depends on the clock range setting in the MII Address register.

[Table 274](#) shows how to set the clock ranges.

Table 274. Clock range

| Selection     | HCLK clock  | MDC clock       |
|---------------|-------------|-----------------|
| 000           | 60-100 MHz  | AHB clock / 42  |
| 001           | 100-150 MHz | AHB clock / 62  |
| 010           | 20-35 MHz   | AHB clock / 16  |
| 011           | 35-60 MHz   | AHB clock / 26  |
| 100           | 150-216 MHz | AHB clock / 102 |
| 101, 110, 111 | Reserved    | -               |

### 38.4.2 Media-independent interface: MII

The media-independent interface (MII) defines the interconnection between the MAC sublayer and the PHY for data transfer at 10 Mbit/s and 100 Mbit/s.

**Figure 493. Media independent interface signals**

- **MII\_TX\_CLK**: continuous clock that provides the timing reference for the TX data transfer. The nominal frequency is: 2.5 MHz at 10 Mbit/s speed; 25 MHz at 100 Mbit/s speed.
- **MII\_RX\_CLK**: continuous clock that provides the timing reference for the RX data transfer. The nominal frequency is: 2.5 MHz at 10 Mbit/s speed; 25 MHz at 100 Mbit/s speed.
- **MII\_TX\_EN**: transmission enable indicates that the MAC is presenting nibbles on the MII for transmission. It must be asserted synchronously (MII\_TX\_CLK) with the first nibble of the preamble and must remain asserted while all nibbles to be transmitted are presented to the MII.
- **MII\_TXD[3:0]**: transmit data is a bundle of 4 data signals driven synchronously by the MAC sublayer and qualified (valid data) on the assertion of the MII\_TX\_EN signal. MII\_TXD[0] is the least significant bit, MII\_TXD[3] is the most significant bit. While MII\_TX\_EN is deasserted the transmit data must have no effect upon the PHY.
- **MII\_CR**: carrier sense is asserted by the PHY when either the transmit or receive medium is non idle. It shall be deasserted by the PHY when both the transmit and receive media are idle. The PHY must ensure that the MII\_CS signal remains asserted throughout the duration of a collision condition. This signal is not required to transition synchronously with respect to the TX and RX clocks. In full duplex mode the state of this signal is don't care for the MAC sublayer.
- **MII\_COL**: collision detection must be asserted by the PHY upon detection of a collision on the medium and must remain asserted while the collision condition persists. This signal is not required to transition synchronously with respect to the TX and RX clocks. In full duplex mode the state of this signal is don't care for the MAC sublayer.
- **MII\_RXD[3:0]**: reception data is a bundle of 4 data signals driven synchronously by the PHY and qualified (valid data) on the assertion of the MII\_RX\_DV signal. MII\_RXD[0] is the least significant bit, MII\_RXD[3] is the most significant bit. While MII\_RX\_EN is deasserted and MII\_RX\_ER is asserted, a specific MII\_RXD[3:0] value is used to

transfer specific information from the PHY (see [Table 276](#)).

- **MII\_RX\_DV**: receive data valid indicates that the PHY is presenting recovered and decoded nibbles on the MII for reception. It must be asserted synchronously (**MII\_RX\_CLK**) with the first recovered nibble of the frame and must remain asserted through the final recovered nibble. It must be deasserted prior to the first clock cycle that follows the final nibble. In order to receive the frame correctly, the **MII\_RX\_DV** signal must encompass the frame, starting no later than the SFD field.
- **MII\_RX\_ER**: receive error must be asserted for one or more clock periods (**MII\_RX\_CLK**) to indicate to the MAC sublayer that an error was detected somewhere in the frame. This error condition must be qualified by **MII\_RX\_DV** assertion as described in [Table 276](#).

**Table 275. TX interface signal encoding**

| MII_TX_EN | MII_TXD[3:0]      | Description              |
|-----------|-------------------|--------------------------|
| 0         | 0000 through 1111 | Normal inter-frame       |
| 1         | 0000 through 1111 | Normal data transmission |

**Table 276. RX interface signal encoding**

| MII_RX_DV | MII_RX_ERR | MII_RXD[3:0]      | Description                |
|-----------|------------|-------------------|----------------------------|
| 0         | 0          | 0000 through 1111 | Normal inter-frame         |
| 0         | 1          | 0000              | Normal inter-frame         |
| 0         | 1          | 0001 through 1101 | Reserved                   |
| 0         | 1          | 1110              | False carrier indication   |
| 0         | 1          | 1111              | Reserved                   |
| 1         | 0          | 0000 through 1111 | Normal data reception      |
| 1         | 1          | 0000 through 1111 | Data reception with errors |

### MII clock sources

To generate both **TX\_CLK** and **RX\_CLK** clock signals, the external PHY must be clocked with an external 25 MHz as shown in [Figure 494](#). Instead of using an external 25 MHz quartz to provide this clock, the STM32F75xxx and STM32F74xxx microcontrollers can output this signal on its MCO pin. In this case, the PLL multiplier has to be configured so as to get the desired frequency on the MCO pin, from the 25 MHz external quartz.

Figure 494. MII clock sources

ai15623b

### 38.4.3 Reduced media-independent interface: RMII

The reduced media-independent interface (RMII) specification reduces the pin count between the microcontroller Ethernet peripheral and the external Ethernet in 10/100 Mbit/s. According to the IEEE 802.3u standard, an MII contains 16 pins for data and control. The RMII specification is dedicated to reduce the pin count to 7 pins (a 62.5% decrease in pin count).

The RMII is instantiated between the MAC and the PHY. This helps translation of the MAC's MII into the RMII. The RMII block has the following characteristics:

- It supports 10-Mbit/s and 100-Mbit/s operating rates
- The clock reference must be doubled to 50 MHz
- The same clock reference must be sourced externally to both MAC and external Ethernet PHY
- It provides independent 2-bit wide (dibit) transmit and receive data paths

Figure 495. Reduced media-independent interface signals

ai15624b

### RMII clock sources

Either clock the PHY from an external 50 MHz clock or use a PHY with an embedded PLL to generate the 50 MHz frequency.

Figure 496. RMII clock sources-

### 38.4.4 MII/RMII selection

The mode, MII or RMII, is selected using the configuration bit 23, MII\_RMII\_SEL, in the SYSCFG\_PMC register. The application has to set the MII/RMII mode while the Ethernet controller is under reset or before enabling the clocks.

### MII/RMII internal clock scheme

The clock scheme required to support both the MII and RMII, as well as 10 and 100 Mbit/s operations is described in [Figure 497](#).

Figure 497. Clock scheme

1. The MII/RMII selection is controlled through bit 23, MII\_RMII\_SEL, in the SYSCFG\_PMC register.

To save a pin, the two input clock signals, RMII\_REF\_CLK and MII\_RX\_CLK, are multiplexed on the same GPIO pin.

## 38.5 Ethernet functional description: MAC 802.3

The IEEE 802.3 International Standard for local area networks (LANs) employs the CSMA/CD (carrier sense multiple access with collision detection) as the access method.

The Ethernet peripheral consists of a MAC 802.3 (media access control) controller with media independent interface (MII) and a dedicated DMA controller.

The MAC block implements the LAN CSMA/CD sublayer for the following families of systems: 10 Mbit/s and 100 Mbit/s of data rates for baseband and broadband systems. Half- and full-duplex operation modes are supported. The collision detection access method is applied only to the half-duplex operation mode. The MAC control frame sublayer is supported.

The MAC sublayer performs the following functions associated with a data link control procedure:

- Data encapsulation (transmit and receive)
  - Framing (frame boundary delimitation, frame synchronization)
  - Addressing (handling of source and destination addresses)
  - Error detection
- Media access management
  - Medium allocation (collision avoidance)
  - Contention resolution (collision handling)

Basically there are two operating modes of the MAC sublayer:

- Half-duplex mode: the stations contend for the use of the physical medium, using the CSMA/CD algorithms.
- Full duplex mode: simultaneous transmission and reception without contention resolution (CSMA/CD algorithm are unnecessary) when all the following conditions are met:
  - physical medium capability to support simultaneous transmission and reception
  - exactly 2 stations connected to the LAN
  - both stations configured for full-duplex operation

### 38.5.1 MAC 802.3 frame format

The MAC block implements the MAC sublayer and the optional MAC control sublayer (10/100 Mbit/s) as specified by the IEEE 802.3-2002 standard.

Two frame formats are specified for data communication systems using the CSMA/CD MAC:

- Basic MAC frame format
- Tagged MAC frame format (extension of the basic MAC frame format)

[Figure 499](#) and [Figure 500](#) describe the frame structure (untagged and tagged) that includes the following fields:

- Preamble: 7-byte field used for synchronization purposes (PLS circuitry)  
Hexadecimal value: 55-55-55-55-55-55-55  
Bit pattern: 01010101 01010101 01010101 01010101 01010101 01010101 01010101 (right-to-left bit transmission)
- Start frame delimiter (SFD): 1-byte field used to indicate the start of a frame.  
Hexadecimal value: D5  
Bit pattern: 11010101 (right-to-left bit transmission)
- Destination and Source Address fields: 6-byte fields to indicate the destination and source station addresses as follows (see [Figure 498](#)):
  - Each address is 48 bits in length
  - The first LSB bit (I/G) in the destination address field is used to indicate an individual (I/G = 0) or a group address (I/G = 1). A group address could identify none, one or more, or all the stations connected to the LAN. In the source address the first bit is reserved and reset to 0.
  - The second bit (U/L) distinguishes between locally (U/L = 1) or globally (U/L = 0) administered addresses. For broadcast addresses this bit is also 1.
  - Each byte of each address field must be transmitted least significant bit first.

The address designation is based on the following types:

- Individual address: this is the physical address associated with a particular station on the network.
- Group address. A multdestination address associated with one or more stations on a given network. There are two kinds of multicast address:
  - Multicast-group address: an address associated with a group of logically related stations.
  - Broadcast address: a distinguished, predefined multicast address (all 1's in the destination address field) that always denotes all the stations on a given LAN.

**Figure 498. Address field format**

- QTag Prefix: 4-byte field inserted between the Source address field and the MAC Client Length/Type field. This field is an extension of the basic frame (untagged) to obtain the tagged MAC frame. The untagged MAC frames do not include this field. The extensions for tagging are as follows:
  - 2-byte constant Length/Type field value consistent with the Type interpretation (greater than 0x0600) equal to the value of the 802.1Q Tag Protocol Type (0x8100)

hexadecimal). This constant field is used to distinguish tagged and untagged MAC frames.

- 2-byte field containing the Tag control information field subdivided as follows: a 3-bit user priority, a canonical format indicator (CFI) bit and a 12-bit VLAN Identifier. The length of the tagged MAC frame is extended by 4 bytes by the QTag Prefix.
- MAC client length/type: 2-byte field with different meaning (mutually exclusive), depending on its value:
  - If the value is less than or equal to maxValidFrame (0d1500) then this field indicates the number of MAC client data bytes contained in the subsequent data field of the 802.3 frame (length interpretation).
  - If the value is greater than or equal to MinTypeValue (0d1536 decimal, 0x0600) then this field indicates the nature of the MAC client protocol (Type interpretation) related to the Ethernet frame.

Regardless of the interpretation of the length/type field, if the length of the data field is less than the minimum required for proper operation of the protocol, a PAD field is added after the data field but prior to the FCS (frame check sequence) field. The length/type field is transmitted and received with the higher-order byte first.

For length/type field values in the range between maxValidLength and minTypeValue (boundaries excluded), the behavior of the MAC sublayer is not specified: they may or may not be passed by the MAC sublayer.

- Data and PAD fields: n-byte data field. Full data transparency is provided, it means that any arbitrary sequence of byte values may appear in the data field. The size of the PAD, if any, is determined by the size of the data field. Max and min length of the data and PAD field are:
  - Maximum length = 1500 bytes
  - Minimum length for untagged MAC frames = 46 bytes
  - Minimum length for tagged MAC frames = 42 bytes

When the data field length is less than the minimum required, the PAD field is added to match the minimum length (42 bytes for tagged frames, 46 bytes for untagged frames).

- Frame check sequence: 4-byte field that contains the cyclic redundancy check (CRC) value. The CRC computation is based on the following fields: source address, destination address, QTag prefix, length/type, LLC data and PAD (that is, all fields except the preamble, SFD). The generating polynomial is the following:

$$G(x) = x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x + 1$$

The CRC value of a frame is computed as follows:

- The first 2 bits of the frame are complemented
- The n-bits of the frame are the coefficients of a polynomial  $M(x)$  of degree  $(n - 1)$ . The first bit of the destination address corresponds to the  $x^{n-1}$  term and the last bit of the data field corresponds to the  $x^0$  term
- $M(x)$  is multiplied by  $x^{32}$  and divided by  $G(x)$ , producing a remainder  $R(x)$  of degree  $\leq 31$
- The coefficients of  $R(x)$  are considered as a 32-bit sequence
- The bit sequence is complemented and the result is the CRC
- The 32-bits of the CRC value are placed in the frame check sequence. The  $x^{32}$  term is the first transmitted, the  $x^0$  term is the last one

Figure 499. MAC frame format

Figure 500. Tagged MAC frame format

Each byte of the MAC frame, except the FCS field, is transmitted low-order bit first.

An invalid MAC frame is defined by one of the following conditions:

- The frame length is inconsistent with the expected value as specified by the length/type field. If the length/type field contains a type value, then the frame length is assumed to be consistent with this field (no invalid frame)
- The frame length is not an integer number of bytes (extra bits)
- The CRC value computed on the incoming frame does not match the included FCS

### 38.5.2 MAC frame transmission

The DMA controls all transactions for the transmit path. Ethernet frames read from the system memory are pushed into the FIFO by the DMA. The frames are then popped out and transferred to the MAC core. When the end-of-frame is transferred, the status of the transmission is taken from the MAC core and transferred back to the DMA. The Transmit FIFO has a depth of 2 Kbyte. FIFO-fill level is indicated to the DMA so that it can initiate a data fetch in required bursts from the system memory, using the AHB interface. The data from the AHB Master interface is pushed into the FIFO.

When the SOF is detected, the MAC accepts the data and begins transmitting to the MII. The time required to transmit the frame data to the MII after the application initiates transmission is variable, depending on delay factors like IFG delay, time to transmit preamble/SFD, and any back-off delays for Half-duplex mode. After the EOF is transferred to the MAC core, the core completes normal transmission and then gives the status of transmission back to the DMA. If a normal collision (in Half-duplex mode) occurs during transmission, the MAC core makes the transmit status valid, then accepts and drops all further data until the next SOF is received. The same frame should be retransmitted from SOF on observing a Retry request (in the Status) from the MAC. The MAC issues an underflow status if the data are not provided continuously during the transmission. During the normal transfer of a frame, if the MAC receives an SOF without getting an EOF for the previous frame, then the SOF is ignored and the new frame is considered as the continuation of the previous frame.

There are two modes of operation for popping data towards the MAC core:

- In Threshold mode, as soon as the number of bytes in the FIFO crosses the configured threshold level (or when the end-of-frame is written before the threshold is crossed), the data is ready to be popped out and forwarded to the MAC core. The threshold level is configured using the TTC bits of ETH\_DMABMR.
- In Store-and-forward mode, only after a complete frame is stored in the FIFO, the frame is popped towards the MAC core. If the Tx FIFO size is smaller than the Ethernet frame to be transmitted, then the frame is popped towards the MAC core when the Tx FIFO becomes almost full.

The application can flush the Transmit FIFO of all contents by setting the FTF (ETH\_DMAOMR register [20]) bit. This bit is self-clearing and initializes the FIFO pointers to the default state. If the FTF bit is set during a frame transfer to the MAC core, then transfer is stopped as the FIFO is considered to be empty. Hence an underflow event occurs at the MAC transmitter and the corresponding Status word is forwarded to the DMA.

#### Automatic CRC and pad generation

When the number of bytes received from the application falls below 60 (DA+SA+LT+Data), zeros are appended to the transmitting frame to make the data length exactly 46 bytes to meet the minimum data field requirement of IEEE 802.3. The MAC can be programmed not to append any padding. The cyclic redundancy check (CRC) for the frame check sequence (FCS) field is calculated and appended to the data being transmitted. When the MAC is programmed to not append the CRC value to the end of Ethernet frames, the computed CRC is not transmitted. An exception to this rule is that when the MAC is programmed to append pads for frames (DA+SA+LT+Data) less than 60 bytes, CRC will be appended at the end of the padded frames.

The CRC generator calculates the 32-bit CRC for the FCS field of the Ethernet frame. The encoding is defined by the following polynomial.

$$G(x) = x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x + 1$$

### Transmit protocol

The MAC controls the operation of Ethernet frame transmission. It performs the following functions to meet the IEEE 802.3/802.3z specifications. It:

- generates the preamble and SFD
- generates the jam pattern in Half-duplex mode
- controls the Jabber timeout
- controls the flow for Half-duplex mode (back pressure)
- generates the transmit frame status
- contains time stamp snapshot logic in accordance with IEEE 1588

When a new frame transmission is requested, the MAC sends out the preamble and SFD, followed by the data. The preamble is defined as 7 bytes of 0b10101010 pattern, and the SFD is defined as 1 byte of 0b10101011 pattern. The collision window is defined as 1 slot time (512 bit times for 10/100 Mbit/s Ethernet). The jam pattern generation is applicable only to Half-duplex mode, not to Full-duplex mode.

In MII mode, if a collision occurs at any time from the beginning of the frame to the end of the CRC field, the MAC sends a 32-bit jam pattern of 0x5555 5555 on the MII to inform all other stations that a collision has occurred. If the collision is seen during the preamble transmission phase, the MAC completes the transmission of the preamble and SFD and then sends the jam pattern.

A jabber timer is maintained to cut off the transmission of Ethernet frames if more than 2048 (default) bytes have to be transferred. The MAC uses the deferral mechanism for flow control (back pressure) in Half-duplex mode. When the application requests to stop receiving frames, the MAC sends a JAM pattern of 32 bytes whenever it senses the reception of a frame, provided that transmit flow control is enabled. This results in a collision and the remote station backs off. The application requests flow control by setting the BPA bit (bit 0) in the ETH\_MACFCR register. If the application requests a frame to be transmitted, then it is scheduled and transmitted even when back pressure is activated. Note that if back pressure is kept activated for a long time (and more than 16 consecutive collision events occur) then the remote stations abort their transmissions due to excessive collisions. If IEEE 1588 time stamping is enabled for the transmit frame, this block takes a snapshot of the system time when the SFD is put onto the transmit MII bus.

### Transmit scheduler

The MAC is responsible for scheduling the frame transmission on the MII. It maintains the interframe gap between two transmitted frames and follows the truncated binary exponential backoff algorithm for Half-duplex mode. The MAC enables transmission after satisfying the IFG and backoff delays. It maintains an idle period of the configured interframe gap (IFG bits in the ETH\_MACCCR register) between any two transmitted frames. If frames to be transmitted arrive sooner than the configured IFG time, the MII waits for the enable signal from the MAC before starting the transmission on it. The MAC starts its IFG counter as soon as the carrier signal of the MII goes inactive. At the end of the programmed IFG value, the MAC enables transmission in Full-duplex mode. In Half-duplex mode and when IFG is

configured for 96 bit times, the MAC follows the rule of deference specified in Section 4.2.3.2.1 of the IEEE 802.3 specification. The MAC resets its IFG counter if a carrier is detected during the first two-thirds (64-bit times for all IFG values) of the IFG interval. If the carrier is detected during the final one third of the IFG interval, the MAC continues the IFG count and enables the transmitter after the IFG interval. The MAC implements the truncated binary exponential backoff algorithm when it operates in Half-duplex mode.

### Transmit flow control

When the Transmit Flow Control Enable bit (TFE bit in ETH\_MACFCR) is set, the MAC generates Pause frames and transmits them as necessary, in Full-duplex mode. The Pause frame is appended with the calculated CRC, and is sent. Pause frame generation can be initiated in two ways.

A pause frame is sent either when the application sets the FCB bit in the ETH\_MACFCR register or when the receive FIFO is full (packet buffer).

- If the application has requested flow control by setting the FCB bit in ETH\_MACFCR, the MAC generates and transmits a single Pause frame. The value of the pause time in the generated frame contains the programmed pause time value in ETH\_MACFCR. To extend the pause or end the pause prior to the time specified in the previously transmitted Pause frame, the application must request another Pause frame transmission after programming the Pause Time value (PT in ETH\_MACFCR register) with the appropriate value.
- If the application has requested flow control when the receive FIFO is full, the MAC generates and transmits a Pause frame. The value of the pause time in the generated frame is the programmed pause time value in ETH\_MACFCR. If the receive FIFO remains full at a configurable number of slot-times (PLT bits in ETH\_MACFCR) before this Pause time runs out, a second Pause frame is transmitted. The process is repeated as long as the receive FIFO remains full. If this condition is no more satisfied prior to the sampling time, the MAC transmits a Pause frame with zero pause time to indicate to the remote end that the receive buffer is ready to receive new data frames.

### Single-packet transmit operation

The general sequence of events for a transmit operation is as follows:

1. If the system has data to be transferred, the DMA controller fetches them from the memory through the AHB Master interface and starts forwarding them to the FIFO. It continues to receive the data until the end of frame is transferred.
2. When the threshold level is crossed or a full packet of data is received into the FIFO, the frame data are popped and driven to the MAC core. The DMA continues to transfer data from the FIFO until a complete packet has been transferred to the MAC. Upon completion of the frame, the DMA controller is notified by the status coming from the MAC.

### Transmit operation—Two packets in the buffer

1. Because the DMA must update the descriptor status before releasing it to the Host, there can be at the most two frames inside a transmit FIFO. The second frame is fetched by the DMA and put into the FIFO only if the OSF (operate on second frame) bit is set. If this bit is not set, the next frame is fetched from the memory only after the MAC has completely processed the frame and the DMA has released the descriptors.
2. If the OSF bit is set, the DMA starts fetching the second frame immediately after completing the transfer of the first frame to the FIFO. It does not wait for the status to be updated. In the meantime, the second frame is received into the FIFO while the first

frame is being transmitted. As soon as the first frame has been transferred and the status is received from the MAC, it is pushed to the DMA. If the DMA has already completed sending the second packet to the FIFO, the second transmission must wait for the status of the first packet before proceeding to the next frame.

### Retransmission during collision

While a frame is being transferred to the MAC, a collision event may occur on the MAC line interface in Half-duplex mode. The MAC would then indicate a retry attempt by giving the status even before the end of frame is received. Then the retransmission is enabled and the frame is popped out again from the FIFO. After more than 96 bytes have been popped towards the MAC core, the FIFO controller frees up that space and makes it available to the DMA to push in more data. This means that the retransmission is not possible after this threshold is crossed or when the MAC core indicates a late collision event.

### Transmit FIFO flush operation

The MAC provides a control to the software to flush the Transmit FIFO through the use of Bit 20 in the Operation mode register. The Flush operation is immediate and the Tx FIFO and the corresponding pointers are cleared to the initial state even if the Tx FIFO is in the middle of transferring a frame to the MAC Core. This results in an underflow event in the MAC transmitter, and the frame transmission is aborted. The status of such a frame is marked with both underflow and frame flush events (TDES0 bits 13 and 1). No data are coming to the FIFO from the application (DMA) during the Flush operation. Transfer transmit status words are transferred to the application for the number of frames that is flushed (including partial frames). Frames that are completely flushed have the Frame flush status bit (TDES0 13) set. The Flush operation is completed when the application (DMA) has accepted all of the Status words for the frames that were flushed. The Transmit FIFO Flush control register bit is then cleared. At this point, new frames from the application (DMA) are accepted. All data presented for transmission after a Flush operation are discarded unless they start with an SOF marker.

### Transmit status word

At the end of the Ethernet frame transfer to the MAC core and after the core has completed the transmission of the frame, the transmit status is given to the application. The detailed description of the Transmit Status is the same as for bits [23:0] in TDES0. If IEEE 1588 time stamping is enabled, a specific frames' 64-bit time stamp is returned, along with the transmit status.

### Transmit checksum offload

Communication protocols such as TCP and UDP implement checksum fields, which helps determine the integrity of data transmitted over a network. Because the most widespread use of Ethernet is to encapsulate TCP and UDP over IP datagrams, the Ethernet controller has a transmit checksum offload feature that supports checksum calculation and insertion in the transmit path, and error detection in the receive path. This section explains the operation of the checksum offload feature for transmitted frames.

*Note: The checksum for TCP, UDP or ICMP is calculated over a complete frame, then inserted into its corresponding header field. Due to this requirement, this function is enabled only when the Transmit FIFO is configured for Store-and-forward mode (that is, when the TSF bit*

is set in the ETH\_ETH\_DMAOMR register). If the core is configured for Threshold (cut-through) mode, the Transmit checksum offload is bypassed.

The user must make sure the Transmit FIFO is deep enough to store a complete frame before that frame is transferred to the MAC Core transmitter. If the FIFO depth is less than the input Ethernet frame size, the payload (TCP/UDP/ICMP) checksum insertion function is bypassed and only the frame's IPv4 Header checksum is modified, even in Store-and-forward mode.

The transmit checksum offload supports two types of checksum calculation and insertion. This checksum can be controlled for each frame by setting the CIC bits (Bits 28:27 in TDES1, described in [TDES1: Transmit descriptor Word1 on page 1581](#)).

See IETF specifications RFC 791, RFC 793, RFC 768, RFC 792, RFC 2460 and RFC 4443 for IPv4, TCP, UDP, ICMP, IPv6 and ICMPv6 packet header specifications, respectively.

- IP header checksum

In IPv4 datagrams, the integrity of the header fields is indicated by the 16-bit header checksum field (the eleventh and twelfth bytes of the IPv4 datagram). The checksum offload detects an IPv4 datagram when the Ethernet frame's Type field has the value 0x0800 and the IP datagram's Version field has the value 0x4. The input frame's checksum field is ignored during calculation and replaced by the calculated value. IPv6 headers do not have a checksum field; thus, the checksum offload does not modify IPv6 header fields. The result of this IP header checksum calculation is indicated by the IP Header Error status bit in the Transmit status (Bit 16). This status bit is set whenever the values of the Ethernet Type field and the IP header's Version field are not consistent, or when the Ethernet frame does not have enough data, as indicated by the IP header Length field. In other words, this bit is set when an IP header error is asserted under the following circumstances:

- a) For IPv4 datagrams:

- The received Ethernet type is 0x0800, but the IP header's Version field does not equal 0x4
- The IPv4 Header Length field indicates a value less than 0x5 (20 bytes)
- The total frame length is less than the value given in the IPv4 Header Length field

- b) For IPv6 datagrams:

- The Ethernet type is 0x86DD but the IP header Version field does not equal 0x6
- The frame ends before the IPv6 header (40 bytes) or extension header (as given in the corresponding Header Length field in an extension header) has been completely received. Even when the checksum offload detects such an IP header error, it inserts an IPv4 header checksum if the Ethernet Type field indicates an IPv4 payload.

- TCP/UDP/ICMP checksum

The TCP/UDP/ICMP checksum processes the IPv4 or IPv6 header (including extension headers) and determines whether the encapsulated payload is TCP, UDP or ICMP.

Note that:

- a) For non-TCP, -UDP, or -ICMP/ICMPv6 payloads, this checksum is bypassed and nothing further is modified in the frame.
- b) Fragmented IP frames (IPv4 or IPv6), IP frames with security features (such as an authentication header or encapsulated security payload), and IPv6 frames with routing headers are bypassed and not processed by the checksum.

The checksum is calculated for the TCP, UDP, or ICMP payload and inserted into its corresponding field in the header. It can work in the following two modes:

- In the first mode, the TCP, UDP, or ICMPv6 pseudo-header is not included in the checksum calculation and is assumed to be present in the input frame's checksum field. The checksum field is included in the checksum calculation, and then replaced by the final calculated checksum.
- In the second mode, the checksum field is ignored, the TCP, UDP, or ICMPv6 pseudo-header data are included into the checksum calculation, and the checksum field is overwritten with the final calculated value.

Note that: for ICMP-over-IPv4 packets, the checksum field in the ICMP packet must always be 0x0000 in both modes, because pseudo-headers are not defined for such packets. If it does not equal 0x0000, an incorrect checksum may be inserted into the packet.

The result of this operation is indicated by the payload checksum error status bit in the Transmit Status vector (bit 12). The payload checksum error status bit is set when either of the following is detected:

- the frame has been forwarded to the MAC transmitter in Store-and-forward mode without the end of frame being written to the FIFO
- the packet ends before the number of bytes indicated by the payload length field in the IP header is received.

When the packet is longer than the indicated payload length, the bytes are ignored as stuff bytes, and no error is reported. When the first type of error is detected, the TCP, UDP or ICMP header is not modified. For the second error type, still, the calculated checksum is inserted into the corresponding header field.

### MII/RMII transmit bit order

Each nibble from the MII is transmitted on the RMII a dibit at a time with the order of dibit transmission shown in [Figure 501](#). Lower order bits (D1 and D0) are transmitted first followed by higher order bits (D2 and D3).

### 38.5.3 MAC frame reception

The MAC received frames are pushed into the Rx FIFO. The status (fill level) of this FIFO is indicated to the DMA once it crosses the configured receive threshold (RTC in the ETH\_DMAOMR register) so that the DMA can initiate pre-configured burst transfers towards the AHB interface.

In the default Cut-through mode, when 64 bytes (configured with the RTC bits in the ETH\_DMAOMR register) or a full packet of data are received into the FIFO, the data are popped out and the DMA is notified of its availability. Once the DMA has initiated the transfer to the AHB interface, the data transfer continues from the FIFO until a complete

packet has been transferred. Upon completion of the EOF frame transfer, the status word is popped out and sent to the DMA controller.

In Rx FIFO Store-and-forward mode (configured by the RSF bit in the ETH\_DMAOMR register), a frame is read out only after being written completely into the Receive FIFO. In this mode, all error frames are dropped (if the core is configured to do so) such that only valid frames are read out and forwarded to the application. In Cut-through mode, some error frames are not dropped, because the error status is received at the end of the frame, by which time the start of that frame has already been read out of the FIFO.

A receive operation is initiated when the MAC detects an SFD on the MII. The core strips the preamble and SFD before proceeding to process the frame. The header fields are checked for the filtering and the FCS field used to verify the CRC for the frame. The frame is dropped in the core if it fails the address filter.

### Receive protocol

The received frame preamble and SFD are stripped. Once the SFD has been detected, the MAC starts sending the Ethernet frame data to the receive FIFO, beginning with the first byte following the SFD (destination address). If IEEE 1588 time stamping is enabled, a snapshot of the system time is taken when any frame's SFD is detected on the MII. Unless the MAC filters out and drops the frame, this time stamp is passed on to the application.

If the received frame length/type field is less than 0x600 and if the MAC is programmed for the auto CRC/pad stripping option, the MAC sends the data of the frame to Rx FIFO up to the count specified in the length/type field, then starts dropping bytes (including the FCS field). If the Length/Type field is greater than or equal to 0x600, the MAC sends all received Ethernet frame data to Rx FIFO, regardless of the value on the programmed auto-CRC strip option. The MAC watchdog timer is enabled by default, that is, frames above 2048 bytes (DA + SA + LT + Data + pad + FCS) are cut off. This feature can be disabled by programming the watchdog disable (WD) bit in the MAC configuration register. However, even if the watchdog timer is disabled, frames greater than 16 KB in size are cut off and a watchdog timeout status is given.

### Receive CRC: automatic CRC and pad stripping

The MAC checks for any CRC error in the receiving frame. It calculates the 32-bit CRC for the received frame that includes the Destination address field through the FCS field. The encoding is defined by the following polynomial.

$$G(x) = x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x + 1$$

Regardless of the auto-pad/CRC strip, the MAC receives the entire frame to compute the CRC check for the received frame.

### Receive checksum offload

Both IPv4 and IPv6 frames in the received Ethernet frames are detected and processed for data integrity. The user can enable the receive checksum offload by setting the IPCO bit in the ETH\_MACCCR register. The MAC receiver identifies IPv4 or IPv6 frames by checking for value 0x0800 or 0x86DD, respectively, in the received Ethernet frame Type field. This identification applies to VLAN-tagged frames as well. The receive checksum offload calculates IPv4 header checksums and checks that they match the received IPv4 header checksums. The IP Header Error bit is set for any mismatch between the indicated payload

type (Ethernet Type field) and the IP header version, or when the received frame does not have enough bytes, as indicated by the IPv4 header's Length field (or when fewer than 20 bytes are available in an IPv4 or IPv6 header). The receive checksum offload also identifies a TCP, UDP or ICMP payload in the received IP datagrams (IPv4 or IPv6) and calculates the checksum of such payloads properly, as defined in the TCP, UDP or ICMP specifications. It includes the TCP/UDP/ICMPv6 pseudo-header bytes for checksum calculation and checks whether the received checksum field matches the calculated value. The result of this operation is given as a Payload Checksum Error bit in the receive status word. This status bit is also set if the length of the TCP, UDP or ICMP payload does not match the expected payload length given in the IP header. As mentioned in [TCP/UDP/ICMP checksum on page 1549](#), the receive checksum offload bypasses the payload of fragmented IP datagrams, IP datagrams with security features, IPv6 routing headers, and payloads other than TCP, UDP or ICMP. This information (whether the checksum is bypassed or not) is given in the receive status, as described in the [RDES0: Receive descriptor Word0](#) section. In this configuration, the core does not append any payload checksum bytes to the received Ethernet frames.

As mentioned in [RDES0: Receive descriptor Word0 on page 1588](#), the meaning of certain register bits changes as shown in [Table 277](#).

**Table 277. Frame statuses**

| Bit 18:<br>Ethernet frame | Bit 27: Header<br>checksum error | Bit 28: Payload<br>checksum error | Frame status                                                                                                   |
|---------------------------|----------------------------------|-----------------------------------|----------------------------------------------------------------------------------------------------------------|
| 0                         | 0                                | 0                                 | The frame is an IEEE 802.3 frame (Length field value is less than 0x0600).                                     |
| 1                         | 0                                | 0                                 | IPv4/IPv6 Type frame in which no checksum error is detected.                                                   |
| 1                         | 0                                | 1                                 | IPv4/IPv6 Type frame in which a payload checksum error (as described for PCE) is detected                      |
| 1                         | 1                                | 0                                 | IPv4/IPv6 Type frame in which IP header checksum error (as described for IPCO HCE) is detected.                |
| 1                         | 1                                | 1                                 | IPv4/IPv6 Type frame in which both PCE and IPCO HCE are detected.                                              |
| 0                         | 0                                | 1                                 | IPv4/IPv6 Type frame in which there is no IP HCE and the payload check is bypassed due to unsupported payload. |
| 0                         | 1                                | 1                                 | Type frame which is neither IPv4 or IPv6 (checksum offload bypasses the checksum check completely)             |
| 0                         | 1                                | 0                                 | Reserved                                                                                                       |

### Receive frame controller

If the RA bit is reset in the MAC CSR frame filter register, the MAC performs frame filtering based on the destination/source address (the application still needs to perform another level of filtering if it decides not to receive any bad frames like runt, CRC error frames, etc.). On detecting a filter-fail, the frame is dropped and not transferred to the application. When the filtering parameters are changed dynamically, and in case of (DA-SA) filter-fail, the rest of

the frame is dropped and the Rx Status Word is immediately updated (with zero frame length, CRC error and Runt Error bits set), indicating the filter fail. In Ethernet power down mode, all received frames are dropped, and are not forwarded to the application.

### Receive flow control

The MAC detects the receiving Pause frame and pauses the frame transmission for the delay specified within the received Pause frame (only in Full-duplex mode). The Pause frame detection function can be enabled or disabled with the RFCE bit in ETH\_MACFCR. Once receive flow control has been enabled, the received frame destination address begins to be monitored for any match with the multicast address of the control frame (0x0180 C200 0001). If a match is detected (the destination address of the received frame matches the reserved control frame destination address), the MAC then decides whether or not to transfer the received control frame to the application, based on the level of the PCF bit in ETH\_MACFFR.

The MAC also decodes the type, opcode, and Pause Timer fields of the receiving control frame. If the byte count of the status indicates 64 bytes, and if there is no CRC error, the MAC transmitter pauses the transmission of any data frame for the duration of the decoded Pause time value, multiplied by the slot time (64 byte times for both 10/100 Mbit/s modes). Meanwhile, if another Pause frame is detected with a zero Pause time value, the MAC resets the Pause time and manages this new pause request.

If the received control frame matches neither the type field (0x8808), the opcode (0x00001), nor the byte length (64 bytes), or if there is a CRC error, the MAC does not generate a Pause.

In the case of a pause frame with a multicast destination address, the MAC filters the frame based on the address match.

For a pause frame with a unicast destination address, the MAC filtering depends on whether the DA matched the contents of the MAC address 0 register and whether the UPDF bit in ETH\_MACFCR is set (detecting a pause frame even with a unicast destination address). The PCF register bits (bits [7:6] in ETH\_MACFFR) control filtering for control frames in addition to address filtering.

### Receive operation multiframe handling

Since the status is available immediately following the data, the FIFO is capable of storing any number of frames into it, as long as it is not full.

### Error handling

If the Rx FIFO is full before it receives the EOF data from the MAC, an overflow is declared and the whole frame is dropped, and the overflow counter in the (ETH\_DMAMFBOCR register) is incremented. The status indicates a partial frame due to overflow. The Rx FIFO can filter error and undersized frames, if enabled (using the FEF and FUGF bits in ETH\_DMAOMR).

If the Receive FIFO is configured to operate in Store-and-forward mode, all error frames can be filtered and dropped.

In Cut-through mode, if a frame's status and length are available when that frame's SOF is read from the Rx FIFO, then the complete erroneous frame can be dropped. The DMA can flush the error frame being read from the FIFO, by enabling the receive frame flash bit. The data transfer to the application (DMA) is then stopped and the rest of the frame is internally read and dropped. The next frame transfer can then be started, if available.

### Receive status word

At the end of the Ethernet frame reception, the MAC outputs the receive status to the application (DMA). The detailed description of the receive status is the same as for bits[31:0] in RDES0, given in [RDES0: Receive descriptor Word0](#).

### Frame length interface

In case of switch applications, data transmission and reception between the application and MAC happen as complete frame transfers. The application layer should be aware of the length of the frames received from the ingress port in order to transfer the frame to the egress port. The MAC core provides the frame length of each received frame inside the status at the end of each frame reception.

*Note:* A frame length value of 0 is given for partial frames written into the Rx FIFO due to overflow.

### MII/RMII receive bit order

Each nibble is transmitted to the MII from the dibit received from the RMII in the nibble transmission order shown in [Figure 505](#). The lower-order bits (D0 and D1) are received first, followed by the higher-order bits (D2 and D3).

**Figure 505. Receive bit order**

Figure 506. Reception with no error

Figure 507. Reception with errors

Figure 508. Reception with false carrier indication

### 38.5.4 MAC interrupts

Interrupts can be generated from the MAC core as a result of various events.

The ETH\_MACSR register describes the events that can cause an interrupt from the MAC core. The user can prevent each event from asserting the interrupt by setting the corresponding mask bits in the Interrupt Mask register.

The interrupt register bits only indicate the block from which the event is reported. The user has to read the corresponding status registers and other registers to clear the interrupt. For example, bit 3 of the Interrupt register, set high, indicates that the Magic packet or Wake-on-LAN frame is received in Power-down mode. The user must read the ETH\_MACPMTCSR Register to clear this interrupt event.

**Figure 509. MAC core interrupt masking scheme**

### 38.5.5 MAC filtering

#### Address filtering

Address filtering checks the destination and source addresses on all received frames and the address filtering status is reported accordingly. Address checking is based on different parameters (Frame filter register) chosen by the application. The filtered frame can also be identified: multicast or broadcast frame.

Address filtering uses the station's physical (MAC) address and the Multicast Hash table for address checking purposes.

#### Unicast destination address filter

The MAC supports up to 4 MAC addresses for unicast perfect filtering. If perfect filtering is selected (HU bit in the Frame filter register is reset), the MAC compares all 48 bits of the received unicast address with the programmed MAC address for any match. Default MacAddr0 is always enabled, other addresses MacAddr1–MacAddr3 are selected with an individual enable bit. Each byte of these other addresses (MacAddr1–MacAddr3) can be masked during comparison with the corresponding received DA byte by setting the corresponding Mask Byte Control bit in the register. This helps group address filtering for the DA. In Hash filtering mode (when HU bit is set), the MAC performs imperfect filtering for unicast addresses using a 64-bit Hash table. For hash filtering, the MAC uses the 6 upper CRC (see note 1 below) bits of the received destination address to index the content of the Hash table. A value of 000000 selects bit 0 in the selected register, and a value of 111111 selects bit 63 in the Hash Table register. If the corresponding bit (indicated by the 6-bit CRC)

is set to 1, the unicast frame is said to have passed the Hash filter; otherwise, the frame has failed the Hash filter.

*Note:* This CRC is a 32-bit value coded by the following polynomial (for more details refer to [Section 38.5.3: MAC frame reception](#)):

$$G(x) = x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x + 1$$

### Multicast destination address filter

The MAC can be programmed to pass all multicast frames by setting the PAM bit in the Frame filter register. If the PAM bit is reset, the MAC performs the filtering for multicast addresses based on the HM bit in the Frame filter register. In Perfect filtering mode, the multicast address is compared with the programmed MAC destination address registers (1–3). Group address filtering is also supported. In Hash filtering mode, the MAC performs imperfect filtering using a 64-bit Hash table. For hash filtering, the MAC uses the 6 upper CRC (see note 1 below) bits of the received multicast address to index the content of the Hash table. A value of 000000 selects bit 0 in the selected register and a value of 111111 selects bit 63 in the Hash Table register. If the corresponding bit is set to 1, then the multicast frame is said to have passed the Hash filter; otherwise, the frame has failed the Hash filter.

*Note:* This CRC is a 32-bit value coded by the following polynomial (for more details refer to [Section 38.5.3: MAC frame reception](#)):

$$G(x) = x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x + 1$$

### Hash or perfect address filter

The DA filter can be configured to pass a frame when its DA matches either the Hash filter or the Perfect filter by setting the HPF bit in the Frame filter register and setting the corresponding HU or HM bits. This configuration applies to both unicast and multicast frames. If the HPF bit is reset, only one of the filters (Hash or Perfect) is applied to the received frame.

### Broadcast address filter

The MAC does not filter any broadcast frames in the default mode. However, if the MAC is programmed to reject all broadcast frames by setting the BFD bit in the Frame filter register, any broadcast frames are dropped.

### Unicast source address filter

The MAC can also perform perfect filtering based on the source address field of the received frames. By default, the MAC compares the SA field with the values programmed in the SA registers. The MAC address registers [1:3] can be configured to contain SA instead of DA for comparison, by setting bit 30 in the corresponding register. Group filtering with SA is also supported. The frames that fail the SA filter are dropped by the MAC if the SAF bit in the Frame filter register is set. Otherwise, the result of the SA filter is given as a status bit in the Receive Status word (see [RDES0: Receive descriptor Word0](#)).

When the SAF bit is set, the result of the SA and DA filters is AND'ed to decide whether the frame needs to be forwarded. This means that either of the filter fail result will drop the frame. Both filters have to pass the frame for the frame to be forwarded to the application.

### Inverse filtering operation

For both destination and source address filtering, there is an option to invert the filter-match result at the final output. These are controlled by the DAIF and SAIF bits in the Frame filter register, respectively. The DAIF bit is applicable for both Unicast and Multicast DA frames. The result of the unicast/multicast destination address filter is inverted in this mode. Similarly, when the SAIF bit is set, the result of the unicast SA filter is inverted. [Table 278](#) and [Table 279](#) summarize destination and source address filtering based on the type of frame received.

**Table 278. Destination address filtering**

| Frame type | PM | HPF | HU | DAIF | HM | PAM | DB | DA filter operation                                                                  |
|------------|----|-----|----|------|----|-----|----|--------------------------------------------------------------------------------------|
| Broadcast  | 1  | X   | X  | X    | X  | X   | X  | Pass                                                                                 |
|            | 0  | X   | X  | X    | X  | X   | 0  | Pass                                                                                 |
|            | 0  | X   | X  | X    | X  | X   | 1  | Fail                                                                                 |
| Unicast    | 1  | X   | X  | X    | X  | X   | X  | Pass all frames                                                                      |
|            | 0  | X   | 0  | 0    | X  | X   | X  | Pass on perfect/group filter match                                                   |
|            | 0  | X   | 0  | 1    | X  | X   | X  | Fail on perfect/Group filter match                                                   |
|            | 0  | 0   | 1  | 0    | X  | X   | X  | Pass on hash filter match                                                            |
|            | 0  | 0   | 1  | 1    | X  | X   | X  | Fail on hash filter match                                                            |
|            | 0  | 1   | 1  | 0    | X  | X   | X  | Pass on hash or perfect/Group filter match                                           |
|            | 0  | 1   | 1  | 1    | X  | X   | X  | Fail on hash or perfect/Group filter match                                           |
| Multicast  | 1  | X   | X  | X    | X  | X   | X  | Pass all frames                                                                      |
|            | X  | X   | X  | X    | X  | 1   | X  | Pass all frames                                                                      |
|            | 0  | X   | X  | 0    | 0  | 0   | X  | Pass on Perfect/Group filter match and drop PAUSE control frames if PCF = 0x         |
|            | 0  | 0   | X  | 0    | 1  | 0   | X  | Pass on hash filter match and drop PAUSE control frames if PCF = 0x                  |
|            | 0  | 1   | X  | 0    | 1  | 0   | X  | Pass on hash or perfect/Group filter match and drop PAUSE control frames if PCF = 0x |
|            | 0  | X   | X  | 1    | 0  | 0   | X  | Fail on perfect/Group filter match and drop PAUSE control frames if PCF = 0x         |
|            | 0  | 0   | X  | 1    | 1  | 0   | X  | Fail on hash filter match and drop PAUSE control frames if PCF = 0x                  |
|            | 0  | 1   | X  | 1    | 1  | 0   | X  | Fail on hash or perfect/Group filter match and drop PAUSE control frames if PCF = 0x |

Table 279. Source address filtering

| Frame type | PM | SAIF | SAF | SA filter operation                                                        |
|------------|----|------|-----|----------------------------------------------------------------------------|
| Unicast    | 1  | X    | X   | Pass all frames                                                            |
|            | 0  | 0    | 0   | Pass status on perfect/Group filter match but do not drop frames that fail |
|            | 0  | 1    | 0   | Fail status on perfect/group filter match but do not drop frame            |
|            | 0  | 0    | 1   | Pass on perfect/group filter match and drop frames that fail               |
|            | 0  | 1    | 1   | Fail on perfect/group filter match and drop frames that fail               |

### 38.5.6 MAC loopback mode

The MAC supports loopback of transmitted frames onto its receiver. By default, the MAC loopback function is disabled, but this feature can be enabled by programming the Loopback bit in the MAC ETH\_MACCR register.

### 38.5.7 MAC management counters: MMC

The MAC management counters (MMC) maintain a set of registers for gathering statistics on the received and transmitted frames. These include a control register for controlling the behavior of the registers, two 32-bit registers containing generated interrupts (receive and transmit), and two 32-bit registers containing masks for the Interrupt register (receive and transmit). These registers are accessible from the application. Each register is 32 bits wide.

[Section 38.8: Ethernet register descriptions](#) describes the various counters and lists the addresses of each of the statistics counters. This address is used for read/write accesses to the desired transmit/receive counter.

The Receive MMC counters are updated for frames that pass address filtering. Dropped frames statistics are not updated unless the dropped frames are runt frames of less than 6 bytes (DA bytes are not received fully).

#### Good transmitted and received frames

Transmitted frames are considered “good” if transmitted successfully. In other words, a transmitted frame is good if the frame transmission is not aborted due to any of the following errors:

- + Jabber Timeout
- + No Carrier/Loss of Carrier
- + Late Collision
- + Frame Underflow
- + Excessive Deferral
- + Excessive Collision

Received frames are considered “good” if none of the following errors exists:

- + CRC error
- + Runt Frame (shorter than 64 bytes)
- + Alignment error (in 10/ 100 Mbit/s only)
- + Length error (non-Type frames only)
- + Out of Range (non-Type frames only, longer than maximum size)
- + MII\_RXER Input error

The maximum frame size depends on the frame type, as follows:

- + Untagged frame maxsize = 1518
- + VLAN Frame maxsize = 1522

### 38.5.8 Power management: PMT

This section describes the power management (PMT) mechanisms supported by the MAC. PMT supports the reception of network (remote) wakeup frames and Magic Packet frames. PMT generates interrupts for wakeup frames and Magic Packets received by the MAC. The PMT block is enabled with remote wakeup frame enable and Magic Packet enable. These enable bits (WFE and MPE) are in the ETH\_MACPMTCSR register and are programmed by the application. When the power down mode is enabled in the PMT, then all received frames are dropped by the MAC and they are not forwarded to the application. The MAC comes out of the power down mode only when either a Magic Packet or a Remote wakeup frame is received and the corresponding detection is enabled.

#### Remote wakeup frame filter register

There are eight wakeup frame filter registers. To write on each of them, load the wakeup frame filter register value by value. The wanted values of the wakeup frame filter are loaded by sequentially loading eight times the wakeup frame filter register. The read operation is identical to the write operation. To read the eight values, the user has to read eight times the wakeup frame filter register to reach the last register. Each read/write points the wakeup frame filter register to the next filter register.

Figure 510. Wakeup frame filter register

|                          |                    |                  |                 |                  |                   |                  |                 |                  |
|--------------------------|--------------------|------------------|-----------------|------------------|-------------------|------------------|-----------------|------------------|
| Wakeup frame filter reg0 | Filter 0 Byte Mask |                  |                 |                  |                   |                  |                 |                  |
| Wakeup frame filter reg1 | Filter 1 Byte Mask |                  |                 |                  |                   |                  |                 |                  |
| Wakeup frame filter reg2 | Filter 2 Byte Mask |                  |                 |                  |                   |                  |                 |                  |
| Wakeup frame filter reg3 | Filter 3 Byte Mask |                  |                 |                  |                   |                  |                 |                  |
| Wakeup frame filter reg4 | RSVD               | Filter 3 Command | RSVD            | Filter 2 Command | RSVD              | Filter 1 Command | RSVD            | Filter 0 Command |
| Wakeup frame filter reg5 | Filter 3 Offset    |                  | Filter 2 Offset |                  | Filter 1 Offset   |                  | Filter 0 Offset |                  |

ai15647

- Filter i Byte Mask**  
 This register defines which bytes of the frame are examined by filter i (0, 1, 2, and 3) in order to determine whether or not the frame is a wakeup frame. The MSB (thirty-first bit) must be zero. Bit j [30:0] is the Byte Mask. If bit j (byte number) of the Byte Mask is set, then Filter i Offset + j of the incoming frame is processed by the CRC block; otherwise Filter i Offset + j is ignored.
- Filter i Command**  
 This 4-bit command controls the filter i operation. Bit 3 specifies the address type, defining the pattern's destination address type. When the bit is set, the pattern applies to only multicast frames. When the bit is reset, the pattern applies only to unicast frames. Bit 2 and bit 1 are reserved. Bit 0 is the enable bit for filter i; if bit 0 is not set, filter i is disabled.
- Filter i Offset**  
 This register defines the offset (within the frame) from which the frames are examined by filter i. This 8-bit pattern offset is the offset for the filter i first byte to be examined. The minimum allowed is 12, which refers to the 13th byte of the frame (offset value 0 refers to the first byte of the frame).
- Filter i CRC-16**  
 This register contains the CRC\_16 value calculated from the pattern, as well as the byte mask programmed to the wakeup filter register block.

### Remote wakeup frame detection

When the MAC is in sleep mode and the remote wakeup bit is enabled in the ETH\_MACPMTCSR register, normal operation is resumed after receiving a remote wakeup frame. The application writes all eight wakeup filter registers, by performing a sequential write to the wakeup frame filter register address. The application enables remote wakeup by writing a 1 to bit 2 in the ETH\_MACPMTCSR register. PMT supports four programmable filters that provide different receive frame patterns. If the incoming frame passes the address filtering of Filter Command, and if Filter CRC-16 matches the incoming examined pattern, then the wakeup frame is received. Filter\_offset (minimum value 12, which refers to the 13th byte of the frame) determines the offset from which the frame is to be examined. Filter Byte Mask determines which bytes of the frame must be examined. The thirty-first bit of Byte Mask must be set to zero. The wakeup frame is checked only for length error, FCS error, dribble bit error, MII error, collision, and to ensure that it is not a runt frame. Even if the

wakeup frame is more than 512 bytes long, if the frame has a valid CRC value, it is considered valid. Wakeup frame detection is updated in the ETH\_MACPMTCSR register for every remote wakeup frame received. If enabled, a PMT interrupt is generated to indicate the reception of a remote wakeup frame.

### Magic packet detection

The Magic Packet frame is based on a method that uses Advanced Micro Device's Magic Packet technology to power up the sleeping device on the network. The MAC receives a specific packet of information, called a Magic Packet, addressed to the node on the network. Only Magic Packets that are addressed to the device or a broadcast address are checked to determine whether they meet the wakeup requirements. Magic Packets that pass address filtering (unicast or broadcast) are checked to determine whether they meet the remote Wake-on-LAN data format of 6 bytes of all ones followed by a MAC address appearing 16 times. The application enables Magic Packet wakeup by writing a 1 to bit 1 in the ETH\_MACPMTCSR register. The PMT block constantly monitors each frame addressed to the node for a specific Magic Packet pattern. Each received frame is checked for a 0xFFFF FFFF FFFF pattern following the destination and source address field. The PMT block then checks the frame for 16 repetitions of the MAC address without any breaks or interruptions. In case of a break in the 16 repetitions of the address, the 0xFFFF FFFF FFFF pattern is scanned for again in the incoming frame. The 16 repetitions can be anywhere in the frame, but must be preceded by the synchronization stream (0xFFFF FFFF FFFF). The device also accepts a multicast frame, as long as the 16 duplications of the MAC address are detected. If the MAC address of a node is 0x0011 2233 4455, then the MAC scans for the data sequence:

```
Destination address source address ..... FFFF FFFF FFFF
0011 2233 4455 0011 2233 4455 0011 2233 4455 0011 2233 4455
0011 2233 4455 0011 2233 4455 0011 2233 4455 0011 2233 4455
0011 2233 4455 0011 2233 4455 0011 2233 4455 0011 2233 4455
0011 2233 4455 0011 2233 4455 0011 2233 4455 0011 2233 4455
...CRC
```

Magic Packet detection is updated in the ETH\_MACPMTCSR register for received Magic Packet. If enabled, a PMT interrupt is generated to indicate the reception of a Magic Packet.

### System consideration during power-down

The Ethernet PMT block is able to detect frames while the system is in the Stop mode, provided that the EXTI line 19 is enabled.

The MAC receiver state machine should remain enabled during the power-down mode. This means that the RE bit has to remain set in the ETH\_MACCCR register because it is involved in magic packet/ wake-on-LAN frame detection. The transmit state machine should however be turned off during the power-down mode by clearing the TE bit in the ETH\_MACCCR register. Moreover, the Ethernet DMA should be disabled during the power-down mode, because it is not necessary to copy the magic packet/wake-on-LAN frame into the SRAM. To disable the Ethernet DMA, clear the ST bit and the SR bit (for the transmit DMA and the receive DMA, respectively) in the ETH\_DMAOMR register.

The recommended power-down and wakeup sequences are as follows:

1. Disable the transmit DMA and wait for any previous frame transmissions to complete. These transmissions can be detected when the transmit interrupt ETH\_DMASR register[0] is received.
2. Disable the MAC transmitter and MAC receiver by clearing the RE and TE bits in the ETH\_MACCR configuration register.
3. Wait for the receive DMA to have emptied all the frames in the Rx FIFO.
4. Disable the receive DMA.
5. Configure and enable the EXTI line 19 to generate either an event or an interrupt.
6. If you configure the EXTI line 19 to generate an interrupt, you also have to correctly configure the ETH\_WKUP\_IRQ Handler function, which should clear the pending bit of the EXTI line 19.
7. Enable Magic packet/Wake-on-LAN frame detection by setting the MFE/ WFE bit in the ETH\_MACPMTCSR register.
8. Enable the MAC power-down mode, by setting the PD bit in the ETH\_MACPMTCSR register.
9. Enable the MAC Receiver by setting the RE bit in the ETH\_MACCR register.
10. Enter the system's Stop mode (for more details refer to [Section 4.3.5: Stop mode](#)):
11. On receiving a valid wakeup frame, the Ethernet peripheral exits the power-down mode.
12. Read the ETH\_MACPMTCSR to clear the power management event flag, enable the MAC transmitter state machine, and the receive and transmit DMA.
13. Configure the system clock: enable the HSE and set the clocks.

### 38.5.9 Precision time protocol (IEEE1588 PTP)

The IEEE 1588 standard defines a protocol that allows precise clock synchronization in measurement and control systems implemented with technologies such as network communication, local computing and distributed objects. The protocol applies to systems that communicate by local area networks supporting multicast messaging, including (but not limited to) Ethernet. This protocol is used to synchronize heterogeneous systems that include clocks of varying inherent precision, resolution and stability. The protocol supports system-wide synchronization accuracy in the submicrosecond range with minimum network and local clock computing resources. The message-based protocol, known as the precision time protocol (PTP), is transported over UDP/IP. The system or network is classified into Master and Slave nodes for distributing the timing/clock information. The protocol's technique for synchronizing a slave node to a master node by exchanging PTP messages is described in [Figure 511](#).

Figure 511. Networked time synchronization

1. The master broadcasts PTP Sync messages to all its nodes. The Sync message contains the master's reference time information. The time at which this message leaves the master's system is  $t_1$ . For Ethernet ports, this time has to be captured at the MII.
2. A slave receives the Sync message and also captures the exact time,  $t_2$ , using its timing reference.
3. The master then sends the slave a Follow\_up message, which contains the  $t_1$  information for later use.
4. The slave sends the master a Delay\_Req message, noting the exact time,  $t_3$ , at which this frame leaves the MII.
5. The master receives this message and captures the exact time,  $t_4$ , at which it enters its system.
6. The master sends the  $t_4$  information to the slave in the Delay\_Resp message.
7. The slave uses the four values of  $t_1$ ,  $t_2$ ,  $t_3$ , and  $t_4$  to synchronize its local timing reference to the master's timing reference.

Most of the protocol implementation occurs in the software, above the UDP layer. As described above, however, hardware support is required to capture the exact time when specific PTP packets enter or leave the Ethernet port at the MII. This timing information has to be captured and returned to the software for a proper, high-accuracy implementation of PTP.

### Reference timing source

To get a snapshot of the time, the core requires a reference time in 64-bit format (split into two 32-bit channels, with the upper 32 bits providing time in seconds, and the lower 32 bits indicating time in nanoseconds) as defined in the IEEE 1588 specification.

The PTP reference clock input is used to internally generate the reference time (also called the System Time) and to capture time stamps. The frequency of this reference clock must be greater than or equal to the resolution of time stamp counter. The synchronization accuracy target between the master node and the slaves is around 100 ns.

The generation, update and modification of the System Time are described in the [System Time correction methods](#).

The accuracy depends on the PTP reference clock input period, the characteristics of the oscillator (drift) and the frequency of the synchronization procedure.

Due to the synchronization from the Tx and Rx clock input domain to the PTP reference clock domain, the uncertainty on the time stamp latched value is 1 reference clock period. If we add the uncertainty due to resolution, we will add half the period for time stamping.

### Transmission of frames with the PTP feature

When a frame's SFD is output on the MII, a time stamp is captured. Frames for which time stamp capture is required are controllable on a per-frame basis. In other words, each transmitted frame can be marked to indicate whether a time stamp must be captured or not for that frame. The transmitted frames are not processed to identify PTP frames. Frame control is exercised through the control bits in the transmit descriptor. Captured time stamps are returned to the application in the same way as the status is provided for frames. The time stamp is sent back along with the Transmit status of the frame, inside the corresponding transmit descriptor, thus connecting the time stamp automatically to the specific PTP frame. The 64-bit time stamp information is written back to the TDES2 and TDES3 fields, with TDES2 holding the time stamp's 32 least significant bits.

### Reception of frames with the PTP feature

When the IEEE 1588 time stamping feature is enabled, the Ethernet MAC captures the time stamp of all frames received on the MII. The MAC provides the time stamp as soon as the frame reception is complete. Captured time stamps are returned to the application in the same way as the frame status is provided. The time stamp is sent back along with the Receive status of the frame, inside the corresponding receive descriptor. The 64-bit time stamp information is written back to the RDES2 and RDES3 fields, with RDES2 holding the time stamp's 32 least significant bits.

### System Time correction methods

The 64-bit PTP time is updated using the PTP input reference clock, HCLK. This PTP time is used as a source to take snapshots (time stamps) of the Ethernet frames being transmitted or received at the MII. The System Time counter can be initialized or corrected using either the Coarse or the Fine correction method.

In the Coarse correction method, the initial value or the offset value is written to the Time stamp update register (refer to [Section 38.8.3: IEEE 1588 time stamp registers on page 1623](#)). For initialization, the System Time counter is written with the value in the Time stamp update registers, whereas for system time correction, the offset value (Time stamp update register) is added to or subtracted from the system time.

In the Fine correction method, the slave clock (reference clock) frequency drift with respect to the master clock (as defined in IEEE 1588) is corrected over a period of time, unlike in the Coarse correction method where it is corrected in a single clock cycle. The longer correction time helps maintain linear time and does not introduce drastic changes (or a large jitter) in the reference time between PTP Sync message intervals. In this method, an accumulator

sums up the contents of the Addend register as shown in [Figure 512](#). The arithmetic carry that the accumulator generates is used as a pulse to increment the system time counter. The accumulator and the addend are 32-bit registers. Here, the accumulator acts as a high-precision frequency multiplier or divider. [Figure 512](#) shows this algorithm.

**Figure 512. System time update using the Fine correction method**

The system time update logic requires a 50 MHz clock frequency to achieve 20 ns accuracy. The frequency division is the ratio of the reference clock frequency to the required clock frequency. Hence, if the reference clock (HCLK) is, let us say, 66 MHz, the ratio is calculated as  $66 \text{ MHz} / 50 \text{ MHz} = 1.32$ . Hence, the default addend value to be set in the register is  $2^{32} / 1.32$ , which is equal to 0xC1F0 7C1F.

If the reference clock drifts lower, to 65 MHz for example, the ratio is  $65 / 50$  or 1.3 and the value to set in the addend register is  $2^{32} / 1.30$  equal to 0xC4EC 4EC4. If the clock drifts higher, to 67 MHz for example, the addend register must be set to 0xBF0 B7672. When the clock drift is zero, the default addend value of 0xC1F0 7C1F ( $2^{32} / 1.32$ ) should be programmed.

In [Figure 512](#), the constant value used to increment the subsecond register is 0d43. This makes an accuracy of 20 ns in the system time (in other words, it is incremented by 20 ns steps).

The software has to calculate the drift in frequency based on the Sync messages, and to update the Addend register accordingly. Initially, the slave clock is set with FreqCompensationValue0 in the Addend register. This value is as follows:

$$\text{FreqCompensationValue0} = 2^{32} / \text{FreqDivisionRatio}$$

If MasterToSlaveDelay is initially assumed to be the same for consecutive Sync messages, the algorithm described below must be applied. After a few Sync cycles, frequency lock occurs. The slave clock can then determine a precise MasterToSlaveDelay value and re-synchronize with the master using the new value.

The algorithm is as follows:

- At time MasterSyncTime (n) the master sends the slave clock a Sync message. The slave receives this message when its local clock is SlaveClockTime (n) and computes MasterClockTime (n) as:  

$$\text{MasterClockTime (n)} = \text{MasterSyncTime (n)} + \text{MasterToSlaveDelay (n)}$$
- The master clock count for current Sync cycle, MasterClockCount (n) is given by:  

$$\text{MasterClockCount (n)} = \text{MasterClockTime (n)} - \text{MasterClockTime (n - 1)}$$
 (assuming that MasterToSlaveDelay is the same for Sync cycles n and n - 1)
- The slave clock count for current Sync cycle, SlaveClockCount (n) is given by:  

$$\text{SlaveClockCount (n)} = \text{SlaveClockTime (n)} - \text{SlaveClockTime (n - 1)}$$
- The difference between master and slave clock counts for current Sync cycle, ClockDiffCount (n) is given by:  

$$\text{ClockDiffCount (n)} = \text{MasterClockCount (n)} - \text{SlaveClockCount (n)}$$
- The frequency-scaling factor for slave clock, FreqScaleFactor (n) is given by:  

$$\text{FreqScaleFactor (n)} = (\text{MasterClockCount (n)} + \text{ClockDiffCount (n)}) / \text{SlaveClockCount (n)}$$
- The frequency compensation value for Addend register, FreqCompensationValue (n) is given by:  

$$\text{FreqCompensationValue (n)} = \text{FreqScaleFactor (n)} \times \text{FreqCompensationValue (n - 1)}$$

In theory, this algorithm achieves lock in one Sync cycle; however, it may take several cycles, due to changing network propagation delays and operating conditions.

This algorithm is self-correcting: if for any reason the slave clock is initially set to a value from the master that is incorrect, the algorithm corrects it at the cost of more Sync cycles.

### Programming steps for system time generation initialization

The time stamping feature can be enabled by setting bit 0 in the Time stamp control register (ETH\_PTPTSCR). However, it is essential to initialize the time stamp counter after this bit is set to start time stamp operation. The proper sequence is the following:

1. Mask the Time stamp trigger interrupt by setting bit 9 in the MACIMR register.
2. Program Time stamp register bit 0 to enable time stamping.
3. Program the Subsecond increment register based on the PTP clock frequency.
4. If you are using the Fine correction method, program the Time stamp addend register and set Time stamp control register bit 5 (addend register update).
5. Poll the Time stamp control register until bit 5 is cleared.
6. To select the Fine correction method (if required), program Time stamp control register bit 1.
7. Program the Time stamp high update and Time stamp low update registers with the appropriate time value.
8. Set Time stamp control register bit 2 (Time stamp init).
9. The Time stamp counter starts operation as soon as it is initialized with the value written in the Time stamp update register.
10. Enable the MAC receiver and transmitter for proper time stamping.

**Note:** *If time stamp operation is disabled by clearing bit 0 in the ETH\_PTPTSCR register, the above steps must be repeated to restart the time stamp operation.*

### Programming steps for system time update in the Coarse correction method

To synchronize or update the system time in one process (coarse correction method), perform the following steps:

1. Write the offset (positive or negative) in the Time stamp update high and low registers.
2. Set bit 3 (TSSTU) in the Time stamp control register.
3. The value in the Time stamp update registers is added to or subtracted from the system time when the TSSTU bit is cleared.

### Programming steps for system time update in the Fine correction method

To synchronize or update the system time to reduce system-time jitter (fine correction method), perform the following steps:

1. With the help of the algorithm explained in [System Time correction methods](#), calculate the rate by which you want to speed up or slow down the system time increments.
2. Update the time stamp.
3. Wait the time you want the new value of the Addend register to be active. You can do this by activating the Time stamp trigger interrupt after the system time reaches the target value.
4. Program the required target time in the Target time high and low registers. Unmask the Time stamp interrupt by clearing bit 9 in the ETH\_MACIMR register.
5. Set Time stamp control register bit 4 (TSARU).
6. When this trigger causes an interrupt, read the ETH\_MACCSR register.
7. Reprogram the Time stamp addend register with the old value and set ETH\_TPTSCR bit 5 again.

### PTP trigger internal connection with TIM2

The MAC provides a trigger interrupt when the system time becomes greater than the target time. Using an interrupt introduces a known latency plus an uncertainty in the command execution time.

In order to avoid this uncertainty, a PTP trigger output signal is set high when the system time is greater than the target time. It is internally connected to the TIM2 input trigger. With this signal, the input capture feature, the output compare feature and the waveforms of the timer can be used, triggered by the synchronized PTP system time. No uncertainty is introduced since the clock of the timer (PCLK1: TIM2 APB1 clock) and PTP reference clock (HCLK) are synchronous.

This PTP trigger signal is connected to the TIM2 ITR1 input selectable by software. The connection is enabled through bits 11 and 10 in the TIM2 option register (TIM2\_OR).

[Figure 513](#) shows the connection.

**Figure 513. PTP trigger output to TIM2 ITR1 connection**

### PTP pulse-per-second output signal

This PTP pulse output is used to check the synchronization between all nodes in the network. To be able to test the difference between the local slave clock and the master reference clock, both clocks were given a pulse-per-second (PPS) output signal that may be connected to an oscilloscope if necessary. The deviation between the two signals can therefore be measured. The pulse width of the PPS output is 125 ms.

The PPS output is enabled through bits 11 and 10 in the TIM2 option register (TIM2\_OR).

The default frequency of the PPS output is 1 Hz. PPSFREQ[3:0] (in ETH\_PTPPPSCR) can be used to set the frequency of the PPS output to  $2^{\text{PPSFREQ}}$  Hz.

When set to 1 Hz, the PPS pulse width is 125 ms with binary rollover (TSSSR=0, bit 9 in ETH\_PTPTSCR) and 100 ms with digital rollover (TSSSR=1). When set to 2 Hz and higher, the duty cycle of the PPS output is 50% with binary rollover.

With digital rollover (TSSSR=1), it is recommended not to use the PPS output with a frequency other than 1 Hz as it would have irregular waveforms (though its average frequency would always be correct during any one-second window).

**Figure 514. PPS output**

## 38.6 Ethernet functional description: DMA controller operation

The DMA has independent transmit and receive engines, and a CSR space. The transmit engine transfers data from system memory into the Tx FIFO while the receive engine transfers data from the Rx FIFO into system memory. The controller utilizes descriptors to efficiently move data from source to destination with minimum CPU intervention. The DMA is designed for packet-oriented data transfers such as frames in Ethernet. The controller can be programmed to interrupt the CPU in cases such as frame transmit and receive transfer completion, and other normal/error conditions. The DMA and the STM32F75xxx and STM32F74xxx communicate through two data structures:

- Control and status registers (CSR)
- Descriptor lists and data buffers.

Control and status registers are described in detail in [Section 38.8: Ethernet register descriptions](#). Descriptors are described in detail in [Normal Tx DMA descriptors](#).

The DMA transfers the received data frames to the receive buffer in the STM32F75xxx and STM32F74xxx memory, and transmits data frames from the transmit buffer in the STM32F75xxx and STM32F74xxx memory. Descriptors that reside in the STM32F75xxx and STM32F74xxx memory act as pointers to these buffers. There are two descriptor lists: one for reception, and one for transmission. The base address of each list is written into DMA Registers 3 and 4, respectively. A descriptor list is forward-linked (either implicitly or explicitly). The last descriptor may point back to the first entry to create a ring structure. Explicit chaining of descriptors is accomplished by configuring the second address chained in both the receive and transmit descriptors (RDES1[14] and TDES0[20]). The descriptor lists reside in the Host's physical memory space. Each descriptor can point to a maximum of

two buffers. This enables the use of two physically addressed buffers, instead of two contiguous buffers in memory. A data buffer resides in the Host's physical memory space, and consists of an entire frame or part of a frame, but cannot exceed a single frame. Buffers contain only data. The buffer status is maintained in the descriptor. Data chaining refers to frames that span multiple data buffers. However, a single descriptor cannot span multiple frames. The DMA skips to the next frame buffer when the end of frame is detected. Data chaining can be enabled or disabled. The descriptor ring and chain structure is shown in [Figure 515](#).

**Figure 515. Descriptor ring and chain structure**

### 38.6.1 Initialization of a transfer using DMA

Initialization for the MAC is as follows:

1. Write to ETH\_DMABMR to set STM32F75xxx and STM32F74xxx bus access parameters.
2. Write to the ETH\_DMAIER register to mask unnecessary interrupt causes.
3. The software driver creates the transmit and receive descriptor lists. Then it writes to both the ETH\_DMARDLAR and ETH\_DMATDLAR registers, providing the DMA with the start address of each list.
4. Write to MAC Registers 1, 2, and 3 to choose the desired filtering options.
5. Write to the MAC ETH\_MACCR register to configure and enable the transmit and receive operating modes. The PS and DM bits are set based on the auto-negotiation result (read from the PHY).
6. Write to the ETH\_DMAOMR register to set bits 13 and 1 and start transmission and reception.
7. The transmit and receive engines enter the running state and attempt to acquire descriptors from the respective descriptor lists. The receive and transmit engines then begin processing receive and transmit operations. The transmit and receive processes are independent of each other and can be started or stopped separately.

### 38.6.2 Host bus burst access

The DMA attempts to execute fixed-length burst transfers on the AHB master interface if configured to do so (FB bit in ETH\_DMABMR). The maximum burst length is indicated and

limited by the PBL field (ETH\_DMABMR [13:8]). The receive and transmit descriptors are always accessed in the maximum possible burst size (limited by PBL) for the 16 bytes to be read.

The Transmit DMA initiates a data transfer only when there is sufficient space in the Transmit FIFO to accommodate the configured burst or the number of bytes until the end of frame (when it is less than the configured burst length). The DMA indicates the start address and the number of transfers required to the AHB Master Interface. When the AHB Interface is configured for fixed-length burst, then it transfers data using the best combination of INCR4, INCR8, INCR16 and SINGLE transactions. Otherwise (no fixed-length burst), it transfers data using INCR (undefined length) and SINGLE transactions.

The Receive DMA initiates a data transfer only when sufficient data for the configured burst is available in Receive FIFO or when the end of frame (when it is less than the configured burst length) is detected in the Receive FIFO. The DMA indicates the start address and the number of transfers required to the AHB master interface. When the AHB interface is configured for fixed-length burst, then it transfers data using the best combination of INCR4, INCR8, INCR16 and SINGLE transactions. If the end of frame is reached before the fixed-burst ends on the AHB interface, then dummy transfers are performed in order to complete the fixed-length burst. Otherwise (FB bit in ETH\_DMABMR is reset), it transfers data using INCR (undefined length) and SINGLE transactions.

When the AHB interface is configured for address-aligned beats, both DMA engines ensure that the first burst transfer the AHB initiates is less than or equal to the size of the configured PBL. Thus, all subsequent beats start at an address that is aligned to the configured PBL. The DMA can only align the address for beats up to size 16 (for PBL > 16), because the AHB interface does not support more than INCR16.

### 38.6.3 Host data buffer alignment

The transmit and receive data buffers do not have any restrictions on start address alignment. In our system with 32-bit memory, the start address for the buffers can be aligned to any of the four bytes. However, the DMA always initiates transfers with address aligned to the bus width with dummy data for the byte lanes not required. This typically happens during the transfer of the beginning or end of an Ethernet frame.

- Example of buffer read:  
If the Transmit buffer address is 0x0000 0FF2, and 15 bytes need to be transferred, then the DMA will read five full words from address 0x0000 0FF0, but when transferring data to the Transmit FIFO, the extra bytes (the first two bytes) will be dropped or ignored. Similarly, the last 3 bytes of the last transfer will also be ignored. The DMA always ensures it transfers a full 32-bit data items to the Transmit FIFO, unless it is the end of frame.
- Example of buffer write:  
If the Receive buffer address is 0x0000 0FF2, and 16 bytes of a received frame need to be transferred, then the DMA will write five full 32-bit data items from address 0x0000 0FF0. But the first 2 bytes of the first transfer and the last 2 bytes of the third transfer will have dummy data.

### 38.6.4 Buffer size calculations

The DMA does not update the size fields in the transmit and receive descriptors. The DMA updates only the status fields (xDES0) of the descriptors. The driver has to calculate the sizes. The transmit DMA transfers the exact number of bytes (indicated by buffer size field in

TDES1) towards the MAC core. If a descriptor is marked as first (FS bit in TDES0 is set), then the DMA marks the first transfer from the buffer as the start of frame. If a descriptor is marked as last (LS bit in TDES0), then the DMA marks the last transfer from that data buffer as the end of frame. The receive DMA transfers data to a buffer until the buffer is full or the end of frame is received. If a descriptor is not marked as last (LS bit in RDES0), then the buffer(s) that correspond to the descriptor are full and the amount of valid data in a buffer is accurately indicated by the buffer size field minus the data buffer pointer offset when the descriptor's FS bit is set. The offset is zero when the data buffer pointer is aligned to the databus width. If a descriptor is marked as last, then the buffer may not be full (as indicated by the buffer size in RDES1). To compute the amount of valid data in this final buffer, the driver must read the frame length (FL bits in RDES0[29:16]) and subtract the sum of the buffer sizes of the preceding buffers in this frame. The receive DMA always transfers the start of next frame with a new descriptor.

*Note: Even when the start address of a receive buffer is not aligned to the system databus width the system should allocate a receive buffer of a size aligned to the system bus width. For example, if the system allocates a 1024 byte (1 KB) receive buffer starting from address 0x1000, the software can program the buffer start address in the receive descriptor to have a 0x1002 offset. The receive DMA writes the frame to this buffer with dummy data in the first two locations (0x1000 and 0x1001). The actual frame is written from location 0x1002. Thus, the actual useful space in this buffer is 1022 bytes, even though the buffer size is programmed as 1024 bytes, due to the start address offset.*

### 38.6.5 DMA arbiter

The arbiter inside the DMA takes care of the arbitration between transmit and receive channel accesses to the AHB master interface. Two types of arbitrations are possible: round-robin, and fixed-priority. When round-robin arbitration is selected (DA bit in ETH\_DMABMR is reset), the arbiter allocates the databus in the ratio set by the PM bits in ETH\_DMABMR, when both transmit and receive DMAs request access simultaneously. When the DA bit is set, the receive DMA always gets priority over the transmit DMA for data access.

### 38.6.6 Error response to DMA

For any data transfer initiated by a DMA channel, if the slave replies with an error response, that DMA stops all operations and updates the error bits and the fatal bus error bit in the Status register (ETH\_DMASR register). That DMA controller can resume operation only after soft- or hard-resetting the peripheral and re-initializing the DMA.

### 38.6.7 Tx DMA configuration

#### TxDMA operation: default (non-OSF) mode

The transmit DMA engine in default mode proceeds as follows:

1. The user sets up the transmit descriptor (TDES0-TDES3) and sets the OWN bit (TDES0[31]) after setting up the corresponding data buffer(s) with Ethernet frame data.
2. Once the ST bit (ETH\_DMAOMR register[13]) is set, the DMA enters the Run state.
3. While in the Run state, the DMA polls the transmit descriptor list for frames requiring transmission. After polling starts, it continues in either sequential descriptor ring order or chained order. If the DMA detects a descriptor flagged as owned by the CPU, or if an error condition occurs, transmission is suspended and both the Transmit Buffer

- Unavailable (ETH\_DMASR register[2]) and Normal Interrupt Summary (ETH\_DMASR register[16]) bits are set. The transmit engine proceeds to Step 9.
4. If the acquired descriptor is flagged as owned by DMA (TDES0[31] is set), the DMA decodes the transmit data buffer address from the acquired descriptor.
  5. The DMA fetches the transmit data from the STM32F75xxx and STM32F74xxx memory and transfers the data.
  6. If an Ethernet frame is stored over data buffers in multiple descriptors, the DMA closes the intermediate descriptor and fetches the next descriptor. Steps 3, 4, and 5 are repeated until the end of Ethernet frame data is transferred.
  7. When frame transmission is complete, if IEEE 1588 time stamping was enabled for the frame (as indicated in the transmit status) the time stamp value is written to the transmit descriptor (TDES2 and TDES3) that contains the end-of-frame buffer. The status information is then written to this transmit descriptor (TDES0). Because the OWN bit is cleared during this step, the CPU now owns this descriptor. If time stamping was not enabled for this frame, the DMA does not alter the contents of TDES2 and TDES3.
  8. Transmit Interrupt (ETH\_DMASR register [0]) is set after completing the transmission of a frame that has Interrupt on Completion (TDES1[31]) set in its last descriptor. The DMA engine then returns to Step 3.
  9. In the Suspend state, the DMA tries to re-acquire the descriptor (and thereby returns to Step 3) when it receives a transmit poll demand, and the Underflow Interrupt Status bit is cleared.

*Figure 516* shows the TxDMA transmission flow in default mode.

Figure 516. TxDMA operation in default mode

### TxDMA operation: OSF mode

While in the Run state, the transmit process can simultaneously acquire two frames without closing the Status descriptor of the first (if the OSF bit is set in ETH\_DMAOMR register[2]). As the transmit process finishes transferring the first frame, it immediately polls the transmit descriptor list for the second frame. If the second frame is valid, the transmit process transfers this frame before writing the first frame's status information. In OSF mode, the Run-state transmit DMA operates according to the following sequence:

1. The DMA operates as described in steps 1–6 of the TxDMA (default mode).
2. Without closing the previous frame's last descriptor, the DMA fetches the next descriptor.
3. If the DMA owns the acquired descriptor, the DMA decodes the transmit buffer address in this descriptor. If the DMA does not own the descriptor, the DMA goes into Suspend mode and skips to Step 7.
4. The DMA fetches the Transmit frame from the STM32F75xxx and STM32F74xxx memory and transfers the frame until the end of frame data are transferred, closing the intermediate descriptors if this frame is split across multiple descriptors.
5. The DMA waits for the transmission status and time stamp of the previous frame. When the status is available, the DMA writes the time stamp to TDES2 and TDES3, if such time stamp was captured (as indicated by a status bit). The DMA then writes the status, with a cleared OWN bit, to the corresponding TDES0, thus closing the descriptor. If time stamping was not enabled for the previous frame, the DMA does not alter the contents of TDES2 and TDES3.
6. If enabled, the Transmit interrupt is set, the DMA fetches the next descriptor, then proceeds to Step 3 (when Status is normal). If the previous transmission status shows an underflow error, the DMA goes into Suspend mode (Step 7).
7. In Suspend mode, if a pending status and time stamp are received by the DMA, it writes the time stamp (if enabled for the current frame) to TDES2 and TDES3, then writes the status to the corresponding TDES0. It then sets relevant interrupts and returns to Suspend mode.
8. The DMA can exit Suspend mode and enter the Run state (go to Step 1 or Step 2 depending on pending status) only after receiving a Transmit Poll demand (ETH\_DMATPDR register).

*Figure 517* shows the basic flowchart in OSF mode.

Figure 517. TxDMA operation in OSF mode

### Transmit frame processing

The transmit DMA expects that the data buffers contain complete Ethernet frames, excluding preamble, pad bytes, and FCS fields. The DA, SA, and Type/Len fields contain valid data. If the transmit descriptor indicates that the MAC core must disable CRC or pad insertion, the buffer must have complete Ethernet frames (excluding preamble), including the CRC bytes. Frames can be data-chained and span over several buffers. Frames have to be delimited by the first descriptor (TDES0[28]) and the last descriptor (TDES0[29]). As the transmission starts, TDES0[28] has to be set in the first descriptor. When this occurs, the frame data are transferred from the memory buffer to the Transmit FIFO. Concurrently, if the last descriptor (TDES0[29]) of the current frame is cleared, the transmit process attempts to acquire the next descriptor. The transmit process expects TDES0[28] to be cleared in this descriptor. If TDES0[29] is cleared, it indicates an intermediary buffer. If TDES0[29] is set, it indicates the last buffer of the frame. After the last buffer of the frame has been transmitted,

the DMA writes back the final status information to the transmit descriptor 0 (TDES0) word of the descriptor that has the last segment set in transmit descriptor 0 (TDES0[29]). At this time, if Interrupt on Completion (TDES0[30]) is set, Transmit Interrupt (in ETH\_DMASR register [0]) is set, the next descriptor is fetched, and the process repeats. Actual frame transmission begins after the Transmit FIFO has reached either a programmable transmit threshold (ETH\_DMAOMR register[16:14]), or a full frame is contained in the FIFO. There is also an option for the Store and forward mode (ETH\_DMAOMR register[21]). Descriptors are released (OWN bit TDES0[31] is cleared) when the DMA finishes transferring the frame.

### Transmit polling suspended

Transmit polling can be suspended by either of the following conditions:

- The DMA detects a descriptor owned by the CPU (TDES0[31]=0) and the Transmit buffer unavailable flag is set (ETH\_DMASR register[2]). To resume, the driver must give descriptor ownership to the DMA and then issue a Poll Demand command.
- A frame transmission is aborted when a transmit error due to underflow is detected. The appropriate Transmit Descriptor 0 (TDES0) bit is set. If the second condition occurs, both the Abnormal Interrupt Summary (in ETH\_DMASR register [15]) and Transmit Underflow bits (in ETH\_DMASR register[5]) are set, and the information is written to Transmit Descriptor 0, causing the suspension. If the DMA goes into Suspend state due to the first condition, then both the Normal Interrupt Summary (ETH\_DMASR register [16]) and Transmit Buffer Unavailable (ETH\_DMASR register[2]) bits are set. In both cases, the position in the transmit list is retained. The retained position is that of the descriptor following the last descriptor closed by the DMA. The driver must explicitly issue a Transmit Poll Demand command after rectifying the suspension cause.

### Normal Tx DMA descriptors

The normal transmit descriptor structure consists of four 32-bit words as shown in [Figure 518](#). The bit descriptions of TDES0, TDES1, TDES2 and TDES3 are given below.

Note that enhanced descriptors must be used if time stamping is activated (ETH\_PTPTSCR bit 0, TSE=1) or if IPv4 checksum offload is activated (ETH\_MACCCR bit 10, IPCO=1).

**Figure 518. Normal transmit descriptor**

- **TDES0: Transmit descriptor Word0**

The application software has to program the control bits [30:26]+[23:20] plus the OWN bit [31] during descriptor initialization. When the DMA updates the descriptor (or writes it back), it resets all the control bits plus the OWN bit, and reports only the status bits.

| rw  | rw | rw | rw  | rw  | rw | rw   | rw   | rw  | rw | rw  | rw  | rw   | rw   | rw   | rw  |

**Bit 31 OWN:** Own bit

When set, this bit indicates that the descriptor is owned by the DMA. When this bit is reset, it indicates that the descriptor is owned by the CPU. The DMA clears this bit either when it completes the frame transmission or when the buffers allocated in the descriptor are read completely. The ownership bit of the frame's first descriptor must be set after all subsequent descriptors belonging to the same frame have been set.

**Bit 30 IC:** Interrupt on completion

When set, this bit sets the Transmit Interrupt (Register 5[0]) after the present frame has been transmitted.

**Bit 29 LS:** Last segment

When set, this bit indicates that the buffer contains the last segment of the frame.

**Bit 28 FS:** First segment

When set, this bit indicates that the buffer contains the first segment of a frame.

**Bit 27 DC:** Disable CRC

When this bit is set, the MAC does not append a cyclic redundancy check (CRC) to the end of the transmitted frame. This is valid only when the first segment (TDES0[28]) is set.

**Bit 26 DP:** Disable pad

When set, the MAC does not automatically add padding to a frame shorter than 64 bytes. When this bit is reset, the DMA automatically adds padding and CRC to a frame shorter than 64 bytes, and the CRC field is added despite the state of the DC (TDES0[27]) bit. This is valid only when the first segment (TDES0[28]) is set.

**Bit 25 TTSE:** Transmit time stamp enable

When TTSE is set and when TSE is set (ETH\_PTPTSCR bit 0), IEEE1588 hardware time stamping is activated for the transmit frame described by the descriptor. This field is only valid when the First segment control bit (TDES0[28]) is set.

**Bit 24** Reserved, must be kept at reset value.

**Bits 23:22 CIC:** Checksum insertion control

These bits control the checksum calculation and insertion. Bit encoding is as shown below:

00: Checksum Insertion disabled

01: Only IP header checksum calculation and insertion are enabled

10: IP header checksum and payload checksum calculation and insertion are enabled, but pseudo-header checksum is not calculated in hardware

11: IP Header checksum and payload checksum calculation and insertion are enabled, and pseudo-header checksum is calculated in hardware.

**Bit 21 TER:** Transmit end of ring

When set, this bit indicates that the descriptor list reached its final descriptor. The DMA returns to the base address of the list, creating a descriptor ring.

**Bit 20 TCH:** Second address chained

When set, this bit indicates that the second address in the descriptor is the next descriptor address rather than the second buffer address. When TDES0[20] is set, TBS2 (TDES1[28:16]) is a "don't care" value. TDES0[21] takes precedence over TDES0[20].

Bits 19:18 Reserved, must be kept at reset value.

**Bit 17 TTSS:** Transmit time stamp status

This field is used as a status bit to indicate that a time stamp was captured for the described transmit frame. When this bit is set, TDES2 and TDES3 have a time stamp value captured for the transmit frame. This field is only valid when the descriptor's Last segment control bit (TDES0[29]) is set.

Note that when enhanced descriptors are enabled (EDFE=1 in ETH\_DMABMR), TTSS=1 indicates that TDES6 and TDES7 have the time stamp value.

**Bit 16 IHE:** IP header error

When set, this bit indicates that the MAC transmitter detected an error in the IP datagram header. The transmitter checks the header length in the IPv4 packet against the number of header bytes received from the application and indicates an error status if there is a mismatch. For IPv6 frames, a header error is reported if the main header length is not 40 bytes. Furthermore, the Ethernet length/type field value for an IPv4 or IPv6 frame must match the IP header version received with the packet. For IPv4 frames, an error status is also indicated if the Header Length field has a value less than 0x5.

**Bit 15 ES:** Error summary

Indicates the logical OR of the following bits:

TDES0[14]: Jabber timeout  
 TDES0[13]: Frame flush  
 TDES0[11]: Loss of carrier  
 TDES0[10]: No carrier  
 TDES0[9]: Late collision  
 TDES0[8]: Excessive collision  
 TDES0[2]: Excessive deferral  
 TDES0[1]: Underflow error  
 TDES0[16]: IP header error  
 TDES0[12]: IP payload error

**Bit 14 JT:** Jabber timeout

When set, this bit indicates the MAC transmitter has experienced a jabber timeout. This bit is only set when the MAC configuration register's JD bit is not set.

**Bit 13 FF:** Frame flushed

When set, this bit indicates that the DMA/MTL flushed the frame due to a software Flush command given by the CPU.

**Bit 12 IPE:** IP payload error

When set, this bit indicates that MAC transmitter detected an error in the TCP, UDP, or ICMP IP datagram payload. The transmitter checks the payload length received in the IPv4 or IPv6 header against the actual number of TCP, UDP or ICMP packet bytes received from the application and issues an error status in case of a mismatch.

Bit 11 **LCA**: Loss of carrier

When set, this bit indicates that a loss of carrier occurred during frame transmission (that is, the MII\_CRS signal was inactive for one or more transmit clock periods during frame transmission). This is valid only for the frames transmitted without collision when the MAC operates in Half-duplex mode.

Bit 10 **NC**: No carrier

When set, this bit indicates that the Carrier Sense signal from the PHY was not asserted during transmission.

Bit 9 **LCO**: Late collision

When set, this bit indicates that frame transmission was aborted due to a collision occurring after the collision window (64 byte times, including preamble, in MII mode). This bit is not valid if the Underflow Error bit is set.

Bit 8 **EC**: Excessive collision

When set, this bit indicates that the transmission was aborted after 16 successive collisions while attempting to transmit the current frame. If the RD (Disable retry) bit in the MAC Configuration register is set, this bit is set after the first collision, and the transmission of the frame is aborted.

Bit 7 **VF**: VLAN frame

When set, this bit indicates that the transmitted frame was a VLAN-type frame.

Bits 6:3 **CC**: Collision count

This 4-bit counter value indicates the number of collisions occurring before the frame was transmitted. The count is not valid when the Excessive collisions bit (TDES0[8]) is set.

Bit 2 **ED**: Excessive deferral

When set, this bit indicates that the transmission has ended because of excessive deferral of over 24 288 bit times if the Deferral check (DC) bit in the MAC Control register is set high.

Bit 1 **UF**: Underflow error

When set, this bit indicates that the MAC aborted the frame because data arrived late from the RAM memory. Underflow error indicates that the DMA encountered an empty transmit buffer while transmitting the frame. The transmission process enters the Suspended state and sets both Transmit underflow (Register 5[5]) and Transmit interrupt (Register 5[0]).

Bit 0 **DB**: Deferred bit

When set, this bit indicates that the MAC defers before transmission because of the presence of the carrier. This bit is valid only in Half-duplex mode.

- TDES1: Transmit descriptor Word1**

|      |      |      |      |    |    |    |    |    |    |    |    |    |    |    |    |

|      |      |      | rw   | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

31:29 Reserved, must be kept at reset value.

28:16 **TBS2**: Transmit buffer 2 size

These bits indicate the second data buffer size in bytes. This field is not valid if TDES0[20] is set.

15:13 Reserved, must be kept at reset value.

12:0 **TBS1**: Transmit buffer 1 size

These bits indicate the first data buffer byte size, in bytes. If this field is 0, the DMA ignores this buffer and uses Buffer 2 or the next descriptor, depending on the value of TCH (TDES0[20]).

- **TDES2: Transmit descriptor Word2**

TDES2 contains the address pointer to the first buffer of the descriptor or it contains time stamp data.

|                 |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|-----------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|

| rw              | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 31:0 **TBAP1**: Transmit buffer 1 address pointer / Transmit frame time stamp low

These bits have two different functions: they indicate to the DMA the location of data in memory, and after all data are transferred, the DMA can then use these bits to pass back time stamp data.

**TBAP**: When the software makes this descriptor available to the DMA (at the moment that the OWN bit is set to 1 in TDES0), these bits indicate the physical address of Buffer 1. There is no limitation on the buffer address alignment. See [Host data buffer alignment on page 1572](#) for further details on buffer address alignment.

**TTSL**: Before it clears the OWN bit in TDES0, the DMA updates this field with the 32 least significant bits of the time stamp captured for the corresponding transmit frame (overwriting the value for TBAP1). This field has the time stamp only if time stamping is activated for this frame (see TTSE, TDES0 bit 25) and if the Last segment control bit (LS) in the descriptor is set.

- **TDES3: Transmit descriptor Word3**

TDES3 contains the address pointer either to the second buffer of the descriptor or the next descriptor, or it contains time stamp data.

|                  |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|------------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|

| rw               | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |
| 15               | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| TBAP2/TBAP2/TTSH |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw               | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 31:0 **TBAP2**: Transmit buffer 2 address pointer (Next descriptor address) / Transmit frame time stamp high

These bits have two different functions: they indicate to the DMA the location of data in memory, and after all data are transferred, the DMA can then use these bits to pass back time stamp data.

**TBAP2**: When the software makes this descriptor available to the DMA (at the moment when the OWN bit is set to 1 in TDES0), these bits indicate the physical address of Buffer 2 when a descriptor ring structure is used. If the Second address chained (TDES1 [20]) bit is set, this address contains the pointer to the physical memory where the next descriptor is present. The buffer address pointer must be aligned to the bus width only when TDES1 [20] is set. (LSBs are ignored internally.)

**TTSH**: Before it clears the OWN bit in TDES0, the DMA updates this field with the 32 most significant bits of the time stamp captured for the corresponding transmit frame (overwriting the value for TBAP2). This field has the time stamp only if activated for this frame (see TDES0 bit 25, TTSE) and if the Last segment control bit (LS) in the descriptor is set.

### Enhanced Tx DMA descriptors

Enhanced descriptors (enabled with EDFE=1, ETHDMABMR bit 7), must be used if time stamping is activated (TSE=1, ETH\_PTPTSCR bit 0) or if IPv4 checksum offload is activated (IPCO=1, ETH\_MACCR bit 10).

Enhanced descriptors comprise eight 32-bit words, twice the size of normal descriptors. TDES0, TDES1, TDES2 and TDES3 have the same definitions as for normal transmit descriptors (refer to [Normal Tx DMA descriptors](#)). TDES6 and TDES7 hold the time stamp. TDES4, TDES5, TDES6 and TDES7 are defined below.

When the Enhanced descriptor mode is selected, the software needs to allocate 32-bytes (8 DWORDS) of memory for every descriptor. When time stamping or IPv4 checksum offload are not being used, the enhanced descriptor format may be disabled and the software can use normal descriptors with the default size of 16 bytes.

|        |                                                           |                 |                                |            |                 |                     |                     |               |                               |  |  |  |

| TDES 1 | Reserved<br>[31:29]                                       |                 | Buffer 2 byte count<br>[28:16] |            |                 |                     | Reserved<br>[15:13] |               | Buffer 1 byte count<br>[12:0] |  |  |  |
| TDES 2 | Buffer 1 address [31:0]                                   |                 |                                |            |                 |                     |                     |               |                               |  |  |  |
| TDES 3 | Buffer 2 address [31:0] or Next descriptor address [31:0] |                 |                                |            |                 |                     |                     |               |                               |  |  |  |
| TDES 4 | Reserved                                                  |                 |                                |            |                 |                     |                     |               |                               |  |  |  |
| TDES 5 | Reserved                                                  |                 |                                |            |                 |                     |                     |               |                               |  |  |  |
| TDES 6 | Time stamp low [31:0]                                     |                 |                                |            |                 |                     |                     |               |                               |  |  |  |
| TDES 7 | Time stamp high [31:0]                                    |                 |                                |            |                 |                     |                     |               |                               |  |  |  |

- TDES4: Transmit descriptor Word4  
Reserved
- TDES5: Transmit descriptor Word5  
Reserved
- **TDES6: Transmit descriptor Word6**

[illegible]

This field is updated by DMA with the 32 least significant bits of the time stamp captured for the corresponding transmit frame. This field has the time stamp only if the Last segment control bit (LS) in the descriptor is set.

- **TDES7: Transmit descriptor Word7**

[illegible]

Bits 31:0 **TTSH**: Transmit frame time stamp high

This field is updated by DMA with the 32 most significant bits of the time stamp captured for the corresponding transmit frame. This field has the time stamp only if the Last segment control bit (LS) in the descriptor is set.

### 38.6.8 Rx DMA configuration

The Receive DMA engine's reception sequence is illustrated in [Figure 520](#) and described below:

1. The CPU sets up Receive descriptors (RDES0-RDES3) and sets the OWN bit (RDES0[31]).
2. Once the SR (ETH\_DMAOMR register[1]) bit is set, the DMA enters the Run state. While in the Run state, the DMA polls the receive descriptor list, attempting to acquire free descriptors. If the fetched descriptor is not free (is owned by the CPU), the DMA enters the Suspend state and jumps to Step 9.
3. The DMA decodes the receive data buffer address from the acquired descriptors.
4. Incoming frames are processed and placed in the acquired descriptor's data buffers.
5. When the buffer is full or the frame transfer is complete, the Receive engine fetches the next descriptor.
6. If the current frame transfer is complete, the DMA proceeds to step 7. If the DMA does not own the next fetched descriptor and the frame transfer is not complete (EOF is not yet transferred), the DMA sets the Descriptor error bit in RDES0 (unless flushing is disabled). The DMA closes the current descriptor (clears the OWN bit) and marks it as intermediate by clearing the Last segment (LS) bit in the RDES1 value (marks it as last descriptor if flushing is not disabled), then proceeds to step 8. If the DMA owns the next descriptor but the current frame transfer is not complete, the DMA closes the current descriptor as intermediate and returns to step 4.
7. If IEEE 1588 time stamping is enabled, the DMA writes the time stamp (if available) to the current descriptor's RDES2 and RDES3. It then takes the received frame's status and writes the status word to the current descriptor's RDES0, with the OWN bit cleared and the Last segment bit set.
8. The Receive engine checks the latest descriptor's OWN bit. If the CPU owns the descriptor (OWN bit is at 0) the Receive buffer unavailable bit (in ETH\_DMASR register[7]) is set and the DMA Receive engine enters the Suspended state (step 9). If the DMA owns the descriptor, the engine returns to step 4 and awaits the next frame.
9. Before the Receive engine enters the Suspend state, partial frames are flushed from the Receive FIFO (you can control flushing using bit 24 in the ETH\_DMAOMR register).
10. The Receive DMA exits the Suspend state when a Receive Poll demand is given or the start of next frame is available from the Receive FIFO. The engine proceeds to step 2 and re-fetches the next descriptor.

The DMA does not acknowledge accepting the status until it has completed the time stamp write-back and is ready to perform status write-back to the descriptor. If software has enabled time stamping through CSR, when a valid time stamp value is not available for the frame (for example, because the receive FIFO was full before the time stamp could be written to it), the DMA writes all ones to RDES2 and RDES3. Otherwise (that is, if time stamping is not enabled), RDES2 and RDES3 remain unchanged.

Figure 520. Receive DMA operation

### Receive descriptor acquisition

The receive engine always attempts to acquire an extra descriptor in anticipation of an incoming frame. Descriptor acquisition is attempted if any of the following conditions is/are satisfied:

- The receive Start/Stop bit (ETH\_DMAOMR register[1]) has been set immediately after the DMA has been placed in the Run state.
- The data buffer of the current descriptor is full before the end of the frame currently being transferred
- The controller has completed frame reception, but the current receive descriptor has not yet been closed.
- The receive process has been suspended because of a CPU-owned buffer (RDES0[31] = 0) and a new frame is received.
- A Receive poll demand has been issued.

### Receive frame processing

The MAC transfers the received frames to the STM32F75xxx and STM32F74xxx memory only when the frame passes the address filter and the frame size is greater than or equal to the configurable threshold bytes set for the Receive FIFO, or when the complete frame is written to the FIFO in Store-and-forward mode. If the frame fails the address filtering, it is dropped in the MAC block itself (unless Receive All ETH\_MACFFR [31] bit is set). Frames that are shorter than 64 bytes, because of collision or premature termination, can be purged from the Receive FIFO. After 64 (configurable threshold) bytes have been received, the DMA block begins transferring the frame data to the receive buffer pointed to by the current descriptor. The DMA sets the first descriptor (RDES0[9]) after the DMA AHB Interface becomes ready to receive a data transfer (if DMA is not fetching transmit data from the memory), to delimit the frame. The descriptors are released when the OWN (RDES0[31]) bit is reset to 0, either as the data buffer fills up or as the last segment of the frame is transferred to the receive buffer. If the frame is contained in a single descriptor, both the last descriptor (RDES0[8]) and first descriptor (RDES0[9]) bits are set. The DMA fetches the next descriptor, sets the last descriptor (RDES0[8]) bit, and releases the RDES0 status bits in the previous frame descriptor. Then the DMA sets the receive interrupt bit (ETH\_DMASR register [6]). The same process repeats unless the DMA encounters a descriptor flagged as being owned by the CPU. If this occurs, the receive process sets the receive buffer unavailable bit (ETH\_DMASR register[7]) and then enters the Suspend state. The position in the receive list is retained.

### Receive process suspended

If a new receive frame arrives while the receive process is in Suspend state, the DMA re-fetches the current descriptor in the STM32F75xxx and STM32F74xxx memory. If the descriptor is now owned by the DMA, the receive process re-enters the Run state and starts frame reception. If the descriptor is still owned by the host, by default, the DMA discards the current frame at the top of the Rx FIFO and increments the missed frame counter. If more than one frame is stored in the Rx FIFO, the process repeats. The discarding or flushing of the frame at the top of the Rx FIFO can be avoided by setting the DMA Operation mode register bit 24 (DFRF). In such conditions, the receive process sets the receive buffer unavailable status bit and returns to the Suspend state.

## Normal Rx DMA descriptors

The normal receive descriptor structure consists of four 32-bit words (16 bytes). These are shown in [Figure 521](#). The bit descriptions of RDES0, RDES1, RDES2 and RDES3 are given below.

Note that enhanced descriptors must be used if time stamping is activated (TSE=1, ETH\_PTPTSCR bit 0) or if IPv4 checksum offload is activated (IPCO=1, ETH\_MACCR bit 10).

**Figure 521. Normal Rx DMA descriptor structure**

- **RDES0: Receive descriptor Word0**

RDES0 contains the received frame status, the frame length and the descriptor ownership information.

| rw  | rw  | rw  | rw | rw | rw   | rw | rw | rw        | rw  | rw | rw  | rw | rw | rw | rw      |

**Bit 31 OWN:** Own bit

When set, this bit indicates that the descriptor is owned by the DMA of the MAC Subsystem. When this bit is reset, it indicates that the descriptor is owned by the Host. The DMA clears this bit either when it completes the frame reception or when the buffers that are associated with this descriptor are full.

**Bit 30 AFM:** Destination address filter fail

When set, this bit indicates a frame that failed the DA filter in the MAC Core.

**Bits 29:16 FL:** Frame length

These bits indicate the byte length of the received frame that was transferred to host memory (including CRC). This field is valid only when last descriptor (RDES0[8]) is set and descriptor error (RDES0[14]) is reset.

This field is valid when last descriptor (RDES0[8]) is set. When the last descriptor and error summary bits are not set, this field indicates the accumulated number of bytes that have been transferred for the current frame.

- Bit 15 **ES**: Error summary  
 Indicates the logical OR of the following bits:  
 RDES0[1]: CRC error  
 RDES0[3]: Receive error  
 RDES0[4]: Watchdog timeout  
 RDES0[6]: Late collision  
 RDES0[7]: Giant frame (This is not applicable when RDES0[7] indicates an IPV4 header checksum error.)  
 RDES0[11]: Overflow error  
 RDES0[14]: Descriptor error.  
 This field is valid only when the last descriptor (RDES0[8]) is set.
- Bit 14 **DE**: Descriptor error  
 When set, this bit indicates a frame truncation caused by a frame that does not fit within the current descriptor buffers, and that the DMA does not own the next descriptor. The frame is truncated.  
 This field is valid only when the last descriptor (RDES0[8]) is set.
- Bit 13 **SAF**: Source address filter fail  
 When set, this bit indicates that the SA field of frame failed the SA filter in the MAC Core.
- Bit 12 **LE**: Length error  
 When set, this bit indicates that the actual length of the received frame does not match the value in the Length/ Type field. This bit is valid only when the Frame type (RDES0[5]) bit is reset.
- Bit 11 **OE**: Overflow error  
 When set, this bit indicates that the received frame was damaged due to buffer overflow.
- Bit 10 **VLAN**: VLAN tag  
 When set, this bit indicates that the frame pointed to by this descriptor is a VLAN frame tagged by the MAC core.
- Bit 9 **FS**: First descriptor  
 When set, this bit indicates that this descriptor contains the first buffer of the frame. If the size of the first buffer is 0, the second buffer contains the beginning of the frame. If the size of the second buffer is also 0, the next descriptor contains the beginning of the frame.
- Bit 8 **LS**: Last descriptor  
 When set, this bit indicates that the buffers pointed to by this descriptor are the last buffers of the frame.
- Bit 7 **IPHCE/TSV**: IPv header checksum error / time stamp valid  
 If IPHCE is set, it indicates an error in the IPv4 or IPv6 header. This error can be due to inconsistent Ethernet Type field and IP header Version field values, a header checksum mismatch in IPv4, or an Ethernet frame lacking the expected number of IP header bytes. This bit can take on special meaning as specified in [Table 280](#).  
 If enhanced descriptor format is enabled (EDFE=1, bit 7 of ETH\_DMABMR), this bit takes on the TSV function (otherwise it is IPHCE). When TSV is set, it indicates that a snapshot of the timestamp is written in descriptor words 6 (RDES6) and 7 (RDES7). TSV is valid only when the Last descriptor bit (RDES0[8]) is set.
- Bit 6 **LCO**: Late collision  
 When set, this bit indicates that a late collision has occurred while receiving the frame in Half-duplex mode.

**Bit 5 FT:** Frame type

When set, this bit indicates that the Receive frame is an Ethernet-type frame (the LT field is greater than or equal to 0x0600). When this bit is reset, it indicates that the received frame is an IEEE802.3 frame. This bit is not valid for Runt frames less than 14 bytes. When the normal descriptor format is used (ETH\_DMABMR EDFE=0), FT can take on special meaning as specified in [Table 280](#).

**Bit 4 RWT:** Receive watchdog timeout

When set, this bit indicates that the Receive watchdog timer has expired while receiving the current frame and the current frame is truncated after the watchdog timeout.

**Bit 3 RE:** Receive error

When set, this bit indicates that the RX\_ERR signal is asserted while RX\_DV is asserted during frame reception.

**Bit 2 DE:** Dribble bit error

When set, this bit indicates that the received frame has a non-integer multiple of bytes (odd nibbles). This bit is valid only in MII mode.

**Bit 1 CE:** CRC error

When set, this bit indicates that a cyclic redundancy check (CRC) error occurred on the received frame. This field is valid only when the last descriptor (RDES0[8]) is set.

**Bit 0 PCE/ESA:** Payload checksum error / extended status available

When set, it indicates that the TCP, UDP or ICMP checksum the core calculated does not match the received encapsulated TCP, UDP or ICMP segment's Checksum field. This bit is also set when the received number of payload bytes does not match the value indicated in the Length field of the encapsulated IPv4 or IPv6 datagram in the received Ethernet frame. This bit can take on special meaning as specified in [Table 280](#).

If the enhanced descriptor format is enabled (EDFE=1, bit 7 in ETH\_DMABMR), this bit takes on the ESA function (otherwise it is PCE). When ESA is set, it indicates that the extended status is available in descriptor word 4 (RDES4). ESA is valid only when the last descriptor bit (RDES0[8]) is set.

Bits 5, 7, and 0 reflect the conditions discussed in [Table 280](#).

**Table 280. Receive descriptor 0 - encoding for bits 7, 5 and 0 (normal descriptor format only, EDFE=0)**

| Bit 5: frame type | Bit 7: IPC checksum error | Bit 0: payload checksum error | Frame status                                                                                                        |
|-------------------|---------------------------|-------------------------------|---------------------------------------------------------------------------------------------------------------------|
| 0                 | 0                         | 0                             | IEEE 802.3 Type frame (Length field value is less than 0x0600.)                                                     |
| 1                 | 0                         | 0                             | IPv4/IPv6 Type frame, no checksum error detected                                                                    |
| 1                 | 0                         | 1                             | IPv4/IPv6 Type frame with a payload checksum error (as described for PCE) detected                                  |
| 1                 | 1                         | 0                             | IPv4/IPv6 Type frame with an IP header checksum error (as described for IPC CE) detected                            |
| 1                 | 1                         | 1                             | IPv4/IPv6 Type frame with both IP header and payload checksum errors detected                                       |
| 0                 | 0                         | 1                             | IPv4/IPv6 Type frame with no IP header checksum error and the payload check bypassed, due to an unsupported payload |
| 0                 | 1                         | 1                             | A Type frame that is neither IPv4 or IPv6 (the checksum offload engine bypasses checksum completely.)               |
| 0                 | 1                         | 0                             | Reserved                                                                                                            |

Bit 31 **DIC**: Disable interrupt on completion

When set, this bit prevents setting the Status register's RS bit (CSR5[6]) for the received frame ending in the buffer indicated by this descriptor. This, in turn, disables the assertion of the interrupt to Host due to RS for that frame.

Bits 30:29 **Reserved**, must be kept at reset value.

Bits 28:16 **RBS2**: Receive buffer 2 size

These bits indicate the second data buffer size, in bytes. The buffer size must be a multiple of 4, 8, or 16, depending on the bus widths (32, 64 or 128, respectively), even if the value of RDES3 (buffer2 address pointer) is not aligned to bus width. If the buffer size is not an appropriate multiple of 4, 8 or 16, the resulting behavior is undefined. This field is not valid if RDES1 [14] is set.

Bit 15 **RER**: Receive end of ring

When set, this bit indicates that the descriptor list reached its final descriptor. The DMA returns to the base address of the list, creating a descriptor ring.

Bit 14 **RCH**: Second address chained

When set, this bit indicates that the second address in the descriptor is the next descriptor address rather than the second buffer address. When this bit is set, RBS2 (RDES1[28:16]) is a “don’t care” value. RDES1[15] takes precedence over RDES1[14].

Bit 13 Reserved, must be kept at reset value.

Bits 12:0 **RBS1**: Receive buffer 1 size

Indicates the first data buffer size in bytes. The buffer size must be a multiple of 4, 8 or 16, depending upon the bus widths (32, 64 or 128), even if the value of RDES2 (buffer1 address pointer) is not aligned. When the buffer size is not a multiple of 4, 8 or 16, the resulting behavior is undefined. If this field is 0, the DMA ignores this buffer and uses Buffer 2 or next descriptor depending on the value of RCH (bit 14).

- **RDES2: Receive descriptor Word2**

RDES2 contains the address pointer to the first data buffer in the descriptor, or it contains time stamp data.

|             |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|-------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31          | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| RBP1 / RTSL |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rW          | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW |

| RBP1 / RTSL |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rW          | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW |

Bits 31:0 **RBAP1 / RTSL**: Receive buffer 1 address pointer / Receive frame time stamp low

These bits take on two different functions: the application uses them to indicate to the DMA where to store the data in memory, and then after transferring all the data the DMA may use these bits to pass back time stamp data.

**RBAP1**: When the software makes this descriptor available to the DMA (at the moment that the OWN bit is set to 1 in RDES0), these bits indicate the physical address of Buffer 1. There are no limitations on the buffer address alignment except for the following condition: the DMA uses the configured value for its address generation when the RDES2 value is used to store the start of frame. Note that the DMA performs a write operation with the RDES2[3/2/1:0] bits as 0 during the transfer of the start of frame but the frame data is shifted as per the actual Buffer address pointer. The DMA ignores RDES2[3/2/1:0] (corresponding to bus width of 128/64/32) if the address pointer is to a buffer where the middle or last part of the frame is stored.

**RTSL**: Before it clears the OWN bit in RDES0, the DMA updates this field with the 32 least significant bits of the time stamp captured for the corresponding receive frame (overwriting the value for RBAP1). This field has the time stamp only if time stamping is activated for this frame and if the Last segment control bit (LS) in the descriptor is set.

- **RDES3: Receive descriptor Word3**

RDES3 contains the address pointer either to the second data buffer in the descriptor or to the next descriptor, or it contains time stamp data.

|             |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

| 31          | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| RBP2 / RTSH |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rW          | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW |
| 15          | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| RBP2 / RTSH |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rW          | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW |

Bits 31:0 **RBAP2 / RTSH**: Receive buffer 2 address pointer (next descriptor address) / Receive frame time stamp high

These bits take on two different functions: the application uses them to indicate to the DMA the location of where to store the data in memory, and then after transferring all the data the DMA may use these bits to pass back time stamp data.

**RBAP1**: When the software makes this descriptor available to the DMA (at the moment that the OWN bit is set to 1 in RDES0), these bits indicate the physical address of buffer 2 when a descriptor ring structure is used. If the second address chained (RDES1 [24]) bit is set, this address contains the pointer to the physical memory where the next descriptor is present. If RDES1 [24] is set, the buffer (next descriptor) address pointer must be bus width-aligned (RDES3[3, 2, or 1:0] = 0, corresponding to a bus width of 128, 64 or 32. LSBs are ignored internally.) However, when RDES1 [24] is reset, there are no limitations on the RDES3 value, except for the following condition: the DMA uses the configured value for its buffer address generation when the RDES3 value is used to store the start of frame. The DMA ignores RDES3[3, 2, or 1:0] (corresponding to a bus width of 128, 64 or 32) if the address pointer is to a buffer where the middle or last part of the frame is stored.

**RTSH**: Before it clears the OWN bit in RDES0, the DMA updates this field with the 32 most significant bits of the time stamp captured for the corresponding receive frame (overwriting the value for RBAP2). This field has the time stamp only if time stamping is activated and if the Last segment control bit (LS) in the descriptor is set.

### Enhanced Rx DMA descriptors format with IEEE1588 time stamp

Enhanced descriptors (enabled with EDFE=1, ETHDMABMR bit 7), must be used if time stamping is activated (TSE=1, ETH\_PTPTSCR bit 0) or if IPv4 checksum offload is activated (IPCO=1, ETH\_MACCR bit 10).

Enhanced descriptors comprise eight 32-bit words, twice the size of normal descriptors. RDES0, RDES1, RDES2 and RDES3 have the same definitions as for normal receive descriptors (refer to [Normal Rx DMA descriptors](#)). RDES4 contains extended status while RDES6 and RDES7 hold the time stamp. RDES4, RDES5, RDES6 and RDES7 are defined below.

When the Enhanced descriptor mode is selected, the software needs to allocate 32 bytes (8 DWORDS) of memory for every descriptor. When time stamping or IPv4 checksum offload are not being used, the enhanced descriptor format may be disabled and the software can use normal descriptors with the default size of 16 bytes.

Figure 522. Enhanced receive descriptor field format with IEEE1588 time stamp enabled

- RDES4: Receive descriptor Word4

The extended status, shown below, is valid only when there is status related to IPv4 checksum or time stamp available as indicated by bit 0 in RDES0.

- Bits 31:14 Reserved, must be kept at reset value.
- Bit 13 **PV**: PTP version  
When set, indicates that the received PTP message uses the IEEE 1588 version 2 format.  
When cleared, it uses version 1 format. This is valid only if the message type is non-zero.
- Bit 12 **PFT**: PTP frame type  
When set, this bit indicates that the PTP message is sent directly over Ethernet. When this bit is cleared and the message type is non-zero, it indicates that the PTP message is sent over UDP-IPv4 or UDP-IPv6. The information on IPv4 or IPv6 can be obtained from bits 6 and 7.

Bits 11:8 **PMT**: PTP message type

These bits are encoded to give the type of the message received.

- 0000: No PTP message received
- 0001: SYNC (all clock types)
- 0010: Follow\_Up (all clock types)
- 0011: Delay\_Req (all clock types)
- 0100: Delay\_Resp (all clock types)
- 0101: Pdelay\_Req (in peer-to-peer transparent clock) or Announce (in ordinary or boundary clock)
- 0110: Pdelay\_Resp (in peer-to-peer transparent clock) or Management (in ordinary or boundary clock)
- 0111: Pdelay\_Resp\_Follow\_Up (in peer-to-peer transparent clock) or Signaling (for ordinary or boundary clock)
- 1xxx - Reserved

Bit 7 **IPv6PR**: IPv6 packet received

When set, this bit indicates that the received packet is an IPv6 packet.

Bit 6 **IPv4PR**: IPv4 packet received

When set, this bit indicates that the received packet is an IPv4 packet.

Bit 5 **IPCB**: IP checksum bypassed

When set, this bit indicates that the checksum offload engine is bypassed.

Bit 4 **IPPE**: IP payload error

When set, this bit indicates that the 16-bit IP payload checksum (that is, the TCP, UDP, or ICMP checksum) that the core calculated does not match the corresponding checksum field in the received segment. It is also set when the TCP, UDP, or ICMP segment length does not match the payload length value in the IP Header field.

Bit 3 **IPHE**: IP header error

When set, this bit indicates either that the 16-bit IPv4 header checksum calculated by the core does not match the received checksum bytes, or that the IP datagram version is not consistent with the Ethernet Type value.

Bits 2:0 **IPPT**: IP payload type

if IPv4 checksum offload is activated (IPCO=1, ETH\_MACCR bit 10), these bits indicate the type of payload encapsulated in the IP datagram. These bits are '00' if there is an IP header error or fragmented IP.

- 000: Unknown or did not process IP payload
- 001: UDP
- 010: TCP
- 011: ICMP
- 1xx: Reserved

- **RDES5: Receive descriptor Word5**

Reserved.

- **RDES6: Receive descriptor Word6**

The table below describes the fields that have different meaning for RDES6 when the receive descriptor is closed and time stamping is enabled.

|      |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31   | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| RTSL |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rW   | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW |
| 15   | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| RTSL |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rW   | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW |

Bits 31:0 **RTSL**: Receive frame time stamp low

The DMA updates this field with the 32 least significant bits of the time stamp captured for the corresponding receive frame. The DMA updates this field only for the last descriptor of the receive frame indicated by last descriptor status bit (RDES0[8]). When this field and the RTSH field in RDES7 show all ones, the time stamp must be treated as corrupt.

- **RDES7: Receive descriptor Word7**

The table below describes the fields that have a different meaning for RDES7 when the receive descriptor is closed and time stamping is enabled.

|      |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31   | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| RTSH |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rW   | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW |
| 15   | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| RTSH |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rW   | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW |

Bits 31:0 **RTSH**: Receive frame time stamp high

The DMA updates this field with the 32 most significant bits of the time stamp captured for the corresponding receive frame. The DMA updates this field only for the last descriptor of the receive frame indicated by last descriptor status bit (RDES0[8]).

When this field and RDES7's RTSL field show all ones, the time stamp must be treated as corrupt.

### 38.6.9 DMA interrupts

Interrupts can be generated as a result of various events. The ETH\_DMASR register contains all the bits that might cause an interrupt. The ETH\_DMAIER register contains an enable bit for each of the events that can cause an interrupt.

There are two groups of interrupts, Normal and Abnormal, as described in the ETH\_DMASR register. Interrupts are cleared by writing a 1 to the corresponding bit position. When all the enabled interrupts within a group are cleared, the corresponding summary bit is cleared. If the MAC core is the cause for assertion of the interrupt, then any of the TSTS or PMTS bits in the ETH\_DMASR register is set high.

Interrupts are not queued and if the interrupt event occurs before the driver has responded to it, no additional interrupts are generated. For example, the Receive Interrupt bit (ETH\_DMASR register [6]) indicates that one or more frames were transferred to the STM32F75xxx and STM32F74xxx buffer. The driver must scan all descriptors, from the last recorded position to the first one owned by the DMA.

An interrupt is generated only once for simultaneous, multiple events. The driver must scan the ETH\_DMASR register for the cause of the interrupt. The interrupt is not generated again unless a new interrupting event occurs, after the driver has cleared the appropriate bit in the

ETH\_DMASR register. For example, the controller generates a Receive interrupt (ETH\_DMASR register[6]) and the driver begins reading the ETH\_DMASR register. Next, receive buffer unavailable (ETH\_DMASR register[7]) occurs. The driver clears the Receive interrupt. Even then, a new interrupt is generated, due to the active or pending Receive buffer unavailable interrupt.

Figure 523. Interrupt scheme

## 38.7 Ethernet interrupts

The Ethernet controller has two interrupt vectors: one dedicated to normal Ethernet operations and the other, used only for the Ethernet wakeup event (with wakeup frame or Magic Packet detection) when it is mapped on EXTI line19.

The first Ethernet vector is reserved for interrupts generated by the MAC and the DMA as listed in the [MAC interrupts](#) and [DMA interrupts](#) sections.

The second vector is reserved for interrupts generated by the PMT on wakeup events. The mapping of a wakeup event on EXTI line19 causes the STM32F75xxx and STM32F74xxx to exit the low-power mode, and generates an interrupt.

When an Ethernet wakeup event mapped on EXTI Line19 occurs and the MAC PMT interrupt is enabled and the EXTI Line19 interrupt, with detection on rising edge, is also enabled, both interrupts are generated.

A watchdog timer (see ETH\_DMARSWTR register) is given for flexible control of the RS bit (ETH\_DMASR register). When this watchdog timer is programmed with a non-zero value, it

gets activated as soon as the RxDMA completes a transfer of a received frame to system memory without asserting the Receive Status because it is not enabled in the corresponding Receive descriptor (RDES1[31]). When this timer runs out as per the programmed value, the RS bit is set and the interrupt is asserted if the corresponding RIE is enabled in the ETH\_DMAIER register. This timer is disabled before it runs out, when a frame is transferred to memory and the RS is set because it is enabled for that descriptor.

**Note:** *Reading the PMT control and status register automatically clears the Wakeup Frame Received and Magic Packet Received PMT interrupt flags. However, since the registers for these flags are in the CLK\_RX domain, there may be a significant delay before this update is visible by the firmware. The delay is especially long when the RX clock is slow (in 10 Mbit mode) and when the AHB bus is high-frequency. Since interrupt requests from the PMT to the CPU are based on the same registers in the CLK\_RX domain, the CPU may spuriously call the interrupt routine a second time even after reading PMT\_CSR. Thus, it may be necessary that the firmware polls the Wakeup Frame Received and Magic Packet Received bits and exits the interrupt service routine only when they are found to be at '0'.*

## 38.8 Ethernet register descriptions

The peripheral registers can be accessed by bytes (8-bit), half-words (16-bit) or words (32-bit).

### 38.8.1 MAC register description

#### Ethernet MAC configuration register (ETH\_MACCR)

Address offset: 0x0000

Reset value: 0x0000 8000

The MAC configuration register is the operation mode register of the MAC. It establishes receive and transmit operating modes.

|      |      |      |      |      |      |      |      |      |    |      |      |     |    |      |      |

Bits 31:26 Reserved, must be kept at reset value.

Bit 25 **CSTF**: CRC stripping for Type frames

When set, the last 4 bytes (FCS) of all frames of Ether type (type field greater than 0x0600) will be stripped and dropped before forwarding the frame to the application.

Bit 24 Reserved, must be kept at reset value.

Bit 23 **WD**: Watchdog disable

When this bit is set, the MAC disables the watchdog timer on the receiver, and can receive frames of up to 16 384 bytes.

When this bit is reset, the MAC allows no more than 2 048 bytes of the frame being received and cuts off any bytes received after that.

Bit 22 **JD**: Jabber disable

When this bit is set, the MAC disables the jabber timer on the transmitter, and can transfer frames of up to 16 384 bytes.

When this bit is reset, the MAC cuts off the transmitter if the application sends out more than 2 048 bytes of data during transmission.

Bits 21:20 Reserved, must be kept at reset value.

Bits 19:17 **IFG**: Interframe gap

These bits control the minimum interframe gap between frames during transmission.

000: 96 bit times

001: 88 bit times

010: 80 bit times

....

111: 40 bit times

*Note: In Half-duplex mode, the minimum IFG can be configured for 64 bit times (IFG = 100) only. Lower values are not considered.*

Bit 16 **CSD**: Carrier sense disable

When set high, this bit makes the MAC transmitter ignore the MII CRS signal during frame transmission in Half-duplex mode. No error is generated due to Loss of Carrier or No Carrier during such transmission.

When this bit is low, the MAC transmitter generates such errors due to Carrier Sense and even aborts the transmissions.

Bit 15 Reserved, must be kept at reset value.

Bit 14 **FES**: Fast Ethernet speed

Indicates the speed in Fast Ethernet (MII) mode:

0: 10 Mbit/s

1: 100 Mbit/s

Bit 13 **ROD**: Receive own disable

When this bit is set, the MAC disables the reception of frames in Half-duplex mode.

When this bit is reset, the MAC receives all packets that are given by the PHY while transmitting.

This bit is not applicable if the MAC is operating in Full-duplex mode.

Bit 12 **LM**: Loopback mode

When this bit is set, the MAC operates in loopback mode at the MII. The MII receive clock input (RX\_CLK) is required for the loopback to work properly, as the transmit clock is not looped-back internally.

Bit 11 **DM**: Duplex mode

When this bit is set, the MAC operates in a Full-duplex mode where it can transmit and receive simultaneously.

Bit 10 **IPCO**: IPv4 checksum offload

When set, this bit enables IPv4 checksum checking for received frame payloads' TCP/UDP/ICMP headers. When this bit is reset, the checksum offload function in the receiver is disabled and the corresponding PCE and IP HCE status bits (see [Table 277](#)) are always cleared.

**Bit 9 RD:** Retry disable

When this bit is set, the MAC attempts only 1 transmission. When a collision occurs on the MII, the MAC ignores the current frame transmission and reports a Frame Abort with excessive collision error in the transmit frame status.

When this bit is reset, the MAC attempts retries based on the settings of BL.

*Note: This bit is applicable only in the Half-duplex mode.*

**Bit 8** Reserved, must be kept at reset value.**Bit 7 APCS:** Automatic pad/CRC stripping

When this bit is set, the MAC strips the Pad/FCS field on incoming frames only if the length's field value is less than or equal to 1 500 bytes. All received frames with length field greater than or equal to 1 501 bytes are passed on to the application without stripping the Pad/FCS field.

When this bit is reset, the MAC passes all incoming frames unmodified.

**Bits 6:5 BL:** Back-off limit

The Back-off limit determines the random integer number ( $r$ ) of slot time delays (4 096 bit times for 1000 Mbit/s and 512 bit times for 10/100 Mbit/s) the MAC waits before rescheduling a transmission attempt during retries after a collision.

*Note: This bit is applicable only to Half-duplex mode.*

00:  $k = \min(n, 10)$

01:  $k = \min(n, 8)$

10:  $k = \min(n, 4)$

11:  $k = \min(n, 1)$ ,

where  $n$  = retransmission attempt. The random integer  $r$  takes the value in the range  $0 \leq r \leq 2^k$

**Bit 4 DC:** Deferral check

When this bit is set, the deferral check function is enabled in the MAC. The MAC issues a Frame Abort status, along with the excessive deferral error bit set in the transmit frame status when the transmit state machine is deferred for more than 24 288 bit times in 10/100-Mbit/s mode. Deferral begins when the transmitter is ready to transmit, but is prevented because of an active CRS (carrier sense) signal on the MII. Deferral time is not cumulative. If the transmitter defers for 10 000 bit times, then transmits, collides, backs off, and then has to defer again after completion of back-off, the deferral timer resets to 0 and restarts.

When this bit is reset, the deferral check function is disabled and the MAC defers until the CRS signal goes inactive. This bit is applicable only in Half-duplex mode.

**Bit 3 TE:** Transmitter enable

When this bit is set, the transmit state machine of the MAC is enabled for transmission on the MII. When this bit is reset, the MAC transmit state machine is disabled after the completion of the transmission of the current frame, and does not transmit any further frames.

**Bit 2 RE:** Receiver enable

When this bit is set, the receiver state machine of the MAC is enabled for receiving frames from the MII. When this bit is reset, the MAC receive state machine is disabled after the completion of the reception of the current frame, and will not receive any further frames from the MII.

**Bits 1:0** Reserved, must be kept at reset value.

**Ethernet MAC frame filter register (ETH\_MACFFR)**

Address offset: 0x0004

Reset value: 0x0000 0000

The MAC frame filter register contains the filter controls for receiving frames. Some of the controls from this register go to the address check block of the MAC, which performs the first level of address filtering. The second level of filtering is performed on the incoming frame, based on other controls such as pass bad frames and pass control frames.

|      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|
| 31   | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21   | 20   | 19   | 18   | 17   | 16   |

|      |      |      |      |      | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   |

**Bit 31 RA:** Receive all

When this bit is set, the MAC receiver passes all received frames on to the application, irrespective of whether they have passed the address filter. The result of the SA/DA filtering is updated (pass or fail) in the corresponding bits in the receive status word. When this bit is reset, the MAC receiver passes on to the application only those frames that have passed the SA/DA address filter.

Bits 30:11 Reserved, must be kept at reset value.

**Bit 10 HPF:** Hash or perfect filter

When this bit is set and if the HM or HU bit is set, the address filter passes frames that match either the perfect filtering or the hash filtering.

When this bit is cleared and if the HU or HM bit is set, only frames that match the Hash filter are passed.

**Bit 9 SAF:** Source address filter

The MAC core compares the SA field of the received frames with the values programmed in the enabled SA registers. If the comparison matches, then the SAMatch bit in the RxStatus word is set high. When this bit is set high and the SA filter fails, the MAC drops the frame. When this bit is reset, the MAC core forwards the received frame to the application. It also forwards the updated SA Match bit in RxStatus depending on the SA address comparison.

**Bit 8 SAIF:** Source address inverse filtering

When this bit is set, the address check block operates in inverse filtering mode for the SA address comparison. The frames whose SA matches the SA registers are marked as failing the SA address filter.

When this bit is reset, frames whose SA does not match the SA registers are marked as failing the SA address filter.

**Bits 7:6 PCF:** Pass control frames

These bits control the forwarding of all control frames (including unicast and multicast PAUSE frames). Note that the processing of PAUSE control frames depends only on RFCE in Flow Control Register[2].

00: MAC prevents all control frames from reaching the application

01: MAC forwards all control frames to application except Pause control frames

10: MAC forwards all control frames to application even if they fail the address filter

11: MAC forwards control frames that pass the address filter.

These bits control the forwarding of all control frames (including unicast and multicast PAUSE frames). Note that the processing of PAUSE control frames depends only on RFCE in Flow Control Register[2].

00 or 01: MAC prevents all control frames from reaching the application

10: MAC forwards all control frames to application even if they fail the address filter

11: MAC forwards control frames that pass the address filter.

**Bit 5 BFD:** Broadcast frames disable

When this bit is set, the address filters filter all incoming broadcast frames.

When this bit is reset, the address filters pass all received broadcast frames.

**Bit 4 PAM:** Pass all multicast

When set, this bit indicates that all received frames with a multicast destination address (first bit in the destination address field is '1') are passed.

When reset, filtering of multicast frame depends on the HM bit.

**Bit 3 DAIF:** Destination address inverse filtering

When this bit is set, the address check block operates in inverse filtering mode for the DA address comparison for both unicast and multicast frames.

When reset, normal filtering of frames is performed.

**Bit 2 HM:** Hash multicast

When set, MAC performs destination address filtering of received multicast frames according to the hash table.

When reset, the MAC performs a perfect destination address filtering for multicast frames, that is, it compares the DA field with the values programmed in DA registers.

**Bit 1 HU:** Hash unicast

When set, MAC performs destination address filtering of unicast frames according to the hash table.

When reset, the MAC performs a perfect destination address filtering for unicast frames, that is, it compares the DA field with the values programmed in DA registers.

**Bit 0 PM:** Promiscuous mode

When this bit is set, the address filters pass all incoming frames regardless of their destination or source address. The SA/DA filter fails status bits in the receive status word are always cleared when PM is set.

**Ethernet MAC hash table high register (ETH\_MACHTHR)**

Address offset: 0x0008

Reset value: 0x0000 0000

The 64-bit Hash table is used for group address filtering. For hash filtering, the contents of the destination address in the incoming frame are passed through the CRC logic, and the upper 6 bits in the CRC register are used to index the contents of the Hash table. This CRC is a 32-bit value coded by the following polynomial (for more details refer to [Section 38.5.3](#):

*MAC frame reception):*

$$G(x) = x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x + 1$$

The most significant bit determines the register to be used (hash table high/hash table low), and the other 5 bits determine which bit within the register. A hash value of 0b0 0000 selects bit 0 in the selected register, and a value of 0b1 1111 selects bit 31 in the selected register.

For example, if the DA of the incoming frame is received as 0x1F52 419C B6AF (0x1F is the first byte received on the MII interface), then the internally calculated 6-bit Hash value is 0x2C and the HTH register bit[12] is checked for filtering. If the DA of the incoming frame is received as 0xA00A 9800 0045, then the calculated 6-bit Hash value is 0x07 and the HTL register bit[7] is checked for filtering.

If the corresponding bit value in the register is 1, the frame is accepted. Otherwise, it is rejected. If the PAM (pass all multicast) bit is set in the ETH\_MACFFR register, then all multicast frames are accepted regardless of the multicast hash values.

The Hash table high register contains the higher 32 bits of the multicast Hash table.

|     |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

| HTH |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw  | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 31:0 **HTH**: Hash table high

This field contains the upper 32 bits of Hash table.

**Ethernet MAC hash table low register (ETH\_MACHTLR)**

Address offset: 0x000C

Reset value: 0x0000 0000

The Hash table low register contains the lower 32 bits of the multi-cast Hash table.

|     |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

Bits 31:0 **HTL**: Hash table low

This field contains the lower 32 bits of the Hash table.

**Ethernet MAC MII address register (ETH\_MACMIAR)**

Address offset: 0x0010

Reset value: 0x0000 0000

The MII address register controls the management cycles to the external PHY through the management interface.

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:11 **PA**: PHY address

This field tells which of the 32 possible PHY devices are being accessed.

Bits 10:6 **MR**: MII register

These bits select the desired MII register in the selected PHY device.

Bit 5 Reserved, must be kept at reset value.

Bits 4:2 **CR**: Clock range

The CR clock range selection determines the HCLK frequency and is used to decide the frequency of the MDC clock:

Selection HCLK MDC Clock

000 60-100 MHz HCLK/42

001 100-150 MHz HCLK/62

010 20-35 MHz HCLK/16

011 35-60 MHz HCLK/26

100 150-216 MHz HCLK/102

101, 110, 111 Reserved

Bit 1 **MW**: MII write

When set, this bit tells the PHY that this will be a Write operation using the MII Data register. If this bit is not set, this will be a Read operation, placing the data in the MII Data register.

Bit 0 **MB**: MII busy

This bit should read a logic 0 before writing to ETH\_MACMIIAR and ETH\_MACMIIDR. This bit must also be reset to 0 during a Write to ETH\_MACMIIAR. During a PHY register access, this bit is set to 0b1 by the application to indicate that a read or write access is in progress. ETH\_MACMIIDR (MII Data) should be kept valid until this bit is cleared by the MAC during a PHY Write operation. The ETH\_MACMIIDR is invalid until this bit is cleared by the MAC during a PHY Read operation. The ETH\_MACMIIAR (MII Address) should not be written to until this bit is cleared.

## Ethernet MAC MII data register (ETH\_MACMIIDR)

Address offset: 0x0014

Reset value: 0x0000 0000

The MAC MII Data register stores write data to be written to the PHY register located at the address specified in ETH\_MACMIIAR. ETH\_MACMIIDR also stores read data from the PHY register located at the address specified by ETH\_MACMIIAR.

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **MD**: MII data

This contains the 16-bit data value read from the PHY after a Management Read operation, or the 16-bit data value to be written to the PHY before a Management Write operation.

### Ethernet MAC flow control register (ETH\_MACFCR)

Address offset: 0x0018

Reset value: 0x0000 0000

The Flow control register controls the generation and reception of the control (Pause Command) frames by the MAC. A write to a register with the Busy bit set to '1' causes the MAC to generate a pause control frame. The fields of the control frame are selected as specified in the 802.3x specification, and the Pause Time value from this register is used in the Pause Time field of the control frame. The Busy bit remains set until the control frame is transferred onto the cable. The Host must make sure that the Busy bit is cleared before writing to the register.

|      |      |      |      |      |      |      |      |      |      |     |    |      |      |      |          |

| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | ZQPD | Res. | PLT |    | UPFD | RFCE | TFCE | FCB/BPA  |
|      |      |      |      |      |      |      |      | rw   |      | rw  | rw | rw   | rw   | rw   | rc_w1/rw |

Bits 31:16 **PT**: Pause time

This field holds the value to be used in the Pause Time field in the transmit control frame. If the Pause Time bits is configured to be double-synchronized to the MII clock domain, then consecutive write operations to this register should be performed only after at least 4 clock cycles in the destination clock domain.

Bits 15:8 Reserved, must be kept at reset value.

Bit 7 **ZQPD**: Zero-quanta pause disable

When set, this bit disables the automatic generation of Zero-quanta pause control frames on the deassertion of the flow-control signal from the FIFO layer.

When this bit is reset, normal operation with automatic Zero-quanta pause control frame generation is enabled.

Bit 6 Reserved, must be kept at reset value.

**Bits 5:4 PLT:** Pause low threshold

This field configures the threshold of the Pause timer at which the Pause frame is automatically retransmitted. The threshold values should always be less than the Pause Time configured in bits[31:16]. For example, if PT = 100H (256 slot-times), and PLT = 01, then a second PAUSE frame is automatically transmitted if initiated at 228 (256 – 28) slot-times after the first PAUSE frame is transmitted.

**Selection Threshold**

- 00 Pause time minus 4 slot times
- 01 Pause time minus 28 slot times
- 10 Pause time minus 144 slot times
- 11 Pause time minus 256 slot times

Slot time is defined as time taken to transmit 512 bits (64 bytes) on the MII interface.

**Bit 3 UPFD:** Unicast pause frame detect

When this bit is set, the MAC detects the Pause frames with the station's unicast address specified in the ETH\_MACA0HR and ETH\_MACA0LR registers, in addition to detecting Pause frames with the unique multicast address.

When this bit is reset, the MAC detects only a Pause frame with the unique multicast address specified in the 802.3x standard.

**Bit 2 RFCE:** Receive flow control enable

When this bit is set, the MAC decodes the received Pause frame and disables its transmitter for a specified (Pause Time) time.

When this bit is reset, the decode function of the Pause frame is disabled.

**Bit 1 TFCE:** Transmit flow control enable

In Full-duplex mode, when this bit is set, the MAC enables the flow control operation to transmit Pause frames. When this bit is reset, the flow control operation in the MAC is disabled, and the MAC does not transmit any Pause frames.

In Half-duplex mode, when this bit is set, the MAC enables the back-pressure operation. When this bit is reset, the back pressure feature is disabled.

**Bit 0 FCB/BPA:** Flow control busy/back pressure activate

This bit initiates a Pause Control frame in Full-duplex mode and activates the back pressure function in Half-duplex mode if TFCE bit is set.

In Full-duplex mode, this bit should be read as 0 before writing to the Flow control register. To initiate a Pause control frame, the Application must set this bit to 1. During a transfer of the Control frame, this bit continues to be set to signify that a frame transmission is in progress. After completion of the Pause control frame transmission, the MAC resets this bit to 0. The Flow control register should not be written to until this bit is cleared.

In Half-duplex mode, when this bit is set (and TFCE is set), back pressure is asserted by the MAC core. During back pressure, when the MAC receives a new frame, the transmitter starts sending a JAM pattern resulting in a collision. When the MAC is configured to Full-duplex mode, the BPA is automatically disabled.

**Ethernet MAC VLAN tag register (ETH\_MACVLANTR)**

Address offset: 0x001C

Reset value: 0x0000 0000

The VLAN tag register contains the IEEE 802.1Q VLAN Tag to identify the VLAN frames. The MAC compares the 13<sup>th</sup> and 14<sup>th</sup> bytes of the receiving frame (Length/Type) with 0x8100, and the following 2 bytes are compared with the VLAN tag; if a match occurs, the received VLAN bit in the receive frame status is set. The legal length of the frame is increased from 1518 bytes to 1522 bytes.

|        |      |      |      |      |      |      |      |      |      |      |      |      |      |      |        |
|--------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|--------|
| 31     | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21   | 20   | 19   | 18   | 17   | 16     |
| Res.   | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | VLANTC |
|        |      |      |      |      |      |      |      |      |      |      |      |      |      |      | rw     |
| 15     | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0      |
| VLANTI |      |      |      |      |      |      |      |      |      |      |      |      |      |      |        |
| rw     | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw     |

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **VLANTC**: 12-bit VLAN tag comparison

When this bit is set, a 12-bit VLAN identifier, rather than the complete 16-bit VLAN tag, is used for comparison and filtering. Bits[11:0] of the VLAN tag are compared with the corresponding field in the received VLAN-tagged frame.

When this bit is reset, all 16 bits of the received VLAN frame's fifteenth and sixteenth bytes are used for comparison.

Bits 15:0 **VLANTI**: VLAN tag identifier (for receive frames)

This contains the 802.1Q VLAN tag to identify VLAN frames, and is compared to the fifteenth and sixteenth bytes of the frames being received for VLAN frames. Bits[15:13] are the user priority, Bit[12] is the canonical format indicator (CFI) and bits[11:0] are the VLAN tag's VLAN identifier (VID) field. When the VLANTC bit is set, only the VID (bits[11:0]) is used for comparison.

If VLANTI (VLANTI[11:0] if VLANTC is set) is all zeros, the MAC does not check the fifteenth and sixteenth bytes for VLAN tag comparison, and declares all frames with a Type field value of 0x8100 as VLAN frames.

### Ethernet MAC remote wakeup frame filter register (ETH\_MACRWUFFR)

Address offset: 0x0028

Reset value: 0x0000 0000

This is the address through which the remote wakeup frame filter registers are written/read by the application. The Wakeup frame filter register is actually a pointer to eight (not transparent) such wakeup frame filter registers. Eight sequential write operations to this address with the offset (0x0028) will write all wakeup frame filter registers. Eight sequential read operations from this address with the offset (0x0028) will read all wakeup frame filter registers. This register contains the higher 16 bits of the 7<sup>th</sup> MAC address. Refer to [Remote wakeup frame filter register](#) section for additional information.

Figure 524. Ethernet MAC remote wakeup frame filter register (ETH\_MACRWUFR)

|                          |                    |                  |                 |                  |                   |                  |                 |                  |

Bit 31 **WFFRPR**: Wakeup frame filter register pointer reset

When set, it resets the Remote wakeup frame filter register pointer to 0b000. It is automatically cleared after 1 clock cycle.

Bits 30:10 Reserved, must be kept at reset value.

Bit 9 **GU**: Global unicast

When set, it enables any unicast packet filtered by the MAC (DAF) address recognition to be a wakeup frame.

Bits 8:7 Reserved, must be kept at reset value.

Bit 6 **WFR**: Wakeup frame received

When set, this bit indicates the power management event was generated due to reception of a wakeup frame. This bit is cleared by a read into this register.

Bit 5 **MPR**: Magic packet received

When set, this bit indicates the power management event was generated by the reception of a Magic Packet. This bit is cleared by a read into this register.

Bits 4:3 Reserved, must be kept at reset value.

Bit 2 **WFE**: Wakeup frame enable

When set, this bit enables the generation of a power management event due to wakeup frame reception.

Bit 1 **MPE**: Magic Packet enable

When set, this bit enables the generation of a power management event due to Magic Packet reception.

Bit 0 **PD**: Power down

When this bit is set, all received frames will be dropped. This bit is cleared automatically when a magic packet or wakeup frame is received, and Power-down mode is disabled. Frames received after this bit is cleared are forwarded to the application. This bit must only be set when either the Magic Packet Enable or Wakeup Frame Enable bit is set high.

**Ethernet MAC debug register (ETH\_MACDBG)**

Address offset: 0x0034

Reset value: 0x0000 0000

This debug register gives the status of all the main modules of the transmit and receive data paths and the FIFOs. An all-zero status indicates that the MAC core is in Idle state (and FIFOs are empty) and no activity is going on in the data paths.

Bits 31:26 Reserved, must be kept at reset value.

Bit 25 **TFF**: Tx FIFO full

When high, it indicates that the Tx FIFO is full and hence no more frames will be accepted for transmission.

Bit 24 **TFNE**: Tx FIFO not empty

When high, it indicates that the TxFIFO is not empty and has some data left for transmission.

Bit 23 Reserved, must be kept at reset value.

Bit 22 **TFWA**: Tx FIFO write active

When high, it indicates that the TxFIFO write controller is active and transferring data to the TxFIFO.

Bits 21:20 **TFRS**: Tx FIFO read status

This indicates the state of the TxFIFO read controller:

00: Idle state

01: Read state (transferring data to the MAC transmitter)

10: Waiting for TxStatus from MAC transmitter

11: Writing the received TxStatus or flushing the TxFIFO

Bit 19 **MTP**: MAC transmitter in pause

When high, it indicates that the MAC transmitter is in Pause condition (in full-duplex mode only) and hence will not schedule any frame for transmission

Bits 18:17 **MTFCS**: MAC transmit frame controller status

This indicates the state of the MAC transmit frame controller:

00: Idle

01: Waiting for Status of previous frame or IFG/backoff period to be over

10: Generating and transmitting a Pause control frame (in full duplex mode)

11: Transferring input frame for transmission

Bit 16 **MMTEA**: MAC MII transmit engine active

When high, it indicates that the MAC MII transmit engine is actively transmitting data and that it is not in the Idle state.

Bits 15:10 Reserved, must be kept at reset value.

Bits 9:8 **RFLL**: Rx FIFO fill level

This gives the status of the Rx FIFO fill-level:

00: RxFIFO empty

01: RxFIFO fill-level below flow-control de-activate threshold

10: RxFIFO fill-level above flow-control activate threshold

11: RxFIFO full

Bit 7 Reserved, must be kept at reset value.

Bits 6:5 **RFRCS**: Rx FIFO read controller status

It gives the state of the Rx FIFO read controller:

00: IDLE state

01: Reading frame data

10: Reading frame status (or time-stamp)

11: Flushing the frame data and status

Bit 4 **RFWRA**: Rx FIFO write controller active

When high, it indicates that the Rx FIFO write controller is active and transferring a received frame to the FIFO.

Bit 3 Reserved, must be kept at reset value.

Bits 2:1 **MSFRWCS**: MAC small FIFO read / write controllers status

When high, these bits indicate the respective active state of the small FIFO read and write controllers of the MAC receive frame controller module.

Bit 0 **MMRPEA**: MAC MII receive protocol engine active

When high, it indicates that the MAC MII receive protocol engine is actively receiving data and is not in the Idle state.

### Ethernet MAC interrupt status register (ETH\_MACSR)

Address offset: 0x0038

Reset value: 0x0000 0000

The ETH\_MACSR register contents identify the events in the MAC that can generate an interrupt.

| 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6     | 5     | 4    | 3    | 2    | 1    | 0    |
|------|------|------|------|------|------|------|------|------|-------|-------|------|------|------|------|------|

|      |      |      |      |      |      | rc_r |      |      | r     | r     | r    | r    |      |      |      |

Bits 15:10 Reserved, must be kept at reset value.

Bit 9 **TSTS**: Time stamp trigger status

This bit is set high when the system time value equals or exceeds the value specified in the Target time high and low registers. This bit is cleared by reading the ETH\_PTPTSSR register.

Bits 8:7 Reserved, must be kept at reset value.

Bit 6 **MMCTS**: MMC transmit status

This bit is set high whenever an interrupt is generated in the ETH\_MMCTIR Register. This bit is cleared when all the bits in this interrupt register (ETH\_MMCTIR) are cleared.

Bit 5 **MMCRS**: MMC receive status

This bit is set high whenever an interrupt is generated in the ETH\_MMCRIR register. This bit is cleared when all the bits in this interrupt register (ETH\_MMCRIR) are cleared.

Bit 4 **MMCS**: MMC status

This bit is set high whenever any of bits 6:5 is set high. It is cleared only when both bits are low.

Bit 3 **PMTS**: PMT status

This bit is set whenever a Magic packet or Wake-on-LAN frame is received in Power-down mode (See bits 5 and 6 in the ETH\_MACPMTCSR register [Ethernet MAC PMT control and status register \(ETH\\_MACPMTCSR\)](#)). This bit is cleared when both bits[6:5], of this last register, are cleared due to a read operation to the ETH\_MACPMTCSR register.

Bits 2:0 Reserved, must be kept at reset value.

### Ethernet MAC interrupt mask register (ETH\_MACIMR)

Address offset: 0x003C

Reset value: 0x0000 0000

The ETH\_MACIMR register bits make it possible to mask the interrupt signal due to the corresponding event in the ETH\_MACCSR register.

| 15   | 14   | 13   | 12   | 11   | 10   | 9     | 8    | 7    | 6    | 5    | 4    | 3     | 2    | 1    | 0    |
|------|------|------|------|------|------|-------|------|------|------|------|------|-------|------|------|------|

|      |      |      |      |      |      | rw    |      |      |      |      |      | rw    |      |      |      |

Bits 15:10 Reserved, must be kept at reset value.

Bit 9 **TSTIM**: Time stamp trigger interrupt mask

When set, this bit disables the time stamp interrupt generation.

Bits 8:4 Reserved, must be kept at reset value.

Bit 3 **PMTIM**: PMT interrupt mask

When set, this bit disables the assertion of the interrupt signal due to the setting of the PMT Status bit in ETH\_MACCSR.

Bits 2:0 Reserved, must be kept at reset value.

### Ethernet MAC address 0 high register (ETH\_MACA0HR)

Address offset: 0x0040

Reset value: 0x8000 FFFF

The MAC address 0 high register holds the upper 16 bits of the 6-byte first MAC address of the station. Note that the first DA byte that is received on the MII interface corresponds to the LS Byte (bits [7:0]) of the MAC address low register. For example, if 0x1122 3344 5566 is received (0x11 is the first byte) on the MII as the destination address, then the MAC address 0 register [47:0] is compared with 0x6655 4433 2211.

Bit 31 **MO**: Always 1.

Bits 30:16 Reserved, must be kept at reset value.

Bits 15:0 **MACA0H**: MAC address0 high [47:32]

This field contains the upper 16 bits (47:32) of the 6-byte MAC address0. This is used by the MAC for filtering for received frames and for inserting the MAC address in the transmit flow control (Pause) frames.

### Ethernet MAC address 0 low register (ETH\_MACA0LR)

Address offset: 0x0044

Reset value: 0xFFFF FFFF

The MAC address 0 low register holds the lower 32 bits of the 6-byte first MAC address of the station.

|        |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

Bits 31:0 **MACA0L**: MAC address0 low [31:0]

This field contains the lower 32 bits of the 6-byte MAC address0. This is used by the MAC for filtering for received frames and for inserting the MAC address in the transmit flow control (Pause) frames.

### Ethernet MAC address 1 high register (ETH\_MACA1HR)

Address offset: 0x0048

Reset value: 0x0000 FFFF

The MAC address 1 high register holds the upper 16 bits of the 6-byte second MAC address of the station.

|        |    |     |    |    |    |    |    |     |     |     |     |     |     |     |     |

| rW     | rW | rW  | rW | rW | rW | rW | rW | rW  | rW  | rW  | rW  | rW  | rW  | rW  | rW  |

Bit 31 **AE**: Address enable

When this bit is set, the address filters use the MAC address1 for perfect filtering. When this bit is cleared, the address filters ignore the address for filtering.

Bit 30 **SA**: Source address

When this bit is set, the MAC address1[47:0] is used for comparison with the SA fields of the received frame.

When this bit is cleared, the MAC address1[47:0] is used for comparison with the DA fields of the received frame.

Bits 29:24 **MBC**: Mask byte control

These bits are mask control bits for comparison of each of the MAC address1 bytes. When they are set high, the MAC core does not compare the corresponding byte of received DA/SA with the contents of the MAC address1 registers. Each bit controls the masking of the bytes as follows:

- Bit 29: ETH\_MACA1HR [15:8]
- Bit 28: ETH\_MACA1HR [7:0]
- Bit 27: ETH\_MACA1LR [31:24]
- ...
- Bit 24: ETH\_MACA1LR [7:0]

Bits 23:16 Reserved, must be kept at reset value.

Bits 15:0 **MACA1H**: MAC address1 high [47:32]

This field contains the upper 16 bits (47:32) of the 6-byte second MAC address.

### Ethernet MAC address1 low register (ETH\_MACA1LR)

Address offset: 0x004C

Reset value: 0xFFFF FFFF

The MAC address 1 low register holds the lower 32 bits of the 6-byte second MAC address of the station.

|        |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

| rw     | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 31:0 **MACA1L**: MAC address1 low [31:0]

This field contains the lower 32 bits of the 6-byte MAC address1. The content of this field is undefined until loaded by the application after the initialization process.

### Ethernet MAC address 2 high register (ETH\_MACA2HR)

Address offset: 0x0050

Reset value: 0x0000 FFFF

The MAC address 2 high register holds the upper 16 bits of the 6-byte second MAC address of the station.

|        |    |     |    |    |    |    |    |      |      |      |      |      |      |      |      |

| rw     | rw | rw  | rw | rw | rw | rw | rw | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   |

Bit 31 **AE**: Address enable

When this bit is set, the address filters use the MAC address2 for perfect filtering. When reset, the address filters ignore the address for filtering.

Bit 30 **SA**: Source address

When this bit is set, the MAC address 2 [47:0] is used for comparison with the SA fields of the received frame.

When this bit is reset, the MAC address 2 [47:0] is used for comparison with the DA fields of the received frame.

Bits 29:24 **MBC**: Mask byte control

These bits are mask control bits for comparison of each of the MAC address2 bytes. When set high, the MAC core does not compare the corresponding byte of received DA/SA with the contents of the MAC address 2 registers. Each bit controls the masking of the bytes as follows:

- Bit 29: ETH\_MACA2HR [15:8]
- Bit 28: ETH\_MACA2HR [7:0]
- Bit 27: ETH\_MACA2LR [31:24]
- ...
- Bit 24: ETH\_MACA2LR [7:0]

Bits 23:16 Reserved, must be kept at reset value.

Bits 15:0 **MACA2H**: MAC address2 high [47:32]

This field contains the upper 16 bits (47:32) of the 6-byte MAC address2.

### Ethernet MAC address 2 low register (ETH\_MACA2LR)

Address offset: 0x0054

Reset value: 0xFFFF FFFF

The MAC address 2 low register holds the lower 32 bits of the 6-byte second MAC address of the station.

|        |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

| rw     | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 31:0 **MACA2L**: MAC address2 low [31:0]

This field contains the lower 32 bits of the 6-byte second MAC address2. The content of this field is undefined until loaded by the application after the initialization process.

**Ethernet MAC address 3 high register (ETH\_MACA3HR)**

Address offset: 0x0058

Reset value: 0x0000 FFFF

The MAC address 3 high register holds the upper 16 bits of the 6-byte second MAC address of the station.

|        |    |     |    |    |    |    |    |    |          |          |          |          |          |          |          |

| MACA3H |    |     |    |    |    |    |    |    |          |          |          |          |          |          |          |
| rw     | rw | rw  | rw | rw | rw | rw | rw | rw | rw       | rw       | rw       | rw       | rw       | rw       | rw       |

Bit 31 **AE**: Address enable

When this bit is set, the address filters use the MAC address3 for perfect filtering. When this bit is cleared, the address filters ignore the address for filtering.

Bit 30 **SA**: Source address

When this bit is set, the MAC address 3 [47:0] is used for comparison with the SA fields of the received frame.

When this bit is cleared, the MAC address 3[47:0] is used for comparison with the DA fields of the received frame.

Bits 29:24 **MBC**: Mask byte control

These bits are mask control bits for comparison of each of the MAC address3 bytes. When these bits are set high, the MAC core does not compare the corresponding byte of received DA/SA with the contents of the MAC address 3 registers. Each bit controls the masking of the bytes as follows:

- Bit 29: ETH\_MACA3HR [15:8]
- Bit 28: ETH\_MACA3HR [7:0]
- Bit 27: ETH\_MACA3LR [31:24]
- ...
- Bit 24: ETH\_MACA3LR [7:0]

Bits 23:16 **Reserved**, must be kept at reset value.

Bits 15:0 **MACA3H**: MAC address3 high [47:32]

This field contains the upper 16 bits (47:32) of the 6-byte MAC address3.

**Ethernet MAC address 3 low register (ETH\_MACA3LR)**

Address offset: 0x005C

Reset value: 0xFFFF FFFF

The MAC address 3 low register holds the lower 32 bits of the 6-byte second MAC address of the station.

|        |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

Bits 31:0 **MACA3L**: MAC address3 low [31:0]  
This field contains the lower 32 bits of the 6-byte second MAC address3. The content of this field is undefined until loaded by the application after the initialization process.

## 38.8.2 MMC register description

### Ethernet MMC control register (ETH\_MMCCR)

Address offset: 0x0100

Reset value: 0x0000 0000

The Ethernet MMC Control register establishes the operating mode of the management counters.

|      |      |      |      |      |      |      |      |      |      |       |      |      |      |      |      |

Bits 31:6 Reserved, must be kept at reset value.

#### **MCFHP:** MMC counter Full-Half preset

When MCFHP is low and bit4 is set, all MMC counters get preset to almost-half value. All

Bit 5 frame-counters get preset to 0x7FFF\_FFF0 (half - 16)

When MCFHP is high and bit4 is set, all MMC counters get preset to almost-full value. All frame-counters get preset to 0xFFFF\_FFF0 (full - 16)

#### **MCP:** MMC counter preset

When set, all counters will be initialized or preset to almost full or almost half as per

Bit 4 Bit5 above. This bit will be cleared automatically after 1 clock cycle. This bit along with bit5 is useful for debugging and testing the assertion of interrupts due to MMC counter becoming half-full or full.

Bit 3 **MCF:** MMC counter freeze

When set, this bit freezes all the MMC counters to their current value. (None of the MMC counters are updated due to any transmitted or received frame until this bit is cleared to 0. If any MMC counter is read with the Reset on Read bit set, then that counter is also cleared in this mode.)

Bit 2 **ROR:** Reset on read

When this bit is set, the MMC counters is reset to zero after read (self-clearing after reset). The counters are cleared when the least significant byte lane (bits [7:0]) is read.

Bit 1 **CSR:** Counter stop rollover

When this bit is set, the counter does not roll over to zero after it reaches the maximum value.

Bit 0 **CR:** Counter reset

When it is set, all counters are reset. This bit is cleared automatically after 1 clock cycle.

### Ethernet MMC receive interrupt register (ETH\_MMCRIR)

Address offset: 0x0104

Reset value: 0x0000 0000

The Ethernet MMC receive interrupt register maintains the interrupts generated when receive statistic counters reach half their maximum values. (MSB of the counter is set.) It is

a 32-bit wide register. An interrupt bit is cleared when the respective MMC counter that caused the interrupt is read. The least significant byte lane (bits [7:0]) of the respective counter must be read in order to clear the interrupt bit.

Bits 31:18 Reserved, must be kept at reset value.

Bit 17 **RGUFS**: Received Good Unicast Frames Status

This bit is set when the received, good unicast frames, counter reaches half the maximum value.

Bits 16:7 Reserved, must be kept at reset value.

Bit 6 **RFAES**: Received frames alignment error status

This bit is set when the received frames, with alignment error, counter reaches half the maximum value.

Bit 5 **RFCES**: Received frames CRC error status

This bit is set when the received frames, with CRC error, counter reaches half the maximum value.

Bits 4:0 Reserved, must be kept at reset value.

### Ethernet MMC transmit interrupt register (ETH\_MMCTIR)

Address offset: 0x0108

Reset value: 0x0000 0000

The Ethernet MMC transmit Interrupt register maintains the interrupts generated when transmit statistic counters reach half their maximum values. (MSB of the counter is set.) It is a 32-bit wide register. An interrupt bit is cleared when the respective MMC counter that caused the interrupt is read. The least significant byte lane (bits [7:0]) of the respective counter must be read in order to clear the interrupt bit.

Bits 31:22 Reserved, must be kept at reset value.

Bit 21 **TGFS**: Transmitted good frames status

This bit is set when the transmitted, good frames, counter reaches half the maximum value.

Bits 20:16 Reserved, must be kept at reset value.

Bit 15 **TGFMSCS**: Transmitted good frames more single collision status

This bit is set when the transmitted, good frames after more than a single collision, counter reaches half the maximum value.

Bit 14 **TGFSCS**: Transmitted good frames single collision status

This bit is set when the transmitted, good frames after a single collision, counter reaches half the maximum value.

Bits 13:0 Reserved, must be kept at reset value.

### Ethernet MMC receive interrupt mask register (ETH\_MMCRIMR)

Address offset: 0x010C

Reset value: 0x0000 0000

The Ethernet MMC receive interrupt mask register maintains the masks for interrupts generated when the receive statistic counters reach half their maximum value. (MSB of the counter is set.) It is a 32-bit wide register.

|      |      |      |      |      |      |      |      |      |       |      |      |      |      |       |      |

Bits 31:18 Reserved, must be kept at reset value.

Bit 17 **RGUFM**: Received good unicast frames mask

Setting this bit masks the interrupt when the received, good unicast frames, counter reaches half the maximum value.

Bits 16:7 Reserved, must be kept at reset value.

Bit 6 **RFAEM**: Received frames alignment error mask

Setting this bit masks the interrupt when the received frames, with alignment error, counter reaches half the maximum value.

Bit 5 **RFCM**: Received frame CRC error mask

Setting this bit masks the interrupt when the received frames, with CRC error, counter reaches half the maximum value.

Bits 4:0 Reserved, must be kept at reset value.

### Ethernet MMC transmit interrupt mask register (ETH\_MMCTIMR)

Address offset: 0x0110

Reset value: 0x0000 0000

The Ethernet MMC transmit interrupt mask register maintains the masks for interrupts generated when the transmit statistic counters reach half their maximum value. (MSB of the counter is set). It is a 32-bit wide register.

Bits 31:22 Reserved, must be kept at reset value.

Bit 21 **TGFM**: Transmitted good frames mask

Setting this bit masks the interrupt when the transmitted, good frames, counter reaches half the maximum value.

Bits 20:16 Reserved, must be kept at reset value.

Bit 15 **TGFMSCM**: Transmitted good frames more single collision mask

Setting this bit masks the interrupt when the transmitted good frames after more than a single collision counter reaches half the maximum value.

Bit 14 **TGFSCM**: Transmitted good frames single collision mask

Setting this bit masks the interrupt when the transmitted good frames after a single collision counter reaches half the maximum value.

Bits 13:0 Reserved, must be kept at reset value.

### Ethernet MMC transmitted good frames after a single collision counter register (ETH\_MMCTGFSCCR)

Address offset: 0x014C

Reset value: 0x0000 0000

This register contains the number of successfully transmitted frames after a single collision in Half-duplex mode.

|        |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

Bits 31:0 **RFAEC**: Received frames alignment error counter  
Received frames with alignment error counter

### MMC received good unicast frames counter register (ETH\_MMCRGUFCR)

Address offset: 0x01C4

Reset value: 0x0000 0000

This register contains the number of good unicast frames received.

|       |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

Bits 31:0 **RGUFC**: Received good unicast frames counter

## 38.8.3 IEEE 1588 time stamp registers

This section describes the registers required to support precision network clock synchronization functions under the IEEE 1588 standard.

### Ethernet PTP time stamp control register (ETH\_PTPTSCR)

Address offset: 0x0700

Reset value: 0x0000 2000

This register controls the time stamp generation and update logic.

|             |        |               |               |                |               |       |             |      |      |        |       |       |              |       |     |

Bits 31:19 Reserved, must be kept at reset value.

- Bit 18 **TSPFFMAE**: Time stamp PTP frame filtering MAC address enable  
When set, this bit uses the MAC address (except for MAC address 0) to filter the PTP frames when PTP is sent directly over Ethernet.

Bits 17:16 **TSCNT**: Time stamp clock node type  
The following are the available types of clock node:  
00: Ordinary clock  
01: Boundary clock  
10: End-to-end transparent clock  
11: Peer-to-peer transparent clock

- Bit 15 **TSSMRME**: Time stamp snapshot for message relevant to master enable  
When this bit is set, the snapshot is taken for messages relevant to the master node only.  
When this bit is cleared the snapshot is taken for messages relevant to the slave node only.  
This is valid only for the ordinary clock and boundary clock nodes.

- Bit 14 **TSSEME**: Time stamp snapshot for event message enable  
When this bit is set, the time stamp snapshot is taken for event messages only (SYNC, Delay\_Req, Pdelay\_Req or Pdelay\_Resp). When this bit is cleared the snapshot is taken for all other messages except for Announce, Management and Signaling.

- Bit 13 **TSSIPV4FE**: Time stamp snapshot for IPv4 frames enable  
When this bit is set, the time stamp snapshot is taken for IPv4 frames.

- Bit 12 **TSSIPV6FE**: Time stamp snapshot for IPv6 frames enable  
When this bit is set, the time stamp snapshot is taken for IPv6 frames.

- Bit 11 **TSSPTPOEFE**: Time stamp snapshot for PTP over ethernet frames enable  
When this bit is set, the time stamp snapshot is taken for frames which have PTP messages in Ethernet frames (PTP over Ethernet) also. By default snapshots are taken for UDP-IP Ethernet PTP packets.

- Bit 10 **TSTPPSV2E**: Time stamp PTP packet snooping for version2 format enable  
When this bit is set, the PTP packets are snooped using the version 2 format. When the bit is cleared, the PTP packets are snooped using the version 1 format.

*Note: IEEE 1588 Version 1 and Version 2 formats as indicated in IEEE standard 1588-2008 (Revision of IEEE STD. 1588-2002).*

- Bit 9 **TSSSR**: Time stamp subsecond rollover: digital or binary rollover control  
When this bit is set, the Time stamp low register rolls over when the subsecond counter reaches the value 0x3B9A C9FF (999 999 999 in decimal), and increments the Time Stamp (high) seconds.  
When this bit is cleared, the rollover value of the subsecond register reaches 0x7FFF FFFF. The subsecond increment has to be programmed correctly depending on the PTP's reference clock frequency and this bit value.

- Bit 8 **TSSARFE**: Time stamp snapshot for all received frames enable  
When this bit is set, the time stamp snapshot is enabled for all frames received by the core.

Bits 7:6 Reserved, must be kept at reset value.

- Bit 5 **TSARU**: Time stamp addend register update  
When this bit is set, the Time stamp addend register's contents are updated to the PTP block for fine correction. This bit is cleared when the update is complete. This register bit must be read as zero before you can set it.

Bit 4 **TSITE**: Time stamp interrupt trigger enable

When this bit is set, a time stamp interrupt is generated when the system time becomes greater than the value written in the Target time register. When the Time stamp trigger interrupt is generated, this bit is cleared.

Bit 3 **TSSTU**: Time stamp system time update

When this bit is set, the system time is updated (added to or subtracted from) with the value specified in the Time stamp high update and Time stamp low update registers. Both the TSSTU and TSSTI bits must be read as zero before you can set this bit. Once the update is completed in hardware, this bit is cleared.

Bit 2 **TSSTI**: Time stamp system time initialize

When this bit is set, the system time is initialized (overwritten) with the value specified in the Time stamp high update and Time stamp low update registers. This bit must be read as zero before you can set it. When initialization is complete, this bit is cleared.

Bit 1 **TSFCU**: Time stamp fine or coarse update

When set, this bit indicates that the system time stamp is to be updated using the Fine Update method. When cleared, it indicates the system time stamp is to be updated using the Coarse method.

Bit 0 **TSE**: Time stamp enable

When this bit is set, time stamping is enabled for transmit and receive frames. When this bit is cleared, the time stamp function is suspended and time stamps are not added for transmit and receive frames. Because the maintained system time is suspended, you must always initialize the time stamp feature (system time) after setting this bit high.

The table below indicates the messages for which a snapshot is taken depending on the clock, enable master and enable snapshot for event message register settings.

**Table 281. Time stamp snapshot dependency on registers bits**

| <b>TSCNT</b><br>(bits 17:16) | <b>TSSMRME</b><br>(bit 15) <sup>(1)</sup> | <b>TSSEME</b><br>(bit 14) | <b>Messages for which snapshots are taken</b>                   |
|------------------------------|-------------------------------------------|---------------------------|-----------------------------------------------------------------|
| 00 or 01                     | X <sup>(2)</sup>                          | 0                         | SYNC, Follow_Up, Delay_Req, Delay_Resp                          |
| 00 or 01                     | 1                                         | 1                         | Delay_Req                                                       |
| 00 or 01                     | 0                                         | 1                         | SYNC                                                            |
| 10                           | N/A                                       | 0                         | SYNC, Follow_Up, Delay_Req, Delay_Resp                          |
| 10                           | N/A                                       | 1                         | SYNC, Follow_Up                                                 |
| 11                           | N/A                                       | 0                         | SYNC, Follow_Up, Delay_Req, Delay_Resp, Pdelay_Req, Pdelay_Resp |
| 11                           | N/A                                       | 1                         | SYNC, Pdelay_Req, Pdelay_Resp                                   |

1. N/A = not applicable.

2. X = don't care.

### **Ethernet PTP subsecond increment register (ETH\_PTPSSIR)**

Address offset: 0x0704

Reset value: 0x0000 0000

This register contains the 8-bit value by which the subsecond register is incremented. In Coarse update mode (TSFCU bit in ETH\_PTPTSCR), the value in this register is added to

the system time every clock cycle of HCLK. In Fine update mode, the value in this register is added to the system time whenever the accumulator gets an overflow.

|      |      |      |      |      |      |      |      |       |      |      |      |      |      |      |      |
|------|------|------|------|------|------|------|------|-------|------|------|------|------|------|------|------|
| 31   | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23    | 22   | 21   | 20   | 19   | 18   | 17   | 16   |

|      |      |      |      |      |      |      |      |       |      |      |      |      |      |      |      |
| 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7     | 6    | 5    | 4    | 3    | 2    | 1    | 0    |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | STSSI |      |      |      |      |      |      |      |
|      |      |      |      |      |      |      |      | rw    | rw   | rw   | rw   | rw   | rw   | rw   | rw   |

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **STSSI**: System time subsecond increment

The value programmed in this register is added to the contents of the subsecond value of the system time in every update.

For example, to achieve 20 ns accuracy, the value is:  $20 / 0.467 = \sim 43$  (or 0x2A).

### Ethernet PTP time stamp high register (ETH\_PTPTSHR)

Address offset: 0x0708

Reset value: 0x0000 0000

This register contains the most significant (higher) 32 time bits. This read-only register contains the seconds system time value. The Time stamp high register, along with Time stamp low register, indicates the current value of the system time maintained by the MAC. Though it is updated on a continuous basis.

|     |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|-----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31  | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| STS |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| r   | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  |
| 15  | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| STS |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| r   | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  |

Bits 31:0 **STS**: System time second

The value in this field indicates the current value in seconds of the System Time maintained by the core.

### Ethernet PTP time stamp low register (ETH\_PTPTSLR)

Address offset: 0x070C

Reset value: 0x0000 0000

This register contains the least significant (lower) 32 time bits. This read-only register contains the subsecond system time value.

|       |      |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|-------|------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31    | 30   | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| STPNS | STSS |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| r     | r    | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  |
| 15    | 14   | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| STSS  |      |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| r     | r    | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  |

Bit 31 **STPNS**: System time positive or negative sign

This bit indicates a positive or negative time value. When set, the bit indicates that time representation is negative. When cleared, it indicates that time representation is positive. Because the system time should always be positive, this bit is normally zero.

Bits 30:0 **STSS**: System time subseconds

The value in this field has the subsecond time representation, with 0.46 ns accuracy.

### Ethernet PTP time stamp high update register (ETH\_PTPTSHUR)

Address offset: 0x0710

Reset value: 0x0000 0000

This register contains the most significant (higher) 32 bits of the time to be written to, added to, or subtracted from the System Time value. The Time stamp high update register, along with the Time stamp update low register, initializes or updates the system time maintained by the MAC. You have to write both of these registers before setting the TSSTI or TSSTU bits in the Time stamp control register.

|      |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31   | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| TSUS |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw   | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |
| 15   | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| TSUS |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw   | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 31:0 **TSUS**: Time stamp update second

The value in this field indicates the time, in seconds, to be initialized or added to the system time.

**Ethernet PTP time stamp low update register (ETH\_PTPTSLUR)**

Address offset: 0x0714

Reset value: 0x0000 0000

This register contains the least significant (lower) 32 bits of the time to be written to, added to, or subtracted from the System Time value.

|        |       |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|--------|-------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31     | 30    | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| TSUPNS | TSUSS |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw     | rw    | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |
| 15     | 14    | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| TSUSS  |       |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw     | rw    | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bit 31 **TSUPNS**: Time stamp update positive or negative sign

This bit indicates positive or negative time value. When set, the bit indicates that time representation is negative. When cleared, it indicates that time representation is positive. When TSSTI is set (system time initialization) this bit should be zero. If this bit is set when TSSTU is set, the value in the Time stamp update registers is subtracted from the system time. Otherwise it is added to the system time.

Bits 30:0 **TSUSS**: Time stamp update subseconds

The value in this field indicates the subsecond time to be initialized or added to the system time. This value has an accuracy of 0.46 ns (in other words, a value of 0x0000\_0001 is 0.46 ns).

**Ethernet PTP time stamp addend register (ETH\_PTPTSAR)**

Address offset: 0x0718

Reset value: 0x0000 0000

This register is used by the software to readjust the clock frequency linearly to match the master clock frequency. This register value is used only when the system time is configured for Fine update mode (TSFCU bit in ETH\_PTPTSCR). This register content is added to a 32-bit accumulator in every clock cycle and the system time is updated whenever the accumulator overflows.

|     |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|-----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31  | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| TSA |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

| rw  | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 31:0 **TSA**: Time stamp addend

This register indicates the 32-bit time value to be added to the Accumulator register to achieve time synchronization.

**Ethernet PTP target time high register (ETH\_PTPTTHR)**

Address offset: 0x071C

Reset value: 0x0000 0000

This register contains the higher 32 bits of time to be compared with the system time for interrupt event generation. The Target time high register, along with Target time low register, is used to schedule an interrupt event (TSARU bit in ETH\_PTPTSCR) when the system time exceeds the value programmed in these registers.

|      |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31   | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| TTSH |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

| rw   | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 31:0 **TTSH**: Target time stamp high

This register stores the time in seconds. When the time stamp value matches or exceeds both Target time stamp registers, the MAC, if enabled, generates an interrupt.

**Ethernet PTP target time low register (ETH\_PTPTTLR)**

Address offset: 0x0720

Reset value: 0x0000 0000

This register contains the lower 32 bits of time to be compared with the system time for interrupt event generation.

|      |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

| rw   | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 31:0 **TTSL**: Target time stamp low

This register stores the time in (signed) nanoseconds. When the value of the time stamp matches or exceeds both Target time stamp registers, the MAC, if enabled, generates an interrupt.

**Ethernet PTP time stamp status register (ETH\_PTPTSSR)**

Address offset: 0x0728

Reset value: 0x0000 0000

This register contains the time stamp status register.

|      |      |      |      |      |      |      |      |      |      |      |      |      |      |       |      |

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **TSTTR**: Time stamp target time reached

When set, this bit indicates that the value of the system time is greater than or equal to the value specified in the Target time high and low registers. This bit is cleared when the ETH\_PTPTSSR register is read.

Bit 0 **TSSO**: Time stamp second overflow

When set, this bit indicates that the second value of the time stamp has overflowed beyond 0xFFFF FFFF.

### Ethernet PTP PPS control register (ETH\_PTPTPPSCR)

Address offset: 0x072C

Reset value: 0x0000 0000

This register controls the frequency of the PPS output.

|      |      |      |      |      |      |      |      |      |      |      |      |         |      |      |      |

| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res.    | Res. | Res. | Res. |
|      |      |      |      |      |      |      |      |      |      |      |      |         |      |      |      |
| 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5    | 4    | 3       | 2    | 1    | 0    |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | PPSFREQ |      |      |      |
|      |      |      |      |      |      |      |      |      |      |      |      | rw      | rw   | rw   | rw   |

Bits 31:4 Reserved, must be kept at reset value.

Bits 3:0 **PPSFREQ**: PPS frequency selection

The PPS output frequency is set to  $2^{\text{PPSFREQ}}$  Hz.

0000: 1 Hz with a pulse width of 125 ms for binary rollover and, of 100 ms for digital rollover

0001: 2 Hz with 50% duty cycle for binary rollover (digital rollover not recommended)

0010: 4 Hz with 50% duty cycle for binary rollover (digital rollover not recommended)

0011: 8 Hz with 50% duty cycle for binary rollover (digital rollover not recommended)

0100: 16 Hz with 50% duty cycle for binary rollover (digital rollover not recommended)

...

1111: 32768 Hz with 50% duty cycle for binary rollover (digital rollover not recommended)

*Note: If digital rollover is used (TSSSR=1, bit 9 in ETH\_PTPTSSR), it is recommended not to use the PPS output with a frequency other than 1 Hz. Otherwise, with digital rollover, the PPS output has irregular waveforms at higher frequencies (though its average frequency will always be correct during any one-second window).*

### 38.8.4 DMA register description

This section defines the bits for each DMA register. Non-32 bit accesses are allowed as long as the address is word-aligned.

#### Ethernet DMA bus mode register (ETH\_DMABMR)

Address offset: 0x1000

Reset value: 0x0002 0101

The bus mode register establishes the bus operating modes for the DMA.

|      |      |      |      |      |    |     |     |      |     |    |    |    |    |    |    |
|------|------|------|------|------|----|-----|-----|------|-----|----|----|----|----|----|----|
| 31   | 30   | 29   | 28   | 27   | 26 | 25  | 24  | 23   | 22  | 21 | 20 | 19 | 18 | 17 | 16 |
| Res. | Res. | Res. | Res. | Res. | MB | AAB | FPM | USP  | RDP |    |    |    |    |    | FB |
|      |      |      |      |      | rw | rw  | rw  | rw   | rw  | rw | rw | rw | rw | rw | rw |
| 15   | 14   | 13   | 12   | 11   | 10 | 9   | 8   | 7    | 6   | 5  | 4  | 3  | 2  | 1  | 0  |
| PM   |      | PBL  |      |      |    |     |     | EDFE | DSL |    |    |    |    | DA | SR |
| rw   | rw   | rw   | rw   | rw   | rw | rw  | rw  | rw   | rw  | rw | rw | rw | rw | rw | rs |

Bits 31:27 Reserved, must be kept at reset value.

**Bit 26 MB:** Mixed burst

When this bit is set high and the FB bit is low, the AHB master interface starts all bursts of a length greater than 16 with INCR (undefined burst). When this bit is cleared, it reverts to fixed burst transfers (INCRx and SINGLE) for burst lengths of 16 and below.

**Bit 25 AAB:** Address-aligned beats

When this bit is set high and the FB bit equals 1, the AHB interface generates all bursts aligned to the start address LS bits. If the FB bit equals 0, the first burst (accessing the data buffer's start address) is not aligned, but subsequent bursts are aligned to the address.

**Bit 24 FPM:** 4xPBL mode

When set high, this bit multiplies the PBL value programmed (bits [22:17] and bits [13:8]) four times. Thus the DMA transfers data in a maximum of 4, 8, 16, 32, 64 and 128 beats depending on the PBL value.

**Bit 23 USP:** Use separate PBL

When set high, it configures the RxDMA to use the value configured in bits [22:17] as PBL while the PBL value in bits [13:8] is applicable to TxDMA operations only. When this bit is cleared, the PBL value in bits [13:8] is applicable for both DMA engines.

**Bits 22:17 RDP:** Rx DMA PBL

These bits indicate the maximum number of beats to be transferred in one RxDMA transaction. This is the maximum value that is used in a single block read/write operation. The RxDMA always attempts to burst as specified in RDP each time it starts a burst transfer on the host bus. RDP can be programmed with permissible values of 1, 2, 4, 8, 16, and 32. Any other value results in undefined behavior. These bits are valid and applicable only when USP is set high.

**Bit 16 FB:** Fixed burst

This bit controls whether the AHB Master interface performs fixed burst transfers or not. When set, the AHB uses only SINGLE, INCR4, INCR8 or INCR16 during start of normal burst transfers. When reset, the AHB uses SINGLE and INCR burst transfer operations.

Bits 15:14 **PM**: Rx Tx priority ratio

**RxDMA requests are given priority over TxDMA requests in the following ratio:**

00: 1:1

01: 2:1

10: 3:1

11: 4:1

This is valid only when the DA bit is cleared.

Bits 13:8 **PBL**: Programmable burst length

These bits indicate the maximum number of beats to be transferred in one DMA transaction. This is the maximum value that is used in a single block read/write operation. The DMA always attempts to burst as specified in PBL each time it starts a burst transfer on the host bus. PBL can be programmed with permissible values of 1, 2, 4, 8, 16, and 32. Any other value results in undefined behavior. When USP is set, this PBL value is applicable for TxDMA transactions only.

The PBL values have the following limitations:

- The maximum number of beats (PBL) possible is limited by the size of the Tx FIFO and Rx FIFO.
- The FIFO has a constraint that the maximum beat supported is half the depth of the FIFO.
- If the PBL is common for both transmit and receive DMA, the minimum Rx FIFO and Tx FIFO depths must be considered.
- Do not program out-of-range PBL values, because the system may not behave properly.

Bit 7 **EDFE**: Enhanced descriptor format enable

When this bit is set, the enhanced descriptor format is enabled and the descriptor size is increased to 32 bytes (8 DWORDS). This is required when time stamping is activated (TSE=1, ETH\_PTPTSCR bit 0) or if IPv4 checksum offload is activated (IPCO=1, ETH\_MACCCR bit 10).

Bits 6:2 **DSL**: Descriptor skip length

This bit specifies the number of words to skip between two unchained descriptors. The address skipping starts from the end of current descriptor to the start of next descriptor. When DSL value equals zero, the descriptor table is taken as contiguous by the DMA, in Ring mode.

Bit 1 **DA**: DMA Arbitration

0: Round-robin with Rx:Tx priority given in bits [15:14]

1: Rx has priority over Tx

Bit 0 **SR**: Software reset

When this bit is set, the MAC DMA controller resets all MAC Subsystem internal registers and logic. It is cleared automatically after the reset operation has completed in all of the core clock domains. Read a 0 value in this bit before re-programming any register of the core.

## Ethernet DMA transmit poll demand register (ETH\_DMATPDR)

Address offset: 0x1004

Reset value: 0x0000 0000

This register is used by the application to instruct the DMA to poll the transmit descriptor list. The transmit poll demand register enables the Transmit DMA to check whether or not the current descriptor is owned by DMA. The Transmit Poll Demand command is given to wake up the TxDMA if it is in Suspend mode. The TxDMA can go into Suspend mode due to an underflow error in a transmitted frame or due to the unavailability of descriptors owned by

transmit DMA. User can issue this command anytime and the TxDMA resets it once it starts re-fetching the current descriptor from host memory.

|       |       |       |       |       |       |       |       |       |       |       |       |       |       |       |       |
|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|
| 31    | 30    | 29    | 28    | 27    | 26    | 25    | 24    | 23    | 22    | 21    | 20    | 19    | 18    | 17    | 16    |
| TPD   |       |       |       |       |       |       |       |       |       |       |       |       |       |       |       |
| rw_wt | rw_wt | rw_wt | rw_wt | rw_wt | rw_wt | rw_wt | rw_wt | rw_wt | rw_wt | rw_wt | rw_wt | rw_wt | rw_wt | rw_wt | rw_wt |
| 15    | 14    | 13    | 12    | 11    | 10    | 9     | 8     | 7     | 6     | 5     | 4     | 3     | 2     | 1     | 0     |
| TPD   |       |       |       |       |       |       |       |       |       |       |       |       |       |       |       |
| rw_wt | rw_wt | rw_wt | rw_wt | rw_wt | rw_wt | rw_wt | rw_wt | rw_wt | rw_wt | rw_wt | rw_wt | rw_wt | rw_wt | rw_wt | rw_wt |

Bits 31:0 TPD: Transmit poll demand

When these bits are written with any value, the DMA reads the current descriptor pointed to by the ETH\_DMACHTDR register. If that descriptor is not available (owned by Host), transmission returns to the Suspend state and ETH\_DMASR register bit 2 is asserted. If the descriptor is available, transmission resumes.

### ETHERNET DMA receive poll demand register (ETH\_DMARPDR)

Address offset: 0x1008

Reset value: 0x0000 0000

This register is used by the application to instruct the DMA to poll the receive descriptor list. The Receive poll demand register enables the receive DMA to check for new descriptors. This command is given to wake up the RxDMA from Suspend state. The RxDMA can go into Suspend state only due to the unavailability of descriptors owned by it.

|       |       |       |       |       |       |       |       |       |       |       |       |       |       |       |       |
|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|
| 31    | 30    | 29    | 28    | 27    | 26    | 25    | 24    | 23    | 22    | 21    | 20    | 19    | 18    | 17    | 16    |
| RPD   |       |       |       |       |       |       |       |       |       |       |       |       |       |       |       |
| rw_wt | rw_wt | rw_wt | rw_wt | rw_wt | rw_wt | rw_wt | rw_wt | rw_wt | rw_wt | rw_wt | rw_wt | rw_wt | rw_wt | rw_wt | rw_wt |
| 15    | 14    | 13    | 12    | 11    | 10    | 9     | 8     | 7     | 6     | 5     | 4     | 3     | 2     | 1     | 0     |
| RPD   |       |       |       |       |       |       |       |       |       |       |       |       |       |       |       |
| rw_wt | rw_wt | rw_wt | rw_wt | rw_wt | rw_wt | rw_wt | rw_wt | rw_wt | rw_wt | rw_wt | rw_wt | rw_wt | rw_wt | rw_wt | rw_wt |

Bits 31:0 RPD: Receive poll demand

When these bits are written with any value, the DMA reads the current descriptor pointed to by the ETH\_DMACHRDR register. If that descriptor is not available (owned by Host), reception returns to the Suspended state and ETH\_DMASR register bit 7 is not asserted. If the descriptor is available, the Receive DMA returns to active state.

### Ethernet DMA receive descriptor list address register (ETH\_DMARDLAR)

Address offset: 0x100C

Reset value: 0x0000 0000

The Receive descriptor list address register points to the start of the receive descriptor list. The descriptor list resides in the STM32F75xxx and STM32F74xxx physical memory space and must be word-aligned. The DMA internally converts it to bus-width aligned address by making the corresponding LS bits low. Writing to the ETH\_DMARDLAR register is permitted only when reception is stopped. When stopped, the ETH\_DMARDLAR register must be written to before the receive Start command is given.

|     |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|-----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31  | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| SRL |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw  | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |
| 15  | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| SRL |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw  | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 31:0 **SRL**: Start of receive list

This field contains the base address of the first descriptor in the receive descriptor list. The LSB bits [1/2/3:0] for 32/64/128-bit bus width) are internally ignored and taken as all-zero by the DMA. Hence these LSB bits are read only.

### Ethernet DMA transmit descriptor list address register (ETH\_DMATDLAR)

Address offset: 0x1010

Reset value: 0x0000 0000

The Transmit descriptor list address register points to the start of the transmit descriptor list. The descriptor list resides in the STM32F75xxx and STM32F74xxx physical memory space and must be word-aligned. The DMA internally converts it to bus-width-aligned address by taking the corresponding LSB to low. Writing to the ETH\_DMATDLAR register is permitted only when transmission has stopped. Once transmission has stopped, the ETH\_DMATDLAR register can be written before the transmission Start command is given.

|     |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|-----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31  | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| STL |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw  | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |
| 15  | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| STL |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw  | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 31:0 **STL**: Start of transmit list

This field contains the base address of the first descriptor in the transmit descriptor list. The LSB bits [1/2/3:0] for 32/64/128-bit bus width) are internally ignored and taken as all-zero by the DMA. Hence these LSB bits are read-only.

### Ethernet DMA status register (ETH\_DMASR)

Address offset: 0x1014

Reset value: 0x0000 0000

The Status register contains all the status bits that the DMA reports to the application. The ETH\_DMASR register is usually read by the software driver during an interrupt service routine or polling. Most of the fields in this register cause the host to be interrupted. The ETH\_DMASR register bits are not cleared when read. Writing 1 to (unreserved) bits in ETH\_DMASR register[16:0] clears them and writing 0 has no effect. Each field (bits [16:0]) can be masked by masking the appropriate bit in the ETH\_DMAIER register.

Bits 31:30 Reserved, must be kept at reset value.

Bit 29 **TSTS**: Time stamp trigger status

This bit indicates an interrupt event in the MAC core's Time stamp generator block. The software must read the MAC core's status register, clearing its source (bit 9), to reset this bit to 0. When this bit is high an interrupt is generated if enabled.

Bit 28 **PMTS**: PMT status

This bit indicates an event in the MAC core's PMT. The software must read the corresponding registers in the MAC core to get the exact cause of interrupt and clear its source to reset this bit to 0. The interrupt is generated when this bit is high if enabled.

Bit 27 **MMCS**: MMC status

This bit reflects an event in the MMC of the MAC core. The software must read the corresponding registers in the MAC core to get the exact cause of interrupt and clear the source of interrupt to make this bit as 0. The interrupt is generated when this bit is high if enabled.

Bit 26 Reserved, must be kept at reset value.

Bits 25:23 **EBS**: Error bits status

These bits indicate the type of error that caused a bus error (error response on the AHB interface). Valid only with the fatal bus error bit (ETH\_DMASR register [13]) set. This field does not generate an interrupt.

Bit 23 1 Error during data transfer by TxDMA

0 Error during data transfer by RxDMA

Bit 24 1 Error during read transfer

0 Error during write transfer

Bit 25 1 Error during descriptor access

0 Error during data buffer access

Bits 22:20 **TPS**: Transmit process state

These bits indicate the Transmit DMA FSM state. This field does not generate an interrupt.

000: Stopped; Reset or Stop Transmit Command issued

001: Running; Fetching transmit transfer descriptor

010: Running; Waiting for status

011: Running; Reading Data from host memory buffer and queuing it to transmit buffer (Tx FIFO)

100, 101: Reserved for future use

110: Suspended; Transmit descriptor unavailable or transmit buffer underflow

111: Running; Closing transmit descriptor

Bits 19:17 **RPS**: Receive process state

These bits indicate the Receive DMA FSM state. This field does not generate an interrupt.

000: Stopped: Reset or Stop Receive Command issued

001: Running: Fetching receive transfer descriptor

010: Reserved for future use

011: Running: Waiting for receive packet

100: Suspended: Receive descriptor unavailable

101: Running: Closing receive descriptor

110: Reserved for future use

111: Running: Transferring the receive packet data from receive buffer to host memory

Bit 16 **NIS**: Normal interrupt summary

The normal interrupt summary bit value is the logical OR of the following when the corresponding interrupt bits are enabled in the ETH\_DMAIER register:

- ETH\_DMASR [0]: Transmit interrupt
- ETH\_DMASR [2]: Transmit buffer unavailable
- ETH\_DMASR [6]: Receive interrupt
- ETH\_DMASR [14]: Early receive interrupt

Only unmasked bits affect the normal interrupt summary bit.

This is a sticky bit and it must be cleared (by writing a 1 to this bit) each time a corresponding bit that causes NIS to be set is cleared.

Bit 15 **AIS**: Abnormal interrupt summary

The abnormal interrupt summary bit value is the logical OR of the following when the corresponding interrupt bits are enabled in the ETH\_DMAIER register:

- ETH\_DMASR [1]: Transmit process stopped
- ETH\_DMASR [3]: Transmit jabber timeout
- ETH\_DMASR [4]: Receive FIFO overflow
- ETH\_DMASR [5]: Transmit underflow
- ETH\_DMASR [7]: Receive buffer unavailable
- ETH\_DMASR [8]: Receive process stopped
- ETH\_DMASR [9]: Receive watchdog timeout
- ETH\_DMASR [10]: Early transmit interrupt
- ETH\_DMASR [13]: Fatal bus error

Only unmasked bits affect the abnormal interrupt summary bit.

This is a sticky bit and it must be cleared each time a corresponding bit that causes AIS to be set is cleared.

Bit 14 **ERS**: Early receive status

This bit indicates that the DMA had filled the first data buffer of the packet. Receive Interrupt ETH\_DMASR [6] automatically clears this bit.

Bit 13 **FBES**: Fatal bus error status

This bit indicates that a bus error occurred, as detailed in [25:23]. When this bit is set, the corresponding DMA engine disables all its bus accesses.

Bits 12:11 Reserved, must be kept at reset value.

Bit 10 **ETS**: Early transmit status

This bit indicates that the frame to be transmitted was fully transferred to the Transmit FIFO.

Bit 9 **RWTS**: Receive watchdog timeout status

This bit is asserted when a frame with a length greater than 2 048 bytes is received.

Bit 8 **RPSS**: Receive process stopped status

This bit is asserted when the receive process enters the Stopped state.

Bit 7 **RBUS**: Receive buffer unavailable status

This bit indicates that the next descriptor in the receive list is owned by the host and cannot be acquired by the DMA. Receive process is suspended. To resume processing receive descriptors, the host should change the ownership of the descriptor and issue a Receive Poll Demand command. If no Receive Poll Demand is issued, receive process resumes when the next recognized incoming frame is received. ETH\_DMASR [7] is set only when the previous receive descriptor was owned by the DMA.

Bit 6 **RS**: Receive status

This bit indicates the completion of the frame reception. Specific frame status information has been posted in the descriptor. Reception remains in the Running state.

Bit 5 **TUS**: Transmit underflow status

This bit indicates that the transmit buffer had an underflow during frame transmission. Transmission is suspended and an underflow error TDES0[1] is set.

Bit 4 **ROS**: Receive overflow status

This bit indicates that the receive buffer had an overflow during frame reception. If the partial frame is transferred to the application, the overflow status is set in RDES0[11].

Bit 3 **TJTS**: Transmit jabber timeout status

This bit indicates that the transmit jabber timer expired, meaning that the transmitter had been excessively active. The transmission process is aborted and placed in the Stopped state. This causes the transmit jabber timeout TDES0[14] flag to be asserted.

Bit 2 **TBUS**: Transmit buffer unavailable status

This bit indicates that the next descriptor in the transmit list is owned by the host and cannot be acquired by the DMA. Transmission is suspended. Bits [22:20] explain the transmit process state transitions. To resume processing transmit descriptors, the host should change the ownership of the bit of the descriptor and then issue a Transmit Poll Demand command.

Bit 1 **TPSS**: Transmit process stopped status

This bit is set when the transmission is stopped.

Bit 0 **TS**: Transmit status

This bit indicates that frame transmission is finished and TDES1[31] is set in the first descriptor.

### Ethernet DMA operation mode register (ETH\_DMAOMR)

Address offset: 0x1018

Reset value: 0x0000 0000

The operation mode register establishes the Transmit and Receive operating modes and commands. The ETH\_DMAOMR register should be the last CSR to be written as part of DMA initialization.

|      |      |      |      |      |        |      |      |      |      |     |     |      |      |      |     |

| rw   | rw   | rw   |      |      |        |      |      | rw   | rw   |     | rw  | rw   | rw   | rw   |     |

Bits 31:27 Reserved, must be kept at reset value.

Bit 26 **DTCEFD**: Dropping of TCP/IP checksum error frames disable

When this bit is set, the core does not drop frames that only have errors detected by the receive checksum offload engine. Such frames do not have any errors (including FCS error) in the Ethernet frame received by the MAC but have errors in the encapsulated payload only. When this bit is cleared, all error frames are dropped if the FEF bit is reset.

Bit 25 **RSF**: Receive store and forward

When this bit is set, a frame is read from the Rx FIFO after the complete frame has been written to it, ignoring RTC bits. When this bit is cleared, the Rx FIFO operates in Cut-through mode, subject to the threshold specified by the RTC bits.

Bit 24 **DFRF**: Disable flushing of received frames

When this bit is set, the RxDMA does not flush any frames due to the unavailability of receive descriptors/buffers as it does normally when this bit is cleared. (See [Receive process suspended on page 1587](#))

Bits 23:22 Reserved, must be kept at reset value.

Bit 21 **TSF**: Transmit store and forward

When this bit is set, transmission starts when a full frame resides in the Transmit FIFO. When this bit is set, the TTC values specified by the ETH\_DMAOMR register bits [16:14] are ignored.

When this bit is cleared, the TTC values specified by the ETH\_DMAOMR register bits [16:14] are taken into account.

This bit should be changed only when transmission is stopped.

Bit 20 **FTF**: Flush transmit FIFO

When this bit is set, the transmit FIFO controller logic is reset to its default values and thus all data in the Tx FIFO are lost/flushed. This bit is cleared internally when the flushing operation is complete. The Operation mode register should not be written to until this bit is cleared.

Bits 19:17 Reserved, must be kept at reset value.

Bits 16:14 **TTC**: Transmit threshold control

These three bits control the threshold level of the Transmit FIFO. Transmission starts when the frame size within the Transmit FIFO is larger than the threshold. In addition, full frames with a length less than the threshold are also transmitted. These bits are used only when the TSF bit (Bit 21) is cleared.

000: 64

001: 128

010: 192

011: 256

100: 40

101: 32

110: 24

111: 16

Bit 13 **ST**: Start/stop transmission

When this bit is set, transmission is placed in the Running state, and the DMA checks the transmit list at the current position for a frame to be transmitted. Descriptor acquisition is attempted either from the current position in the list, which is the transmit list base address set by the ETH\_DMATDLAR register, or from the position retained when transmission was stopped previously. If the current descriptor is not owned by the DMA, transmission enters the Suspended state and the transmit buffer unavailable bit (ETH\_DMASR [2]) is set. The Start Transmission command is effective only when transmission is stopped. If the command is issued before setting the DMA ETH\_DMATDLAR register, the DMA behavior is unpredictable.

When this bit is cleared, the transmission process is placed in the Stopped state after completing the transmission of the current frame. The next descriptor position in the transmit list is saved, and becomes the current position when transmission is restarted. The Stop Transmission command is effective only when the transmission of the current frame is complete or when the transmission is in the Suspended state.

Bits 12:8 Reserved, must be kept at reset value.

Bit 7 **FEF**: Forward error frames

When this bit is set, all frames except runt error frames are forwarded to the DMA.

When this bit is cleared, the Rx FIFO drops frames with error status (CRC error, collision error, giant frame, watchdog timeout, overflow). However, if the frame's start byte (write) pointer is already transferred to the read controller side (in Threshold mode), then the frames are not dropped. The Rx FIFO drops the error frames if that frame's start byte is not transferred (output) on the ARI bus.

Bit 6 **FUGF**: Forward undersized good frames

When this bit is set, the Rx FIFO forwards undersized frames (frames with no error and length less than 64 bytes) including pad-bytes and CRC).

When this bit is cleared, the Rx FIFO drops all frames of less than 64 bytes, unless such a frame has already been transferred due to lower value of receive threshold (e.g., RTC = 01).

Bit 5 Reserved, must be kept at reset value.

Bits 4:3 **RTC**: Receive threshold control

These two bits control the threshold level of the Receive FIFO. Transfer (request) to DMA starts when the frame size within the Receive FIFO is larger than the threshold. In addition, full frames with a length less than the threshold are transferred automatically.

*Note:* Note that value of 11 is not applicable if the configured Receive FIFO size is 128 bytes.

*Note:* These bits are valid only when the RSF bit is zero, and are ignored when the RSF bit is set to 1.

00: 64

01: 32

10: 96

11: 128

Bit 2 **OSF**: Operate on second frame

When this bit is set, this bit instructs the DMA to process a second frame of Transmit data even before status for first frame is obtained.

**Bit 1 SR:** Start/stop receive

When this bit is set, the receive process is placed in the Running state. The DMA attempts to acquire the descriptor from the receive list and processes incoming frames. Descriptor acquisition is attempted from the current position in the list, which is the address set by the DMA ETH\_DMARDLAR register or the position retained when the receive process was previously stopped. If no descriptor is owned by the DMA, reception is suspended and the receive buffer unavailable bit (ETH\_DMASR [7]) is set. The Start Receive command is effective only when reception has stopped. If the command was issued before setting the DMA ETH\_DMARDLAR register, the DMA behavior is unpredictable.

When this bit is cleared, RxDMA operation is stopped after the transfer of the current frame. The next descriptor position in the receive list is saved and becomes the current position when the receive process is restarted. The Stop Receive command is effective only when the Receive process is in either the Running (waiting for receive packet) or the Suspended state.

Bit 0 Reserved, must be kept at reset value.

**Ethernet DMA interrupt enable register (ETH\_DMAIER)**

Address offset: 0x101C

Reset value: 0x0000 0000

The Interrupt enable register enables the interrupts reported by ETH\_DMASR. Setting a bit to 1 enables a corresponding interrupt. After a hardware or software reset, all interrupts are disabled.

|      |      |       |      |      |      |       |       |       |      |      |      |       |       |       |      |

Bits 31:17 Reserved, must be kept at reset value.

**Bit 16 NISE:** Normal interrupt summary enable

When this bit is set, a normal interrupt is enabled. When this bit is cleared, a normal interrupt is disabled. This bit enables the following bits:

- ETH\_DMASR [0]: Transmit Interrupt
- ETH\_DMASR [2]: Transmit buffer unavailable
- ETH\_DMASR [6]: Receive interrupt
- ETH\_DMASR [14]: Early receive interrupt

**Bit 15 AISE:** Abnormal interrupt summary enable

When this bit is set, an abnormal interrupt is enabled. When this bit is cleared, an abnormal interrupt is disabled. This bit enables the following bits:

- ETH\_DMASR [1]: Transmit process stopped
- ETH\_DMASR [3]: Transmit jabber timeout
- ETH\_DMASR [4]: Receive overflow
- ETH\_DMASR [5]: Transmit underflow
- ETH\_DMASR [7]: Receive buffer unavailable
- ETH\_DMASR [8]: Receive process stopped
- ETH\_DMASR [9]: Receive watchdog timeout
- ETH\_DMASR [10]: Early transmit interrupt
- ETH\_DMASR [13]: Fatal bus error

**Bit 14 ERIE:** Early receive interrupt enable

When this bit is set with the normal interrupt summary enable bit (ETH\_DMAIER register[16]), the early receive interrupt is enabled.

When this bit is cleared, the early receive interrupt is disabled.

**Bit 13 FBEIE:** Fatal bus error interrupt enable

When this bit is set with the abnormal interrupt summary enable bit (ETH\_DMAIER register[15]), the fatal bus error interrupt is enabled.

When this bit is cleared, the fatal bus error enable interrupt is disabled.

Bits 12:11 Reserved, must be kept at reset value.

**Bit 10 ETIE:** Early transmit interrupt enable

When this bit is set with the abnormal interrupt summary enable bit (ETH\_DMAIER register[15]), the early transmit interrupt is enabled.

When this bit is cleared, the early transmit interrupt is disabled.

**Bit 9 RWTIE:** receive watchdog timeout interrupt enable

When this bit is set with the abnormal interrupt summary enable bit (ETH\_DMAIER register[15]), the receive watchdog timeout interrupt is enabled.

When this bit is cleared, the receive watchdog timeout interrupt is disabled.

**Bit 8 RPSIE:** Receive process stopped interrupt enable

When this bit is set with the abnormal interrupt summary enable bit (ETH\_DMAIER register[15]), the receive stopped interrupt is enabled. When this bit is cleared, the receive stopped interrupt is disabled.

**Bit 7 RBUIE:** Receive buffer unavailable interrupt enable

When this bit is set with the abnormal interrupt summary enable bit (ETH\_DMAIER register[15]), the receive buffer unavailable interrupt is enabled.

When this bit is cleared, the receive buffer unavailable interrupt is disabled.

**Bit 6 RIE:** Receive interrupt enable

When this bit is set with the normal interrupt summary enable bit (ETH\_DMAIER register[16]), the receive interrupt is enabled.

When this bit is cleared, the receive interrupt is disabled.

**Bit 5 TUIE:** Underflow interrupt enable

When this bit is set with the abnormal interrupt summary enable bit (ETH\_DMAIER register[15]), the transmit underflow interrupt is enabled.

When this bit is cleared, the underflow interrupt is disabled.

- Bit 4 **ROIE**: Overflow interrupt enable  
 When this bit is set with the abnormal interrupt summary enable bit (ETH\_DMAIER register[15]), the receive overflow interrupt is enabled.  
 When this bit is cleared, the overflow interrupt is disabled.
- Bit 3 **TJTIE**: Transmit jabber timeout interrupt enable  
 When this bit is set with the abnormal interrupt summary enable bit (ETH\_DMAIER register[15]), the transmit jabber timeout interrupt is enabled.  
 When this bit is cleared, the transmit jabber timeout interrupt is disabled.
- Bit 2 **TBUIE**: Transmit buffer unavailable interrupt enable  
 When this bit is set with the normal interrupt summary enable bit (ETH\_DMAIER register[16]), the transmit buffer unavailable interrupt is enabled.  
 When this bit is cleared, the transmit buffer unavailable interrupt is disabled.
- Bit 1 **TPSIE**: Transmit process stopped interrupt enable  
 When this bit is set with the abnormal interrupt summary enable bit (ETH\_DMAIER register[15]), the transmission stopped interrupt is enabled.  
 When this bit is cleared, the transmission stopped interrupt is disabled.
- Bit 0 **TIE**: Transmit interrupt enable  
 When this bit is set with the normal interrupt summary enable bit (ETH\_DMAIER register[16]), the transmit interrupt is enabled.  
 When this bit is cleared, the transmit interrupt is disabled.

The Ethernet interrupt is generated only when the TSTS or PMTS bits of the DMA Status register is asserted with their corresponding interrupt are unmasked, or when the NIS/AIS Status bit is asserted and the corresponding Interrupt Enable bits (NISE/AISE) are enabled.

### Ethernet DMA missed frame and buffer overflow counter register (ETH\_DMAMFBOCR)

Address offset: 0x1020

Reset value: 0x0000 0000

The DMA maintains two counters to track the number of missed frames during reception. This register reports the current value of the counter. The counter is used for diagnostic purposes. Bits [15:0] indicate missed frames due to the STM32F75xxx and STM32F74xxx buffer being unavailable (no receive descriptor was available). Bits [27:17] indicate missed frames due to Rx FIFO overflow conditions and runt frames (good frames of less than 64 bytes).

Bits 31:29 Reserved, must be kept at reset value.

Bit 28 **OFOC**: Overflow bit for FIFO overflow counter

Bits 27:17 **MFA**: Missed frames by the application

Indicates the number of frames missed by the application

Bit 16 **OMFC**: Overflow bit for missed frame counter

Bits 15:0 **MFC**: Missed frames by the controller

Indicates the number of frames missed by the Controller due to the host receive buffer being unavailable. This counter is incremented each time the DMA discards an incoming frame.

### Ethernet DMA receive status watchdog timer register (ETH\_DMARSWTR)

Address offset: 0x1024

Reset value: 0x0000 0000

This register, when written with a non-zero value, enables the watchdog timer for the receive status (RS, ETH\_DMASR[6]).

|      |      |      |      |      |      |      |      |       |      |      |      |      |      |      |      |

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **RSWTC**: Receive status (RS) watchdog timer count

Indicates the number of HCLK clock cycles multiplied by 256 for which the watchdog timer is set. The watchdog timer gets triggered with the programmed value after the RxDMA completes the transfer of a frame for which the RS status bit is not set due to the setting of RDES1[31] in the corresponding descriptor. When the watchdog timer runs out, the RS bit is set and the timer is stopped. The watchdog timer is reset when the RS bit is set high due to automatic setting of RS as per RDES1[31] of any received frame.

### Ethernet DMA current host transmit descriptor register (ETH\_DMACHTDR)

Address offset: 0x1048

Reset value: 0x0000 0000

The Current host transmit descriptor register points to the start address of the current transmit descriptor read by the DMA.

Bits 31:0 **HTDAP**: Host transmit descriptor address pointer

Cleared . Pointer updated by DMA during operation.

### Ethernet DMA current host receive descriptor register (ETH\_DMACHRDR)

Address offset: 0x104C

Reset value: 0x0000 0000

The Current host receive descriptor register points to the start address of the current receive descriptor read by the DMA.

### Ethernet DMA current host transmit buffer address register (ETH\_DMACHTBAR)

Address offset: 0x1050

Reset value: 0x0000 0000

The Current host transmit buffer address register points to the current transmit buffer address being read by the DMA.

Refer to [Section 2.2.2 on page 69](#) for the register boundary addresses.

## 39 HDMI-CEC controller (HDMI-CEC)

### 39.1 Introduction

Consumer electronics control (CEC) is part of HDMI (high-definition multimedia interface) standard as appendix supplement 1. It contains a protocol that provides high-level control functions between various audiovisual products. CEC operates at low speeds, with minimum processing and memory overhead.

The HDMI-CEC controller provides hardware support for this protocol.

### 39.2 HDMI-CEC controller main features

- Complies with HDMI-CEC v1.4 specification
- 32 kHz CEC kernel with 2 clock source options
  - HSI RC oscillator with fixed prescaler (HSI/488)
  - LSE oscillator
- Works in Stop mode for ultra-low-power applications
- Configurable signal-free time before start of transmission
  - Automatic by hardware, according to CEC state and transmission history
  - Fixed by software (7 timing options)
- Configurable peripheral address (OAR)
- Supports Listen mode
  - Enables reception of CEC messages sent to destination address different from OAR without interfering with the CEC line
- Configurable Rx-tolerance margin
  - Standard tolerance
  - Extended tolerance
- Receive-error detection
  - Bit rising error (BRE), with optional stop of reception (BRESTP)
  - Short bit period error (SBPE)
  - Long bit period error (LBPE)
- Configurable error-bit generation
  - on BRE detection (BREGEN)
  - on LBPE detection (LBPEGEN)
  - always generated on SBPE detection
- Transmission error detection (TXERR)
- Arbitration lost detection (ARBLST)
  - With automatic transmission retry
- Transmission underrun detection (TXUDR)
- Reception overrun detection (RXOVR)

## 39.3 HDMI-CEC functional description

### 39.3.1 HDMI-CEC pin

The CEC bus consists of a single bidirectional line that is used to transfer data in and out of the device. It is connected to a +3.3 V supply voltage via a 27 kΩ pull-up resistor. The output stage of the device must have an open-drain or open-collector to allow a wired-AND connection.

The HDMI-CEC controller manages the CEC bidirectional line as an alternate function of a standard GPIO, assuming that it is configured as alternate function open drain. The 27 kΩ pull-up must be added externally to the microcontroller.

To not interfere with the CEC bus when the application power is removed, it is mandatory to isolate the CEC pin from the bus in such conditions. This can be done by using a MOS transistor, as shown on [Figure 525](#).

Table 283. HDMI pin

| Name | Signal type   | Remarks                                                                                                  |
|------|---------------|----------------------------------------------------------------------------------------------------------|
| CEC  | Bidirectional | Two states:<br>– 1 = high impedance<br>– 0 = low impedance<br>A 27 kΩ resistor must be added externally. |

### 39.3.2 HDMI-CEC block diagram

Figure 525. HDMI-CEC block diagram

### 39.3.3 Message description

All transactions on the CEC line consist of an initiator and one or more followers. The initiator is responsible for sending the message structure and the data. The follower is the recipient of any data and is responsible for setting any acknowledgment bits.

A message is conveyed in a single frame that consists of a start bit followed by a header block and optionally an opcode and a variable number of operand blocks.

All these blocks are made of a 8-bit payload - most significant bit is transmitted first - followed by an end of message (EOM) bit and an acknowledge (ACK) bit.

The EOM bit is set in the last block of a message and kept reset in all others. In case a message contains additional blocks after an EOM is indicated, those additional blocks must be ignored. The EOM bit may be set in the header block to 'ping' other devices, to make sure they are active.

The acknowledge bit is always set to high impedance by the initiator so that it can be driven low either by the follower that has read its own address in the header, or by the follower that needs to reject a broadcast message.

The header consists of the source logical address field, and the destination logical address field. Note that the special address 0xF is used for broadcast messages.

Figure 526. Message structure

Figure 527. Blocks

39.3.4 Bit timing

The format of the start bit is unique and identifies the start of a message. It must be validated by its low duration and its total duration.

All remaining data bits in the message, after the start bit, have consistent timing. The high-to-low transition at the end of the data bit is the start of the next data bit except for the final bit where the CEC line remains high.

Figure 528. Bit timings

### 39.4 Arbitration

All devices transmitting - or retransmitting - a message onto the CEC line must ensure that it has been inactive for a number of bit periods. This signal-free time is defined as the time starting from the final bit of the previous frame and depends on the initiating device and the current status as shown in the table below.

Figure 529. Signal free time

Since only one initiator is allowed at any one time, an arbitration mechanism is provided to avoid conflict when more than one initiator begins transmitting at the same time.

CEC line arbitration starts with the leading edge of the start bit and continues until the end of the initiator address bits within the header block. During this period, the initiator must monitor the CEC line, if whilst driving the line to high impedance it reads it back to 0. Assuming then it has lost arbitration, it stops transmitting and becomes a follower.

Figure 530. Arbitration phase

Figure 531 shows an example for a SFT of three nominal bit periods

Figure 531. SFT of three nominal bit periods

A configurable time window is counted before starting the transmission.

In the SFT = 0 configuration, HDMI-CEC performs automatic SFT calculation ensuring compliance with the HDMI-CEC standard:

- 2.5 data bit periods if the CEC is the last bus initiator with unsuccessful transmission
- 4 data bit periods if the CEC is the new bus initiator
- 6 data bit periods if the CEC is the last bus initiator with successful transmission

This is done to guarantee the maximum priority to a failed transmission and the lowest one to the last initiator that completed successfully its transmission.

Otherwise there is the possibility to configure the SFT bits to count a fixed timing value. Possible values are 0.5, 1.5, 2.5, 3.5, 4.5, 5.5, 6.5 data bit periods.

### 39.4.1 SFT option bit

In case of SFTOPT = 0 configuration, SFT starts being counted when the start-of-transmission command is set by software (TXSOM=1).

In case of SFTOPT=1, SFT starts automatically being counted by the HDMI-CEC device when a bus-idle or line error condition is detected. If the SFT timer is completed at the time TXSOM command is set then transmission starts immediately without latency. If the SFT timer is still running instead, the system waits until the timer elapses before transmission can start.

In case of SFTOPT = 1 a bus-event condition starting the SFT timer is detected in the following cases:

- In case of a regular end of transmission/reception, when TXEND/RXEND bits are set at the minimum nominal data bit duration of the last bit in the message (ACK bit).
- In case of a transmission error detection, SFT timer starts when the TXERR transmission error is detected (TXERR=1).
- In case of a missing acknowledge from the CEC follower, the SFT timer starts when the TXACHE bit is set, that is at the nominal sampling time of the ACK bit.
- In case of a transmission underrun error, the SFT timer starts when the TXUDR bit is set at the end of the ACK bit.
- In case of a receive error detection implying reception abort, the SFT timer starts at the same time the error is detected. If an error bit is generated, then SFT starts being counted at the end of the error bit.
- In case of a wrong start bit or of any uncodified low impedance bus state from idle, the SFT timer is restarted as soon as the bus comes back to hi-impedance idleness.

## 39.5 Error handling

### 39.5.1 Bit error

If a data bit - excluding the start bit - is considered invalid, the follower is expected to notify such error by generating a low bit period on the CEC line of 1.4 to 1.6 times the nominal data bit period, i.e. 3.6 ms nominally.

Figure 532. Error bit timing

### 39.5.2 Message error

A message is considered lost and therefore may be retransmitted under the following conditions:

- a message is not acknowledged in a directly addressed message
- a message is negatively acknowledged in a broadcast message
- a low impedance is detected on the CEC line while it is not expected (line error)

Three kinds of error flag can be detected when the CEC interface is receiving a data bit:

### 39.5.3 Bit Rising Error (BRE)

BRE (bit rising error): is set when a bit rising edge is detected outside the windows where it is expected (see [Figure 533](#)). BRE flag also generates a CEC interrupt if the BREIE=1.

In the case of a BRE detection, the message reception can be stopped according to the BRESTOP bit value and an error bit can be generated if BREGEN bit is set.

When BRE is detected in a broadcast message with BRESTOP=1 an error bit is generated even if BREGEN=0 to enforce initiator's retry of the failed transmission. Error bit generation can be disabled by configuring BREGEN=0, BRDNOGEN=1.

#### 39.5.4 Short Bit Period Error (SBPE)

SBPE is set when a bit falling edge is detected earlier than expected (see [Figure 533](#)). SBPE flag also generates a CEC interrupt if the SBPEIE=1.

An error bit is always generated on the line in case of a SBPE error detection. An Error Bit is not generated upon SBPE detection only when Listen mode is set (LSTN=1) and the following conditions are met:

- A directly addressed message is received containing SBPE
- A broadcast message is received containing SBPE AND BRDNOGEN=1

#### 39.5.5 Long Bit Period Error (LBPE)

LBPE is set when a bit falling edge is not detected in a valid window (see [Figure 533](#)). LBPE flag also generates a CEC interrupt if the LBPEIE=1.

LBPE always stops the reception, an error bit is generated on the line when LBPEGEN bit is set.

When LBPE is detected in a broadcast message an error bit is generated even if LBPEGEN=0 to enforce initiator's retry of the failed transmission. Error bit generation can be disabled by configuring LBPEGEN=0, BRDNOGEN=1.

*Note: The BREGEN=1, BRESTOP=0 configuration must be avoided*

**Figure 533. Error handling**

Table 284. Error handling timing parameters

| Time     | RXTOL | ms   | Description                                                                           |
|----------|-------|------|---------------------------------------------------------------------------------------|
| $T_s$    | x     | 0    | Bit start event.                                                                      |
| $T_1$    | 1     | 0.3  | The earliest time for a low - high transition when indicating a logical 1.            |
|          | 0     | 0.4  |                                                                                       |
| $T_{n1}$ | x     | 0.6  | The nominal time for a low - high transition when indicating a logical 1.             |
| $T_2$    | 0     | 0.8  | The latest time for a low - high transition when indicating a logical 1.              |
|          | 1     | 0.9  |                                                                                       |
| $T_{ns}$ | x     | 1.05 | Nominal sampling time.                                                                |
| $T_3$    | 1     | 1.2  | The earliest time a device is permitted return to a high impedance state (logical 0). |
|          | 0     | 1.3  |                                                                                       |
| $T_{n0}$ | x     | 1.5  | The nominal time a device is permitted return to a high impedance state (logical 0).  |
| $T_4$    | 0     | 1.7  | The latest time a device is permitted return to a high impedance state (logical 0).   |
|          | 1     | 1.8  |                                                                                       |
| $T_5$    | 1     | 1.85 | The earliest time for the start of a following bit.                                   |
|          | 0     | 2.05 |                                                                                       |
| $T_{nf}$ | x     | 2.4  | The nominal data bit period.                                                          |
| $T_6$    | 0     | 2.75 | The latest time for the start of a following bit.                                     |
|          | 1     | 2.95 |                                                                                       |

### 39.5.6 Transmission Error Detection (TXERR)

The CEC initiator sets the TXERR flag if detecting low impedance on the CEC line when it is transmitting high impedance and is not expecting a follower asserted bit. TXERR flag also generates a CEC interrupt if the TXERRIE=1.

TXERR assertion stops the message transmission. Application is in charge to retry the failed transmission up to 5 times.

TXERR checks are performed differently depending on the different states of the CEC line and on the RX tolerance configuration.

**Figure 534. TXERR detection**

**Table 285. TXERR timing parameters**

| Time     | RXTOL | ms   | Description                                                                           |
|----------|-------|------|---------------------------------------------------------------------------------------|
| $T_s$    | x     | 0    | Bit start event.                                                                      |
| $T_1$    | 1     | 0.3  | The earliest time for a low - high transition when indicating a logical 1.            |
|          | 0     | 0.4  |                                                                                       |
| $T_{n1}$ | x     | 0.6  | The nominal time for a low - high transition when indicating a logical 1.             |
| $T_2$    | 0     | 0.8  | The latest time for a low - high transition when indicating a logical 1.              |
|          | 1     | 0.9  |                                                                                       |
| $T_{ns}$ | x     | 1.05 | Nominal sampling time.                                                                |
| $T_3$    | 1     | 1.2  | The earliest time a device is permitted return to a high impedance state (logical 0). |
|          | 0     | 1.3  |                                                                                       |

Table 285. TXERR timing parameters (continued)

| Time     | RXTOL | ms   | Description                                                                          |
|----------|-------|------|--------------------------------------------------------------------------------------|
| $T_{n0}$ | x     | 1.5  | The nominal time a device is permitted return to a high impedance state (logical 0). |
| $T_4$    | 0     | 1.7  | The latest time a device is permitted return to a high impedance state (logical 0).  |
|          | 1     | 1.8  |                                                                                      |
| $T_5$    | 1     | 1.85 | The earliest time for the start of a following bit.                                  |
|          | 0     | 2.05 |                                                                                      |
| $T_{nf}$ | x     | 2.4  | The nominal data bit period.                                                         |
| $T_6$    | 0     | 2.75 | The latest time for the start of a following bit.                                    |
|          | 1     | 2.95 |                                                                                      |

## 39.6 HDMI-CEC interrupts

An interrupt can be produced:

- during reception if a Receive Block Transfer is finished or if a Receive Error occurs.
- during transmission if a Transmit Block Transfer is finished or if a Transmit Error occurs.

Table 286. HDMI-CEC interrupts

| Interrupt event              | Event flag | Enable Control bit |
|------------------------------|------------|--------------------|
| Rx-Byte Received             | RXBR       | RXBRIE             |
| End of reception             | RXEND      | RXENDIE            |
| Rx-Overflow                  | RXOVR      | RXOVRIE            |
| RxBit Rising Error           | BRE        | BREIE              |
| Rx-Short Bit Period Error    | SBPE       | SBPEIE             |
| Rx-Long Bit Period Error     | LBPE       | LBPEIE             |
| Rx-Missing Acknowledge Error | RXACKE     | RXACKIE            |
| Arbitration lost             | ARBLST     | ARBLSTIE           |
| Tx-Byte Request              | TXBR       | TXBRIE             |
| End of transmission          | TXEND      | TXENDIE            |
| Tx-Buffer Underrun           | TXUDR      | TXUDRIE            |
| Tx-Error                     | TXERR      | TXERRIE            |
| Tx-Missing Acknowledge Error | TXACKE     | TXACKIE            |

39.7 HDMI-CEC registers

Refer to [Section 1.2 on page 62](#) for a list of abbreviations used in register descriptions.

39.7.1 CEC control register (CEC\_CR)

Address offset: 0x00

Reset value: 0x0000 0000

|      |      |      |      |      |      |      |      |      |      |      |      |      |           |           |       |

Bits 31:3 Reserved, must be kept at reset value.

**Bit 2 TXEOM:** Tx End Of Message

The TXEOM bit is set by software to command transmission of the last byte of a CEC message. TXEOM is cleared by hardware at the same time and under the same conditions as for TXSOM.

0: TXDR data byte is transmitted with EOM=0

1: TXDR data byte is transmitted with EOM=1

*Note: TXEOM must be set when CECEN=1.*

*TXEOM must be set before writing transmission data to TXDR.*

*If TXEOM is set when TXSOM=0, transmitted message will consist of 1 byte (HEADER) only (PING message)*

**Bit 1 TXSOM:** Tx Start Of Message

TXSOM is set by software to command transmission of the first byte of a CEC message. If the CEC message consists of only one byte, TXEOM must be set before of TXSOM.

Start-Bit is effectively started on the CEC line after SFT is counted. If TXSOM is set while a message reception is ongoing, transmission will start after the end of reception.

TXSOM is cleared by hardware after the last byte of the message is sent with a positive acknowledge (TXEND=1), in case of transmission underrun (TXUDR=1), negative acknowledge (TXACKE=1), and transmission error (TXERR=1). It is also cleared by CECEN=0. It is not cleared and transmission is automatically retried in case of arbitration lost (ARBLST=1).

TXSOM can be also used as a status bit informing application whether any transmission request is pending or under execution. The application can abort a transmission request at any time by clearing the CECEN bit.

0: No CEC transmission is on-going

1: CEC transmission command

*Note: TXSOM must be set when CECEN=1.*

*TXSOM must be set when transmission data is available into TXDR.*

*HEADER first four bits containing own peripheral address are taken from TXDR[7:4], not from CEC\_CFGR.OAR which is used only for reception.*

**Bit 0 CECEN:** CEC enable

The CECEN bit is set and cleared by software. CECEN=1 starts message reception and enables the TXSOM control. CECEN=0 disables the CEC peripheral, clears all bits of CEC\_CR register and aborts any on-going reception or transmission.

0: CEC peripheral is off

1: CEC peripheral is on

**39.7.2 CEC configuration register (CEC\_CFGR)**

This register is used to configure the HDMI-CEC controller.

Address offset: 0x04

Reset value: 0x0000 0000

**Caution:** It is mandatory to write CEC\_CFGR only when CECEN=0.

**Bit 31 LSTN:** Listen mode

LSTN bit is set and cleared by software.

0: CEC peripheral receives only message addressed to its own address (OAR). Messages addressed to different destination are ignored. Broadcast messages are always received.

1: CEC peripheral receives messages addressed to its own address (OAR) with positive acknowledge. Messages addressed to different destination are received, but without interfering with the CEC bus: no acknowledge sent.

**Bits 30:16 OAR[14:0]:** Own addresses configuration

The OAR bits are set by software to select which destination logical addresses has to be considered in receive mode. Each bit, when set, enables the CEC logical address identified by the given bit position.

At the end of HEADER reception, the received destination address is compared with the enabled addresses. In case of matching address, the incoming message is acknowledged and received. In case of non-matching address, the incoming message is received only in listen mode (LSTN=1), but without acknowledge sent. Broadcast messages are always received.

Example:

OAR = 0b000 0000 0010 0001 means that CEC acknowledges addresses 0x0 and 0x5.

Consequently, each message directed to one of these addresses is received.

Bits 15:9 Reserved, must be kept at reset value.

**Bit 8 SFTOP:** SFT Option Bit

The SFTOPT bit is set and cleared by software.

0: SFT timer starts when TXSOM is set by software

1: SFT timer starts automatically at the end of message transmission/reception.

**Bit 7 BRDNOGEN:** Avoid Error-Bit Generation in Broadcast

The BRDNOGEN bit is set and cleared by software.

0: BRE detection with BRESTOP=1 and BREGEN=0 on a broadcast message generates an Error-Bit on the CEC line. LBPE detection with LBPEGEN=0 on a broadcast message generates an Error-Bit on the CEC line

1: Error-Bit is not generated in the same condition as above. An Error-Bit is not generated even in case of an SBPE detection in a broadcast message if listen mode is set.

**Bit 6 LBPEGEN:** Generate Error-Bit on Long Bit Period Error

The LBPEGEN bit is set and cleared by software.

0: LBPE detection does not generate an Error-Bit on the CEC line

1: LBPE detection generates an Error-Bit on the CEC line

*Note: If BRDNOGEN=0, an Error-bit is generated upon LBPE detection in broadcast even if LBPEGEN=0*

**Bit 5 BREGEN:** Generate Error-Bit on Bit Rising Error

The BREGEN bit is set and cleared by software.

0: BRE detection does not generate an Error-Bit on the CEC line

1: BRE detection generates an Error-Bit on the CEC line (if BRESTOP is set)

*Note: If BRDNOGEN=0, an Error-bit is generated upon BRE detection with BRESTOP=1 in broadcast even if BREGEN=0*

Bit 4 **BRESTP**: Rx-Stop on Bit Rising Error

The BRESTP bit is set and cleared by software.

0: BRE detection does not stop reception of the CEC message. Data bit is sampled at 1.05 ms.

1: BRE detection stops message reception

Bit 3 **RXTOL**: Rx-Tolerance

The RXTOL bit is set and cleared by software.

0: Standard tolerance margin:

- Start-Bit, +/- 200  $\mu$ s rise, +/- 200  $\mu$ s fall.
- Data-Bit: +/- 200  $\mu$ s rise, +/- 350  $\mu$ s fall.

1: Extended Tolerance

- Start-Bit: +/- 400  $\mu$ s rise, +/- 400  $\mu$ s fall
- Data-Bit: +/-300  $\mu$ s rise, +/- 500  $\mu$ s fall

Bits 2:0 **SFT[2:0]**: Signal Free Time

SFT bits are set by software. In the SFT=0x0 configuration the number of nominal data bit periods waited before transmission is ruled by hardware according to the transmission history. In all the other configurations the SFT number is determined by software.

- " 0x0
  - 2.5 Data-Bit periods if CEC is the last bus initiator with unsuccessful transmission (ARBLST=1, TXERR=1, TXUDR=1 or TXACKE= 1)
  - 4 Data-Bit periods if CEC is the new bus initiator
  - 6 Data-Bit periods if CEC is the last bus initiator with successful transmission (TXEOM=1)
- " 0x1: 0.5 nominal data bit periods
- " 0x2: 1.5 nominal data bit periods
- " 0x3: 2.5 nominal data bit periods
- " 0x4: 3.5 nominal data bit periods
- " 0x5: 4.5 nominal data bit periods
- " 0x6: 5.5 nominal data bit periods
- " 0x7: 6.5 nominal data bit periods

### 39.7.3 CEC Tx data register (CEC\_TXDR)

Address offset: 0x8

Reset value: 0x0000 0000

|      |      |      |      |      |      |      |      |          |      |      |      |      |      |      |      |

| Res. | Res. | Res. | TX<br>ACKE | TX<br>ERR | TX<br>UDR | TX<br>END | TXBR  | ARB<br>LST | RX<br>ACKE | LBPE  | SBPE  | BRE   | RX<br>OVR | RX<br>END | RXBR  |
|      |      |      | rc_w1      | rc_w1     | rc_w1     | rc_w1     | rc_w1 | rc_w1      | rc_w1      | rc_w1 | rc_w1 | rc_w1 | rc_w1     | rc_w1     | rc_w1 |

Bits 31:13 Reserved, must be kept at reset value.

Bit 12 **TXACHE**: Tx-Missing Acknowledge Error

In transmission mode, TXACHE is set by hardware to inform application that no acknowledge was received. In case of broadcast transmission, TXACHE informs application that a negative acknowledge was received. TXACHE aborts message transmission and clears TXSOM and TXEOM controls.

TXACHE is cleared by software write at 1.

Bit 11 **TXERR**: Tx-Error

In transmission mode, TXERR is set by hardware if the CEC initiator detects low impedance on the CEC line while it is released. TXERR aborts message transmission and clears TXSOM and TXEOM controls.

TXERR is cleared by software write at 1.

Bit 10 **TXUDR**: Tx-Buffer Underrun

In transmission mode, TXUDR is set by hardware if application was not in time to load TXDR before of next byte transmission. TXUDR aborts message transmission and clears TXSOM and TXEOM control bits.

TXUDR is cleared by software write at 1

Bit 9 **TXEND**: End of Transmission

TXEND is set by hardware to inform application that the last byte of the CEC message has been successfully transmitted. TXEND clears the TXSOM and TXEOM control bits.

TXEND is cleared by software write at 1.

Bit 8 **TXBR**: Tx-Byte Request

TXBR is set by hardware to inform application that the next transmission data has to be written to TXDR. TXBR is set when the 4th bit of currently transmitted byte is sent. Application must write the next byte to TXDR within 6 nominal data-bit periods before transmission underrun error occurs (TXUDR).

TXBR is cleared by software write at 1.

Bit 7 **ARBLST**: Arbitration Lost

ARBLST is set by hardware to inform application that CEC device is switching to reception due to arbitration lost event following the TXSOM command. ARBLST can be due either to a contending CEC device starting earlier or starting at the same time but with higher HEADER priority. After ARBLST assertion TXSOM bit keeps pending for next transmission attempt.

ARBLST is cleared by software write at 1.

Bit 6 **RXACHE**: Rx-Missing Acknowledge

In receive mode, RXACHE is set by hardware to inform application that no acknowledge was seen on the CEC line. RXACHE applies only for broadcast messages and in listen mode also for not directly addressed messages (destination address not enabled in OAR). RXACHE aborts message reception.

RXACHE is cleared by software write at 1.

Bit 5 **LBPE**: Rx-Long Bit Period Error

LBPE is set by hardware in case a Data-Bit waveform is detected with Long Bit Period Error. LBPE is set at the end of the maximum bit-extension tolerance allowed by RXTOL, in case falling edge is still longing. LBPE always stops reception of the CEC message. LBPE generates an Error-Bit on the CEC line if LBPEGEN=1. In case of broadcast, Error-Bit is generated even in case of LBPEGEN=0. LBPE is cleared by software write at 1.

Bit 4 **SBPE**: Rx-Short Bit Period Error

SBPE is set by hardware in case a Data-Bit waveform is detected with Short Bit Period Error. SBPE is set at the time the anticipated falling edge occurs. SBPE generates an Error-Bit on the CEC line. SBPE is cleared by software write at 1.

**Bit 3 BRE:** Rx-Bit Rising Error

BRE is set by hardware in case a Data-Bit waveform is detected with Bit Rising Error. BRE is set either at the time the misplaced rising edge occurs, or at the end of the maximum BRE tolerance allowed by RXTOL, in case rising edge is still longing. BRE stops message reception if BRESTOP=1. BRE generates an Error-Bit on the CEC line if BREGEN=1. BRE is cleared by software write at 1.

**Bit 2 RXOVR:** Rx-Overrun

RXOVR is set by hardware if RXBR is not yet cleared at the time a new byte is received on the CEC line and stored into RXD. RXOVR assertion stops message reception so that no acknowledge is sent. In case of broadcast, a negative acknowledge is sent. RXOVR is cleared by software write at 1.

**Bit 1 RXEND:** End Of Reception

RXEND is set by hardware to inform application that the last byte of a CEC message is received from the CEC line and stored into the RXD buffer. RXEND is set at the same time of RXBR. RXEND is cleared by software write at 1.

**Bit 0 RXBR:** Rx-Byte Received

The RXBR bit is set by hardware to inform application that a new byte has been received from the CEC line and stored into the RXD buffer. RXBR is cleared by software write at 1.

**39.7.6 CEC interrupt enable register (CEC\_IER)**

Address offset: 0x14

Bits 31:13 Reserved, must be kept at reset value.

**Bit 12 TXACKIE:** Tx-Missing Acknowledge Error Interrupt Enable

The TXACKIE bit is set and cleared by software.  
0: TXACKIE interrupt disabled  
1: TXACKIE interrupt enabled

**Bit 11 TXERRIE:** Tx-Error Interrupt Enable

The TXERRIE bit is set and cleared by software.  
0: TXERR interrupt disabled  
1: TXERR interrupt enabled

**Bit 10 TXUDRIE:** Tx-Underrun Interrupt Enable

The TXUDRIE bit is set and cleared by software.  
0: TXUDR interrupt disabled  
1: TXUDR interrupt enabled

- Bit 9 **TXENDIE**: Tx-End Of Message Interrupt Enable  
The TXENDIE bit is set and cleared by software.  
0: TXEND interrupt disabled  
1: TXEND interrupt enabled
- Bit 8 **TXBRIE**: Tx-Byte Request Interrupt Enable  
The TXBRIE bit is set and cleared by software.  
0: TXBR interrupt disabled  
1: TXBR interrupt enabled
- Bit 7 **ARBLSTIE**: Arbitration Lost Interrupt Enable  
The ARBLSTIE bit is set and cleared by software.  
0: ARBLST interrupt disabled  
1: ARBLST interrupt enabled
- Bit 6 **RXACKIE**: Rx-Missing Acknowledge Error Interrupt Enable  
The RXACKIE bit is set and cleared by software.  
0: RXACKE interrupt disabled  
1: RXACKE interrupt enabled
- Bit 5 **LBPEIE**: Long Bit Period Error Interrupt Enable  
The LBPEIE bit is set and cleared by software.  
0: LBPE interrupt disabled  
1: LBPE interrupt enabled
- Bit 4 **SBPEIE**: Short Bit Period Error Interrupt Enable  
The SBPEIE bit is set and cleared by software.  
0: SBPE interrupt disabled  
1: SBPE interrupt enabled
- Bit 3 **BREIE**: Bit Rising Error Interrupt Enable  
The BREIE bit is set and cleared by software.  
0: BRE interrupt disabled  
1: BRE interrupt enabled
- Bit 2 **RXOVRIE**: Rx-Buffer Overrun Interrupt Enable  
The RXOVRIE bit is set and cleared by software.  
0: RXOVR interrupt disabled  
1: RXOVR interrupt enabled
- Bit 1 **RXENDIE**: End Of Reception Interrupt Enable  
The RXENDIE bit is set and cleared by software.  
0: RXEND interrupt disabled  
1: RXEND interrupt enabled
- Bit 0 **RXBRIE**: Rx-Byte Received Interrupt Enable  
The RXBRIE bit is set and cleared by software.  
0: RXBR interrupt disabled  
1: RXBR interrupt enabled

**Caution:** (\*) It is mandatory to write CEC\_IER only when CECEN=0

### 39.7.7 HDMI-CEC register map

The following table summarizes the HDMI-CEC registers.

**Table 287. HDMI-CEC register map and reset values**

| Offset | Register name | 31   | 30        | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21   | 20   | 19   | 18   | 17   | 16   | 15   | 14   | 13   | 12      | 11      | 10      | 9       | 8      | 7         | 6       | 5      | 4      | 3      | 2        | 1       | 0      |        |       |          |  |  |  |

Refer to [Section 2.2.2 on page 69](#) for the register boundary addresses.

## 40 Debug support (DBG)

### 40.1 Overview

The STM32F75xxx and STM32F74xxx are built around a Cortex<sup>®</sup>-M7 with FPU core which contains hardware extensions for advanced debugging features. The debug extensions allow the core to be stopped either on a given instruction fetch (breakpoint) or data access (watchpoint). When stopped, the core's internal state and the system's external state may be examined. Once examination is complete, the core and the system may be restored and program execution resumed.

The debug features are used by the debugger host when connecting to and debugging the STM32F75xxx and STM32F74xxx MCUs.

Two interfaces for debug are available:

- Serial wire
- JTAG debug port

**Figure 535. Block diagram of STM32 MCU and Cortex<sup>®</sup>-M7 with FPU -level debug support**

**Note:** The debug features embedded in the Cortex<sup>®</sup>-M7 with FPU core are a subset of the Arm<sup>®</sup> CoreSight Components Technical Reference Manual.

The Arm® Cortex®-M7 with FPU core provides integrated on-chip debug support. It is comprised of:

- SWJ-DP: Serial wire / JTAG debug port
- AHP-AP: AHB access port
- ITM: Instrumentation trace macrocell
- FPB: Flash patch breakpoint
- DWT: Data watchpoint trigger
- TPIU: Trace port unit interface (available on larger packages, where the corresponding pins are mapped)
- ETM: Embedded Trace Macrocell (available on larger packages, where the corresponding pins are mapped)

It also includes debug features dedicated to the STM32F75xxx and STM32F74xxx:

- Flexible debug pinout assignment
- MCU debug box (support for low-power modes, control over peripheral clocks, etc.)

*Note:* For further information on debug functionality supported by the Arm® Cortex®-M7 with FPU core, refer to the Cortex®-M7 with FPU technical reference manual and to the CoreSight Components Technical Reference Manual (see [Section 40.2: Reference Arm® documentation](#)).

## 40.2 Reference Arm® documentation

- Cortex®-M7 with FPU technical reference manual (TRM)  
(see Related documents on page 1)
- Arm® Debug Interface V5 architecture specification
- Arm® CoreSight Components Technical Reference Manual

## 40.3 SWJ debug port (serial wire and JTAG)

The core of the STM32F75xxx and STM32F74xxx integrates the Serial Wire / JTAG Debug Port (SWJ-DP). It is an Arm® standard CoreSight debug port that combines a JTAG-DP (5-pin) interface and a SW-DP (2-pin) interface.

- The JTAG Debug Port (JTAG-DP) provides a 5-pin standard JTAG interface to the AHP-AP port.
- The Serial Wire Debug Port (SW-DP) provides a 2-pin (clock + data) interface to the AHP-AP port.

In the SWJ-DP, the two JTAG pins of the SW-DP are multiplexed with some of the five JTAG pins of the JTAG-DP.

**Figure 536. SWJ debug port**

Figure 536 shows that the asynchronous TRACE output (TRACESWO) is multiplexed with TDO. This means that the asynchronous trace can only be used with SW-DP, not JTAG-DP.

### 40.3.1 Mechanism to select the JTAG-DP or the SW-DP

By default, the JTAG-Debug Port is active.

If the debugger host wants to switch to the SW-DP, it must provide a dedicated JTAG sequence on TMS/TCK (respectively mapped to SWDIO and SWCLK) which disables the JTAG-DP and enables the SW-DP. This way it is possible to activate the SWDP using only the SWCLK and SWDIO pins.

This sequence is:

1. Send more than 50 TCK cycles with TMS (SWDIO) = 1
2. Send the 16-bit sequence on TMS (SWDIO) = 0111100111100111 (MSB transmitted first)
3. Send more than 50 TCK cycles with TMS (SWDIO) = 1

## 40.4 Pinout and debug port pins

The STM32F75xxx and STM32F74xxx MCUs are available in various packages with different numbers of available pins. As a result, some functionality related to pin availability (TPIU parallel output interface) may differ between packages.

### 40.4.1 SWJ debug port pins

Five pins are used as outputs from the STM32F75xxx and STM32F74xxx for the SWJ-DP as *alternate functions* of general-purpose I/Os. These pins are available on all packages.

**Table 288. SWJ debug port pins**

| SWJ-DP pin name | JTAG debug port |                          | SW debug port |                                    | Pin assignment |
|-----------------|-----------------|--------------------------|---------------|------------------------------------|----------------|
|                 | Type            | Description              | Type          | Debug assignment                   |                |
| JTMS/SWDIO      | I               | JTAG Test Mode Selection | IO            | Serial Wire Data Input/Output      | PA13           |
| JTCK/SWCLK      | I               | JTAG Test Clock          | I             | Serial Wire Clock                  | PA14           |
| JTDI            | I               | JTAG Test Data Input     | -             | -                                  | PA15           |
| JTDO/TRACESWO   | O               | JTAG Test Data Output    | -             | TRACESWO if async trace is enabled | PB3            |
| NJTRST          | I               | JTAG Test nReset         | -             | -                                  | PB4            |

### 40.4.2 Flexible SWJ-DP pin assignment

After RESET (SYSRESETn or PORESETn), all five pins used for the SWJ-DP are assigned as dedicated pins immediately usable by the debugger host (note that the trace outputs are not assigned except if explicitly programmed by the debugger host).

However, the STM32F75xxx and STM32F74xxx MCUs offer the possibility of disabling some or all of the SWJ-DP ports and so, of releasing (in gray in the table below) the associated pins for general-purpose IO (GPIO) usage. For more details on how to disable SWJ-DP port pins, refer to [Section 6.3.2: I/O pin alternate function multiplexer and mapping](#).

**Table 289. Flexible SWJ-DP pin assignment**

| Available debug ports                         | SWJ IO pin assigned |                     |             |            |              |
|-----------------------------------------------|---------------------|---------------------|-------------|------------|--------------|
|                                               | PA13 / JTMS / SWDIO | PA14 / JTCK / SWCLK | PA15 / JTDI | PB3 / JTDO | PB4 / NJTRST |
| Full SWJ (JTAG-DP + SW-DP) - Reset State      | X                   | X                   | X           | X          | X            |
| Full SWJ (JTAG-DP + SW-DP) but without NJTRST | X                   | X                   | X           | X          |              |
| JTAG-DP Disabled and SW-DP Enabled            | X                   | X                   | -           | -          | -            |
| JTAG-DP Disabled and SW-DP Disabled           | -                   | -                   | Released    |            |              |

*Note:*

When the APB bridge write buffer is full, it takes one extra APB cycle when writing the GPIO\_AFR register. This is because the deactivation of the JTAGSW pins is done in two cycles to guarantee a clean level on the nTRST and TCK input signals of the core.

- Cycle 1: the JTAGSW input signals to the core are tied to 1 or 0 (to 1 for TRST, TDI and TMS, to 0 for TCK)
- Cycle 2: the GPIO controller takes the control signals of the SWJTAG IO pins (like controls of direction, pull-up/down, Schmitt trigger activation, etc.).

### 40.4.3 Internal pull-up and pull-down on JTAG pins

It is necessary to ensure that the JTAG input pins are not floating since they are directly connected to flip-flops to control the debug mode features. Special care must be taken with the SWCLK/TCK pin which is directly connected to the clock of some of these flip-flops.

To avoid any uncontrolled IO levels, the device embeds internal pull-ups and pull-downs on the JTAG input pins:

- NJTRST: Internal pull-up
- JTDI: Internal pull-up
- JTMS/SWDIO: Internal pull-up
- TCK/SWCLK: Internal pull-down

Once a JTAG IO is released by the user software, the GPIO controller takes control again. The reset states of the GPIO control registers put the I/Os in the equivalent state:

- NJTRST: AF input pull-up
- JTDI: AF input pull-up
- JTMS/SWDIO: AF input pull-up
- JTCK/SWCLK: AF input pull-down
- JTDO: AF output floating

The software can then use these I/Os as standard GPIOs.

*Note: The JTAG IEEE standard recommends to add pull-ups on TDI, TMS and nTRST but there is no special recommendation for TCK. However, for JTCK, the device needs an integrated pull-down.*

*Having embedded pull-ups and pull-downs removes the need to add external resistors.*

#### 40.4.4 Using serial wire and releasing the unused debug pins as GPIOs

To use the serial wire DP to release some GPIOs, the user software must change the GPIO (PA15, PB3 and PB4) configuration mode in the GPIO\_MODER register. This releases PA15, PB3 and PB4 which now become available as GPIOs.

When debugging, the host performs the following actions:

- Under system reset, all SWJ pins are assigned (JTAG-DP + SW-DP).
- Under system reset, the debugger host sends the JTAG sequence to switch from the JTAG-DP to the SW-DP.
- Still under system reset, the debugger sets a breakpoint on vector reset.
- The system reset is released and the Core halts.
- All the debug communications from this point are done using the SW-DP. The other JTAG pins can then be reassigned as GPIOs by the user software.

*Note:* For user software designs, note that:

*To release the debug pins, remember that they will be first configured either in input-pull-up (nTRST, TMS, TDI) or pull-down (TCK) or output tristate (TDO) for a certain duration after reset until the instant when the user software releases the pins.*

*When debug pins (JTAG or SW or TRACE) are mapped, changing the corresponding IO pin configuration in the IOPORT controller has no effect.*

### 40.5 STM32F75xxx and STM32F74xxx JTAG Debug Port connection

The STM32F75xxx and STM32F74xxx MCUs integrate two serially connected JTAG Debug Ports, the boundary scan Debug Port (IR is 5-bit wide) and the Cortex®-M7 with FPU Debug Port (IR is 4-bit wide).

To access the Debug Port of the Cortex®-M7 with FPU for debug purposes:

1. First, it is necessary to shift the BYPASS instruction of the boundary scan Debug Port.
2. Then, for each IR shift, the scan chain contains 9 bits (=5+4) and the unused Debug Port instruction must be shifted in using the BYPASS instruction.
3. For each data shift, the unused Debug Port, which is in BYPASS mode, adds 1 extra data bit in the data scan chain.

*Note:* **Important:** Once Serial-Wire is selected using the dedicated Arm® JTAG sequence, the boundary scan Debug Port is automatically disabled (JTMS forced high).

Figure 537. JTAG Debug Port connections

## 40.6 ID codes and locking mechanism

There are several ID codes inside the STM32F75xxx and STM32F74xxx MCUs. ST strongly recommends tools designers to lock their debuggers using the MCU DEVICE ID code located in the external PPB memory map at address 0xE0042000.

### 40.6.1 MCU device ID code

The STM32F75xxx and STM32F74xxx MCUs integrate an MCU ID code. This ID identifies the ST MCU part-number and the die revision. It is part of the DBG\_MCU component and is mapped on the external PPB bus (see [Section 40.16 on page 1689](#)). This code is accessible using the JTAG debug port (4 to 5 pins) or the SW debug port (two pins) or by the user software. It is even accessible while the MCU is under system reset.

Only the DEV\_ID(11:0) should be used for identification by the debugger/programmer tools.

#### DBGMCU\_IDCODE

Address: 0xE004 2000

Only 32-bits access supported. Read-only.

|        |      |      |      |        |    |    |    |    |    |    |    |    |    |    |    |

|        |      |      |      | r      | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  |

Bits 31:16 **REV\_ID[15:0]** Revision identifier

This field indicates the revision of the device:

0x1000 = Revision A

0x1001 = Revision Z and 1

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:0 **DEV\_ID[11:0]**: Device identifier

The device ID is 0x449.

### 40.6.2 Boundary scan Debug Port

#### JTAG ID code

The Debug Port of the STM32F75xxx and STM32F74xxx BSC (boundary scan) integrates a JTAG ID code equal to 0x06449041.

### 40.6.3 Cortex<sup>®</sup>-M7 with FPU Debug Port

The Debug Port of the Arm<sup>®</sup> Cortex<sup>®</sup>-M7 with FPU integrates a JTAG ID code. This ID code is the Arm<sup>®</sup> default one and has not been modified. This code is only accessible by the JTAG Debug Port.

This code is 0x5BA00477 (corresponds to Cortex<sup>®</sup>-M7 with FPU, see [Section 40.2: Reference Arm<sup>®</sup> documentation](#)).

#### 40.6.4 Cortex<sup>®</sup>-M7 with FPU JEDEC-106 ID code

The Arm<sup>®</sup> Cortex<sup>®</sup>-M7 with FPU integrates a JEDEC-106 ID code. It is located in the 4KB ROM table mapped on the internal PPB bus at address 0xE00FF000\_0xE00FFFFF.

This code is accessible by the JTAG Debug Port (4 to 5 pins) or by the SW Debug Port (two pins) or by the user software.

### 40.7 JTAG debug port

A standard JTAG state machine is implemented with a 4-bit instruction register (IR) and five data registers (for full details, refer to the Cortex<sup>®</sup>-M7 with FPU technical *reference manual (TRM)*, for references, see [Section 40.2: Reference Arm<sup>®</sup> documentation](#)).

**Table 290. JTAG debug port data registers**

| IR(3:0) | Data register       | Details                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

## 40.8 SW debug port

### 40.8.1 SW protocol introduction

This synchronous serial protocol uses two pins:

- SWCLK: clock from host to target
- SWDIO: bidirectional

The protocol allows two banks of registers (DPACC registers and APACC registers) to be read and written to.

Bits are transferred LSB-first on the wire.

For SWDIO bidirectional management, the line must be pulled-up on the board (100 kΩ recommended by Arm®).

Each time the direction of SWDIO changes in the protocol, a turnaround time is inserted where the line is not driven by the host nor the target. By default, this turnaround time is one bit time, however this can be adjusted by configuring the SWCLK frequency.

### 40.8.2 SW protocol sequence

Each sequence consist of three phases:

1. Packet request (8 bits) transmitted by the host
2. Acknowledge response (3 bits) transmitted by the target
3. Data transfer phase (33 bits) transmitted by the host or the target

**Table 292. Packet request (8-bits)**

| Bit | Name   | Description                                                                      |
|-----|--------|----------------------------------------------------------------------------------|
| 0   | Start  | Must be “1”                                                                      |
| 1   | APnDP  | 0: DP Access<br>1: AP Access                                                     |
| 2   | RnW    | 0: Write Request<br>1: Read Request                                              |
| 4:3 | A(3:2) | Address field of the DP or AP registers (refer to <a href="#">Table 291</a> )    |
| 5   | Parity | Single bit parity of preceding bits                                              |
| 6   | Stop   | 0                                                                                |
| 7   | Park   | Not driven by the host. Must be read as “1” by the target because of the pull-up |

Refer to the Cortex<sup>®</sup>-M7 with FPU *TRM* for a detailed description of DPACC and APACC registers.

The packet request is always followed by the turnaround time (default 1 bit) where neither the host nor target drive the line.

**Table 293. ACK response (3 bits)**

| Bit  | Name | Description                        |
|------|------|------------------------------------|
| 0..2 | ACK  | 001: FAULT<br>010: WAIT<br>100: OK |

The ACK Response must be followed by a turnaround time only if it is a READ transaction or if a WAIT or FAULT acknowledge has been received.

**Table 294. DATA transfer (33 bits)**

| Bit   | Name           | Description                       |
|-------|----------------|-----------------------------------|
| 0..31 | WDATA or RDATA | Write or Read data                |
| 32    | Parity         | Single parity of the 32 data bits |

The DATA transfer must be followed by a turnaround time only if it is a READ transaction.

### 40.8.3 SW-DP state machine (reset, idle states, ID code)

The State Machine of the SW-DP has an internal ID code which identifies the SW-DP. It follows the JEP-106 standard. This ID code is the default Arm<sup>®</sup> one and is set to **0x5BA02477** (corresponding to Cortex<sup>®</sup>-M7 with FPU).

*Note:* Note that the SW-DP state machine is inactive until the target reads this ID code.

- The SW-DP state machine is in RESET STATE either after power-on reset, or after the DP has switched from JTAG to SWD or after the line is high for more than 50 cycles
- The SW-DP state machine is in IDLE STATE if the line is low for at least two cycles after RESET state.
- After RESET state, it is **mandatory** to first enter into an IDLE state AND to perform a READ access of the DP-SW ID CODE register. Otherwise, the target will issue a FAULT acknowledge response on another transactions.

Further details of the SW-DP state machine can be found in the *Cortex®-M7 with FPU TRM* and the *CoreSight Components Technical Reference Manual*.

#### 40.8.4 DP and AP read/write accesses

- Read accesses to the DP are not posted: the target response can be immediate (if ACK=OK) or can be delayed (if ACK=WAIT).
- Read accesses to the AP are posted. This means that the result of the access is returned on the next transfer. If the next access to be done is NOT an AP access, then the DP-RDBUFF register must be read to obtain the result.  
The READOK flag of the DP-CTRL/STAT register is updated on every AP read access or RDBUFF read request to know if the AP read access was successful.
- The SW-DP implements a write buffer (for both DP or AP writes), that enables it to accept a write operation even when other transactions are still outstanding. If the write buffer is full, the target acknowledge response is "WAIT". With the exception of IDCODE read or CTRL/STAT read or ABORT write which are accepted even if the write buffer is full.
- Because of the asynchronous clock domains SWCLK and HCLK, two extra SWCLK cycles are needed after a write transaction (after the parity bit) to make the write effective internally. These cycles should be applied while driving the line low (IDLE state)  
This is particularly important when writing the CTRL/STAT for a power-up request. If the next transaction (requiring a power-up) occurs immediately, it will fail.

#### 40.8.5 SW-DP registers

Access to these registers are initiated when APnDP=0

**Table 295. SW-DP registers**

| A(3:2) | R/W   | CTRLSEL bit of SELECT register | Register | Notes                                                                          |
|--------|-------|--------------------------------|----------|--------------------------------------------------------------------------------|
| 00     | Read  | -                              | IDCODE   | The manufacturer code is not set to ST code. 0x5BA02477 (identifies the SW-DP) |
| 00     | Write | -                              | ABORT    | -                                                                              |

Table 295. SW-DP registers (continued)

| A(3:2) | R/W        | CTRLSEL bit of SELECT register | Register     | Notes                                                                                                                                                                                                                                                                                                    |
|--------|------------|--------------------------------|--------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 01     | Read/Write | 0                              | DP-CTRL/STAT | Purpose is to: <ul style="list-style-type: none"> <li>– request a system or debug power-up</li> <li>– configure the transfer operation for AP accesses</li> <li>– control the pushed compare and pushed verify operations.</li> <li>– read some status flags (overrun, power-up acknowledges)</li> </ul> |
| 01     | Read/Write | 1                              | WIRE CONTROL | Purpose is to configure the physical serial port protocol (like the duration of the turnaround time)                                                                                                                                                                                                     |
| 10     | Read       | -                              | READ RESEND  | Enables recovery of the read data from a corrupted debugger transfer, without repeating the original AP transfer.                                                                                                                                                                                        |
| 10     | Write      | -                              | SELECT       | The purpose is to select the current access port and the active 4-words register window                                                                                                                                                                                                                  |
| 11     | Read/Write | -                              | READ BUFFER  | This read buffer is useful because AP accesses are posted (the result of a read AP request is available on the next AP transaction).<br>This read buffer captures data from the AP, presented as the result of a previous read, without initiating a new transaction                                     |

#### 40.8.6 SW-AP registers

Access to these registers are initiated when APnDP=1

There are many AP Registers (see AHB-AP) addressed as the combination of:

- The shifted value A[3:2]
- The current value of the DP SELECT register

## 40.9 AHB-AP (AHB access port) - valid for both JTAG-DP and SW-DP

### Features:

- System access is independent of the processor status.
- Either SW-DP or JTAG-DP accesses AHB-AP.
- The AHB-AP is an AHB master into the Bus Matrix. Consequently, it can access all the data buses (Dcode Bus, System Bus, internal and external PPB bus) but the ICode bus.
- Bitband transactions are supported.
- AHB-AP transactions bypass the FPB.

The address of the 32-bits AHB-AP registers are 6-bits wide (up to 64 words or 256 bytes) and consists of:

- c) Bits [7:4] = the bits [7:4] APBANKSEL of the DP SELECT register
- d) Bits [3:2] = the 2 address bits of A(3:2) of the 35-bit packet request for SW-DP.

The AHB-AP of the Cortex<sup>®</sup>-M7 with FPU includes 9 x 32-bits registers:

**Table 296. Cortex<sup>®</sup>-M7 with FPU AHB-AP registers**

| Address offset | Register name                  | Notes                                                                                                                         |
|----------------|--------------------------------|-------------------------------------------------------------------------------------------------------------------------------|
| 0x00           | AHB-AP Control and Status Word | Configures and controls transfers through the AHB interface (size, hprot, status on current transfer, address increment type) |
| 0x04           | AHB-AP Transfer Address        | -                                                                                                                             |
| 0x0C           | AHB-AP Data Read/Write         | -                                                                                                                             |
| 0x10           | AHB-AP Banked Data 0           | Directly maps the 4 aligned data words without rewriting the Transfer Address Register.                                       |
| 0x14           | AHB-AP Banked Data 1           |                                                                                                                               |
| 0x18           | AHB-AP Banked Data 2           |                                                                                                                               |
| 0x1C           | AHB-AP Banked Data 3           |                                                                                                                               |
| 0xF8           | AHB-AP Debug ROM Address       | Base Address of the debug interface                                                                                           |
| 0xFC           | AHB-AP ID Register             | -                                                                                                                             |

Refer to the *Cortex<sup>®</sup>-M7 with FPU TRM* for further details.

## 40.10 Core debug

Core debug is accessed through the core debug registers. Debug access to these registers is by means of the *Advanced High-performance Bus* (AHB-AP) port. The processor can access these registers directly over the internal *Private Peripheral Bus* (PPB).

It consists of 4 registers:

**Table 297. Core debug registers**

| Register | Description                                                                                                                                                                                            |
|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DHCSR    | The 32-bit Debug Halting Control and Status Register<br>This provides status information about the state of the processor enable core debug halt and step the processor                                |
| DCRSR    | The 17-bit Debug Core Register Selector Register:<br>This selects the processor register to transfer data to or from.                                                                                  |
| DCRDR    | The 32-bit Debug Core Register Data Register:<br>This holds data for reading and writing registers to and from the processor selected by the DCRSR (Selector) register.                                |
| DEMCR    | The 32-bit Debug Exception and Monitor Control Register:<br>This provides Vector Catching and Debug Monitor Control. This register contains a bit named <b>TRCENA</b> which enable the use of a TRACE. |

*Note:* **Important:** these registers are not reset by a system reset. They are only reset by a power-on reset.

Refer to the *Cortex®-M7 with FPU TRM* for further details.

To Halt on reset, it is necessary to:

- enable the bit0 (VC\_CORRESET) of the Debug and Exception Monitor Control Register
- enable the bit0 (C\_DEBUGEN) of the Debug Halting Control and Status Register.

## 40.11 Capability of the debugger host to connect under system reset

The reset system of the STM32F75xxx and STM32F74xxx MCU comprises the following reset sources:

- POR (power-on reset) which asserts a RESET at each power-up.
- Internal watchdog reset
- Software reset
- External reset

The Cortex®-M7 with FPU differentiates the reset of the debug part (generally PORRESETn) and the other one (SYSRESETn)

This way, it is possible for the debugger to connect under System Reset, programming the Core Debug Registers to halt the core when fetching the reset vector. Then the host can release the system reset and the core will immediately halt without having executed any instructions. In addition, it is possible to program any debug features under System Reset.

*Note: It is highly recommended for the debugger host to connect (set a breakpoint in the reset vector) under system reset.*

## 40.12 FPB (Flash patch breakpoint)

Typically in Cortex-M architecture the FPB unit allows to:

- implement hardware breakpoints
- patch code and data from code space to system space. This feature gives the possibility to correct software bugs located in the Code Memory Space.

Where the use of a Software Patch or a Hardware Breakpoint is exclusive.

But there are some major changes in Pelican FPB:

- Flash patching is no more supported (there is no FP\_REMAP register)
- All comparators are for instruction addresses (up to 8 instruction breakpoints)
- Programmer's model for breakpoint comparators is enhanced to allow hardware breakpoint in full address range.

## 40.13 DWT (data watchpoint trigger)

The DWT unit consists of four comparators. They are configurable as:

- a hardware watchpoint or
- a trigger to an ETM or
- a PC sampler or
- a data address sampler

The DWT also provides some means to give some profiling informations. For this, some counters are accessible to give the number of:

- Clock cycle
- Folded instructions
- Load store unit (LSU) operations
- Sleep cycles
- CPI (clock per instructions)
- Interrupt overhead

## 40.14 ITM (instrumentation trace macrocell)

### 40.14.1 General description

The ITM is an application-driven trace source that supports *printf* style debugging to trace *Operating System* (OS) and application events, and emits diagnostic system information. The ITM emits trace information as packets which can be generated as:

- **Software trace.** Software can write directly to the ITM stimulus registers to emit packets.
- **Hardware trace.** The DWT generates these packets, and the ITM emits them.
- **Time stamping.** Timestamps are emitted relative to packets. The ITM contains a 21-bit counter to generate the timestamp. The Cortex<sup>®</sup>-M7 with FPU clock or the bit clock rate of the *Serial Wire Viewer* (SWV) output clocks the counter.

The packets emitted by the ITM are output to the TPIU (Trace Port Interface Unit). The formatter of the TPIU adds some extra packets (refer to TPIU) and then output the complete packets sequence to the debugger host.

The bit TRCEN of the Debug Exception and Monitor Control Register must be enabled before you program or use the ITM.

### 40.14.2 Time stamp packets, synchronization and overflow packets

Time stamp packets encode time stamp information, generic control and synchronization. It uses a 21-bit timestamp counter (with possible prescalers) which is reset at each time stamp packet emission. This counter can be either clocked by the CPU clock or the SWV clock.

A synchronization packet consists of 6 bytes equal to 0x80\_00\_00\_00\_00\_00 which is emitted to the TPIU as 00 00 00 00 00 80 (LSB emitted first).

A synchronization packet is a timestamp packet control. It is emitted at each DWT trigger.

For this, the DWT must be configured to trigger the ITM: the bit CYCCNTENA (bit0) of the DWT Control Register must be set. In addition, the bit2 (SYNCENA) of the ITM Trace Control Register must be set.

*Note: If the SYNENA bit is not set, the DWT generates Synchronization triggers to the TPIU which will send only TPIU synchronization packets and not ITM synchronization packets.*

An overflow packet consists is a special timestamp packets which indicates that data has been written but the FIFO was full.

**Table 298. Main ITM registers**

| Address                | Register                     | Details                                                                                                                                                   |

### Example of configuration

To output a simple value to the TPIU:

- Configure the TPIU and assign TRACE I/Os by configuring the DBGMCU\_CR (refer to [Section 40.17.2: TRACE pin assignment](#) and [Section 40.16.3: Debug MCU](#))

[configuration register](#))

- Write 0xC5ACCE55 to the ITM Lock Access Register to unlock the write access to the ITM registers
- Write 0x00010005 to the ITM Trace Control Register to enable the ITM with Sync enabled and an ATB ID different from 0x00
- Write 0x1 to the ITM Trace Enable Register to enable the Stimulus Port 0
- Write 0x1 to the ITM Trace Privilege Register to unmask stimulus ports 7:0
- Write the value to output in the Stimulus Port Register 0: this can be done by software (using a printf function)

## 40.15 ETM (Embedded trace macrocell)

### 40.15.1 General description

The ETM enables the reconstruction of program execution. Data are traced using the Data Watchpoint and Trace (DWT) component or the Instruction Trace Macrocell (ITM) whereas instructions are traced using the Embedded Trace Macrocell (ETM).

The ETM transmits information as packets and is triggered by embedded resources. These resources must be programmed independently and the trigger source is selected using the Trigger Event Register (0xE0041008). An event could be a simple event (address match from an address comparator) or a logic equation between 2 events. The trigger source is one of the fourth comparators of the DWT module, The following events can be monitored:

- Clock cycle matching
- Data address matching

For more informations on the trigger resources refer to [Section 40.13: DWT \(data watchpoint trigger\)](#).

The packets transmitted by the ETM are output to the TPIU (Trace Port Interface Unit). The formatter of the TPIU adds some extra packets (refer to [Section 40.17: Pelican TPIU \(trace port interface unit\)](#)) and then outputs the complete packet sequence to the debugger host.

*Note:* N.B: Cortex-M7 ETM is compliant with Arm ETM architecture v4, which programming model is not backward compatible with Cortex-M4 ETM one (ETM architecture v3.5).

### 40.15.2 Signal protocol, packet types

This part is described in the chapter 6 ETM v4 architecture specification (IHI0064B).

### 40.15.3 Main ETM registers

For more information on registers refer to the Pelican ETM technical reference manual (DDI0494-2a) and the ETM v4 architecture specification (IHI0064B).

### 40.15.4 Configuration example

To output a simple value to the TPIU:

- Configure trace I/Os: enable TRACE\_CLKINEN in the STM32F75xxx and STM32F74xxx debug configuration register (DBGMCU\_CR).
- Write @ E000EDFC 01000000; SCS: set TRCENA, otherwise trace registers are not accessible.
- Write @ E00400F0 00000000; TPIU: select SYNC PORT Mode
- Write @ E0040004 00000008; TPIU: select TPIU PORT SIZE=4
- Write @ E0001020 002002CA; WT: PC MATCH Comparator (PC=0x2002CA)
- Write @ E0001024 00000000; DWT: No mask apply on comparator
- Write @ E0001028 00000008; DWT: ETM trig on PC on match

ETM:

- Write @ E0041004 00000000; Disable ETM
- Read @ E004100C 00000003; ETM should be in Idle state
- Write @ E0041040 00000002; Instruction trace source ID = 0x2
- Write @ E0041080 00000001; Resource for ViewInst enabling event is "always TRUE"
- Write @ E004108C 000000FF; Processor comparator selection for Start: pc\_match0 (=>DWT match)
- Write @ E0041004 00000001; Enable ETM

## 40.16 MCU debug component (DBGMCU)

The MCU debug component helps the debugger provide support for:

- Low-power modes
- Clock control for timers, watchdog, I2C and bxCAN during a breakpoint
- Control of the trace pins assignment

### 40.16.1 Debug support for low-power modes

To enter low-power mode, the instruction WFI or WFE must be executed.

The MCU implements several low-power modes which can either deactivate the CPU clock or reduce the power of the CPU.

The core does not allow FCLK or HCLK to be turned off during a debug session. As these are required for the debugger connection, during a debug, they must remain active. The MCU integrates special means to allow the user to debug software in low-power modes.

For this, the debugger host must first set some debug configuration registers to change the low-power mode behavior:

- In Sleep mode, DBG\_SLEEP bit of DBGMCU\_CR register must be previously set by the debugger. This will feed HCLK with the same clock that is provided to FCLK (system clock previously configured by the software).
- In Stop mode, the bit DBG\_STOP must be previously set by the debugger. This will enable the internal RC oscillator clock to feed FCLK and HCLK in STOP mode.

#### 40.16.2 Debug support for timers, watchdog, bxCAN and I<sup>2</sup>C

During a breakpoint, it is necessary to choose how the counter of timers and watchdog should behave:

- They can continue to count inside a breakpoint. This is usually required when a PWM is controlling a motor, for example.
- They can stop to count inside a breakpoint. This is required for watchdog purposes.

For the bxCAN, the user can choose to block the update of the receive register during a breakpoint.

For the I<sup>2</sup>C, the user can choose to block the SMBUS timeout during a breakpoint.

For timers having complementary outputs, when the counter is stopped (DBG\_TIMx\_STOP=1), the outputs are disabled (as if the MOE bit was reset) for safety purposes.

#### 40.16.3 Debug MCU configuration register

This register allows the configuration of the MCU under DEBUG. This concerns:

- Low-power mode support
- Timer and watchdog counter support
- bxCAN communication support
- Trace pin assignment

This DBGMCU\_CR is mapped on the External PPB bus at address 0xE0042004

It is asynchronously reset by the PORESET (and not the system reset). It can be written by the debugger under system reset.

If the debugger host does not support these features, it is still possible for the user software to write to these registers.

#### 40.16.4 DBGMCU\_CR register

Address: 0xE004 2004

Only 32-bit access supported

POR Reset: 0x0000 0000 (not reset by system reset)

|      |      |      |      |      |      |      |      |                 |      |                |      |      |             |          |           |

| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | TRACE_MODE[1:0] |      | TRACE_CLKIN_EN | Res. | Res. | DBG_STANDBY | DBG_STOP | DBG_SLEEP |
|      |      |      |      |      |      |      |      | rw              | rw   | rw             |      |      | rw          | rw       | rw        |

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:5 **TRACE\_MODE[1:0] and TRACE\_CLKINEN**: Trace clock and pin assignment control

– With TRACE\_CLKINEN=0:

TRACE\_MODE=xx: TRACE output disabled (both synchronous and asynchronous)

– With TRACE\_CLKINEN=1:

– TRACE\_MODE[1:0]=00: Asynchronous trace interface enabled at pad level (TRACESWO available only on TDO pad when using Serial Wire mode) / Synchronous trace interface enabled

– TRACE\_MODE[1:0] different to =00: Asynchronous trace interface disabled / Synchronous trace interface enabled

Bits 4:3 Reserved, must be kept at reset value.

**Bit 2 DBG\_STANDBY:** Debug Standby mode

0: (FCLK=Off, HCLK=Off) The whole digital part is unpowered.

From software point of view, exiting from Standby is identical than fetching reset vector (except a few status bit indicated that the MCU is resuming from Standby)

1: (FCLK=On, HCLK=On) In this case, the digital part is not unpowered and FCLK and HCLK are provided by the internal RC oscillator which remains active. In addition, the MCU generate a system reset during Standby mode so that exiting from Standby is identical than fetching from reset

**Bit 1 DBG\_STOP:** Debug Stop mode

0: (FCLK=Off, HCLK=Off) In STOP mode, the clock controller disables all clocks (including HCLK and FCLK). When exiting from STOP mode, the clock configuration is identical to the one after RESET (CPU clocked by the 8 MHz internal RC oscillator (HSI)). Consequently, the software must reprogram the clock controller to enable the PLL, the Xtal, etc.

1: (FCLK=On, HCLK=On) In this case, when entering STOP mode, FCLK and HCLK are provided by the internal RC oscillator which remains active in STOP mode. When exiting STOP mode, the software must reprogram the clock controller to enable the PLL, the Xtal, etc. (in the same way it would do in case of DBG\_STOP=0)

**Bit 0 DBG\_SLEEP:** Debug Sleep mode

0: (FCLK=On, HCLK=Off) In Sleep mode, FCLK is clocked by the system clock as previously configured by the software while HCLK is disabled.

In Sleep mode, the clock controller configuration is not reset and remains in the previously programmed state. Consequently, when exiting from Sleep mode, the software does not need to reconfigure the clock controller.

1: (FCLK=On, HCLK=On) In this case, when entering Sleep mode, HCLK is fed by the same clock that is provided to FCLK (system clock as previously configured by the software).

#### 40.16.5 Debug MCU APB1 freeze register (DBGMCU\_APB1\_FZ)

The DBGMCU\_APB1\_FZ register is used to configure the MCU under DEBUG. It concerns APB2 peripherals. It is mapped on the external PPB bus at address 0xE004 2008

It is asynchronously reset by the POR (and not the system reset). It can be written by the debugger under system reset.

Address: 0xE004 2008

Only 32-bit access is supported.

Power-on-reset (POR): 0x0000 0000 (not reset by system reset)

|      |      |      |               |               |               |                 |                        |                        |                        |                        |               |               |               |               |               |

Bits 31:27 Reserved, must be kept at reset value.

Bit 26 **DBG\_CAN2\_STOP**: Debug CAN2 stopped when Core is halted

- 0: Same behavior as in normal mode
- 1: The CAN2 receive registers are frozen

Bit 25 **DBG\_CAN1\_STOP**: Debug CAN2 stopped when Core is halted

- 0: Same behavior as in normal mode
- 1: The CAN2 receive registers are frozen

Bit 24 **DBG\_I2C4\_SMBUS\_TIMEOUT**: SMBUS timeout mode stopped when Core is halted

- 0: Same behavior as in normal mode
- 1: The SMBUS timeout is frozen

Bit 23 **DBG\_I2C3\_SMBUS\_TIMEOUT**: SMBUS timeout mode stopped when Core is halted

- 0: Same behavior as in normal mode
- 1: The SMBUS timeout is frozen

Bit 22 **DBG\_I2C2\_SMBUS\_TIMEOUT**: SMBUS timeout mode stopped when Core is halted

- 0: Same behavior as in normal mode
- 1: The SMBUS timeout is frozen

Bit 21 **DBG\_I2C1\_SMBUS\_TIMEOUT**: SMBUS timeout mode stopped when Core is halted

- 0: Same behavior as in normal mode
- 1: The SMBUS timeout is frozen

Bits 20:13 Reserved, must be kept at reset value.

Bit 12 **DBG\_IWDG\_STOP**: Debug independent watchdog stopped when core is halted

- 0: The independent watchdog counter clock continues even if the core is halted
- 1: The independent watchdog counter clock is stopped when the core is halted

Bit 11 **DBG\_WWDG\_STOP**: Debug Window Watchdog stopped when Core is halted

- 0: The window watchdog counter clock continues even if the core is halted
- 1: The window watchdog counter clock is stopped when the core is halted

Bit 10 **DBG\_RTC\_STOP**: RTC stopped when Core is halted

- 0: The RTC counter clock continues even if the core is halted
- 1: The RTC counter clock is stopped when the core is halted

Bit 9 **DBG\_LPTIM1\_STOP**: LPTIM1 counter stopped when core is halted

- 0: The clock of LPTIM1 counter is fed even if the core is halted
- 1: The clock of LPTIM1 counter is stopped when the core is halted

Bits 8:0 **DBG\_TIMx\_STOP**: TIMx counter stopped when core is halted (x=2..7, 12..14)

- 0: The clock of the involved Timer Counter is fed even if the core is halted
- 1: The clock of the involved Timer counter is stopped and the outputs are disabled when the core is halted

#### 40.16.6 Debug MCU APB2 Freeze register (DBGMCU\_APB2\_FZ)

The DBGMCU\_APB2\_FZ register is used to configure the MCU under Debug. It concerns APB2 peripherals.

This register is mapped on the external PPB bus at address 0xE004 200C

It is asynchronously reset by the POR (and not the system reset). It can be written by the debugger under system reset.

Address: 0xE004 200C

Only 32-bit access is supported.

POR: 0x0000 0000 (not reset by system reset)

| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res.           | DBG_TIM8_STOP  | DBG_TIM1_STOP |
|      |      |      |      |      |      |      |      |      |      |      |      |      |                | rw             | rw            |

Bits 31:19 Reserved, must be kept at reset value.

Bits 18:16 **DBG\_TIMx\_STOP**: TIMx counter stopped when core is halted (x=9..11)

- 0: The clock of the involved Timer Counter is fed even if the core is halted
- 1: The clock of the involved Timer counter is stopped and the outputs are disabled when the core is halted

Bits 15:2 Reserved, must be kept at reset value.

Bit 1 **DBG\_TIM8\_STOP**: TIM8 counter stopped when core is halted

- 0: The clock of the involved Timer Counter is fed even if the core is halted
- 1: The clock of the involved Timer counter is stopped and the output is disabled when the core is halted

Bit 0 **DBG\_TIM1\_STOP**: TIM1 counter stopped when core is halted

- 0: The clock of the involved Timer Counter is fed even if the core is halted
- 1: The clock of the involved Timer counter is stopped and the output is disabled when the core is halted

## 40.17 Pelican TPIU (trace port interface unit)

### 40.17.1 Introduction

The TPIU acts as a bridge between the on-chip trace data from the ITM, the ETM and the external trace capture device.

The output data stream encapsulates the trace source ID, that is then captured by a *trace port analyzer* (TPA).

The core embeds a simple TPIU, especially designed for low-cost debug (consisting of a special version of the CoreSight TPIU).

**Figure 538. TPIU block diagram**

## 40.17.2 TRACE pin assignment

- **Asynchronous mode**  
The asynchronous mode requires 1 extra pin and is available on all packages. It is only available if using Serial Wire mode (not in JTAG mode).

**Table 299. Asynchronous TRACE pin assignment**

| TPIU pin name | Trace synchronous mode |                         |
|---------------|------------------------|-------------------------|
|               | Type                   | Description             |
| TRACESWO      | O                      | TRACE Async Data Output |

- **Synchronous mode**  
The synchronous mode requires from 2 to 6 extra pins depending on the data trace size and is only available in the larger packages. In addition it is available in JTAG mode and in Serial Wire mode and provides better bandwidth output capabilities than asynchronous trace.

**Table 300. Synchronous TRACE pin assignment**

| TPIU pin name | Trace synchronous mode |                                              |
|---------------|------------------------|----------------------------------------------|
|               | Type                   | Description                                  |
| TRACECK       | O                      | TRACE Clock                                  |
| TRACED[3:0]   | O                      | TRACE Sync Data Outputs<br>Can be 1, 2 or 4. |

### TPIU TRACE pin assignment

By default, these pins are NOT assigned. They can be assigned by setting the TRACE\_CLKINEN and TRACE\_MODE bits in the **MCU Debug component configuration register**. This configuration has to be done by the debugger host.

In addition, the number of pins to assign depends on the trace configuration (asynchronous or synchronous).

- **Asynchronous mode:** 1 extra pin is needed
- **Synchronous mode:** from 2 to 5 extra pins are needed depending on the size of the data trace port register (1, 2 or 4):
  - TRACECK
  - TRACED(0) if port size is configured to 1, 2 or 4
  - TRACED(1) if port size is configured to 2 or 4
  - TRACED(2) if port size is configured to 4
  - TRACED(3) if port size is configured to 4

To assign the TRACE pin, the debugger host must program the bits TRACE\_CLKINEN and TRACE\_MODE[1:0] of the Debug MCU configuration register (DBGMCU\_CR). By default the TRACE pins are not assigned.

This register is mapped on the external PPB and is reset by the PORESET (and not by the SYSTEM reset). It can be written by the debugger under SYSTEM reset.

Table 301. Flexible TRACE pin assignment

| DBGMCU_CR register |                  | Pins assigned for:                     | TRACE IO pin assigned   |         |           |                           |           |           |
|--------------------|------------------|----------------------------------------|-------------------------|---------|-----------|---------------------------|-----------|-----------|
| TRACE_CLKINEN      | TRACE_MODE [1:0] |                                        | JTDO/TRACESWO           | TRACECK | TRACED[0] | TRACED[1]                 | TRACED[2] | TRACED[3] |
| 0                  | XX               | No Trace (default state)               | Released <sup>(1)</sup> | -       |           |                           |           |           |
| 1                  | 00               | Asynchronous Trace                     | TRACESWO                | -       | -         | Released (usable as GPIO) |           |           |
| 1                  | different of 00  | Synchronous Trace 1 bit <sup>(2)</sup> | Released <sup>(1)</sup> | TRACECK | TRACED[0] | -                         | -         | -         |
| 1                  | different of 00  | Synchronous Trace 2 bit <sup>(2)</sup> |                         | TRACECK | TRACED[0] | TRACED[1]                 | -         | -         |
| 1                  | different of 00  | Synchronous Trace 4 bit <sup>(2)</sup> |                         | TRACECK | TRACED[0] | TRACED[1]                 | TRACED[2] | TRACED[3] |

1. When Serial Wire mode is used, it is released. But when JTAG is used, it is assigned to JTDO.

2. Selected with Bit[3:0] Current port size from TPIU register.

**Note:** By default, the TRACECLKIN input clock of the TPIU is tied to GND. It is assigned to HCLK two clock cycles after the bit TRACE\_CLKINEN has been set.

The debugger must then program the Trace Mode by writing the PROTOCOL[1:0] bits in the SPP\_R (Selected Pin Protocol) register of the TPIU.

- PROTOCOL=00: Trace Port Mode (synchronous)
- PROTOCOL=01 or 10: Serial Wire (Manchester or NRZ) Mode (asynchronous mode). Default state is 01

It then also configures the TRACE port size by writing the bits [3:0] in the CPSPS\_R (Current Sync Port Size Register) of the TPIU:

- 0x1 for 1 pin (default state)
- 0x2 for 2 pins
- 0x8 for 4 pins

### 40.17.3 TPIU formatter

The purpose of this formatter is to build 128 bit frames containing trace data from, potentially, both the ETM and the ITM, and to allow at a trace analyzer level a correlation between trace packets and emitters.

The formatter protocol outputs data in 16-byte frames:

- seven bytes of data
- eight bytes of mixed-use bytes consisting of:
  - 1 bit (LSB) to indicate it is a DATA byte ('0') or an ID byte ('1').
  - 7 bits (MSB) which can be data or change of source ID trace.
- one byte of auxiliary bits where each bit corresponds to one of the eight mixed-use bytes:
  - if the corresponding byte was a data, this bit gives bit0 of the data.
  - if the corresponding byte was an ID change, this bit indicates when that ID change takes effect.

*Note:* Refer to the Arm® CoreSight Architecture Specification v1.0 (Arm® IHI 0029B) for further information

### 40.17.4 TPIU frame synchronization packets

The TPIU can generate two types of synchronization packets:

- The Frame Synchronization packet (or Full Word Synchronization packet)  
It consists of the word: 0x7F\_FF\_FF\_FF (LSB emitted first). This sequence can not occur at any other time provided that the ID source code 0x7F has not been used.  
It is output periodically **between** frames.  
In continuous mode, the TPA must discard all these frames once a synchronization frame has been found.
- The Half-Word Synchronization packet  
It consists of the half word: 0x7F\_FF (LSB emitted first).  
It is output periodically **between or within** frames.  
These packets are only generated in continuous mode and enable the TPA to detect that the TRACE port is in IDLE mode (no TRACE to be captured). When detected by the TPA, it must be discarded.

### 40.17.5 Transmission of the synchronization frame packet

There is no Synchronization Counter register implemented in the TPIU of the core. Consequently, the synchronization trigger can only be generated by the **DWT**. Refer to the registers DWT Control Register (bits SYNCTAP[11:10]) and the DWT Current PC Sampler Cycle Count Register.

The TPIU Frame synchronization packet (0x7F\_FF\_FF\_FF) is emitted:

- after each TPIU reset release. This reset is synchronously released with the rising edge of the TRACECLKIN clock. This means that this packet is transmitted when the

TRACE\_CLKINEN bit in the DBGMCU\_CFG register is set. In this case, the word 0x7F\_FF\_FF\_FF is not followed by any formatted packet.

- at each DWT trigger (assuming DWT has been previously configured). Two cases occur:
  - If the bit SYNENA of the ITM is reset, only the word 0x7F\_FF\_FF\_FF is emitted without any formatted stream which follows.
  - If the bit SYNENA of the ITM is set, then the ITM synchronization packets will follow (0x80\_00\_00\_00\_00\_00), formatted by the TPIU (trace source ID added).

#### 40.17.6 Synchronous mode

The trace data output size can be configured to 4, 2 or 1 pin: TRACED(3:0)

The output clock is output to the debugger (TRACECK)

Here, TRACECLKIN is driven internally and is connected to HCLK only when TRACE is used.

*Note:* In this synchronous mode, it is not required to provide a stable clock frequency.

The TRACE I/Os (including TRACECK) are driven by the rising edge of TRACLKIN (equal to HCLK). Consequently, the output frequency of TRACECK is equal to HCLK/2.

#### 40.17.7 Asynchronous mode

This is a low cost alternative to output the trace using only 1 pin: this is the asynchronous output pin TRACESWO. Obviously there is a limited bandwidth.

Single IO trace mode is typically suitable for ITM trace output. Also, formatter is disabled in case of asynchronous trace, so merging of ETM and ITM trace streams is not possible.

TRACESWO is multiplexed with JTDO when using the SW-DP pin. This way, this functionality is available in all STM32F75xxx and STM32F74xxx packages.

This asynchronous mode requires a constant frequency for TRACECLKIN. For the standard UART (NRZ) capture mechanism, 5% accuracy is needed. The Manchester encoded version is tolerant up to 10%.

#### 40.17.8 TRACECLKIN connection inside the STM32F75xxx and STM32F74xxx

In the STM32F75xxx and STM32F74xxx, this TRACECLKIN input is internally connected to HCLK. This means that when in asynchronous trace mode, the application is restricted to use time frames where the CPU frequency is stable.

*Note:* **Important:** when using asynchronous trace: it is important to be aware that:

*The default clock of the STM32F75xxx and STM32F74xxx MCUs is the internal RC oscillator. Its frequency under reset is different from the one after reset release. This is because the RC calibration is the default one under system reset and is updated at each system reset release.*

*Consequently, the trace port analyzer (TPA) should not enable the trace (with the TRACE\_CLKINEN bit) under system reset, because a Synchronization Frame Packet will be issued with a different bit time than trace packets which will be transmitted after reset release.*

### 40.17.9 TPIU registers

The TPIU APB registers can be read and written only if the bit TRCENA of the Debug Exception and Monitor Control Register (DEMCR) is set. Otherwise, the registers are read as zero (the output of this bit enables the PCLK of the TPIU).

**Table 302. Important TPIU registers**

| Address    | Register                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| 0xE0040304 | Formatter and flush control | Bits 31-9 = always '0<br>Bit 8 = TrgIn = always '1 to indicate that triggers are indicated<br>Bits 7-4 = always 0<br>Bits 3-2 = always 0<br>Bit 1 = EnFCont. In Sync Trace mode (Select_Pin_Protocol register bit1:0=00), this bit is forced to '1: the formatter is automatically enabled in continuous mode. In asynchronous mode (Select_Pin_Protocol register bit1:0 <> 00), this bit can be written to activate or not the formatter.<br>Bit 0 = always 0<br>The resulting default value is 0x102<br><b>Note:</b> In synchronous mode, because the TRACECTL pin is not mapped outside the chip, the formatter is always enabled in continuous mode -this way the formatter inserts some control packets to identify the source of the trace packets). |
| 0xE0040300 | Formatter and flush status  | Not used in Cortex®-M7 with FPU, always read as 0x00000008                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

### 40.17.10 Example of configuration

- Set the bit TRCENA in the Debug Exception and Monitor Control Register (DEMCR)
- Write the TPIU Current Port Size Register to the desired value (default is 0x1 for a 1-bit port size)
- Write TPIU Formatter and Flush Control Register to 0x102 (default value)
- Write the TPIU Select Pin Protocol to select the sync or async mode. Example: 0x2 for async NRZ mode (UART like)
- Write the DBGMCU control register to 0x20 (bit IO\_TRACEN) to assign TRACE I/Os for async mode. A TPIU Sync packet is emitted at this time (FF\_FF\_FF\_7F)
- Configure the ITM and write the ITM Stimulus register to output a value

## 40.18 DBG register map

The following table summarizes the Debug registers.

**Table 303. DBG register map and reset values**

| Addr.       | Register                   | 31     | 30   | 29   | 28   | 27   | 26            | 25            | 24                     | 23                     | 22                     | 21                     | 20             | 19             | 18            | 17            | 16                     | 15   | 14   | 13   | 12            | 11            | 10              | 9            | 8              | 7                 | 6              | 5             | 4             | 3             | 2             | 1             | 0             |

1. The reset value is product dependent. For more information, refer to [Section 40.6.1: MCU device ID code](#).

## 41 Device electronic signature

The electronic signature is stored in the Flash memory area. It can be read using the JTAG/SWD or the CPU. It contains factory-programmed identification data that allow the user firmware or other external devices to automatically match its interface to the characteristics of the STM32F75xxx and STM32F74xxx microcontrollers.

### 41.1 Unique device ID register (96 bits)

The unique device identifier is ideally suited:

- for use as serial numbers (for example USB string serial numbers or other end applications)
- for use as security keys in order to increase the security of code in Flash memory while using and combining this unique ID with software cryptographic primitives and protocols before programming the internal Flash memory
- to activate secure boot processes, etc.

The 96-bit unique device identifier provides a reference number which is unique for any device and in any context. These bits can never be altered by the user.

The 96-bit unique device identifier can also be read in single bytes/half-words/words in different ways and then be concatenated using a custom algorithm.

**Base address: 0x1FF0 F420**
