

# THE DATASHEET OF STM32F756IGT6

---

**STM32F75xxx and STM32F74xxx advanced Arm<sup>®</sup>-based  
32-bit MCUs**

---

## **Introduction**

This reference manual targets application developers. It provides complete information on how to use the STM32F75xxx and STM32F74xxx microcontroller memory and peripherals.

The STM32F75xxx and STM32F74xxx is a family of microcontrollers with different memory sizes, packages and peripherals.

For ordering information, mechanical and electrical device characteristics refer to the datasheets.

For information on the Arm<sup>®</sup> Cortex<sup>®</sup>-M7 with FPU core, refer to the *Cortex<sup>®</sup>-M7 with FPU* technical reference manual.

| 3.4      | FLASH Option bytes                                     | 84        |
| 3.4.1    | Option bytes description                               | 84        |
| 3.4.2    | Option bytes programming                               | 87        |
| 3.5      | FLASH memory protection                                | 88        |
| 3.5.1    | Read protection (RDP)                                  | 88        |
| 3.5.2    | Write protections                                      | 89        |
| 3.6      | One-time programmable bytes                            | 90        |
| 3.7      | FLASH registers                                        | 91        |
| 3.7.1    | Flash access control register (FLASH_ACR)              | 91        |
| 3.7.2    | Flash key register (FLASH_KEYR)                        | 92        |
| 3.7.3    | Flash option key register (FLASH_OPTKEYR)              | 92        |
| 3.7.4    | Flash status register (FLASH_SR)                       | 93        |
| 3.7.5    | Flash control register (FLASH_CR)                      | 94        |
| 3.7.6    | Flash option control register (FLASH_OPTCR)            | 95        |
| 3.7.7    | Flash option control register (FLASH_OPTCR1)           | 96        |
| 3.7.8    | Flash interface register map                           | 98        |
| <b>4</b> | <b>Power controller (PWR)</b>                          | <b>99</b> |
| 4.1      | Power supplies                                         | 99        |
| 4.1.1    | Independent A/D converter supply and reference voltage | 100       |
| 4.1.2    | Independent USB transceivers supply                    | 101       |
| 4.1.3    | Battery backup domain                                  | 102       |
| 4.1.4    | Voltage regulator                                      | 104       |
| 4.2      | Power supply supervisor                                | 107       |
| 4.2.1    | Power-on reset (POR)/power-down reset (PDR)            | 107       |
| 4.2.2    | Brownout reset (BOR)                                   | 108       |
| 4.2.3    | Programmable voltage detector (PVD)                    | 108       |
| 4.3      | Low-power modes                                        | 109       |
| 4.3.1    | Debug mode                                             | 113       |

|          |                                                                                                     |            |
|----------|-----------------------------------------------------------------------------------------------------|------------|
| 4.3.2    | Run mode .....                                                                                      | 113        |
| 4.3.3    | Low-power mode .....                                                                                | 113        |
| 4.3.4    | Sleep mode .....                                                                                    | 114        |
| 4.3.5    | Stop mode .....                                                                                     | 116        |
| 4.3.6    | Standby mode .....                                                                                  | 119        |
| 4.3.7    | Programming the RTC alternate functions to wake up the device from the Stop and Standby modes ..... | 120        |
| 4.4      | Power control registers .....                                                                       | 123        |
| 4.4.1    | PWR power control register (PWR_CR1) .....                                                          | 123        |
| 4.4.2    | PWR power control/status register (PWR_CSR1) .....                                                  | 125        |
| 4.4.3    | PWR power control/status register 2 (PWR_CR2) .....                                                 | 127        |
| 4.4.4    | PWR power control register 2 (PWR_CSR2) .....                                                       | 129        |
| 4.5      | PWR register map .....                                                                              | 131        |
| <b>5</b> | <b>Reset and clock control (RCC) .....</b>                                                          | <b>132</b> |
| 5.1      | Reset .....                                                                                         | 132        |
| 5.1.1    | System reset .....                                                                                  | 132        |
| 5.1.2    | Power reset .....                                                                                   | 132        |
| 5.1.3    | Backup domain reset .....                                                                           | 133        |
| 5.2      | Clocks .....                                                                                        | 133        |
| 5.2.1    | HSE clock .....                                                                                     | 136        |
| 5.2.2    | HSI clock .....                                                                                     | 137        |
| 5.2.3    | PLL .....                                                                                           | 138        |
| 5.2.4    | LSE clock .....                                                                                     | 139        |
| 5.2.5    | LSI clock .....                                                                                     | 139        |
| 5.2.6    | System clock (SYSCLK) selection .....                                                               | 139        |
| 5.2.7    | Clock security system (CSS) .....                                                                   | 139        |
| 5.2.8    | RTC/AWU clock .....                                                                                 | 140        |
| 5.2.9    | Watchdog clock .....                                                                                | 141        |
| 5.2.10   | Clock-out capability .....                                                                          | 141        |
| 5.2.11   | Internal/external clock measurement using TIM5/TIM11 .....                                          | 141        |
| 5.2.12   | Peripheral clock enable register (RCC_AHBxENR, RCC_APBxENRy) .....                                  | 143        |
| 5.3      | RCC registers .....                                                                                 | 143        |
| 5.3.1    | RCC clock control register (RCC_CR) .....                                                           | 143        |
| 5.3.2    | RCC PLL configuration register (RCC_PLLCFGR) .....                                                  | 146        |
| 5.3.3    | RCC clock configuration register (RCC_CFGR) .....                                                   | 148        |

|          |                                                                                       |            |
|----------|---------------------------------------------------------------------------------------|------------|
| 5.3.4    | RCC clock interrupt register (RCC_CIR) .....                                          | 150        |
| 5.3.5    | RCC AHB1 peripheral reset register (RCC_AHB1RSTR) .....                               | 153        |
| 5.3.6    | RCC AHB2 peripheral reset register (RCC_AHB2RSTR) .....                               | 156        |
| 5.3.7    | RCC AHB3 peripheral reset register (RCC_AHB3RSTR) .....                               | 157        |
| 5.3.8    | RCC APB1 peripheral reset register (RCC_APB1RSTR) .....                               | 157        |
| 5.3.9    | RCC APB2 peripheral reset register (RCC_APB2RSTR) .....                               | 161        |

## 24 General-purpose timers (TIM9/TIM10/TIM11/TIM12/TIM13/TIM14) .. 813

|         |                                                                  |     |
|---------|------------------------------------------------------------------|-----|
| 24.1    | TIM9/TIM10/TIM11/TIM12/TIM13/TIM14 introduction .....            | 813 |
| 24.2    | TIM9/TIM10/TIM11/TIM12/TIM13/TIM14 main features .....           | 813 |
| 24.2.1  | TIM9/TIM12 main features .....                                   | 813 |
| 24.2.2  | TIM10/TIM11/TIM13/TIM14 main features .....                      | 814 |
| 24.3    | TIM9/TIM10/TIM11/TIM12/TIM13/TIM14 functional description .....  | 816 |
| 24.3.1  | Time-base unit .....                                             | 816 |
| 24.3.2  | Counter modes .....                                              | 818 |
| 24.3.3  | Clock selection .....                                            | 821 |
| 24.3.4  | Capture/compare channels .....                                   | 823 |
| 24.3.5  | Input capture mode .....                                         | 825 |
| 24.3.6  | PWM input mode (only for TIM9/TIM12) .....                       | 826 |
| 24.3.7  | Forced output mode .....                                         | 827 |
| 24.3.8  | Output compare mode .....                                        | 827 |
| 24.3.9  | PWM mode .....                                                   | 828 |
| 24.3.10 | Combined PWM mode (TIM9/TIM12 only) .....                        | 829 |
| 24.3.11 | One-pulse mode .....                                             | 831 |
| 24.3.12 | Retriggerable one pulse mode (OPM) (TIM12 only) .....            | 832 |
| 24.3.13 | UIF bit remapping .....                                          | 833 |
| 24.3.14 | TIM9/TIM12 external trigger synchronization .....                | 833 |
| 24.3.15 | Slave mode – combined reset + trigger mode .....                 | 836 |
| 24.3.16 | Timer synchronization (TIM9/TIM12) .....                         | 837 |
| 24.3.17 | Debug mode .....                                                 | 837 |
| 24.4    | TIM9/TIM12 registers .....                                       | 837 |
| 24.4.1  | TIMx control register 1 (TIMx_CR1)(x = 9, 12) .....              | 837 |
| 24.4.2  | TIMx slave mode control register (TIMx_SMCR)(x = 9, 12) .....    | 838 |
| 24.4.3  | TIMx Interrupt enable register (TIMx_DIER)(x = 9, 12) .....      | 840 |
| 24.4.4  | TIMx status register (TIMx_SR)(x = 9, 12) .....                  | 840 |
| 24.4.5  | TIMx event generation register (TIMx_EGR)(x = 9, 12) .....       | 841 |
| 24.4.6  | TIMx capture/compare mode register 1 (TIMx_CCMR1)(x = 9, 12) ..  | 842 |
| 24.4.7  | TIMx capture/compare enable register (TIMx_CCER)(x = 9, 12) .... | 846 |
| 24.4.8  | TIMx counter (TIMx_CNT)(x = 9, 12) .....                         | 847 |
| 24.4.9  | TIMx prescaler (TIMx_PSC)(x = 9, 12) .....                       | 847 |
| 24.4.10 | TIMx auto-reload register (TIMx_ARR)(x = 9, 12) .....            | 848 |
| 24.4.11 | TIMx capture/compare register 1 (TIMx_CCR1)(x = 9, 12) .....     | 848 |
| 24.4.12 | TIMx capture/compare register 2 (TIMx_CCR2)(x = 9, 12) .....     | 848 |
| 24.4.13 | TIM9/TIM12 register map .....                                    | 850 |

|           |                                                                       |            |

## List of tables

|           |                                                                                    |     |
|-----------|------------------------------------------------------------------------------------|-----|
| Table 1.  | STM32F75xxx and STM32F74xxx register boundary addresses . . . . .                  | 70  |
| Table 2.  | Boot modes . . . . .                                                               | 74  |
| Table 3.  | STM32F756xx and STM32F74xxx Flash memory organization . . . . .                    | 78  |
| Table 4.  | STM32F750xx Flash memory organization . . . . .                                    | 78  |
| Table 5.  | Number of wait states according to CPU clock (HCLK) frequency . . . . .            | 79  |
| Table 6.  | Program/erase parallelism . . . . .                                                | 81  |
| Table 7.  | Flash interrupt request . . . . .                                                  | 84  |
| Table 8.  | Option byte organization . . . . .                                                 | 84  |
| Table 9.  | Access versus read protection level . . . . .                                      | 89  |
| Table 10. | OTP area organization . . . . .                                                    | 90  |
| Table 11. | Flash register map and reset values . . . . .                                      | 98  |
| Table 12. | Voltage regulator configuration mode versus device operating mode . . . . .        | 105 |
| Table 13. | Low-power mode summary . . . . .                                                   | 110 |
| Table 14. | Features over all modes . . . . .                                                  | 111 |
| Table 15. | Sleep-now entry and exit . . . . .                                                 | 115 |
| Table 16. | Sleep-on-exit entry and exit . . . . .                                             | 116 |
| Table 17. | Stop operating modes . . . . .                                                     | 116 |
| Table 18. | Stop mode entry and exit (STM32F75xxx and STM32F74xxx) . . . . .                   | 118 |
| Table 19. | Standby mode entry and exit . . . . .                                              | 120 |
| Table 20. | PWR - register map and reset values . . . . .                                      | 131 |
| Table 21. | RCC register map and reset values . . . . .                                        | 196 |
| Table 22. | Port bit configuration table . . . . .                                             | 201 |
| Table 23. | GPIO register map and reset values . . . . .                                       | 214 |
| Table 24. | SYSCFG register map and reset values . . . . .                                     | 221 |
| Table 25. | DMA1 request mapping . . . . .                                                     | 226 |
| Table 26. | DMA2 request mapping . . . . .                                                     | 226 |
| Table 27. | Source and destination address . . . . .                                           | 227 |
| Table 28. | Source and destination address registers in double-buffer mode (DBM = 1) . . . . . | 232 |
| Table 29. | Packing/unpacking and endian behavior (bit PINC = MINC = 1) . . . . .              | 233 |
| Table 30. | Restriction on NDT versus PSIZE and MSIZE . . . . .                                | 233 |
| Table 31. | FIFO threshold configurations . . . . .                                            | 235 |
| Table 32. | Possible DMA configurations . . . . .                                              | 239 |
| Table 33. | DMA interrupt requests . . . . .                                                   | 242 |
| Table 34. | DMA register map and reset values . . . . .                                        | 253 |
| Table 35. | Supported color mode in input . . . . .                                            | 260 |
| Table 36. | Data order in memory . . . . .                                                     | 261 |
| Table 37. | Alpha mode configuration . . . . .                                                 | 262 |
| Table 38. | Supported CLUT color mode . . . . .                                                | 263 |
| Table 39. | CLUT data order in system memory . . . . .                                         | 263 |
| Table 40. | Supported color mode in output . . . . .                                           | 264 |
| Table 41. | Data order in memory . . . . .                                                     | 264 |
| Table 42. | DMA2D interrupt requests . . . . .                                                 | 269 |
| Table 43. | DMA2D register map and reset values . . . . .                                      | 287 |
| Table 44. | STM32F75xxx and STM32F74xxx vector table . . . . .                                 | 289 |
| Table 45. | External interrupt/event controller register map and reset values . . . . .        | 300 |
| Table 46. | CRC internal input/output signals . . . . .                                        | 302 |
| Table 47. | CRC register map and reset values . . . . .                                        | 306 |
| Table 48. | NOR/PSRAM bank selection . . . . .                                                 | 312 |

# 1 Documentation conventions

## 1.1 General information

The STM32F75xxx and STM32F74xxx devices have an Arm<sup>®(a)</sup> Cortex<sup>®</sup>-M7 core

## 1.2 List of abbreviations for registers

The following abbreviations<sup>(b)</sup> are used in register descriptions:

|                                 |                                                                                                                                |
|---------------------------------|--------------------------------------------------------------------------------------------------------------------------------|
| read/write (rw)                 | Software can read and write to this bit.                                                                                       |
| read-only (r)                   | Software can only read this bit.                                                                                               |
| write-only (w)                  | Software can only write to this bit. Reading this bit returns the reset value.                                                 |
| read/clear write0 (rc_w0)       | Software can read as well as clear this bit by writing 0. Writing 1 has no effect on the bit value.                            |
| read/clear write1 (rc_w1)       | Software can read as well as clear this bit by writing 1. Writing 0 has no effect on the bit value.                            |
| read/clear write (rc_w)         | Software can read as well as clear this bit by writing to the register. The value written to this bit is not important.        |
| read/clear by read (rc_r)       | Software can read this bit. Reading this bit automatically clears it to 0. Writing this bit has no effect on the bit value.    |
| read/set by read (rs_r)         | Software can read this bit. Reading this bit automatically sets it to 1. Writing this bit has no effect on the bit value.      |
| read/set (rs)                   | Software can read as well as set this bit. Writing 0 has no effect on the bit value.                                           |
| read/write once (rwo)           | Software can only write once to this bit and can also read it at any time. Only a reset can return the bit to its reset value. |
| toggle (t)                      | The software can toggle this bit by writing 1. Writing 0 has no effect.                                                        |
| read-only write trigger (rt_w1) | Software can read this bit. Writing 1 triggers an event but has no effect on the bit value.                                    |
| Reserved (Res.)                 | Reserved bit, must be kept at reset value.                                                                                     |

a. Arm is a registered trademark of Arm Limited (or its subsidiaries) in the US and/or elsewhere.

b. This is an exhaustive list of all abbreviations applicable to STM microcontrollers, some of them may not be used in the current document.

## 1.3 Glossary

This section gives a brief definition of acronyms and abbreviations used in this document:

- The CPU core integrates two debug ports:
  - JTAG debug port (**JTAG-DP**) provides a 5-pin standard interface based on the Joint Test Action Group (JTAG) protocol.
  - SWD debug port (**SWD-DP**) provides a 2-pin (clock and data) interface based on the Serial Wire Debug (SWD) protocol.For both the JTAG and SWD protocols, refer to the Cortex<sup>®</sup>-M7 Technical Reference Manual.
- **Word**: data of 32-bit length.
- **Half-word**: data of 16-bit length.
- **Byte**: data of 8-bit length.
- **Double word**: data of 64-bit length.
- **IAP (in-application programming)**: IAP is the ability to re-program the Flash memory of a microcontroller while the user program is running.
- **ICP (in-circuit programming)**: ICP is the ability to program the Flash memory of a microcontroller using the JTAG protocol, the SWD protocol or the bootloader while the device is mounted on the user application board.
- **Option bytes**: product configuration bits stored in the Flash memory.
- **AHB**: advanced high-performance bus.
- **AHBS**: AHB Slave bus.
- **AXIM**: AXI master bus.
- **ITCM**: Instruction Tightly Coupled Memory.
- **DTCM**: Data Tightly Coupled Memory.
- **CPU**: refers to the Cortex<sup>®</sup>-M7 core.

## 1.4 Availability of peripherals

For availability of peripherals and their number across all sales types, refer to the particular device datasheet.

The multi-AHB Bus-Matrix interconnects all the masters and slaves and it consists on:

- 32-bit multi-AHB Bus-Matrix
- 64-bit multi-AHB Bus-Matrix: It interconnects the 64-bit AHB bus from CPU through the AXI to AHB bridge and the 32-bit AHB bus from GP DMAs and peripheral DMAs upsized to 64-bit to the internal flash.

The multi AHB bus matrix interconnects:

- 12 bus masters:
  - 3x32-bit AHB bus Cortex<sup>®</sup>-M7 AXI Master bus 64-bits, splitted 4 masters through the AXI to AHB bridge.
  - 1x64-bit AHB bus connected to the embedded flash
  - Cortex<sup>®</sup>-M7 AHB Peripherals bus
  - DMA1 memory bus
  - DMA2 memory bus
  - DMA2 peripheral bus
  - Ethernet DMA bus
  - USB OTG HS DMA bus
  - LCD Controller DMA-bus
  - Chrom-Art Accelerator<sup>™</sup> (DMA2D) memory bus
- Eight bus slaves:
  - the embedded Flash on AHB bus (for Flash read/write access, for code execution and data access)
  - Cortex<sup>®</sup>-M7 AHBS slave interface for DMAs data transfer on DTCM RAM only.
  - Main internal SRAM1 (240 KB)
  - Auxiliary internal SRAM2 (16 KB)
  - AHB1peripherals including AHB to APB bridges and APB peripherals
  - AHB2 peripherals including AHB to APB bridges and APB peripherals
  - FMC
  - Quad SPI

### 2.1.1 Multi AHB BusMatrix

The multi AHB BusMatrix manages the access arbitration between masters. The arbitration uses a round-robin algorithm.

It provides access from a master to a slave, enabling concurrent access and efficient operation even when several high-speed peripherals work simultaneously.

The DTCM and ITCM RAMs (tightly coupled memories) are not part of the bus matrix.

The Data TCM RAM is accessible by the GP-DMAs and peripherals DMAs through specific AHB slave bus of the CPU.

The instruction TCM RAM is reserved only for CPU. it is accessed at CPU clock speed with 0 wait states. The architecture is shown in [Figure 1](#).

### 2.1.2 AHB/APB bridges (APB)

The two AHB/APB bridges, APB1 and APB2, provide full synchronous connections between the AHB and the two APB buses, allowing flexible selection of the peripheral frequency.

Refer to the device datasheets for more details on APB1 and APB2 maximum frequencies, and to [Table 1](#) for the address mapping of AHB and APB peripherals.

After each device reset, all peripheral clocks are disabled (except for the SRAM, DTCM, ITCM RAM and Flash memory interface). Before using a peripheral its clock has to be enabled in the RCC\_AHBxENR or RCC\_APBxENR register.

*Note: When a 16- or an 8-bit access is performed on an APB register, the access is transformed into a 32-bit access: the bridge duplicates the 16- or 8-bit data to feed the 32-bit vector.*

### 2.1.3 CPU AXIM bus

This bus connects the Instruction and data bus of the Cortex®-M7 with FPU core to the multi-AHB Bus-Matrix through AXI to AHB bridge. There are 4 AXI bus accesses:

- CPU AXI bus access 1: The target of this AXI bus is the external memory FMC containing code or data. For the NAND Bank mapped at address 0x8000 0000 to 0x8FFF FFFF, the MPU memory attribute for this space must be reconfigured by software to Device.
- CPU AXI bus access 2: The target of this AXI bus is the external memory Quad SPI containing code or data.
- CPU AXI bus access 3: The target of this AXI bus is the internal SRAMs (SRAM1 and SRAM2) containing code or data.
- CPU AXI bus access 4: The target of this AXI bus is the embedded Flash mapped on AXI interface containing code or data.

### 2.1.4 ITCM bus

This bus is used by the Cortex®-M7 for instruction fetches and data access on the embedded flash mapped on ITCM interface and instruction fetches only on ITCM RAM.

### 2.1.5 DTCM bus

This bus is used by the Cortex®-M7 for data access on the DTCM RAM. It can be also used for instruction fetches.

### 2.1.6 CPU AHBS bus

This bus connects the AHB Slave bus of the Cortex®-M7 to the BusMatrix. This bus is used by DMAs and Peripherals DMAs for Data transfer on DTCM RAM only.

The ITCM bus is not accessible on AHBS. So the DMA data transfer to/from ITCM RAM is not supported. For DMA transfer to/from Flash on ITCM interface, all the transfers are forced through AHB bus

### 2.1.7 AHB peripheral bus

This bus connects the AHB Peripheral bus of the Cortex®-M7 to the BusMatrix. This bus is used by the core to perform all data accesses to peripherals.

The target of this bus is the AHB1 peripherals including the APB peripherals and the AHB2 peripherals.

### **2.1.8 DMA memory bus**

This bus connects the DMA memory bus master interface to the BusMatrix. It is used by the DMA to perform transfer to/from memories. The targets of this bus are data memories: internal SRAM1, SRAM2 and DTCM (through the AHBS bus of Cortex<sup>®</sup>-M7) internal Flash memory and external memories through the FMC or Quad SPI.

### **2.1.9 DMA peripheral bus**

This bus connects the DMA peripheral master bus interface to the BusMatrix. This bus is used by the DMA to access AHB peripherals or to perform memory-to-memory transfers. The targets of this bus are the AHB and APB peripherals plus data memories: internal SRAM1, SRAM2 and DTCM (through the AHBS bus of Cortex<sup>®</sup>-M7) internal Flash memory and external memories through the FMC or Quad SPI.

### **2.1.10 Ethernet DMA bus**

This bus connects the Ethernet DMA master interface to the BusMatrix. This bus is used by the Ethernet DMA to load/store data to a memory. The targets of this bus are data memories: internal SRAM1, SRAM2 and DTCM (through the AHBS bus of Cortex<sup>®</sup>-M7) internal Flash memory, and external memories through the FMC or Quad SPI.

### **2.1.11 USB OTG HS DMA bus**

This bus connects the USB OTG HS DMA master interface to the BusMatrix. This bus is used by the USB OTG DMA to load/store data to a memory. The targets of this bus are data memories: internal SRAM1, SRAM2 and DTCM (through the AHBS bus of Cortex<sup>®</sup>-M7), internal Flash memory, and external memories through the FMC or Quad SPI.

### **2.1.12 LCD-TFT controller DMA bus**

This bus connects the LCD controller DMA master interface to the BusMatrix. It is used by the LCD-TFT DMA to load data from a memory. The targets of this bus are data memories: internal SRAM1, SRAM2 and DTCM (through the AHBS bus of Cortex<sup>®</sup>-M7), external memories through FMC or Quad SPI, and internal Flash memory.

### **2.1.13 DMA2D bus**

This bus connect the DMA2D master interface to the BusMatrix. This bus is used by the DMA2D graphic Accelerator to load/store data to a memory. The targets of this bus are data memories: internal SRAM1, SRAM2 and DTCM (through the AHBS bus of Cortex<sup>®</sup>-M7), external memories through FMC or Quad SPI, and internal Flash memory.

## **2.2 Memory organization**

### **2.2.1 Introduction**

Program memory, data memory, registers and I/O ports are organized within the same linear 4-Gbyte address space.

The bytes are coded in memory in Little Endian format. The lowest numbered byte in a word is considered the word's least significant byte and the highest numbered byte the most significant.

The addressable memory space is divided into eight main blocks, of 512 Mbytes each.

2.2.2 Memory map and register boundary addresses

Figure 2. Memory map

MS34165V2

All the memory map areas that are not allocated to on-chip memories and peripherals are considered “Reserved”. For the detailed mapping of available memory and register areas, refer to the following table.

The following table gives the boundary addresses of the peripherals available in the devices.

**Table 1. STM32F75xxx and STM32F74xxx register boundary addresses**

| Boundary address          | Peripheral               | Bus  | Register map                                                              |
|---------------------------|--------------------------|------|---------------------------------------------------------------------------|
| 0xA000 1000 - 0xA000 1FFF | QuadSPI Control Register | AHB3 | <a href="#">Section 14.5.14: QUADSPI register map on page 412</a>         |
| 0xA000 0000 - 0xA000 0FFF | FMC control register     |      | <a href="#">Section 13.8: FMC register map on page 382</a>                |
| 0x5006 0800 - 0x5006 0BFF | RNG                      | AHB2 | <a href="#">Section 19.8.4: RNG register map on page 554</a>              |
| 0x5006 0400 - 0x5006 07FF | HASH                     |      | <a href="#">Section 21.6.8: HASH register map on page 647</a>             |

## 2.3 Embedded SRAM

The STM32F75xxx and STM32F74xxx feature:

- System SRAM up to 320 Kbytes including Data TCM RAM 64 Kbytes
- Instruction RAM (ITCM-RAM) 16 Kbytes.
- 4 Kbytes of backup SRAM (see section 5.1.2: Battery backup domain)

The embedded SRAM is divided into up to four blocks:

- System SRAM:
  - SRAM1 mapped at address 0x2001 0000 and accessible by all AHB masters from AHB bus Matrix.
  - SRAM2 mapped at address 0x2004 C000 and accessible by all AHB masters from AHB bus Matrix.
  - DTCM-RAM on TCM interface (Tightly Coupled Memory interface) mapped at address 0x2000 0000 and accessible by all AHB masters from AHB bus Matrix but through a specific AHB slave bus of the CPU.
- Instruction SRAM:
  - Instruction RAM (ITCM-RAM) mapped at address 0x0000 0000 and accessible only by CPU.

The SRAM1 and SRAM2 can be accessed as bytes, half-words (16 bits) or full words (32 bits). While DTCM and ITCM RAMs can be accessed as bytes, half-words (16 bits), full words (32 bits) or double words (64 bits). These memories can be addressed at maximum system clock frequency without wait state.

The AHB masters support concurrent SRAM accesses (from the Ethernet or the USB OTG HS): for instance, the Ethernet MAC can read/write from/to SRAM2 while the CPU is reading/writing from/to SRAM1.

## 2.4 Flash memory overview

The Flash memory interface manages CPU AXI and TCM accesses to the Flash memory. It implements the erase and program Flash memory operations and the read and write protection mechanisms. It accelerates code execution with ART on TCM interface or L1-Cache on AXIM interface.

The Flash memory is organized as follows:

- A main memory block divided into sectors.
- An information block:
  - System memory from which the device boots in System memory boot mode
  - 1024 OTP (one-time programmable) bytes for user data.
  - Option bytes to configure read and write protection, BOR level, software/hardware watchdog, boot memory base address and reset when the device is in Standby or Stop mode.

Refer to [Section 3: Embedded Flash memory \(FLASH\)](#) for more details.

## 2.5 Boot configuration

In the STM32F75xxx and STM32F74xxx, two different boot areas can be selected through the BOOT pin and the boot base address programmed in the BOOT\_ADD0 and BOOT\_ADD1 option bytes as shown in the [Table 2](#).

**Table 2. Boot modes**

| Boot mode selection |                           | Boot area                                                                                                         |
|---------------------|---------------------------|-------------------------------------------------------------------------------------------------------------------|
| BOOT                | Boot address option bytes |                                                                                                                   |
| 0                   | BOOT_ADD0[15:0]           | Boot address defined by user option byte BOOT_ADD0[15:0]<br>ST programmed value: Flash on ITCM at 0x0020 0000     |
| 1                   | BOOT_ADD1[15:0]           | Boot address defined by user option byte BOOT_ADD1[15:0]<br>ST programmed value: System bootloader at 0x0010 0000 |

The values on the BOOT pin are latched on the 4th rising edge of SYSCLK after reset release. It is up to the user to set the BOOT pin after reset.

The BOOT pin is also resampled when the device exits the Standby mode. Consequently, they must be kept in the required Boot mode configuration when the device is in the Standby mode.

After startup delay, the selection of the boot area is done before releasing the processor reset.

The BOOT\_ADD0 and BOOT\_ADD1 address option bytes allows to program any boot memory address from 0x0000 0000 to 0x3FFF FFFF which includes:

- All Flash address space mapped on ITCM or AXIM interface
- All RAM address space: ITCM, DTCM RAMs and SRAMs mapped on AXIM interface
- The System memory bootloader

The BOOT\_ADD0 / BOOT\_ADD1 option bytes can be modified after reset in order to boot from any other boot address after next reset.

If the programmed boot memory address is out of the memory mapped area or a reserved area, the default boot fetch address is programmed as follows:

- Boot address 0: ITCM-FLASH at 0x0020 0000
- Boot address 1: ITCM-RAM at 0x0000 0000

When flash level 2 protection is enabled, only boot from Flash (on ITCM or AXIM interface) or system bootloader will be available. If the already programmed boot address in the BOOT\_ADD0 and/or BOOT\_ADD1 option bytes is out of the memory range or RAM address (on ITCM or AXIM) the default fetch will be forced from Flash on ITCM interface at address 0x00200000.

### Embedded bootloader

The embedded bootloader code is located in the system memory. It is programmed by ST during production. For full information, refer to the application note (AN2606) STM32 microcontroller system memory boot mode.

By default, when the boot from system bootloader is selected, the code is executed from TCM interface. It could be executed from AXIM interface by reprogramming the BOOT\_ADDx address option bytes to 0x1FF0 0000.

## 3 Embedded Flash memory (FLASH)

### 3.1 Introduction

The Flash memory interface manages Cortex®-M7 AXI and TCM accesses to the Flash memory. It implements the erase and program Flash memory operations and the read and write protection mechanisms.

The Flash memory interface accelerates code execution with a system of instruction prefetch and cache lines on ITCM interface (ART Accelerator™).

### 3.2 Flash main features

- Flash memory read operations
- Flash memory program/erase operations
- Read / write protections
- 64 cache lines of 256 bits on ITCM interface (ART Accelerator™)
- Prefetch on TCM instruction code

Figure 3 shows the Flash memory interface connection inside the system architecture.

**Figure 3. Flash memory interface connection inside system architecture (STM32F75xxx and STM32F74xxx)**

### 3.3 Flash functional description

#### 3.3.1 Flash memory organization

The Flash memory has the following main features:

- Capacity up to 1 Mbyte on STM32F756xx and STM32F74xx devices and 64 Kbytes on STM32F750xx devices
- 256 bits wide data read
- Byte, half-word, word and double word write
- Sector and mass erase

The Flash memory is organized as follows:

- On STM32F756xx and STM32F74xx devices, a main memory block divided into 4 sectors of 32 Kbytes, 1 sector of 128 Kbytes and 3 sectors of 256 Kbytes
- On STM32F750xx devices, a main memory block divided into 2 sectors of 32 Kbytes.
- Information blocks containing:
  - System memory from which the device boots in System memory boot mode
  - 1024 OTP (one-time programmable) for user data
  - The OTP area contains 16 additional bytes used to lock the corresponding OTP data block.
  - Option bytes to configure read and write protection, BOR level, software/hardware watchdog, boot memory base address and reset when the device is in Standby or Stop mode.

The embedded flash has three main interfaces:

- 64-bits ITCM interface:
  - It is connected to the ITCM bus of Cortex-M7 and used for instruction execution and data read access.
  - Write accesses are not supported on ITCM interface
  - Supports a unified 64 cache lines of 256 bits (ART accelerator)
- 64-bits AHB interface:
  - It is connected to the AXI bus of Cortex-M7 through the AHB bus matrix and used for code execution, read and write accesses.
  - DMAs and peripherals DMAs data transfer on Flash are done through the AHB interface whatever the addressed flash interface TCM or AHB.
- 32-bits AHB register interface:
  - It is used for control and status register accesses.

The main memory and information block organization are shown in [Table 3](#).

Table 3. STM32F756xx and STM32F74xxx Flash memory organization

| Block             | Name          | Bloc base address on AXIM interface | Block base address on ICTM interface | Sector size |
|-------------------|---------------|-------------------------------------|--------------------------------------|-------------|
| Main memory block | Sector 0      | 0x0800 0000 - 0x0800 7FFF           | 0x0020 0000 - 0x0020 7FFF            | 32 Kbytes   |
|                   | Sector 1      | 0x0800 8000 - 0x0800 FFFF           | 0x0020 8000 - 0x0020 FFFF            | 32 Kbytes   |
|                   | Sector 2      | 0x0801 0000 - 0x0801 7FFF           | 0x0021 0000 - 0x0021 7FFF            | 32 Kbytes   |
|                   | Sector 3      | 0x0801 8000 - 0x0801 FFFF           | 0x0021 8000 - 0x0021 FFFF            | 32 Kbytes   |
|                   | Sector 4      | 0x0802 0000 - 0x0803 FFFF           | 0x0022 0000 - 0x0023 FFFF            | 128 Kbytes  |
|                   | Sector 5      | 0x0804 0000 - 0x0807 FFFF           | 0x0024 0000 - 0x0027 FFFF            | 256 Kbytes  |
|                   | Sector 6      | 0x0808 0000 - 0x080B FFFF           | 0x0028 0000 - 0x002B FFFF            | 256 Kbytes  |
|                   | Sector 7      | 0x080C 0000 - 0x080F FFFF           | 0x002C 0000 - 0x002F FFFF            | 256 Kbytes  |
| Information block | System memory | 0x1FF0 0000 - 0x1FF0 EDBF           | 0x0010 0000 - 0x0010 EDBF            | 60 Kbytes   |
|                   | OTP           | 0x1FF0 F000 - 0x1FF0 F41F           | 0x0010 F000 - 0x0010 F41F            | 1024 bytes  |
|                   | Option bytes  | 0x1FFF 0000 - 0x1FFF 001F           | -                                    | 32 bytes    |

Table 4. STM32F750xx Flash memory organization

| Block             | Name          | Bloc base address on AXIM interface | Block base address on ICTM interface | Sector size |
|-------------------|---------------|-------------------------------------|--------------------------------------|-------------|
| Main memory block | Sector 0      | 0x0800 0000 - 0x0800 7FFF           | 0x0020 0000 - 0x0020 7FFF            | 32 Kbytes   |
|                   | Sector 1      | 0x0800 8000 - 0x0800 FFFF           | 0x0020 8000 - 0x0020 FFFF            | 32 Kbytes   |
| Information block | System memory | 0x1FF0 0000 - 0x1FF0 EDBF           | 0x0010 0000 - 0x0010 EDBF            | 60 Kbytes   |
|                   | OTP           | 0x1FF0 F000 - 0x1FF0 F41F           | 0x0010 F000 - 0x0010 F41F            | 1024 bytes  |
|                   | Option bytes  | 0x1FFF 0000 - 0x1FFF 001F           | -                                    | 32 bytes    |

### 3.3.2 Read access latency

To correctly read data from Flash memory, the number of wait states (LATENCY) must be correctly programmed in the Flash access control register (FLASH\_ACR) according to the frequency of the CPU clock (HCLK) and the supply voltage of the device.

The correspondence between wait states and CPU clock frequency is given in [Table 14](#) and [Table 5](#).

- Note:*
- when  $VOS[1:0] = '0x01'$ , the maximum value of  $f_{HCLK}$  is 144 MHz.
  - when  $VOS[1:0] = '0x10'$ , the maximum value of  $f_{HCLK}$  is 168 MHz. It can be extended to 180 MHz by activating the over-drive mode.
  - when  $VOS[1:0] = '0x11'$ , the maximum value of  $f_{HCLK}$  is 180 MHz. It can be extended to 216 MHz by activating the over-drive mode.
  - The over-drive mode is not available when  $V_{DD}$  ranges from 1.8 to 2.1 V.
- Refer to [Section 4.1.4: Voltage regulator](#) for details on how to activate the over-drive mode.

**Table 5. Number of wait states according to CPU clock (HCLK) frequency**

| Wait states (WS)<br>(LATENCY) | HCLK (MHz)                     |                                |                                |                                |
|-------------------------------|--------------------------------|--------------------------------|--------------------------------|--------------------------------|
|                               | Voltage range<br>2.7 V - 3.6 V | Voltage range<br>2.4 V - 2.7 V | Voltage range<br>2.1 V - 2.4 V | Voltage range<br>1.8 V - 2.1 V |
| 0 WS (1 CPU cycle)            | $0 < \text{HCLK} \leq 30$      | $0 < \text{HCLK} \leq 24$      | $0 < \text{HCLK} \leq 22$      | $0 < \text{HCLK} \leq 20$      |
| 1 WS (2 CPU cycles)           | $30 < \text{HCLK} \leq 60$     | $24 < \text{HCLK} \leq 48$     | $22 < \text{HCLK} \leq 44$     | $20 < \text{HCLK} \leq 40$     |
| 2 WS (3 CPU cycles)           | $60 < \text{HCLK} \leq 90$     | $48 < \text{HCLK} \leq 72$     | $44 < \text{HCLK} \leq 66$     | $40 < \text{HCLK} \leq 60$     |
| 3 WS (4 CPU cycles)           | $90 < \text{HCLK} \leq 120$    | $72 < \text{HCLK} \leq 96$     | $66 < \text{HCLK} \leq 88$     | $60 < \text{HCLK} \leq 80$     |
| 4 WS (5 CPU cycles)           | $120 < \text{HCLK} \leq 150$   | $96 < \text{HCLK} \leq 120$    | $88 < \text{HCLK} \leq 110$    | $80 < \text{HCLK} \leq 100$    |
| 5 WS (6 CPU cycles)           | $150 < \text{HCLK} \leq 180$   | $120 < \text{HCLK} \leq 144$   | $110 < \text{HCLK} \leq 132$   | $100 < \text{HCLK} \leq 120$   |
| 6 WS (7 CPU cycles)           | $180 < \text{HCLK} \leq 210$   | $144 < \text{HCLK} \leq 168$   | $132 < \text{HCLK} \leq 154$   | $120 < \text{HCLK} \leq 140$   |
| 7 WS (8 CPU cycles)           | $210 < \text{HCLK} \leq 216$   | $168 < \text{HCLK} \leq 192$   | $154 < \text{HCLK} \leq 176$   | $140 < \text{HCLK} \leq 160$   |
| 8 WS (9 CPU cycles)           | -                              | $192 < \text{HCLK} \leq 216$   | $176 < \text{HCLK} \leq 198$   | $160 < \text{HCLK} \leq 180$   |
| 9 WS (10 CPU cycles)          | -                              | -                              | $198 < \text{HCLK} \leq 216$   | -                              |

After reset, the CPU clock frequency is 16 MHz and 0 wait state (WS) is configured in the FLASH\_ACR register.

It is highly recommended to use the following software sequences to tune the number of wait states to access the Flash memory with the CPU frequency.

#### Increasing the CPU frequency

1. Program the new number of wait states to the LATENCY bits in the FLASH\_ACR register
2. Check that the new number of wait states is taken into account to access the Flash memory by reading the FLASH\_ACR register
3. Modify the CPU clock source by writing the SW bits in the RCC\_CFGR register
4. If needed, modify the CPU clock prescaler by writing the HPRE bits in RCC\_CFGR
5. Check that the new CPU clock source or/and the new CPU clock prescaler value is/are taken into account by reading the clock source status (SWS bits) or/and the AHB prescaler value (HPRE bits), respectively, in the RCC\_CFGR register.

#### Decreasing the CPU frequency

1. Modify the CPU clock source by writing the SW bits in the RCC\_CFGR register
2. If needed, modify the CPU clock prescaler by writing the HPRE bits in RCC\_CFGR
3. Check that the new CPU clock source or/and the new CPU clock prescaler value is/are taken into account by reading the clock source status (SWS bits) or/and the AHB prescaler value (HPRE bits), respectively, in the RCC\_CFGR register
4. Program the new number of wait states to the LATENCY bits in FLASH\_ACR
5. Check that the new number of wait states is used to access the Flash memory by reading the FLASH\_ACR register

*Note:* A change in CPU clock configuration or wait state (WS) configuration may not be effective straight away. To make sure that the current CPU clock frequency is the one the user has configured, the user can check the AHB prescaler factor and clock source status values. To make sure that the number of WS programmed is effective, the user can read the FLASH\_ACR register.

### Instruction prefetch

Each flash read operation provides 256 bits representing 8 instructions of 32 bits to 16 instructions of 16 bits according to the program launched. So, in case of sequential code, at least 8 CPU cycles are needed to execute the previous instruction line read. The prefetch on ITCM bus allows to read the sequential next line of instructions in the flash while the current instruction line is requested by the CPU. The prefetch can be enabled by setting the PRFTEN bit of the FLASH\_ACR register. This feature is useful if at least one Wait State is needed to access the flash. When the code is not sequential (branch), the instruction may not be present neither in the current instruction line used nor in the prefetched instruction line. In this case (miss), the penalty in term of number of cycles is at least equal to the number of Wait States.

### Adaptive real-time memory accelerator (ART Accelerator™)

The proprietary Adaptive real-time (ART) memory accelerator is optimized for STM32 industry-standard Arm® Cortex®-M7 with FPU processors. It balances the inherent performance advantage of the Arm® Cortex®-M7 with FPU over Flash memory technologies, which normally requires the processor to wait for the Flash memory at higher operating frequencies.

To release the processor full performance, the accelerator implements a unified cache of an instruction and branch cache which increases program execution speed from the 256-bit Flash memory. Based on CoreMark benchmark, the performance achieved thanks to the ART accelerator is equivalent to 0 wait state program execution from Flash memory at a CPU frequency up to 216 MHz.

The ART accelerator is available only for flash access on ITCM interface.

To limit the time lost due to jumps, it is possible to retain 64 lines of 256 bits in the ART accelerator. This feature can be enabled by setting the ARTEN bit of the FLASH\_CR register. The ART Accelerator is unified, it contains instruction as well as data literal pools. Each time a miss occurs (requested data not present in the current data line used or in the instruction cache memory), the read line is copied in the instruction cache memory of ART. If a data contained in the instruction cache memory is requested by the CPU, the data is provided without inserting delay. Once all the cache memory lines are filled, the LRU (Least Recently Used) policy is used to determine the line to replace in the memory cache. This feature is particularly useful in case of code containing loops.

*Note:* Data in user configuration sector are not cacheable.

### 3.3.3 Flash program and erase operations

For any Flash memory program operation (erase or program), the CPU clock frequency (HCLK) must be at least 1 MHz. The contents of the Flash memory are not guaranteed if a device reset occurs during a Flash memory operation.

Any attempt to read the Flash memory while it is being written or erased, causes the bus to stall. Read operations are processed correctly once the program operation has completed.

This means that code or data fetches cannot be performed while a write/erase operation is ongoing.

### 3.3.4 Unlocking the Flash control register

After reset, write is not allowed in the Flash control register (FLASH\_CR) to protect the Flash memory against possible unwanted operations due, for example, to electric disturbances. The following sequence is used to unlock this register:

1. Write KEY1 = 0x45670123 in the Flash key register (FLASH\_KEYR)
2. Write KEY2 = 0xCDEF89AB in the Flash key register (FLASH\_KEYR)

Any wrong sequence will return a bus error and lock up the FLASH\_CR register until the next reset.

The FLASH\_CR register can be locked again by software by setting the LOCK bit in the FLASH\_CR register.

**Note:** *The FLASH\_CR register is not accessible in write mode when the BSY bit in the FLASH\_SR register is set. Any attempt to write to it with the BSY bit set will cause the AHB bus to stall until the BSY bit is cleared.*

### 3.3.5 Program/erase parallelism

The Parallelism size is configured through the PSIZE field in the FLASH\_CR register. It represents the number of bytes to be programmed each time a write operation occurs to the Flash memory. PSIZE is limited by the supply voltage and by whether the external  $V_{PP}$  supply is used or not. It must therefore be correctly configured in the FLASH\_CR register before any programming/erasing operation.

A Flash memory erase operation can only be performed by sector, bank or for the whole Flash memory (mass erase). The erase time depends on PSIZE programmed value. For more details on the erase time, refer to the electrical characteristics section of the device datasheet.

[Table 6](#) provides the correct PSIZE values.

**Table 6. Program/erase parallelism**

|                  | Voltage range 2.7 - 3.6 V<br>with External $V_{PP}$ | Voltage range<br>2.7 - 3.6 V | Voltage range<br>2.4 - 2.7 V | Voltage range<br>2.1 - 2.4 V | Voltage range<br>1.8 V - 2.1 V |
|------------------|-----------------------------------------------------|------------------------------|------------------------------|------------------------------|--------------------------------|
| Parallelism size | x64                                                 | x32                          | x16                          |                              | x8                             |
| PSIZE(1:0)       | 11                                                  | 10                           | 01                           |                              | 00                             |

**Note:** *Any program or erase operation started with inconsistent program parallelism/voltage range settings may lead to unpredictable results. Even if a subsequent read operation indicates that the logical value was effectively written to the memory, this value may not be retained.*

*To use  $V_{PP}$  an external high-voltage supply (between 8 and 9 V) must be applied to the  $V_{PP}$  pad. The external supply must be able to sustain this voltage range even if the DC consumption exceeds 10 mA. It is advised to limit the use of  $V_{PP}$  to initial programming on the factory line. The  $V_{PP}$  supply must not be applied for more than an hour, otherwise the Flash memory might be damaged.*

### 3.3.6 Flash erase sequences

The Flash memory erase operation can be performed at sector level or on the whole Flash memory (Mass Erase). Mass Erase does not affect the OTP sector or the configuration sector.

#### Sector Erase

To erase a sector, follow the procedure below:

1. Check that no Flash memory operation is ongoing by checking the BSY bit in the FLASH\_SR register
2. Set the SER bit and select the sector out of the 8 in the main memory block) wished to erase (SNB) in the FLASH\_CR register
3. Set the STRT bit in the FLASH\_CR register
4. Wait for the BSY bit to be cleared

#### Mass Erase

To perform Mass Erase, the following sequence is recommended:

1. Check that no Flash memory operation is ongoing by checking the BSY bit in the FLASH\_SR register
2. Set the MER bit in the FLASH\_CR register
3. Set the STRT bit in the FLASH\_CR register
4. Wait for the BSY bit to be cleared

*Note:* If MERx and SER bits are both set in the FLASH\_CR register, mass erase is performed. If both MERx and SER bits are reset and the STRT bit is set, an unpredictable behavior may occur without generating any error flag. This condition should be forbidden.

*Note:* When setting the STRT bit in the FLASH\_CR register and before polling the BSY bit to be cleared, the software can issue a DSB instruction to guarantee the completion of a previous access to FLASH\_CR register.

### 3.3.7 Flash programming sequences

#### Standard programming

The Flash memory programming sequence is as follows:

1. Check that no main Flash memory operation is ongoing by checking the BSY bit in the FLASH\_SR register.
2. Set the PG bit in the FLASH\_CR register
3. Perform the data write operation(s) to the desired memory address (inside main memory block or OTP area):
  - Byte access in case of x8 parallelism
  - Half-word access in case of x16 parallelism
  - Word access in case of x32 parallelism
  - Double word access in case of x64 parallelism
4. Wait for the BSY bit to be cleared.

*Note:* Successive write operations are possible without the need of an erase operation when changing bits from '1' to '0'. Writing '1' requires a Flash memory erase operation.

*If an erase and a program operation are requested simultaneously, the erase operation is performed first.*

*Note:* After performing a data write operation and before polling the BSY bit to be cleared, the software can issue a DSB instruction to guarantee the completion of a previous data write operation.

### Programming errors

In case of error, the Flash operation (programming or erasing) is aborted with one of the following errors:

- **PGAERR:** Alignment Programming error  
It is not allowed to program data to the Flash memory that would cross the 128-bit row boundary. In such a case, the write operation is not performed and the program alignment error flag (PGAERR) is set in the FLASH\_SR register.
- **PGEPRR:** Programming parallelism error  
The write access type (byte, half-word, word or double word) must correspond to the type of parallelism chosen (x8, x16, x32 or x64). If not, the write operation is not performed and the program parallelism error flag (PGEPRR) is set in the FLASH\_SR register.
- **ERSERR:** Erase sequence error  
When an erase operation to the flash is performed by the code while the control register has not been correctly configured, the ERSERR error flag is set
- **WRPERR:** Write Protection Error  
WRPERR is set if one of the following conditions occurs:
  - Attempt to program or erase in a write protected area (WRP)
  - Attempt to program or erase the system memory area.
  - A write in the OTP area which is already locked
  - Attempt to modify the option bytes when the read protection (RDP) is set to Level
  - The Flash memory is read protected and an intrusion is detected

If an erase operation in Flash memory also concerns data in the ART accelerator, the user has to make sure that these data are rewritten before they are accessed during code execution. If this cannot be done safely, it is recommended to flush and/or deactivate the ART accelerator by setting respectively the bits ARTRST or ARTEN of the FLASH\_CR register.

*Note:* The ART cache can be flushed only if the ART accelerator is disabled (ARTEN = 0).

### 3.3.8 Flash Interrupts

Setting the end of operation interrupt enable bit (EOPIE) in the FLASH\_CR register enables interrupt generation when an erase or program operation ends, that is when the busy bit (BSY) in the FLASH\_SR register is cleared (operation completed, correctly or not). In this case, the end of operation (EOP) bit in the FLASH\_SR register is set.

If an error occurs during a program, an erase, or a read operation request, one of the following error flags is set in the FLASH\_SR register:

- PGAERR, PGPERR, ERSERR (Program error flags)
- WRPERR (Protection error flag)

In this case, if the error interrupt enable bit (ERRIE) is set in the FLASH\_CR register, an interrupt is generated and the operation error bit (OPERR) is set in the FLASH\_SR register.

*Note: If several successive errors are detected (for example, in case of DMA transfer to the Flash memory), the error flags cannot be cleared until the end of the successive write requests.*

**Table 7. Flash interrupt request**

| Interrupt event        | Event flag             | Enable control bit |
|------------------------|------------------------|--------------------|
| End of operation       | EOP                    | EOPIE              |
| Write protection error | WRPERR                 | ERRIE              |
| Programming error      | PGAERR, PGPERR, ERSERR | ERRIE              |

## 3.4 FLASH Option bytes

### 3.4.1 Option bytes description

The option bytes are configured by the end user depending on the application requirements. [Table 8](#) shows the organization of these bytes inside the information block.

The option bytes can be read from the user configuration memory locations or from the Option byte registers:

- [Flash option control register \(FLASH\\_OPTCR\)](#)
- [Flash option control register \(FLASH\\_OPTCR1\)](#)

**Table 8. Option byte organization**

| AXI address | [63:16]  | [15:0]                                                                               |
|-------------|----------|--------------------------------------------------------------------------------------|
| 0x1FFF 0000 | Reserved | ROP & user option bytes ( <b>RDP &amp; USER</b> )                                    |
| 0x1FFF 0008 | Reserved | IWDG_STOP, IWDG_STBY and Write protection nWRP (sector 0 to 7) and user option bytes |
| 0x1FFF 0010 | Reserved | BOOT_ADD0                                                                            |
| 0x1FFF 0018 | Reserved | BOOT_ADD1                                                                            |

### User and read protection option bytes

Memory address: 0x1FFF 0000

ST programmed value: 0x5500AAFF

|      |      |      |      |      |      |      |      |            |           |         |         |              |      |      |      |
|------|------|------|------|------|------|------|------|------------|-----------|---------|---------|--------------|------|------|------|
| 31   | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23         | 22        | 21      | 20      | 19           | 18   | 17   | 16   |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res.       | Res.      | Res.    | Res.    | Res.         | Res. | Res. | Res. |
| 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7          | 6         | 5       | 4       | 3            | 2    | 1    | 0    |
| RDP  |      |      |      |      |      |      |      | nRST_STDBY | nRST_STOP | IWDG_SW | WWDG_SW | BOR_LEV[1:0] |      | Res. | Res. |
| r    |      |      |      |      |      |      |      | r          | r         | r       | r       | r            | r    |      |      |

Bits 31:13 Not used.

Bits 15:8 **RDP**: Read Out Protection

The read protection helps the user protect the software code stored in Flash memory.

0xAA: Level0, no Protection

0xCC: Level2, chip protection (debug & boot in RAM features disabled)

others: Level1, read protection of memories (debug features limited)

Bit 7 **nRST\_STDBY**

0: Reset generated when entering Standby mode.

1: No reset generated.

Bit 6 **nRST\_STOP**

0: Reset generated when entering Stop mode.

1: No reset generated.

Bit 5 **IWDG\_SW**: Independant watchdog selection

0: Hardware independant watchdog.

1: Software independant watchdog.

Bit 4 **WWDG\_SW**: Window watchdog selection

0: Hardware window watchdog.

1: Software window watchdog.

Bits 3:2 **BOR\_LEV**: BOR reset Level

These bits contain the supply level threshold that activates/releases the reset. They can be written to program a new BOR level value into Flash memory.

00: BOR Level 3 (VBOR3), brownout threshold level 3

01: BOR Level 2 (VBOR2), brownout threshold level 2

10: BOR Level 1 (VBOR1), brownout threshold level 1

11: BOR off, POR/PDR reset threshold level is applied

Note: For full details on BOR characteristics, refer to the “Electrical characteristics” section of the product datasheet.

Bits 1:0 Not used

## User and write protection option bytes

Memory address: 0x1FFF 0008

ST programmed value: 0x0000FFFF

|               |                |      |      |      |      |      |      |       |      |      |      |      |      |      |      |
|---------------|----------------|------|------|------|------|------|------|-------|------|------|------|------|------|------|------|

| r             | r              |      |      |      |      |      |      | r     | r    | r    | r    | r    | r    | r    | r    |

Bits 31:16 Not used.

Bit 15 **IWDG\_STOP**: Independent watchdog counter freeze in stop mode

0: Freeze IWDG counter in stop mode.

1: IWDG counter active in stop mode.

Bit 14 **IWDG\_STDBY**: Independent watchdog counter freeze in Standby mode

1: IWDG counter active in standby mode.

Bits 13:8 Not used

Bits 7:0 **nWRPi**: Non Write Protection of sector i

0: Write protection active on sector i.

1: Write protection not active on sector i.

### Boot address option bytes when Boot pin =0

Memory address: 0x1FFF 0010

ST programmed value: 0xFF7F 0080 (ITCM-FLASH base address)

|                 |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
|-----------------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|
| 31              | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21   | 20   | 19   | 18   | 17   | 16   |
| Res.            | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. |
| 15              | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0    |
| BOOT_ADD0[15:0] |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
| r               | r    | r    | r    | r    | r    | r    | r    | r    | r    | r    | r    | r    | r    | r    | r    |

Bits 31:16 Not used.

Bits 15:0 **BOOT\_ADD0[15:0]**: Boot memory base address when Boot pin =0

BOOT\_ADD0[15:0] correspond to address [29:14],

The boot base address supports address range only from 0x0000 0000 to 0x2004 FFFF with a granularity of 16KB.

Example:

BOOT\_ADD0 = 0x0000: Boot from ITCM RAM (0x0000 0000)

BOOT\_ADD0 = 0x0040: Boot from system memory bootloader (0x0010 0000)

BOOT\_ADD0 = 0x0080: Boot from Flash on ITCM interface (0x0020 0000)

BOOT\_ADD0 = 0x2000: Boot from Flash on AXIM interface (0x0800 0000)

BOOT\_ADD0 = 0x8000: Boot from DTCM RAM (0x2000 0000)

BOOT\_ADD0 = 0x8004: Boot from SRAM1 (0x2001 0000)

BOOT\_ADD0 = 0x8013: Boot from SRAM2 (0x2004 C000)

### Boot address option bytes when Boot pin =1

Memory address: 0x1FFF 0018

ST programmed value: 0xFFBF0040 (system memory bootloader address)

|                 |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
|-----------------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|
| 31              | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21   | 20   | 19   | 18   | 17   | 16   |
| Res.            | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. |
|                 |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
| 15              | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0    |
| BOOT_ADD1[15:0] |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
| r               | r    | r    | r    | r    | r    | r    | r    | r    | r    | r    | r    | r    | r    | r    | r    |

Bits 31:16 **Not used**

Bits 15:0 **BOOT\_ADD1[15:0]**: Boot memory base address when Boot pin =1  
 BOOT\_ADD1[15:0] correspond to address [29:14],  
 The boot base address supports address range only from 0x0000 0000 to 0x2004 FFFF  
 with a granularity of 16KB.  
 Example:  
 BOOT\_ADD1 = 0x0000: Boot from ITCM RAM(0x0000 0000)  
 BOOT\_ADD1 = 0x0040: Boot from system memory bootloader (0x0010 0000)  
 BOOT\_ADD1 = 0x0080: Boot from Flash on ITCM interface (0x0020 0000)  
 BOOT\_ADD1 = 0x2000: Boot from Flash on AXIM interface (0x0800 0000)  
 BOOT\_ADD1 = 0x8000: Boot from DTCM RAM (0x2000 0000)  
 BOOT\_ADD1 = 0x8004: Boot from SRAM1 (0x2001 0000)  
 BOOT\_ADD1 = 0x8013: Boot from SRAM2 (0x2004 C000)

### 3.4.2 Option bytes programming

To run any operation on this sector, the option lock bit (OPTLOCK) in the Flash option control register (FLASH\_OPTCR) must be cleared. To be allowed to clear this bit, the user has to perform the following sequence:

1. Write OPTKEY1 = 0x0819 2A3B in the Flash option key register (FLASH\_OPTKEYR)
2. Write OPTKEY2 = 0x4C5D 6E7F in the Flash option key register (FLASH\_OPTKEYR)

The user option bytes can be protected against unwanted erase/program operations by setting the OPTLOCK bit by software.

#### Modifying user option bytes

To modify the user option value, follow the sequence below:

1. Check that no Flash memory operation is ongoing by checking the BSY bit in the FLASH\_SR register
2. Write the desired option value in the FLASH\_OPTCR register.
3. Set the option start bit (OPTSTRT) in the FLASH\_OPTCR register
4. Wait for the BSY bit to be cleared.

**Note:** *The value of an option is automatically modified by first erasing the information block and then programming all the option bytes with the values contained in the FLASH\_OPTCR register.*

**Note:** *When setting the OPTSTRT bit in the FLASH\_OPTCR register and before polling the BSY bit to be cleared, the software can issue a DSB instruction to guarantee the completion of a previous access to the FLASH\_OPTCR register.*

## 3.5 FLASH memory protection

### 3.5.1 Read protection (RDP)

The user area in the Flash memory can be protected against read operations by an entrusted code. Three read protection levels are defined:

- Level 0: no read protection  
When the read protection level is set to Level 0 by writing 0xAA into the read protection option byte (RDP), all read/write operations (if no write protection is set) from/to the Flash memory or the backup SRAM are possible in all boot configurations (Flash user boot, debug or boot from RAM).
- Level 1: read protection enabled  
It is the default read protection level after option byte erase. The read protection Level 1 is activated by writing any value (except for 0xAA and 0xCC used to set Level 0 and Level 2, respectively) into the RDP option byte. When the read protection Level 1 is set:
  - No access (read, erase, program) to Flash memory or backup SRAM can be performed while the debug feature is connected or while booting from RAM or system memory bootloader. A bus error is generated in case of read request.
  - When booting from Flash memory, accesses (read, erase, program) to Flash memory and backup SRAM from user code are allowed.

When Level 1 is active, programming the protection option byte (RDP) to Level 0 causes the Flash memory and the backup SRAM to be mass-erased. As a result the user code area is cleared before the read protection is removed. The mass erase only erases the user code area. The other option bytes including write protections remain unchanged from before the mass-erase operation. The OTP area is not affected by mass erase and remains unchanged. Mass erase is performed only when Level 1 is active and Level 0 requested. When the protection level is increased (0->1, 1->2, 0->2) there is no mass erase.

- Level 2: debug/chip read disabled  
The read protection Level 2 is activated by writing 0xCC to the RDP option byte. When the read protection Level 2 is set:
  - All protections provided by Level 1 are active.
  - Booting from RAM is no more allowed.
  - Booting system memory bootloader is possible and all the commands are not accessible except Get, GetID and GetVersion. Refer to AN2606.
  - JTAG, SWV (serial-wire viewer), ETM, and boundary scan are disabled.
  - User option bytes can no longer be changed.
  - When booting from Flash memory, accesses (read, erase and program) to Flash memory and backup SRAM from user code are allowed.

Memory read protection Level 2 is an irreversible operation. When Level 2 is activated, the level of protection cannot be decreased to Level 0 or Level 1.

**Note:** *The JTAG port is permanently disabled when Level 2 is active (acting as a JTAG fuse). As a consequence, boundary scan cannot be performed. STMicroelectronics is not able to perform analysis on defective parts on which the Level 2 protection has been set.*

**Note:** *If the read protection is set while the debugger is still connected through JTAG/SWD, apply a POR (power-on reset).*

Table 9. Access versus read protection level

| Memory area                       | Protection Level | Debug features, Boot from RAM or from System memory bootloader |       |                   | Bootling from Flash memory |       |       |
|-----------------------------------|------------------|----------------------------------------------------------------|-------|-------------------|----------------------------|-------|-------|
|                                   |                  | Read                                                           | Write | Erase             | Read                       | Write | Erase |
| Main Flash Memory and Backup SRAM | Level 1          | NO                                                             |       | NO <sup>(1)</sup> | YES                        |       |       |
|                                   | Level 2          | NO                                                             |       |                   | YES                        |       |       |
| Option Bytes                      | Level 1          | YES                                                            |       |                   | YES                        |       |       |
|                                   | Level 2          | NO                                                             |       |                   | NO                         |       |       |
| OTP                               | Level 1          | NO                                                             |       | NA                | YES                        |       | NA    |
|                                   | Level 2          | NO                                                             |       | NA                | YES                        |       | NA    |

1. The main Flash memory and backup SRAM are only erased when the RDP changes from level 1 to 0. The OTP area remains unchanged.

Figure 4 shows how to go from one RDP level to another.

Figure 4. RDP levels

### 3.5.2 Write protections

Up to 8 user sectors in Flash memory can be protected against unwanted write operations due to loss of program counter contexts. When the non-write protection nWRPi bit ( $0 \leq i \leq 7$ ) in the FLASH\_OPTCR or FLASH\_OPTCR1 registers is low, the corresponding sector cannot be erased or programmed. Consequently, a mass erase cannot be performed if one of the sectors is write-protected.

If an erase/program operation to a write-protected part of the Flash memory is attempted (sector protected by write protection bit, OTP part locked or part of the Flash memory that can never be written like the ICP), the write protection error flag (WRPERR) is set in the FLASH\_SR register.

*Note:* When the memory read protection level is selected (RDP level = 1), it is not possible to program or erase Flash memory sector *i* if the CPU debug features are connected (JTAG or single wire) or boot code is being executed from RAM, even if  $nWRP_i = 1$ .

### Write protection error flag

If an erase/program operation to a write protected area of the Flash memory is performed, the Write Protection Error flag (WRPERR) is set in the FLASH\_SR register.

If an erase operation is requested, the WRPERR bit is set when:

- A sector erase is requested and the Sector Number SNB field is not valid
- A mass erase is requested while at least one of the user sector is write protected by option bit (MER and  $nWR_i = 0$  with  $0 \leq i \leq 7$  bits in the FLASH\_OPTCR register)
- A sector erase is requested on a write protected sector. (SER = 1, SNB = *i* and  $nWRP_i = 0$  with  $0 \leq i \leq 7$  bits in the FLASH\_OPTCR register)
- The Flash memory is readout protected and an intrusion is detected.

If a program operation is requested, the WRPERR bit is set when:

- A write operation is performed on system memory or on the reserved part of the user specific sector.
- A write operation is performed to the information block
- A write operation is performed on a sector write protected by option bit.
- A write operation is requested on an OTP area which is already locked
- The Flash memory is read protected and an intrusion is detected.

## 3.6 One-time programmable bytes

Table 10 shows the organization of the one-time programmable (OTP) part of the OTP area.

Table 10. OTP area organization

| OTP Block   | [255:224] | [223:193] | [192:161] | [160:128] | [127:96] | [95:64] | [63:32] | [31:0] | Address byte 0 |
|-------------|-----------|-----------|-----------|-----------|----------|---------|---------|--------|----------------|
| 0           | OTP0      | OTP0      | OTP0      | OTP0      | OTP0     | OTP0    | OTP0    | OTP0   | 0x1FF0 F000    |
|             | OTP0      | OTP0      | OTP0      | OTP0      | OTP0     | OTP0    | OTP0    | OTP0   | 0x1FF0 F020    |
| 1           | OTP1      | OTP1      | OTP1      | OTP1      | OTP1     | OTP1    | OTP1    | OTP1   | 0x1FF0 F040    |
|             | OTP1      | OTP1      | OTP1      | OTP1      | OTP1     | OTP1    | OTP1    | OTP1   | 0x1FF0 F060    |
| -<br>-<br>- | -         | -         | -         | -         | -        | -       | -       | -      | -              |
| 14          | OPT14     | OPT14     | OPT14     | OPT14     | OPT14    | OPT14   | OPT14   | OPT14  | 0x1FF0 F380    |
|             | OPT14     | OPT14     | OPT14     | OPT14     | OPT14    | OPT14   | OPT14   | OPT14  | 0x1FF0 F3A0    |

Table 10. OTP area organization (continued)

| OTP Block  | [255:224] | [223:193] | [192:161] | [160:128] | [127:96]             | [95:64]             | [63:32]            | [31:0]             | Address byte 0 |
|------------|-----------|-----------|-----------|-----------|----------------------|---------------------|--------------------|--------------------|----------------|
| 15         | OPT15     | OPT15     | OPT15     | OPT15     | OPT15                | OPT15               | OPT15              | OPT15              | 0x1FF0 F3C0    |
|            | OPT15     | OPT15     | OPT15     | OPT15     | OPT15                | OPT15               | OPT15              | OPT15              | 0x1FF0 F3E0    |
| Lock block | reserved  | reserved  | reserved  | reserved  | LOCK15...<br>LOCKB12 | LOCK11...<br>LOCKB8 | LOCK7...<br>LOCKB4 | LOCK3...<br>LOCKB0 | 0x1FF0 F400    |

The OTP area is divided into 16 OTP data blocks of 64 bytes and one lock OTP block of 16 bytes. The OTP data and lock blocks cannot be erased. The lock block contains 16 bytes LOCKBi (0 ≤ i ≤ 15) to lock the corresponding OTP data block (blocks 0 to 15). Each OTP data block can be programmed until the value 0x00 is programmed in the corresponding OTP lock byte. The lock bytes must only contain 0x00 and 0xFF values, otherwise the OTP bytes might not be taken into account correctly.

## 3.7 FLASH registers

### 3.7.1 Flash access control register (FLASH\_ACR)

The Flash access control register is used to enable/disable the acceleration features and control the Flash memory access time according to CPU frequency.

Address offset: 0x00

Reset value: 0x0000 0000

Access: no wait state, word, half-word and byte access

|      |      |      |      |        |      |       |        |      |      |      |      |              |      |      |      |
|------|------|------|------|--------|------|-------|--------|------|------|------|------|--------------|------|------|------|
| 31   | 30   | 29   | 28   | 27     | 26   | 25    | 24     | 23   | 22   | 21   | 20   | 19           | 18   | 17   | 16   |
| Res. | Res. | Res. | Res. | Res.   | Res. | Res.  | Res.   | Res. | Res. | Res. | Res. | Res.         | Res. | Res. | Res. |
|      |      |      |      |        |      |       |        |      |      |      |      |              |      |      |      |
| 15   | 14   | 13   | 12   | 11     | 10   | 9     | 8      | 7    | 6    | 5    | 4    | 3            | 2    | 1    | 0    |
| Res. | Res. | Res. | Res. | ARTRST | Res. | ARTEN | PRFTEN | Res. | Res. | Res. | Res. | LATENCY[3:0] |      |      |      |
|      |      |      |      | rw     |      | rw    | rw     |      |      |      |      | rw           | rw   | rw   | rw   |

Bits 31:12 Reserved, must be kept cleared.

Bit 11 **ARTRST**: ART Accelerator reset  
 0: ART Accelerator is not reset  
 1: ART Accelerator is reset

Bit 10 Reserved, must be kept cleared.

Bit 9 **ARTEN**: ART Accelerator Enable  
 0: ART Accelerator is disabled  
 1: ART Accelerator is enabled

Bit 8 **PRFTEN**: Prefetch enable

0: Prefetch is disabled

1: Prefetch is enabled

Bits 7:4 Reserved, must be kept cleared.

Bits 3:0 **LATENCY[3:0]**: Latency

These bits represent the ratio of the CPU clock period to the Flash memory access time.

0000: Zero wait state

0001: One wait state

0010: Two wait states

-

-

-

1110: Fourteen wait states

1111: Fifteen wait states

### 3.7.2 Flash key register (FLASH\_KEYR)

The Flash key register is used to allow access to the Flash control register and so, to allow program and erase operations.

Address offset: 0x04

Reset value: 0x0000 0000

Access: no wait state, word access

|            |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31         | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| KEY[31:16] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| w          | w  | w  | w  | w  | w  | w  | w  | w  | w  | w  | w  | w  | w  | w  | w  |
| 15         | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| KEY[15:0]  |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| w          | w  | w  | w  | w  | w  | w  | w  | w  | w  | w  | w  | w  | w  | w  | w  |

Bits 31:0 **FKEYR[31:0]**: FPEC key

The following values must be programmed consecutively to unlock the FLASH\_CR register and allow programming/erasing it:

a) KEY1 = 0x45670123

b) KEY2 = 0xCDEF89AB

### 3.7.3 Flash option key register (FLASH\_OPTKEYR)

The Flash option key register is used to allow program and erase operations in the information block.

Address offset: 0x08

Reset value: 0x0000 0000

Access: no wait state, word access

|                |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|----------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31             | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| OPTKEYR[31:16] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| w              | w  | w  | w  | w  | w  | w  | w  | w  | w  | w  | w  | w  | w  | w  | w  |
| 15             | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| OPTKEYR[15:0]  |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| w              | w  | w  | w  | w  | w  | w  | w  | w  | w  | w  | w  | w  | w  | w  | w  |

Bits 31:0 **OPTKEYR[31:0]**: Option byte key

The following values must be programmed consecutively to unlock the FLASH\_OPTCR register and allow programming it:

- a) OPTKEY1 = 0x08192A3B
- b) OPTKEY2 = 0x4C5D6E7F

### 3.7.4 Flash status register (FLASH\_SR)

The Flash status register gives information on ongoing program and erase operations.

Address offset: 0x0C

Reset value: 0x0000 0000

Access: no wait state, word, half-word and byte access

Bits 31:17 Reserved, must be kept cleared.

Bit 16 **BSY**: Busy

This bit indicates that a Flash memory operation is in progress. It is set at the beginning of a Flash memory operation and cleared when the operation finishes or an error occurs.

- 0: no Flash memory operation ongoing
- 1: Flash memory operation ongoing

Bits 15:8 Reserved, must be kept cleared.

Bit 7 **ERSERR**: Erase Sequence Error

Set by hardware when a write access to the Flash memory is performed by the code while the control register has not been correctly configured.

Cleared by writing 1.

Bit 6 **PGPERR**: Programming parallelism error

Set by hardware when the size of the access (byte, half-word, word, double word) during the program sequence does not correspond to the parallelism configuration PSIZE (x8, x16, x32, x64).

Cleared by writing 1.

Bit 5 **PGAERR**: Programming alignment error

Set by hardware when the data to program cannot be contained in the same 128-bit Flash memory row.

Cleared by writing 1.

Bit 4 **WRPERR**: Write protection error

Set by hardware when an address to be erased/programmed belongs to a write-protected part of the Flash memory.

Cleared by writing 1.

Bits 3:2 Reserved, must be kept cleared.

Bit 1 **OPERR**: Operation error

Set by hardware when a flash operation (programming / erase /read) request is detected and can not be run because of parallelism, alignment, or write protection error. This bit is set only if error interrupts are enabled (ERRIE = 1).

Bit 0 **EOP**: End of operation

Set by hardware when one or more Flash memory operations (program/erase) has/have completed successfully. It is set only if the end of operation interrupts are enabled (EOPIE = 1).

Cleared by writing a 1.

### 3.7.5 Flash control register (FLASH\_CR)

The Flash control register is used to configure and start Flash memory operations.

Address offset: 0x10

Reset value: 0x8000 0000

Access: no wait state when no Flash memory operation is ongoing, word, half-word and byte access.

|      |      |      |      |      |      |            |       |      |          |      |      |      |      |      |      |

Bit 31 **LOCK**: Lock

Write to 1 only. When it is set, this bit indicates that the FLASH\_CR register is locked. It is cleared by hardware after detecting the unlock sequence.

In the event of an unsuccessful unlock operation, this bit remains set until the next reset.

Bits 30:26 Reserved, must be kept cleared.

Bit 25 **ERRIE**: Error interrupt enable

This bit enables the interrupt generation when the OPERR bit in the FLASH\_SR register is set to 1.

0: Error interrupt generation disabled

1: Error interrupt generation enabled

Bit 24 **EOPIE**: End of operation interrupt enable

This bit enables the interrupt generation when the EOP bit in the FLASH\_SR register goes to 1.

0: Interrupt generation disabled

1: Interrupt generation enabled

Bits 23:17 Reserved, must be kept cleared.

Bit 16 **STRT**: Start

This bit triggers an erase operation when set. It is set only by software and cleared when the BSY bit is cleared.

Bits 15:10 Reserved, must be kept cleared.

Bits 9:8 **PSIZE**: Program size

These bits select the program parallelism.

00 program x8

01 program x16

10 program x32

11 program x64

Bit 7 Reserved, must be kept cleared.

Bits 6:3 **SNB[3:0]**: Sector number

These bits select the sector to erase.

0000 sector 0

0001 sector 1

...

0111 sector 7

Others not allowed

Bit 2 **MER**: Mass Erase

Erase activated for all user sectors.

Bit 1 **SER**: Sector Erase

Sector Erase activated.

Bit 0 **PG**: Programming

Flash programming activated.

### 3.7.6 Flash option control register (FLASH\_OPTCR)

The FLASH\_OPTCR register is used to modify the user option bytes.

Address offset: 0x14

Reset value: 0xC0FFAAFD. The option bytes are loaded with values from Flash memory at reset release.

Access: no wait state when no Flash memory operation is ongoing, word, half-word and byte access.

- Bit 31 **IWDG\_STOP**: Independent watchdog counter freeze in Stop mode  
 0: Freeze IWDG counter in STOP mode.  
 1: IWDG counter active in STOP mode.
- Bit 30 **IWDG\_STDBY**: Independent watchdog counter freeze in standby mode  
 0: Freeze IWDG counter in standby mode.  
 1: IWDG counter active in standby mode.
- Bits 29:24 Reserved, must be kept cleared.
- Bits 23:16 **nWRP[7:0]**: Not write protect  
 These bits contain the value of the write-protection option bytes for sectors 0 to 7 after reset. They can be written to program a new write-protect into Flash memory.  
 0: Write protection active on sector i  
 1: Write protection not active on sector i
- Bits 15:8 **RDP[7:0]**: Read protect  
 These bits contain the value of the read-protection option level after reset. They can be written to program a new read protection value into Flash memory.  
 0xAA: Level 0, read protection not active  
 0xCC: Level 2, chip read protection active  
 Others: Level 1, read protection of memories active
- Bits 7:4 **USER**: User option bytes  
 These bits contain the value of the user option byte after reset. They can be written to program a new user option byte value into Flash memory.  
 Bit 7: nRST\_STDBY  
 Bit 6: nRST\_STOP  
 Bit 5: IWDG\_SW  
 Bit 4: WWDG\_SW
- Bits 3:2 **BOR\_LEV[1:0]**: BOR reset Level  
 These bits contain the supply level threshold that activates/releases the reset. They can be written to program a new BOR level. By default, BOR is off. When the supply voltage ( $V_{DD}$ ) drops below the selected BOR level, a device reset is generated.  
 00: BOR Level 3 (VBOR3), brownout threshold level 3  
 01: BOR Level 2 (VBOR2), brownout threshold level 2  
 10: BOR Level 1 (VBOR1), brownout threshold level 1  
 11: BOR off, POR/PDR reset threshold level is applied  
*Note: For full details on BOR characteristics, refer to the “Electrical characteristics” section of the product datasheet.*
- Bit 1 **OPTSTRT**: Option start  
 This bit triggers a user option operation when set. It is set only by software and cleared when the BSY bit is cleared.
- Bit 0 **OPTLOCK**: Option lock  
 Write to 1 only. When this bit is set, it indicates that the FLASH\_OPTCR register is locked. This bit is cleared by hardware after detecting the unlock sequence. In the event of an unsuccessful unlock operation, this bit remains set until the next reset.

*Note:* When modifying the IWDG\_SW, IWDG\_STOP or IWDG\_STDBY option byte, a system reset is required to make the change effective.

### 3.7.7 Flash option control register (FLASH\_OPTCR1)

The FLASH\_OPTCR1 register is used to modify the user option bytes.

Address offset: 0x18

Reset value: 0x0040 0080 (ITCM-FLASH). The option bytes are loaded with values from Flash memory at reset release.

Access: no wait state when no Flash memory operation is ongoing, word, half-word and byte access.

Bits 31:16 **BOOT\_ADD1[15:0]**: Boot base address when Boot pin =1

BOOT\_ADD1[15:0] correspond to address [29:14],

The boot memory address can be programmed to any address in the range 0x0000 0000 to 0x2004 FFFF with a granularity of 16KB.

Example:

BOOT\_ADD1 = 0x0000: Boot from ITCM RAM (0x0000 0000)

BOOT\_ADD1 = 0x0040: Boot from System memory bootloader (0x0010 0000)

BOOT\_ADD1 = 0x0080: Boot from Flash on ITCM interface (0x0020 0000)

BOOT\_ADD1 = 0x2000: Boot from Flash on AXIM interface (0x0800 0000)

BOOT\_ADD1 = 0x8000: Boot from DTCM RAM (0x2000 0000)

BOOT\_ADD1 = 0x8004: Boot from SRAM1 (0x2001 0000)

BOOT\_ADD1 = 0x8013: Boot from SRAM2 (0x2004 C000)

Bits 15:0 **BOOT\_ADD0[15:0]**: Boot base address when Boot pin =0

BOOT\_ADD0[15:0] correspond to address [29:14],

The boot base address can be programmed to any address in the range 0x0000 0000 to 0x2004 FFFF with a granularity of 16KB.

Example:

BOOT\_ADD0 = 0x0000: Boot from ITCM RAM (0x0000 0000)

BOOT\_ADD0 = 0x0040: Boot from System memory bootloader (0x0010 0000)

BOOT\_ADD0 = 0x0080: Boot from Flash on ITCM interface (0x0020 0000)

BOOT\_ADD0 = 0x2000: Boot from Flash on AXIM interface (0x0800 0000)

BOOT\_ADD0 = 0x8000: Boot from DTCM RAM (0x2000 0000)

BOOT\_ADD0 = 0x8004: Boot from SRAM1 (0x2001 0000)

BOOT\_ADD0 = 0x8013: Boot from SRAM2 (0x2004 C000)

## 3.7.8 Flash interface register map

Table 11. Flash register map and reset values

| Offset | Register      | 31              | 30         | 29  | 28  | 27  | 26  | 25    | 24    | 23        | 22  | 21  | 20  | 19  | 18  | 17  | 16   | 15              | 14  | 13  | 12  | 11     | 10  | 9          | 8      | 7          | 6         | 5       | 4       | 3            | 2     | 1       | 0       |

## 4 Power controller (PWR)

### 4.1 Power supplies

The device requires a 1.8 to 3.6 V operating voltage supply ( $V_{DD}$ ). An embedded linear voltage regulator is used to supply the internal 1.2 V digital power.

The real-time clock (RTC), the RTC backup registers, and the backup SRAM (BKP SRAM) can be powered from the  $V_{BAT}$  voltage when the main  $V_{DD}$  supply is powered off.

*Note: Depending on the operating power supply range, some peripheral may be used with limited functionality and performance. For more details refer to section "General operating conditions" in STM32F75xxx and STM32F74xxx datasheets.*

#### 4.1.1 Independent A/D converter supply and reference voltage

- The ADC voltage supply input is available on a separate  $V_{DDA}$  pin.
- An isolated supply ground connection is provided on pin  $V_{SSA}$ .

To ensure a better accuracy of low voltage inputs, the user can connect a separate external reference voltage ADC input on  $V_{REF}$ . The voltage on  $V_{REF}$  ranges from 1.8 V to  $V_{DDA}$ .

### 4.1.2 Independent USB transceivers supply

The  $V_{DDUSB}$  is an independent USB power supply for full speed transceivers (USB OTG FS and USB OTG HS in FS mode). It can be connected either to  $V_{DD}$  or an external independent power supply (3.0 to 3.6V) for USB transceivers (refer [Figure 6](#) and [Figure 7](#)). For example, when the device is powered at 1.8V, an independent power supply 3.3V can be connected to  $V_{DDUSB}$ . When the  $V_{DDUSB}$  is connected to a separated power supply, it is independent from  $V_{DD}$  or  $V_{DDA}$  but it must be the last supply to be provided and the first to disappear. The following conditions  $V_{DDUSB}$  must be respected:

- During power-on phase ( $V_{DD} < V_{DD\_MIN}$ ),  $V_{DDUSB}$  should be always lower than  $V_{DD}$
- During power-down phase ( $V_{DD} < V_{DD\_MIN}$ ),  $V_{DDUSB}$  should be always lower than  $V_{DD}$
- $V_{DDUSB}$  rising and falling time rate specifications must be respected
- In operating mode phase,  $V_{DDUSB}$  could be lower or higher than  $V_{DD}$ :
  - If USB (USB OTG\_HS/OTG\_FS) is used, the associated GPIOs powered by  $V_{DDUSB}$  are operating between  $V_{DDUSB\_MIN}$  and  $V_{DDUSB\_MAX}$ .
  - The  $V_{DDUSB}$  supplies both USB transceiver (USB OTG\_HS and USB OTG\_FS). If only one USB transceiver is used in the application, the GPIOs associated to the other USB transceiver are still supplied at by  $V_{DDUSB}$ .
  - If USB (USB OTG\_HS/OTG\_FS) is not used, the associated GPIOs powered by  $V_{DDUSB}$  are operating between  $V_{DD\_MIN}$  and  $V_{DD\_MAX}$ .

**Figure 6.  $V_{DDUSB}$  connected to  $V_{DD}$  power supply**

Figure 7.  $V_{DDUSB}$  connected to external independent power supply

### 4.1.3 Battery backup domain

#### Backup domain description

To retain the content of the RTC backup registers, backup SRAM, and supply the RTC when  $V_{DD}$  is turned off,  $V_{BAT}$  pin can be connected to an optional standby voltage supplied by a battery or by another source.

To allow the RTC to operate even when the main digital supply ( $V_{DD}$ ) is turned off, the  $V_{BAT}$  pin powers the following blocks:

- The RTC
- The LSE oscillator
- The backup SRAM when the low-power backup regulator is enabled
- PC13 to PC15 I/Os, plus PI8 I/O (when available)

The switch to the  $V_{BAT}$  supply is controlled by the power-down reset embedded in the Reset block.

**Warning:** During  $t_{RSTTEMPO}$  (temporization at  $V_{DD}$  startup) or after a PDR is detected, the power switch between  $V_{BAT}$  and  $V_{DD}$  remains connected to  $V_{BAT}$ .

During the startup phase, if  $V_{DD}$  is established in less than  $t_{RSTTEMPO}$  (Refer to the datasheet for the value of  $t_{RSTTEMPO}$ ) and  $V_{DD} > V_{BAT} + 0.6$  V, a current may be injected into  $V_{BAT}$  through an internal diode connected between  $V_{DD}$  and the power switch ( $V_{BAT}$ ).

If the power supply/battery connected to the  $V_{BAT}$  pin cannot support this current injection, it is strongly recommended to

**connect an external low-drop diode between this power supply and the  $V_{BAT}$  pin.**

If no external battery is used in the application, it is recommended to connect the  $V_{BAT}$  pin to  $V_{DD}$  with a 100 nF external decoupling ceramic capacitor in parallel.

When the backup domain is supplied by  $V_{DD}$  (analog switch connected to  $V_{DD}$ ), the following functions are available:

- PC14 and PC15 can be used as either GPIO or LSE pins
- PC13 and PI8 can be used as a GPIO pin (refer to [Table 147: RTC pin PC13 configuration](#) and [Table 148: RTC pin PI8 configuration](#) for more details about these pins configuration)

*Note:* Due to the fact that the switch only sinks a limited amount of current (3 mA), the use of GPIOs PI8 and PC13 to PC15 are restricted: the speed has to be limited to 2 MHz with a maximum load of 30 pF and these I/Os must not be used as a current source (e.g. to drive an LED).

When the backup domain is supplied by  $V_{BAT}$  (analog switch connected to  $V_{BAT}$  because  $V_{DD}$  is not present), the following functions are available:

- PC14 and PC15 can be used as LSE pins only
- PC13 can be used as tamper pin (TAMP1)
- PI8 can be used as tamper pin (TAMP2)

### Backup domain access

After reset, the backup domain (RTC registers, RTC backup register and backup SRAM) is protected against possible unwanted write accesses. To enable access to the backup domain, proceed as follows:

- Access to the RTC and RTC backup registers
  1. Enable the power interface clock by setting the PWREN bits in the RCC\_APB1ENR register (see [Section 5.3.13](#))
  2. Set the DBP bit in the [PWR power control register \(PWR\\_CR1\)](#) to enable access to the backup domain
  3. Select the RTC clock source: see [Section 5.2.8: RTC/AWU clock](#)
  4. Enable the RTC clock by programming the RTCEN [15] bit in the [RCC backup domain control register \(RCC\\_BDCR\)](#)
- Access to the backup SRAM
  1. Enable the power interface clock by setting the PWREN bits in the RCC\_APB1ENR register (see [Section 5.3.13](#))
  2. Set the DBP bit in the [PWR power control register \(PWR\\_CR1\)](#) to enable access to the backup domain
  3. Enable the backup SRAM clock by setting BKPSRAMEN bit in the [RCC AHB1 peripheral clock register \(RCC\\_AHB1ENR\)](#).

### RTC and RTC backup registers

The real-time clock (RTC) is an independent BCD timer/counter. The RTC provides a time-of-day clock/calendar, two programmable alarm interrupts, and a periodic programmable wake-up flag with interrupt capability. The RTC contains 32 backup data registers (128 bytes)

which are reset when a tamper detection event occurs. For more details refer to [Section 29: Real-time clock \(RTC\)](#).

### Backup SRAM

The backup domain includes 4 Kbytes of backup SRAM addressed in 32-bit, 16-bit or 8-bit mode. Its content is retained even in Standby or  $V_{BAT}$  mode when the low-power backup regulator is enabled. It can be considered as an internal EEPROM when  $V_{BAT}$  is always present.

When the backup domain is supplied by  $V_{DD}$  (analog switch connected to  $V_{DD}$ ), the backup SRAM is powered from  $V_{DD}$  which replaces the  $V_{BAT}$  power supply to save battery life.

When the backup domain is supplied by  $V_{BAT}$  (analog switch connected to  $V_{BAT}$  because  $V_{DD}$  is not present), the backup SRAM is powered by a dedicated low-power regulator. This regulator can be ON or OFF depending whether the application needs the backup SRAM function in Standby and  $V_{BAT}$  modes or not. The power-down of this regulator is controlled by a dedicated bit, the BRE control bit of the PWR\_CSR1 register (see [Section 4.4.2: PWR power control/status register \(PWR\\_CSR1\)](#)).

The backup SRAM is not mass erased by an tamper event. It is read protected to prevent confidential data, such as cryptographic private key, from being accessed. The backup SRAM can be erased only through the Flash interface when a protection level change from level 1 to level 0 is requested. Refer to the description of Read protection (RDP) option byte.

**Figure 8. Backup domain**

#### 4.1.4 Voltage regulator

An embedded linear voltage regulator supplies all the digital circuitries except for the backup domain and the Standby circuitry. The regulator output voltage is around 1.2 V.

This voltage regulator requires two external capacitors to be connected to two dedicated pins,  $V_{CAP\_1}$  and  $V_{CAP\_2}$  available in all packages. Specific pins must be connected either to  $V_{SS}$  or  $V_{DD}$  to activate or deactivate the voltage regulator. These pins depend on the package.

When activated by software, the voltage regulator is always enabled after Reset. It works in three different modes depending on the application modes (Run, Stop, or Standby mode).

- In **Run mode**, the main regulator supplies full power to the 1.2 V domain (core, memories and digital peripherals). In this mode, the regulator output voltage (around 1.2 V) can be scaled by software to different voltage values (scale 1, scale 2, and scale 3 can be configured through VOS[1:0] bits of the PWR\_CR1 register). The scale can be modified only when the PLL is OFF and the HSI or HSE clock source is selected as system clock source. The new value programmed is active only when the PLL is ON. When the PLL is OFF, the voltage scale 3 is automatically selected.

The voltage scaling allows optimizing the power consumption when the device is clocked below the maximum system frequency. After exit from Stop mode, the voltage scale 3 is automatically selected. (see [Section 4.4.1: PWR power control register \(PWR\\_CR1\)](#)).

2 operating modes are available:

- **Normal mode**: The CPU and core logic operate at maximum frequency at a given voltage scaling (scale 1, scale 2 or scale 3)
- **Over-drive mode**: This mode allows the CPU and the core logic to operate at a higher frequency than the normal mode for the voltage scaling scale 1 and scale 2.
- In **Stop mode**: the main regulator or low-power regulator supplies a low-power voltage to the 1.2V domain, thus preserving the content of registers and internal SRAM. The voltage regulator can be put either in main regulator mode (MR) or in low-power mode (LPR). Both modes can be configured by software as follows:
  - **Normal mode**: the 1.2 V domain is preserved in nominal leakage mode. It is the default mode when the main regulator (MR) or the low-power regulator (LPR) is enabled.
  - **Under-drive mode**: the 1.2 V domain is preserved in reduced leakage mode. This mode is only available with the main regulator or the low-power regulator mode (see [Table 12](#)).
- In **Standby mode**: the regulator is powered down. The content of the registers and SRAM are lost except for the Standby circuitry and the backup domain.

*Note: Over-drive and under-drive mode are not available when the regulator is bypassed.  
For more details, refer to the voltage regulator section in the datasheets.*

**Table 12. Voltage regulator configuration mode versus device operating mode<sup>(1)</sup>**

| Voltage regulator configuration | Run mode | Sleep mode | Stop mode | Standby mode |
|---------------------------------|----------|------------|-----------|--------------|
| Normal mode                     | MR       | MR         | MR or LPR | -            |
| Over-drive mode <sup>(2)</sup>  | MR       | MR         | -         | -            |
| Under-drive mode                | -        | -          | MR or LPR | -            |
| Power-down mode                 | -        | -          | -         | Yes          |

1. '-' means that the corresponding configuration is not available.

2. The over-drive mode is not available when  $V_{DD} = 1.8$  to 2.1 V.

## Entering Over-drive mode

It is recommended to enter Over-drive mode when the application is not running critical tasks and when the system clock source is either HSI or HSE. To optimize the configuration time, enable the Over-drive mode during the PLL lock phase.

To enter Over-drive mode, follow the sequence below:

1. Select HSI or HSE as system clock.
2. Configure RCC\_PLLCFGR register and set PLLON bit of RCC\_CR register.
3. Set ODEN bit of PWR\_CR1 register to enable the Over-drive mode and wait for the ODRDY flag to be set in the PWR\_CSR1 register.
4. Set the ODSW bit in the PWR\_CR1 register to switch the voltage regulator from Normal mode to Over-drive mode. The System will be stalled during the switch but the PLL clock system will be still running during locking phase.
5. Wait for the ODSWRDY flag in the PWR\_CSR1 to be set.
6. Select the required Flash latency as well as AHB and APB prescalers.
7. Wait for PLL lock.
8. Switch the system clock to the PLL.
9. Enable the peripherals that are not generated by the System PLL (I2S clock, LCD-TFT clock, SAI1 clock, USB\_48MHz clock....).

**Note:** *The PLLI2S and PLLSAI can be configured at the same time as the system PLL.*

*During the Over-drive switch activation, no peripheral clocks should be enabled. The peripheral clocks must be enabled once the Over-drive mode is activated.*

*Entering Stop mode disables the Over-drive mode, as well as the PLL. The application software has to configure again the Over-drive mode and the PLL after exiting from Stop mode.*

## Exiting from Over-drive mode

It is recommended to exit from Over-drive mode when the application is not running critical tasks and when the system clock source is either HSI or HSE. There are two sequences that allow exiting from over-drive mode:

- By resetting simultaneously the ODEN and ODSW bits in the PWR\_CR1 register (sequence 1)
- By resetting first the ODSW bit to switch the voltage regulator to Normal mode and then resetting the ODEN bit to disable the Over-drive mode (sequence 2).

Example of sequence 1:

1. Select HSI or HSE as system clock source.
2. Disable the peripheral clocks that are not generated by the System PLL (I2S clock, LCD-TFT clock, SAI1 clock, USB\_48MHz clock,...)
3. Reset simultaneously the ODEN and the ODSW bits in the PWR\_CR1 register to switch back the voltage regulator to Normal mode and disable the Over-drive mode.
4. Wait for the ODWRDY flag of PWR\_CSR1 to be reset.

Example of sequence 2:

1. Select HSI or HSE as system clock source.
2. Disable the peripheral clocks that are not generated by the System PLL (I2S clock, LCD-TFT clock, SAI1 clock, USB\_48MHz clock,...).
3. Reset the ODSW bit in the PWR\_CR1 register to switch back the voltage regulator to Normal mode. The system clock is stalled during voltage switching.
4. Wait for the ODWRDY flag of PWR\_CSR1 to be reset.
5. Reset the ODEN bit in the PWR\_CR1 register to disable the Over-drive mode.

*Note:* During step 3, the ODEN bit remains set and the Over-drive mode is still enabled but not active (ODSW bit is reset). If the ODEN bit is reset instead, the Over-drive mode is disabled and the voltage regulator is switched back to the initial voltage.

## 4.2 Power supply supervisor

### 4.2.1 Power-on reset (POR)/power-down reset (PDR)

The device has an integrated POR/PDR circuitry that allows proper operation starting from 1.8 V.

The device remains in Reset mode when  $V_{DD}/V_{DDA}$  is below a specified threshold,  $V_{POR/PDR}$ , without the need for an external reset circuit. For more details concerning the power on/power-down reset threshold, refer to the electrical characteristics of the datasheet.

**Figure 9. Power-on reset/power-down reset waveform**

### 4.2.2 Brownout reset (BOR)

During power on, the Brownout reset (BOR) keeps the device under reset until the supply voltage reaches the specified  $V_{BOR}$  threshold.

$V_{BOR}$  is configured through device option bytes. By default, BOR is off. 3 programmable  $V_{BOR}$  threshold levels can be selected:

- BOR Level 3 (VBOR3). Brownout threshold level 3.
- BOR Level 2 (VBOR2). Brownout threshold level 2.
- BOR Level 1 (VBOR1). Brownout threshold level 1.

*Note:* For full details about BOR characteristics, refer to the "Electrical characteristics" section in the device datasheet.

When the supply voltage ( $V_{DD}$ ) drops below the selected  $V_{BOR}$  threshold, a device reset is generated.

The BOR can be disabled by programming the device option bytes. In this case, the power-on and power-down is then monitored by the POR/ PDR (see [Section 4.2.1: Power-on reset \(POR\)/power-down reset \(PDR\)](#)).

The BOR threshold hysteresis is ~100 mV (between the rising and the falling edge of the supply voltage).

Figure 10. BOR thresholds

### 4.2.3 Programmable voltage detector (PVD)

The user can use the PVD to monitor the  $V_{DD}$  power supply by comparing it to a threshold selected by the PLS[2:0] bits in the [PWR power control register \(PWR\\_CR1\)](#).

The PVD is enabled by setting the PVDE bit.

A PVDO flag is available, in the [PWR power control/status register \(PWR\\_CSR1\)](#), to indicate if  $V_{DD}$  is higher or lower than the PVD threshold. This event is internally connected

to the EXTI line16 and can generate an interrupt if enabled through the EXTI registers. The PVD output interrupt can be generated when  $V_{DD}$  drops below the PVD threshold and/or when  $V_{DD}$  rises above the PVD threshold depending on EXTI line16 rising/falling edge configuration. As an example the service routine could perform emergency shutdown tasks.

**Figure 11. PVD thresholds**

MS30432V2

## 4.3 Low-power modes

By default, the microcontroller is in Run mode after a system or a power-on reset. In Run mode the CPU is clocked by HCLK and the program code is executed. Several low-power modes are available to save power when the CPU does not need to be kept running, for example when waiting for an external event. It is up to the user to select the mode that gives the best compromise between low-power consumption, short startup time and available wakeup sources.

The devices feature three low-power modes:

- Sleep mode (Cortex<sup>®</sup>-M7 core stopped, peripherals kept running)
- Stop mode (all clocks are stopped)
- Standby mode (1.2 V domain powered off)

In addition, the power consumption in Run mode can be reduced by one of the following means:

- Slowing down the system clocks
- Gating the clocks to the APBx and AHBx peripherals when they are unused.

### Entering low-power mode

Low-power modes are entered by the MCU by executing the WFI (Wait For Interrupt), or WFE (Wait for Event) instructions, or when the SLEEPONEXIT bit in the Cortex<sup>®</sup>-M7 System Control register is set on Return from ISR.

Entering Low-power mode through WFI or WFE will be executed only if no interrupt is pending or no event is pending.

### Exiting low-power mode

The MCU exits from Sleep and Stop modes low-power mode depending on the way the low-power mode was entered:

- If the WFI instruction or Return from ISR was used to enter the low-power mode, any peripheral interrupt acknowledged by the NVIC can wake up the device.
- If the WFE instruction is used to enter the low-power mode, the MCU exits the low-power mode as soon as an event occurs. The wakeup event can be generated either by:
  - NVIC IRQ interrupt:  
When SEVONPEND = 0 in the Cortex<sup>®</sup>-M7 System Control register: by enabling an interrupt in the peripheral control register and in the NVIC. When the MCU resumes from WFE, the peripheral interrupt pending bit and the NVIC peripheral IRQ channel pending bit (in the NVIC interrupt clear pending register) have to be cleared. Only NVIC interrupts with sufficient priority will wakeup and interrupt the MCU.  
When SEVONPEND = 1 in the Cortex<sup>®</sup>-M7 System Control register: by enabling an interrupt in the peripheral control register and optionally in the NVIC. When the MCU resumes from WFE, the peripheral interrupt pending bit and when enabled the NVIC peripheral IRQ channel pending bit (in the NVIC interrupt clear pending register) have to be cleared. All NVIC interrupts will wakeup the MCU, even the disabled ones. Only enabled NVIC interrupts with sufficient priority will wakeup and interrupt the MCU.
  - Event  
This is done by configuring a EXTI line in event mode. When the CPU resumes from WFE, it is not necessary to clear the EXTI peripheral interrupt pending bit or the NVIC IRQ channel pending bit as the pending bits corresponding to the event line is not set. It may be necessary to clear the interrupt flag in the peripheral.

The MCU exits from Standby low-power mode through an external reset (NRST pin), an IWDG reset, a rising edge on one of the enabled WKUPx pins or a RTC event occurs (see [Figure 284: RTC block diagram](#)).

After waking up from Standby mode, program execution restarts in the same way as after a Reset (boot pin sampling, option bytes loading, reset vector is fetched, etc.).

Only enabled NVIC interrupts with sufficient priority will wakeup and interrupt the MCU.

**Table 13. Low-power mode summary**

| Mode name                          | Entry | Wakeup        | Effect on 1.2 V domain clocks                                    | Effect on V <sub>DD</sub> domain clocks | Voltage regulator |

1. Legend: Y = Yes (Enable), O = Optional (Disable by default. Can be enabled by software), - = Not available. Wakeup highlighted in gray.
2. Some peripherals with wakeup from Stop capability can request HSI to be enabled. In this case, HSI is woken up by the peripheral, and only feeds the peripheral which requested it. HSI is automatically put off when the peripheral does not need it anymore.

### 4.3.1 Debug mode

By default, the debug connection is lost when the device enters in Stop or Standby mode while the debug features are used. This is due to the fact that the Cortex<sup>®</sup>-M7 core is no longer clocked.

However, by setting some configuration bits in the DBGMCU\_CR register, the software can be debugged even when using the low-power modes extensively. For more details, refer to [Section 40.16.1: Debug support for low-power modes](#).

### 4.3.2 Run mode

#### Slowing down system clocks

In Run mode the speed of the system clocks (SYSCLK, HCLK, PCLK1, PCLK2) can be reduced by programming the prescaler registers. These prescalers can also be used to slow down peripherals before entering Sleep mode.

For more details refer to [Section 5.3.3: RCC clock configuration register \(RCC\\_CFGR\)](#).

#### Peripheral clock gating

In Run mode, the HCLKx and PCLKx for individual peripherals and memories can be stopped at any time to reduce power consumption.

To further reduce power consumption in Sleep mode the peripheral clocks can be disabled prior to executing the WFI or WFE instructions.

Peripheral clock gating is controlled by the AHB1 peripheral clock enable register (RCC\_AHB1ENR), AHB2 peripheral clock enable register (RCC\_AHB2ENR), AHB3 peripheral clock enable register (RCC\_AHB3ENR) (see [Section 5.3.10: RCC AHB1 peripheral clock register \(RCC\\_AHB1ENR\)](#), [Section 5.3.11: RCC AHB2 peripheral clock enable register \(RCC\\_AHB2ENR\)](#), and [Section 5.3.12: RCC AHB3 peripheral clock enable register \(RCC\\_AHB3ENR\)](#)).

Disabling the peripherals clocks in Sleep mode can be performed automatically by resetting the corresponding bit in RCC\_AHBxLPENR and RCC\_APBxLPENR registers.

### 4.3.3 Low-power mode

#### Entering low-power mode

Low-power modes are entered by the MCU executing the WFI (Wait For Interrupt), or WFE (Wait For Event) instructions, or when the SLEEPONEXIT bit in the Cortex<sup>®</sup>-M7 System Control register is set on Return from ISR.

### Exiting low-power mode

From Sleep and Stop modes the MCU exits low-power mode depending on the way the mode was entered:

- If the WFI instruction or Return from ISR was used to enter the low-power mode, any peripheral interrupt acknowledged by the NVIC can wake up the device
- If the WFE instruction was used to enter the low-power mode, the MCU exits the mode as soon as an event occurs. The wakeup event can be generated either by:

- NVIC IRQ interrupt

- When SEVEONPEND=0 in the Cortex®-M7 System Control register.

By enabling an interrupt in the peripheral control register and in the NVIC. When the MCU resumes from WFE, the peripheral interrupt pending bit and the NVIC peripheral IRQ channel pending bit (in the NVIC interrupt clear pending register) have to be cleared.

Only NVIC interrupts with sufficient priority will wakeup and interrupt the MCU.

- When SEVEONPEND=1 in the Cortex®-M7 System Control register.

By enabling an interrupt in the peripheral control register and optionally in the NVIC. When the MCU resumes from WFE, the peripheral interrupt pending bit and (when enabled) the NVIC peripheral IRQ channel pending bit (in the NVIC interrupt clear pending register) have to be cleared.

All NVIC interrupts will wakeup the MCU, even the disabled ones.

Only enabled NVIC interrupts with sufficient priority will wakeup and interrupt the MCU.

- Event

Configuring a EXTI line in event mode. When the CPU resumes from WFE, it is not necessary to clear the EXTI peripheral interrupt pending bit or the NVIC IRQ channel pending bit as the pending bits corresponding to the event line is not set. It may be necessary to clear the interrupt flag in the peripheral.

From Standby mode the MCU exits Low-power mode through an external reset (NRST pin), an IWDG reset, a rising edge on one of the enabled WKUPx pins or a RTC event (see [Figure 284: RTC block diagram](#)).

## 4.3.4 Sleep mode

### I/O states in Sleep mode

In Sleep mode, all I/O pins keep the same state as in Run mode.

### Entering Sleep mode

The Sleep mode is entered by executing the WFI (Wait For Interrupt) or WFE (Wait for Event) instructions. Two options are available to select the Sleep mode entry mechanism, depending on the SLEEPONEXIT bit in the Cortex®-M7 System Control register:

- Sleep-now: if the SLEEPONEXIT bit is cleared, the MCU enters Sleep mode as soon as WFI or WFE instruction is executed.
- Sleep-on-exit: if the SLEEPONEXIT bit is set, the MCU enters Sleep mode as soon as it exits the lowest priority ISR.

Refer to [Table 15](#) and [Table 16](#) for details on how to enter Sleep mode.

## Exiting Sleep mode

If the WFI instruction is used to enter Sleep mode, any peripheral interrupt acknowledged by the nested vectored interrupt controller (NVIC) can wake up the device from Sleep mode.

If the WFE instruction is used to enter Sleep mode, the MCU exits Sleep mode as soon as an event occurs. The wakeup event can be generated either by:

- Enabling an interrupt in the peripheral control register but not in the NVIC, and enabling the SEVONPEND bit in the Cortex<sup>®</sup>-M7 System Control register. When the MCU resumes from WFE, the peripheral interrupt pending bit and the peripheral NVIC IRQ channel pending bit (in the NVIC interrupt clear pending register) have to be cleared.
- Or configuring an external or internal EXTI line in event mode. When the CPU resumes from WFE, it is not necessary to clear the peripheral interrupt pending bit or the NVIC IRQ channel pending bit as the pending bit corresponding to the event line is not set.

This mode offers the lowest wakeup time as no time is wasted in interrupt entry/exit.

Refer to [Table 15](#) and [Table 16](#) for more details on how to exit Sleep mode.

**Table 15. Sleep-now entry and exit**

| Sleep-now mode | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

### 4.3.5 Stop mode

The Stop mode is based on the Cortex<sup>®</sup>-M7 deepsleep mode combined with peripheral clock gating. The voltage regulator can be configured either in normal or low-power mode. In Stop mode, all clocks in the 1.2 V domain are stopped, the PLLs, the HSI and the HSE RC oscillators are disabled. Internal SRAM and register contents are preserved.

In Stop mode, the power consumption can be further reduced by using additional settings in the PWR\_CR1 register. However this will induce an additional startup delay when waking up from Stop mode (see [Table 17](#)).

Table 17. Stop operating modes

| Voltage Regulator Mode |                          | UDEN[1:0] bits | MRUDS bit | LPUDS bit | LPDS bit | FPDS bit | Wakeup latency                                                                                          |
|------------------------|--------------------------|----------------|-----------|-----------|----------|----------|---------------------------------------------------------------------------------------------------------|

|                        | STOP ULP-FPD | 3                 | -            | 1            | 1           | -           | HSI RC startup time +<br>Flash wakeup time from power-down mode +<br>regulator wakeup time from LP under-drive mode + Core logic to nominal mode   |

### I/O states in Stop mode

In stop mode, all I/Os pins keep the same state as in the run mode

### Entering Stop mode

The Stop mode is entered according to *Entering low-power mode*, when the SLEEPDEEP bit in Cortex®-M7 System Control register is set.

Refer to [Table 18](#) for details on how to enter the Stop mode.

When the microcontroller enters in Stop mode, the voltage scale 3 is automatically selected. To further reduce power consumption in Stop mode, the internal voltage regulator can be put in low-power or low voltage mode. This is configured by the LPDS, MRUDS, LPUDS and UDEN bits of the [PWR power control register \(PWR\\_CR1\)](#).

If Flash memory programming is ongoing, the Stop mode entry is delayed until the memory access is finished.

If an access to the APB domain is ongoing, The Stop mode entry is delayed until the APB access is finished.

If the Over-drive mode was enabled before entering Stop mode, it is automatically disabled during when the Stop mode is activated.

In Stop mode, the following features can be selected by programming individual control bits:

- Independent watchdog (IWDG): the IWDG is started by writing to its Key register or by hardware option. Once started it cannot be stopped except by a Reset. See [Section 27.3](#) in [Section 27: Independent watchdog \(IWDG\)](#).
- Real-time clock (RTC): this is configured by the RTCEN bit in the [RCC backup domain control register \(RCC\\_BDCR\)](#)
- Internal RC oscillator (LSI RC): this is configured by the LSION bit in the [RCC clock control & status register \(RCC\\_CSR\)](#).
- External 32.768 kHz oscillator (LSE OSC): this is configured by the LSEON bit in the [RCC backup domain control register \(RCC\\_BDCR\)](#).

The ADC or DAC can also consume power during the Stop mode, unless they are disabled before entering it. To disable them, the ADON bit in the ADC\_CR2 register and the ENx bit in the DAC\_CR register must both be written to 0.

**Note:** *Before entering Stop mode, it is recommended to enable the clock security system (CSS) feature to prevent external oscillator (HSE) failure from impacting the internal MCU behavior.*

### Exiting Stop mode

Refer to [Table 18](#) for more details on how to exit Stop mode.

When exiting Stop mode by issuing an interrupt or a wakeup event, the HSI RC oscillator is selected as system clock.

If the Under-drive mode was enabled, it is automatically disabled after exiting Stop mode.

When the voltage regulator operates in low-power mode, an additional startup delay is incurred when waking up from Stop mode. By keeping the internal regulator ON during Stop mode, the consumption is higher although the startup time is reduced.

When the voltage regulator operates in Under-drive mode, an additional startup delay is induced when waking up from Stop mode.

**Table 18. Stop mode entry and exit (STM32F75xxx and STM32F74xxx)**

| Stop mode  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

#### 4.3.6 Standby mode

The Standby mode allows to achieve the lowest power consumption. It is based on the Cortex®-M7 deepsleep mode, with the voltage regulator disabled. The 1.2 V domain is consequently powered off. The PLLs, the HSI oscillator and the HSE oscillator are also switched off. SRAM and register contents are lost except for registers in the backup domain (RTC registers, RTC backup register and backup SRAM), and Standby circuitry (see [Figure 5](#)).

##### Entering Standby mode

The Standby mode is entered according to Entering low-power mode, when the SLEEPDEEP bit in the Cortex®-M7 System Control register is set.

Refer to [Table 19](#) for more details on how to enter Standby mode.

In Standby mode, the following features can be selected by programming individual control bits:

- Independent watchdog (IWDG): the IWDG is started by writing to its Key register or by hardware option. Once started it cannot be stopped except by a reset. See [Section 27.3](#) in [Section 27: Independent watchdog \(IWDG\)](#).
- Real-time clock (RTC): this is configured by the RTCEN bit in the backup domain control register (RCC\_BDCR)
- Internal RC oscillator (LSI RC): this is configured by the LSION bit in the Control/status register (RCC\_CSR).
- External 32.768 kHz oscillator (LSE OSC): this is configured by the LSEON bit in the backup domain control register (RCC\_BDCR)

##### Exiting Standby mode

The microcontroller exits Standby mode when an external Reset (NRST pin), an IWDG Reset, a rising or falling edge on WKUP pin, an RTC alarm, a tamper event, or a time stamp

event is detected. All registers are reset after wakeup from Standby except for *PWR power control/status register (PWR\_CSR1)*.

After waking up from Standby mode, program execution restarts in the same way as after a Reset (boot pin sampling, vector reset is fetched, etc.). The SBF status flag in the *PWR power control/status register (PWR\_CSR1)* indicates that the MCU was in Standby mode.

Refer to *Table 19* for more details on how to exit Standby mode.

**Table 19. Standby mode entry and exit**

| Standby mode          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| <b>Wakeup latency</b> | Reset phase.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

### I/O states in Standby mode

In Standby mode, all I/O pins are high impedance except for:

- Reset pad (still available)
- PC13 if configured for tamper, time stamp, RTC Alarm out, or RTC clock calibration out
- WKUP pins (PA0/PA2/PC1/PC13/PI8/PI11), if enabled

### 4.3.7 Programming the RTC alternate functions to wake up the device from the Stop and Standby modes

The MCU can be woken up from a low-power mode by an RTC alternate function.

The RTC alternate functions are the RTC alarms (Alarm A and Alarm B), RTC wakeup, RTC tamper event detection and RTC time stamp event detection.

These RTC alternate functions can wake up the system from the Stop and Standby low-power modes.

The system can also wake up from low-power modes without depending on an external interrupt (Auto-wakeup mode), by using the RTC alarm or the RTC wakeup events.

The RTC provides a programmable time base for waking up from the Stop or Standby mode at regular intervals.

For this purpose, two of the three alternate RTC clock sources can be selected by programming the RTCSEL[1:0] bits in the [RCC backup domain control register \(RCC\\_BDCR\)](#):

- Low-power 32.768 kHz external crystal oscillator (LSE OSC)  
This clock source provides a precise time base with a very low-power consumption (additional consumption of less than 1  $\mu$ A under typical conditions)
- Low-power internal RC oscillator (LSI RC)  
This clock source has the advantage of saving the cost of the 32.768 kHz crystal. This internal RC oscillator is designed to use minimum power.

### RTC alternate functions to wake up the device from the Stop mode

- To wake up the device from the Stop mode with an RTC alarm event, it is necessary to:
  - a) Configure the EXTI Line 17 to be sensitive to rising edges (Interrupt or Event modes)
  - b) Enable the RTC Alarm Interrupt in the RTC\_CR register
  - c) Configure the RTC to generate the RTC alarm
- To wake up the device from the Stop mode with an RTC tamper or time stamp event, it is necessary to:
  - a) Configure the EXTI Line 21 to be sensitive to rising edges (Interrupt or Event modes)
  - b) Enable the RTC time stamp Interrupt in the RTC\_CR register or the RTC tamper interrupt in the RTC\_TAFCR register
  - c) Configure the RTC to detect the tamper or time stamp event
- To wake up the device from the Stop mode with an RTC wakeup event, it is necessary to:
  - a) Configure the EXTI Line 22 to be sensitive to rising edges (Interrupt or Event modes)
  - b) Enable the RTC wakeup interrupt in the RTC\_CR register
  - c) Configure the RTC to generate the RTC Wakeup event

**RTC alternate functions to wake up the device from the Standby mode**

- To wake up the device from the Standby mode with an RTC alarm event, it is necessary to:
  - a) Enable the RTC alarm interrupt in the RTC\_CR register
  - b) Configure the RTC to generate the RTC alarm
  - c) Enable the RTC internal wakeup event from standby by setting the EIWUP bit in the PWR\_CSR1 register
- To wake up the device from the Standby mode with an RTC tamper or time stamp event, it is necessary to:
  - a) Enable the RTC time stamp interrupt in the RTC\_CR register or the RTC tamper interrupt in the RTC\_TAFCR register
  - b) Configure the RTC to detect the tamper or time stamp event
  - c) Enable the RTC internal wakeup event from standby by setting the EIWUP bit in the PWR\_CSR1 register
- To wake up the device from the Standby mode with an RTC wakeup event, it is necessary to:
  - a) Enable the RTC wakeup interrupt in the RTC\_CR register
  - b) Configure the RTC to generate the RTC wakeup event
  - c) Enable the RTC internal wakeup event from standby by setting the EIWUP bit in the PWR\_CSR1 register

**Safe RTC alternate function wakeup flag clearing sequence**

To avoid bouncing on the pins onto which the RTC alternate functions are mapped, and exit correctly from the Stop and Standby modes, it is recommended to follow the sequence below before entering the Standby mode:

- When using RTC alarm to wake up the device from the low-power modes:
  - a) Disable the RTC alarm interrupt (ALRAIE or ALRBIE bits in the RTC\_CR register)
  - b) Clear the RTC alarm (ALRAF/ALRBF) flag
  - c) Enable the RTC alarm interrupt
  - d) Re-enter the low-power mode
- When using RTC wakeup to wake up the device from the low-power modes:
  - a) Disable the RTC Wakeup interrupt (WUTIE bit in the RTC\_CR register)
  - b) Enable the RTC Wakeup interrupt
  - c) Re-enter the low-power mode
- When using RTC tamper to wake up the device from the low-power modes:
  - a) Disable the RTC tamper interrupt (TAMPIE bit in the RTC\_TAFCR register)
  - b) Clear the Tamper (TAMP1F/TSF) flag
  - c) Enable the RTC tamper interrupt
  - d) Re-enter the low-power mode
- When using RTC time stamp to wake up the device from the low-power modes:
  - a) Disable the RTC time stamp interrupt (TSIE bit in RTC\_CR)
  - b) Clear the RTC time stamp (TSF) flag
  - c) Enable the RTC TimeStamp interrupt
  - d) Re-enter the low-power mode

## 4.4 Power control registers

### 4.4.1 PWR power control register (PWR\_CR1)

Address offset: 0x00

Reset value: 0x0000 C000 (reset by wakeup from Standby mode)

| 31       | 30    | 29   | 28    | 27    | 26   | 25   | 24       | 23   | 22   | 21   | 20   | 19        | 18   | 17     | 16   |

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:18 **UDEN[1:0]**: Under-drive enable in stop mode

These bits are set by software. They allow to achieve a lower power consumption in Stop mode but with a longer wakeup time.

When set, the digital area has less leakage consumption when the device enters Stop mode.

00: Under-drive disable

01: Reserved

10: Reserved

11: Under-drive enable

Bit 17 **ODSWEN**: Over-drive switching enabled.

This bit is set by software. It is cleared automatically by hardware after exiting from Stop mode or when the ODEN bit is reset. When set, It is used to switch to Over-drive mode.

To set or reset the ODSWEN bit, the HSI or HSE must be selected as system clock.

The ODSWEN bit must only be set when the ODRDY flag is set to switch to Over-drive mode.

0: Over-drive switching disabled

1: Over-drive switching enabled

*Note: On any over-drive switch (enabled or disabled), the system clock will be stalled during the internal voltage set up.*

Bit 16 **ODEN**: Over-drive enable

This bit is set by software. It is cleared automatically by hardware after exiting from Stop mode. It is used to enable the Over-drive mode in order to reach a higher frequency.

To set or reset the ODEN bit, the HSI or HSE must be selected as system clock. When the ODEN bit is set, the application must first wait for the Over-drive ready flag (ODRDY) to be set before setting the ODSWEN bit.

0: Over-drive disabled

1: Over-drive enabled

Bits 15:14 **VOS[1:0]**: Regulator voltage scaling output selection

These bits control the main internal voltage regulator output voltage to achieve a trade-off between performance and power consumption when the device does not operate at the maximum frequency (refer to the STM32F75xxx and STM32F74xxx datasheets for more details).

These bits can be modified only when the PLL is OFF. The new value programmed is active only when the PLL is ON. When the PLL is OFF, the voltage scale 3 is automatically selected.

00: Reserved (Scale 3 mode selected)

01: Scale 3 mode

10: Scale 2 mode

11: Scale 1 mode (reset value)

Bit 13 **ADCD1**:

0: No effect.

1: Refer to AN4073 for details on how to use this bit.

*Note: This bit can only be set when operating at supply voltage range 2.7 to 3.6V.*

Bit 12 Reserved, must be kept at reset value.

Bit 11 **MRUDS**: Main regulator in deepsleep under-drive mode

This bit is set and cleared by software.

0: Main regulator ON when the device is in Stop mode

1: Main Regulator in under-drive mode and Flash memory in power-down when the device is in Stop under-drive mode.

Bit 10 **LPUDS**: Low-power regulator in deepsleep under-drive mode

This bit is set and cleared by software.

0: Low-power regulator ON if LPDS bit is set when the device is in Stop mode

1: Low-power regulator in under-drive mode if LPDS bit is set and Flash memory in power-down when the device is in Stop under-drive mode.

Bit 9 **FPDS**: Flash power-down in Stop mode

When set, the Flash memory enters power-down mode when the device enters Stop mode. This allows to achieve a lower consumption in stop mode but a longer restart time.

0: Flash memory not in power-down when the device is in Stop mode

1: Flash memory in power-down when the device is in Stop mode

Bit 8 **DBP**: Disable backup domain write protection

In reset state, the RCC\_BDCR register, the RTC registers (including the backup registers), and the BRE bit of the PWR\_CSR1 register, are protected against parasitic write access. This bit must be set to enable write access to these registers.

0: Access to RTC and RTC Backup registers and backup SRAM disabled

1: Access to RTC and RTC Backup registers and backup SRAM enabled

Bits 7:5 **PLS[2:0]**: PVD level selection

These bits are written by software to select the voltage threshold detected by the Power Voltage Detector

000: 2.0 V  
 001: 2.1 V  
 010: 2.3 V  
 011: 2.5 V  
 100: 2.6 V  
 101: 2.7 V  
 110: 2.8 V  
 111: 2.9 V

*Note: Refer to the electrical characteristics of the datasheet for more details.*

Bit 4 **PVDE**: Power voltage detector enable

This bit is set and cleared by software.

0: PVD disabled  
 1: PVD enabled

Bit 3 **CSBF**: Clear standby flag

This bit is always read as 0.

0: No effect  
 1: Clear the SDF Standby Flag (write)

Bit 2 Reserved, must be kept at reset value

Bit 1 **PDDS**: Power-down deepsleep

This bit is set and cleared by software. It works together with the LPDS bit.

0: Enter Stop mode when the CPU enters deepsleep. The regulator status depends on the LPDS bit.  
 1: Enter Standby mode when the CPU enters deepsleep.

Bit 0 **LPDS**: Low-power deepsleep

This bit is set and cleared by software. It works together with the PDDS bit.

0: Main voltage regulator ON during Stop mode  
 1: Low-power voltage regulator ON during Stop mode

#### 4.4.2 PWR power control/status register (PWR\_CSR1)

Address offset: 0x04

Reset value: 0x0000 0000 (not reset by wakeup from Standby mode)

Additional APB cycles are needed to read this register versus a standard APB read.

| 31   | 30      | 29   | 28   | 27   | 26   | 25   | 24    | 23   | 22   | 21   | 20   | 19         | 18    | 17      | 16    |

|      | r       |      |      |      |      | rw   | rw    |      |      |      |      | r          | r     | r       | r     |

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:18 **UDRDY[1:0]**: Under-drive ready flag

These bits are set by hardware when MCU enters stop Under-drive mode and exits. When the Under-drive mode is enabled, these bits are not set as long as the MCU has not entered stop mode yet. they are cleared by programming them to 1.

00: Under-drive is disabled

01: Reserved

10: Reserved

11: Under-drive mode is activated in Stop mode.

Bit 17 **ODSWRDY**: Over-drive mode switching ready

0: Over-drive mode is not active.

1: Over-drive mode is active on digital area on 1.2 V domain

Bit 16 **ODRDY**: Over-drive mode ready

0: Over-drive mode not ready.

1: Over-drive mode ready

Bit 14 **VOSRDY**: Regulator voltage scaling output selection ready bit

0: Not ready

1: Ready

Bits 13:10 Reserved, must be kept at reset value.

Bit 9 **BRE**: Backup regulator enable

When set, the Backup regulator (used to maintain backup SRAM content in Standby and V<sub>BAT</sub> modes) is enabled. If BRE is reset, the backup regulator is switched off. The backup SRAM can still be used but its content will be lost in the Standby and V<sub>BAT</sub> modes. Once set, the application must wait that the Backup Regulator Ready flag (BRR) is set to indicate that the data written into the RAM will be maintained in the Standby and V<sub>BAT</sub> modes.

0: Backup regulator disabled

1: Backup regulator enabled

*Note: This bit is not reset when the device wakes up from Standby mode, by a system reset, or by a power reset.*

Bit 8 **EIWUP**: Enable internal wakeup

This bit must be set when RTC events (Alarm A or Alarm B, RTC Tamper, RTC TimeStamp or RTC Wakeup time) are used to wake up the system from Standby mode.

This bit is always read as 0.

0: Disable internal wakeup sources (RTC events) during Standby mode

1: Enable internal wakeup sources (RTC events) during Standby mode

Bits 7:4 Reserved, must be kept at reset value.

Bit 3 **BRR**: Backup regulator ready

Set by hardware to indicate that the Backup Regulator is ready.

0: Backup Regulator not ready

1: Backup Regulator ready

*Note: This bit is not reset when the device wakes up from Standby mode or by a system reset or power reset.*

Bit 2 **PVDO**: PVD output

This bit is set and cleared by hardware. It is valid only if PVD is enabled by the PVDE bit.

0:  $V_{DD}$  is higher than the PVD threshold selected with the PLS[2:0] bits.

1:  $V_{DD}$  is lower than the PVD threshold selected with the PLS[2:0] bits.

*Note: The PVD is stopped by Standby mode. For this reason, this bit is equal to 0 after Standby or reset until the PVDE bit is set.*

Bit 1 **SBF**: Standby flag

This bit is set by hardware and cleared only by a POR/PDR (power-on reset/power-down reset) or by setting the CSBF bit in the [PWR power control register \(PWR\\_CR1\)](#)

0: Device has not been in Standby mode

1: Device has been in Standby mode

Bit 0 **WUIF**: Wakeup internal flag

This bit is set when a wakeup is detected on the internal wakeup line in standby mode. It is cleared when all internal wakeup sources are cleared.

0: No wakeup internal event occurred

1: A wakeup event was detected from the RTC alarm (Alarm A or Alarm B), RTC Tamper event, RTC TimeStamp event or RTC Wakeup

### 4.4.3 PWR power control/status register 2 (PWR\_CR2)

Address offset: 0x08

Reset value: 0x0000 0000 (not reset by wakeup from Standby mode)

| 31   | 30   | 29    | 28    | 27    | 26    | 25    | 24    | 23   | 22   | 21     | 20     | 19     | 18     | 17     | 16     |

Bits 31:14 Reserved, always read as 0.

Bit 13 **WUPP6**: Wakeup pin polarity bit for PI11

These bits define the polarity used for event detection on external wake-up pin PI11.

0: Detection on rising edge

1: Detection on falling edge

Bit 12 **WUPP5**: Wakeup pin polarity bit for PI8

These bits define the polarity used for event detection on external wake-up pin PI8.

0: Detection on rising edge

1: Detection on falling edge

Bit 11 **WUPP4**: Wakeup pin polarity bit for PC13

These bits define the polarity used for event detection on external wake-up pin PC13.

0: Detection on rising edge

1: Detection on falling edge

Bit 10 **WUPP3**: Wakeup pin polarity bit for PC1

These bits define the polarity used for event detection on external wake-up pin PC1.

0: Detection on rising edge

1: Detection on falling edge

Bit 9 **WUPP2**: Wakeup pin polarity bit for PA2

These bits define the polarity used for event detection on external wake-up pin PA2.

0: Detection on rising edge

1: Detection on falling edge

Bit 8 **WUPP1**: Wakeup pin polarity bit for PA0

These bits define the polarity used for event detection on external wake-up pin PA0.

0: Detection on rising edge

1: Detection on falling edge

Bits 7:6 Reserved, always read as 0

Bit 5 **CWUPF6**: Clear Wakeup Pin flag for PI11

These bits are always read as 0

0: No effect

1: Clear the WUPF Wakeup Pin flag after 2 System clock cycles.

Bit 4 **CWUPF5**: Clear Wakeup Pin flag for PI8

These bits are always read as 0

0: No effect

1: Clear the WUPF Wakeup Pin flag after 2 System clock cycles.

Bit 3 **CWUPF4**: Clear Wakeup Pin flag for PC13

These bits are always read as 0

0: No effect

1: Clear the WUPF Wakeup Pin flag after 2 System clock cycles.

Bit 2 **CWUPF3**: Clear Wakeup Pin flag for PC1

These bits are always read as 0

0: No effect

1: Clear the WUPF Wakeup Pin flag after 2 System clock cycles.

Bit 1 **CWUPF2**: Clear Wakeup Pin flag for PA2

These bits are always read as 0

0: No effect

1: Clear the WUPF Wakeup Pin flag after 2 System clock cycles.

Bit 0 **CWUPF1**: Clear Wakeup Pin flag for PA0

These bits are always read as 0

0: No effect

1: Clear the WUPF Wakeup Pin flag after 2 System clock cycles.

#### 4.4.4 PWR power control register 2 (PWR\_CSR2)

Address offset: 0x0C

Reset value: 0x0000 0000 (reset by wakeup from Standby mode, except wakeup flags which are reset by RESET pin)

Additional APB cycles are needed to read this register versus a standard APB read.

Bits 31:14 Reserved, always read as 0.

Bit 13 **EWUP6**: Enable Wakeup pin for PI11

This bit is set and cleared by software.

0: An event on WKUP pin PI11 does not wake-up the device from Standby mode.

1: A rising or falling edge on WKUP pin PI11 wakes-up the system from Standby mode.

Bit 12 **EWUP5**: Enable Wakeup pin for PI8

This bit is set and cleared by software.

0: An event on WKUP pin PI8 does not wake-up the device from Standby mode.

1: A rising or falling edge on WKUP pin PI8 wakes-up the system from Standby mode.

Bit 11 **EWUP4**: Enable Wakeup pin for PC13

This bit is set and cleared by software.

0: An event on WKUP pin PC13 does not wake-up the device from Standby mode.

1: A rising or falling edge on WKUP pin PC13 wakes-up the system from Standby mode.

Bit 10 **EWUP3**: Enable Wakeup pin for PC1

This bit is set and cleared by software.

0: An event on WKUP pin PC1 does not wake-up the device from Standby mode.

1: A rising or falling edge on WKUP pin PC1 wakes-up the system from Standby mode.

Bit 9 **EWUP2**: Enable Wakeup pin for PA2

This bit is set and cleared by software.

0: An event on WKUP pin PA2 does not wake-up the device from Standby mode.

1: A rising or falling edge on WKUP pin PA2 wakes-up the system from Standby mode.

Bit 8 **EWUP1**: Enable Wakeup pin for PA0

This bit is set and cleared by software.

0: An event on WKUP pin PA0 does not wake-up the device from Standby mode.

1: A rising or falling edge on WKUP pin PA0 wakes-up the system from Standby mode.

Bits 7:6 Reserved, always read as 0

**Bit 5 WUPF6:** Wakeup Pin flag for PI11

This bit is set by hardware and cleared only by a Reset pin or by setting the CWUPF6 bit in the PWR power control register 2 (PWR\_CR2).

0: No Wakeup event occurred

1: A wakeup event is detected on WKUP PI11

*Note: An additional wakeup event is detected if WKUP pin is enabled (by setting the EWUP6 bit) when WKUP pin PI11 level is already high.*

**Bit 4 WUPF5:** Wakeup Pin flag for PI8

This bit is set by hardware and cleared only by a Reset pin or by setting the CWUPF5 bit in the PWR power control register 2 (PWR\_CR2).

0: No Wakeup event occurred

1: A wakeup event is detected on WKUP PI8

*Note: An additional wakeup event is detected if WKUP pin is enabled (by setting the EWUP5 bit) when WKUP pin PI8 level is already high.*

**Bit 3 WUPF4:** Wakeup Pin flag for PC13

This bit is set by hardware and cleared only by a Reset pin or by setting the CWUPF4 bit in the PWR power control register 2 (PWR\_CR2).

0: No Wakeup event occurred

1: A wakeup event is detected on WKUP PC13

*Note: An additional wakeup event is detected if WKUP pin is enabled (by setting the EWUP4 bit) when WKUP pin PC13 level is already high.*

**Bit 2 WUPF3:** Wakeup Pin flag for PC1

This bit is set by hardware and cleared only by a Reset pin or by setting the CWUPF3 bit in the PWR power control register 2 (PWR\_CR2).

0: No Wakeup event occurred

1: A wakeup event is detected on WKUP PC1

*Note: An additional wakeup event is detected if WKUP pin is enabled (by setting the EWUP3 bit) when WKUP pin PC1 level is already high.*

**Bit 1 WUPF2:** Wakeup Pin flag for PA2

This bit is set by hardware and cleared only by a Reset pin or by setting the CWUPF2 bit in the PWR power control register 2 (PWR\_CR2).

0: No Wakeup event occurred

1: A wakeup event is detected on WKUP PA2

*Note: An additional wakeup event is detected if WKUP pin is enabled (by setting the EWUP2 bit) when WKUP pin PA2 level is already high.*

**Bit 0 WUPF1:** Wakeup Pin flag for PA0

This bit is set by hardware and cleared only by a Reset pin or by setting the CWUPF1 bit in the PWR power control register 2 (PWR\_CR2).

0: No Wakeup event occurred

1: A wakeup event is detected on WKUP PA0

*Note: An additional wakeup event is detected if WKUP pin is enabled (by setting the EWUP1 bit) when WKUP pin PA0 level is already high.*

## 4.5 PWR register map

The following table summarizes the PWR registers.

**Table 20. PWR - register map and reset values**

| Offset | Register    | 31   | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21   | 20   | 19         | 18   | 17      | 16    | 15       | 14     | 13    | 12    | 11    | 10    | 9     | 8     | 7        | 6    | 5    | 4    | 3    | 2    | 1    | 0    |

Refer to [Section 2.2.2 on page 69](#) for the register boundary addresses.

## 5 Reset and clock control (RCC)

### 5.1 Reset

There are three types of reset, defined as system Reset, power Reset and backup domain Reset.

#### 5.1.1 System reset

A system reset sets all registers to their reset values except the reset flags in the clock controller CSR register and the registers in the Backup domain (see [Figure 12](#)).

A system reset is generated when one of the following events occurs:

1. A low level on the NRST pin (external reset)
2. Window watchdog end of count condition (WWDG reset)
3. Independent watchdog end of count condition (IWDG reset)
4. A software reset (SW reset) (see [Software reset](#))
5. Low-power management reset (see [Low-power management reset](#))

##### Software reset

The reset source can be identified by checking the reset flags in the [RCC clock control & status register \(RCC\\_CSR\)](#).

The SYSRESETREQ bit in Cortex<sup>®</sup>-M7 Application Interrupt and Reset Control Register must be set to force a software reset on the device. Refer to the Cortex<sup>®</sup>-M7 technical reference manual for more details.

##### Low-power management reset

There are two ways of generating a low-power management reset:

1. Reset generated when entering the Standby mode:  
This type of reset is enabled by resetting the nRST\_STDBY bit in the user option bytes. In this case, whenever a Standby mode entry sequence is successfully executed, the device is reset instead of entering the Standby mode.
2. Reset when entering the Stop mode:  
This type of reset is enabled by resetting the nRST\_STOP bit in the user option bytes. In this case, whenever a Stop mode entry sequence is successfully executed, the device is reset instead of entering the Stop mode.

#### 5.1.2 Power reset

A power reset is generated when one of the following events occurs:

1. Power-on/power-down reset (POR/PDR reset) or brownout (BOR) reset
2. When exiting the Standby mode

A power reset sets all registers to their reset values except the Backup domain (see [Figure 12](#))

These sources act on the NRST pin and it is always kept low during the delay phase. The RESET service routine vector is fixed at address 0x0000\_0004 in the memory map.

The system reset signal provided to the device is output on the NRST pin. The pulse generator guarantees a minimum reset pulse duration of 20  $\mu$ s for each internal reset source. In case of an external reset, the reset pulse is generated while the NRST pin is asserted low.

**Figure 12. Simplified diagram of the reset circuit**

The Backup domain has two specific resets that affect only the Backup domain (see [Figure 12](#)).

### 5.1.3 Backup domain reset

The backup domain reset sets all RTC registers and the RCC\_BDCR register to their reset values. The BKPSRAM is not affected by this reset. The only way of resetting the BKPSRAM is through the Flash interface by requesting a protection level change from 1 to 0.

A backup domain reset is generated when one of the following events occurs:

1. Software reset, triggered by setting the BDRST bit in the [RCC backup domain control register \(RCC\\_BDCR\)](#).
2.  $V_{DD}$  or  $V_{BAT}$  power on, if both supplies have previously been powered off.

## 5.2 Clocks

Three different clock sources can be used to drive the system clock (SYSCLK):

- HSI oscillator clock
- HSE oscillator clock
- Main PLL (PLL) clock

The devices have the two following secondary clock sources:

- 32 kHz low-speed internal RC (LSI RC) which drives the independent watchdog and, optionally, the RTC used for Auto-wakeup from the Stop/Standby mode.
- 32.768 kHz low-speed external crystal (LSE crystal) which optionally drives the RTC clock (RTCCLK)

Each clock source can be switched on or off independently when it is not used, to optimize power consumption.

Figure 13. Clock tree

1. For full details about the internal and external clock source characteristics, refer to the Electrical characteristics section in the device datasheet.
2. When TIMPRE bit of the RCC\_DCKCFGR1 register is reset, if APBx prescaler is 1, then TIMxCLK = PCLKx, otherwise TIMxCLK = 2x PCLKx.
3. When TIMPRE bit in the RCC\_DCKCFGR1 register is set, if APBx prescaler is 1,2 or 4, then TIMxCLK = HCLK, otherwise TIMxCLK = 4x PCLKx.

The clock controller provides a high degree of flexibility to the application in the choice of the external crystal or the oscillator to run the core and peripherals at the highest frequency

All peripheral clocks are derived from their bus clock (HCLK, PLCK1, PCLK2) except for:

- The 48MHz clock, used for USB OTG FS, SDMMC and RNG. This clock is derived from one of the following sources:
  - main PLL VCO (PLLQ Clock)
  - PLLSAI VCO (PLLSAI clock)
- The U(S)ARTs clocks which are derived from one of the following sources:
  - System clock (SYSCLK)
  - HSI clock
  - LSE clock
  - APB1 or APB2 clock (PCLK1 or PCLK2 depending on which APB is mapped the U(S)ART)
- The I2Cs clocks which are derived from one of the following sources:
  - System clock (SYSCLK)
  - HSI clock
  - APB1 clock (PCLK1)
- I2S clock
 

To achieve high-quality audio performance, the I2S clock can be derived either from a specific PLL (PLLI2S) or from an external clock mapped on the I2S\_CKIN pin. For more information about I2S clock frequency and precision, refer to [Section 32.7.5: Clock generator](#).
- The SAI1 and SAI2 clocks which are derived from one of the following sources:
  - PLLSAI VCO (PLLSAIQ)
  - PLLI2S VCO (PLLI2SQ)
  - External clock mapped on the I2S\_CKIN pin.
- LTDC clock
 

The LTDC clock is generated from a specific PLL (PLLSAI).
- The low-power timer (LPTIM1) clock which is derived from one of the following sources:
  - LSI clock
  - LSE clock
  - HSI clock
  - APB1 clock (PCLK1)
  - External clock mapped on LPTIM1\_IN1
- The USB OTG HS (60 MHz) clock which is provided from the external PHY
- The Ethernet MAC clocks (TX, RX and RMII) which are provided from the external PHY. For further information on the Ethernet configuration, refer to [Section 38.4.4: MII/RMII selection](#) in the Ethernet peripheral description. When the Ethernet is used, the AHB clock frequency must be at least 25 MHz.
- SPDIFRX clock: which is generated from PLLI2SP VCO.
- The HDMI-CEC clock which is derived from one of the following sources:
  - LSE clock
  - HSI clock divided by 488

- The RTC clock which is derived from one of the following sources:
  - LSE clock
  - LSI clock
  - HSE clock divided by 32
- The IWDG clock which is always the LSI clock.
- The timer clock frequencies are automatically set by hardware. There are two cases depending on the value of TIMPRE bit in RCC\_CFGR register:
  - If TIMPRE bit in RCC\_DCKCFGR1 register is reset:

If the APB prescaler is configured to a division factor of 1, the timer clock frequencies (TIMxCLK) are set to PCLKx. Otherwise, the timer clock frequencies are twice the frequency of the APB domain to which the timers are connected:  
 $TIMxCLK = 2 \times PCLKx$ .
  - If TIMPRE bit in RCC\_DCKCFGR1 register is set:

If the APB prescaler is configured to a division factor of 1, 2 or 4, the timer clock frequencies (TIMxCLK) are set to HCLK. Otherwise, the timer clock frequencies is four times the frequency of the APB domain to which the timers are connected:  
 $TIMxCLK = 4 \times PCLKx$ .

The RCC feeds the external clock of the Cortex System Timer (SysTick) with the AHB clock (HCLK) divided by 8. The SysTick can work either with this clock or with the Cortex clock (HCLK), configurable in the SysTick control and status register.

FCLK acts as Cortex®-M7 free-running clock. For more details, refer to the Cortex®-M7 technical reference manual.

### 5.2.1 HSE clock

The high speed external clock signal (HSE) can be generated from two possible clock sources:

- HSE external crystal/ceramic resonator
- HSE external user clock

The resonator and the load capacitors have to be placed as close as possible to the oscillator pins in order to minimize output distortion and startup stabilization time. The loading capacitance values must be adjusted according to the selected oscillator.

Figure 14. HSE/ LSE clock sources

### External source (HSE bypass)

In this mode, an external clock source must be provided. This mode is selected by setting the HSEBYP and HSEON bits in the [RCC clock control register \(RCC\\_CR\)](#). The external clock signal (square, sinus or triangle) with ~50% duty cycle has to drive the OSC\_IN pin while the OSC\_OUT pin should be left HI-Z. See [Figure 14](#).

### External crystal/ceramic resonator (HSE crystal)

The HSE has the advantage of producing a very accurate rate on the main clock.

The associated hardware configuration is shown in [Figure 14](#). Refer to the electrical characteristics section of the *datasheet* for more details.

The HSERDY flag in the [RCC clock control register \(RCC\\_CR\)](#) indicates if the high-speed external oscillator is stable or not. At startup, the clock is not released until this bit is set by hardware. An interrupt can be generated if enabled in the [RCC clock interrupt register \(RCC\\_CIR\)](#).

The HSE Crystal can be switched on and off using the HSEON bit in the [RCC clock control register \(RCC\\_CR\)](#).

## 5.2.2 HSI clock

The HSI clock signal is generated from an internal 16 MHz RC oscillator and can be used directly as a system clock, or used as PLL input.

The HSI RC oscillator has the advantage of providing a clock source at low cost (no external components). It also has a faster startup time than the HSE crystal oscillator however, even

with calibration the frequency is less accurate than an external crystal oscillator or ceramic resonator.

### Calibration

RC oscillator frequencies can vary from one chip to another due to manufacturing process variations, this is why each device is factory calibrated by ST for 1% accuracy at  $T_A = 25\text{ }^{\circ}\text{C}$ .

After reset, the factory calibration value is loaded in the HSICAL[7:0] bits in the [RCC clock control register \(RCC\\_CR\)](#).

If the application is subject to voltage or temperature variations this may affect the RC oscillator speed. The HSI frequency can be trimmed in the application using the HSITRIM[4:0] bits in the [RCC clock control register \(RCC\\_CR\)](#).

The HSIRDY flag in the [RCC clock control register \(RCC\\_CR\)](#) indicates if the HSI RC is stable or not. At startup, the HSI RC output clock is not released until this bit is set by hardware.

The HSI RC can be switched on and off using the HSION bit in the [RCC clock control register \(RCC\\_CR\)](#).

The HSI signal can also be used as a backup source (Auxiliary clock) if the HSE crystal oscillator fails. Refer to [Section 5.2.7: Clock security system \(CSS\) on page 139](#).

## 5.2.3 PLL

The devices feature three PLLs:

- A main PLL (PLL) clocked by the HSE or HSI oscillator and featuring two different output clocks:
  - The first output is used to generate the high speed system clock (up to 216 MHz)
  - The second output is used to generate 48MHz clock for the USB OTG FS, SDMMC and RNG.
- PLLI2S is used to generate an accurate clock to achieve high-quality audio performance on the I2S, SAI and SPDIFRX interfaces.
- PLLSAI is used to generate clock for SAI interfaces, LCD-TFT clock and the 48MHz (PLLSAI48CLK) that can be selected for the USB OTG FS, SDMMC and RNG.

Since the main-PLL configuration parameters cannot be changed once PLL is enabled, it is recommended to configure PLL before enabling it (selection of the HSI or HSE oscillator as PLL clock source, and configuration of division factors M, N, P, and Q).

The PLLI2S and PLLSAI use the same input clock as PLL (PLLM[5:0] and PLLSRC bits are common to both PLLs). However, the PLLI2S and PLLSAI have dedicated enable/disable and division factors (N and R) configuration bits. Once the PLLI2S and PLLSAI are enabled, the configuration parameters cannot be changed.

The three PLLs are disabled by hardware when entering Stop and Standby modes, or when an HSE failure occurs when HSE or PLL (clocked by HSE) are used as system clock. [RCC PLL configuration register \(RCC\\_PLLCFGR\)](#), [RCC clock configuration register \(RCC\\_CFGR\)](#), and [RCC dedicated clocks configuration register \(RCC\\_DCKCFGR1\)](#) can be used to configure PLL, PLLI2S, and PLLSAI.

### 5.2.4 LSE clock

The LSE clock is generated from a 32.768 kHz low-speed external crystal or ceramic resonator. It has the advantage providing a low-power but highly accurate clock source to the real-time clock peripheral (RTC) for clock/calendar or other timing functions.

The LSE oscillator is switched on and off using the LSEON bit in *RCC backup domain control register (RCC\_BDCR)*.

The LSERDY flag in the *RCC backup domain control register (RCC\_BDCR)* indicates if the LSE crystal is stable or not. At startup, the LSE crystal output clock signal is not released until this bit is set by hardware. An interrupt can be generated if enabled in the *RCC clock interrupt register (RCC\_CIR)*.

#### External source (LSE bypass)

In this mode, an external clock source must be provided. It must have a frequency up to 1 MHz. This mode is selected by setting the LSEBYP and LSEON bits in the *RCC backup domain control register (RCC\_BDCR)*. The external clock signal (square, sinus or triangle) with ~50% duty cycle has to drive the OSC32\_IN pin while the OSC32\_OUT pin should be left HI-Z. See *Figure 14*.

### 5.2.5 LSI clock

The LSI RC acts as a low-power clock source that can be kept running in Stop and Standby mode for the independent watchdog (IWDG) and Auto-wakeup unit (AWU). The clock frequency is around 32 kHz. For more details, refer to the electrical characteristics section of the datasheets.

The LSI RC can be switched on and off using the LSION bit in the *RCC clock control & status register (RCC\_CSR)*.

The LSIRDY flag in the *RCC clock control & status register (RCC\_CSR)* indicates if the low-speed internal oscillator is stable or not. At startup, the clock is not released until this bit is set by hardware. An interrupt can be generated if enabled in the *RCC clock interrupt register (RCC\_CIR)*.

### 5.2.6 System clock (SYSCLK) selection

After a system reset, the HSI oscillator is selected as the system clock. When a clock source is used directly or through PLL as the system clock, it is not possible to stop it.

A switch from one clock source to another occurs only if the target clock source is ready (clock stable after startup delay or PLL locked). If a clock source that is not yet ready is selected, the switch occurs when the clock source is ready. Status bits in the *RCC clock control register (RCC\_CR)* indicate which clock(s) is (are) ready and which clock is currently used as the system clock.

### 5.2.7 Clock security system (CSS)

The clock security system can be activated by software. In this case, the clock detector is enabled after the HSE oscillator startup delay, and disabled when this oscillator is stopped.

If a failure is detected on the HSE clock, this oscillator is automatically disabled, a clock failure event is sent to the break inputs of advanced-control timers TIM1 and TIM8, and an interrupt is generated to inform the software about the failure (clock security system).

interrupt CSSI), allowing the MCU to perform rescue operations. The CSSI is linked to the Cortex®-M7 NMI (non-maskable interrupt) exception vector.

**Note:** *When the CSS is enabled, if the HSE clock happens to fail, the CSS generates an interrupt, which causes the automatic generation of an NMI. The NMI is executed indefinitely unless the CSS interrupt pending bit is cleared. As a consequence, the application has to clear the CSS interrupt in the NMI ISR by setting the CSSC bit in the Clock interrupt register (RCC\_CIR).*

If the HSE oscillator is used directly or indirectly as the system clock (indirectly meaning that it is directly used as PLL input clock, and that PLL clock is the system clock) and a failure is detected, then the system clock switches to the HSI oscillator and the HSE oscillator is disabled.

If the HSE oscillator clock was the clock source of PLL used as the system clock when the failure occurred, PLL is also disabled. In this case, if the PLLI2S or PLLSAI was enabled, it is also disabled when the HSE fails.

### 5.2.8 RTC/AWU clock

Once the RTCCLK clock source has been selected, the only possible way of modifying the selection is to reset the power domain.

The RTCCLK clock source can be either the HSE 1 MHz (HSE divided by a programmable prescaler), the LSE or the LSI clock. This is selected by programming the RTCSEL[1:0] bits in the [RCC backup domain control register \(RCC\\_BDCR\)](#) and the RTCPRE[4:0] bits in [RCC clock configuration register \(RCC\\_CFGR\)](#). This selection cannot be modified without resetting the Backup domain.

If the LSE is selected as the RTC clock, the RTC will work normally if the backup or the system supply disappears. If the LSI is selected as the AWU clock, the AWU state is not guaranteed if the system supply disappears. If the HSE oscillator divided by a value between 2 and 31 is used as the RTC clock, the RTC state is not guaranteed if the backup or the system supply disappears.

The LSE clock is in the Backup domain, whereas the HSE and LSI clocks are not. As a consequence:

- If LSE is selected as the RTC clock:
  - The RTC continues to work even if the  $V_{DD}$  supply is switched off, provided the  $V_{BAT}$  supply is maintained.
  - The RTC remains clocked and functional under system reset.
- If LSI is selected as the Auto-wakeup unit (AWU) clock:
  - The AWU state is not guaranteed if the  $V_{DD}$  supply is powered off. Refer to [Section 5.2.5: LSI clock on page 139](#) for more details on LSI calibration.
- If the HSE clock is used as the RTC clock:
  - The RTC state is not guaranteed if the  $V_{DD}$  supply is powered off or if the internal voltage regulator is powered off (removing power from the 1.2 V domain) and also when entering in Stop mode

**Note:** *To read the RTC calendar register when the APB1 clock frequency is less than seven times the RTC clock frequency ( $f_{APB1} < 7 \times f_{RTCCLK}$ ), the software must read the calendar time and date registers twice. The data are correct if the second read access to RTC\_TR gives the same result than the first one. Otherwise a third read access must be performed.*

### 5.2.9 Watchdog clock

If the independent watchdog (IWDG) is started by either hardware option or software access, the LSI oscillator is forced ON and cannot be disabled. After the LSI oscillator temporization, the clock is provided to the IWDG.

### 5.2.10 Clock-out capability

Two microcontroller clock output (MCO) pins are available:

- MCO1  
The user can output four different clock sources onto the MCO1 pin (PA8) using the configurable prescaler (from 1 to 5):
  - HSI clock
  - LSE clock
  - HSE clock
  - PLL clockThe desired clock source is selected using the MCO1PRE[2:0] and MCO1[1:0] bits in the [RCC clock configuration register \(RCC\\_CFGR\)](#).
- MCO2  
The user can output four different clock sources onto the MCO2 pin (PC9) using the configurable prescaler (from 1 to 5):
  - HSE clock
  - PLL clock
  - System clock (SYSCLK)
  - PLLI2S clockThe desired clock source is selected using the MCO2PRE[2:0] and MCO2 bits in the [RCC clock configuration register \(RCC\\_CFGR\)](#).

For the different MCO pins, the corresponding GPIO port has to be programmed in alternate function mode.

### 5.2.11 Internal/external clock measurement using TIM5/TIM11

It is possible to indirectly measure the frequencies of all on-board clock source generators by means of the input capture of TIM5 channel4 and TIM11 channel1 as shown in [Figure 15](#) and [Figure 16](#).

#### Internal/external clock measurement using TIM5 channel4

TIM5 has an input multiplexer which allows choosing whether the input capture is triggered by the I/O or by an internal clock. This selection is performed through the TI4\_RMP [1:0] bits in the TIM5\_OR register.

The primary purpose of having the LSE connected to the channel4 input capture is to be able to precisely measure the HSI (this requires to have the HSI used as the system clock source). The number of HSI clock counts between consecutive edges of the LSE signal provides a measurement of the internal clock period. Taking advantage of the high precision of LSE crystals (typically a few tens of ppm) we can determine the internal clock frequency with the same resolution, and trim the source to compensate for manufacturing-process and/or temperature- and voltage-related frequency deviations.

The HSI oscillator has dedicated, user-accessible calibration bits for this purpose.

The basic concept consists in providing a relative measurement (e.g. HSI/LSE ratio): the precision is therefore tightly linked to the ratio between the two clock sources. The greater the ratio, the better the measurement.

It is also possible to measure the LSI frequency: this is useful for applications that do not have a crystal. The ultra-low-power LSI oscillator has a large manufacturing process deviation: by measuring it versus the HSI clock source, it is possible to determine its frequency with the precision of the HSI. The measured value can be used to have more accurate RTC time base timeouts (when LSI is used as the RTC clock source) and/or an IWDG timeout with an acceptable accuracy.

Use the following procedure to measure the LSI frequency:

1. Enable the TIM5 timer and configure channel4 in Input capture mode.
2. This bit is set the TI4\_RMP bits in the TIM5\_OR register to 0x01 to connect the LSI clock internally to TIM5 channel4 input capture for calibration purposes.
3. Measure the LSI clock frequency using the TIM5 capture/compare 4 event or interrupt.
4. Use the measured LSI frequency to update the prescaler of the RTC depending on the desired time base and/or to compute the IWDG timeout.

**Figure 15. Frequency measurement with TIM5 in Input capture mode**

### Internal/external clock measurement using TIM11 channel1

TIM11 has an input multiplexer which allows choosing whether the input capture is triggered by the I/O or by an internal clock. This selection is performed through TI1\_RMP [1:0] bits in the TIM11\_OR register. The HSE\_RTC clock (HSE divided by a programmable prescaler) is connected to channel 1 input capture to have a rough indication of the external crystal frequency. This requires that the HSI is the system clock source. This can be useful for instance to ensure compliance with the IEC 60730/IEC 61335 standards which require to be able to determine harmonic or subharmonic frequencies (–50/+100% deviations).

Figure 16. Frequency measurement with TIM11 in Input capture mode

### 5.2.12 Peripheral clock enable register (RCC\_AHBxENR, RCC\_APBxENRy)

Each peripheral clock can be enabled by the xxxxEN bit of the RCC\_AHBxENR or RCC\_APBxENRy registers.

When the peripheral clock is not active, the peripheral registers read or write accesses are not supported. The peripheral enable bit has a synchronization mechanism to create a glitch free clock for the peripheral.

After the enable bit is set, there is a 2 peripheral clock cycles delay before the clock being active.

**Caution:** Just after enabling the clock for a peripheral, software must wait for a 2 peripheral clock cycles delay before accessing the peripheral registers.

## 5.3 RCC registers

Refer to [Section 1.2: List of abbreviations for registers](#) for a list of abbreviations used in register descriptions.

### 5.3.1 RCC clock control register (RCC\_CR)

Address offset: 0x00

Reset value: 0x0000 XX83 where X is undefined.

Access: no wait state, word, half-word and byte access

|             |      |               |              |               |              |             |        |              |      |      |      |           |            |            |           |

Bits 31:28 Reserved, must be kept at reset value.

Bit 29 **PLLSAIRDY**: PLLSAI clock ready flag

Set by hardware to indicate that the PLLSAI is locked.

0: PLLSAI unlocked

1: PLLSAI locked

Bit 28 **PLLSAION**: PLLSAI enable

Set and cleared by software to enable PLLSAI.

Cleared by hardware when entering Stop or Standby mode.

0: PLLSAI OFF

1: PLLSAI ON

Bit 27 **PLLI2SRDY**: PLLI2S clock ready flag

Set by hardware to indicate that the PLLI2S is locked.

0: PLLI2S unlocked

1: PLLI2S locked

Bit 26 **PLLI2SON**: PLLI2S enable

Set and cleared by software to enable PLLI2S.

Cleared by hardware when entering Stop or Standby mode.

0: PLLI2S OFF

1: PLLI2S ON

Bit 25 **PLLRDY**: Main PLL (PLL) clock ready flag

Set by hardware to indicate that PLL is locked.

0: PLL unlocked

1: PLL locked

Bit 24 **PLLON**: Main PLL (PLL) enable

Set and cleared by software to enable PLL.

Cleared by hardware when entering Stop or Standby mode. This bit cannot be reset if PLL clock is used as the system clock.

0: PLL OFF

1: PLL ON

Bits 23:20 Reserved, must be kept at reset value.

Bit 19 **CSSON**: Clock security system enable

Set and cleared by software to enable the clock security system. When CSSON is set, the clock detector is enabled by hardware when the HSE oscillator is ready, and disabled by hardware if an oscillator failure is detected.

0: Clock security system OFF (Clock detector OFF)

1: Clock security system ON (Clock detector ON if HSE oscillator is stable, OFF if not)

Bit 18 **HSEBYP**: HSE clock bypass

Set and cleared by software to bypass the oscillator with an external clock. The external clock must be enabled with the HSEON bit, to be used by the device.

The HSEBYP bit can be written only if the HSE oscillator is disabled.

0: HSE oscillator not bypassed

1: HSE oscillator bypassed with an external clock

Bit 17 **HSERDY**: HSE clock ready flag

Set by hardware to indicate that the HSE oscillator is stable. After the HSEON bit is cleared, HSERDY goes low after 6 HSE oscillator clock cycles.

0: HSE oscillator not ready

1: HSE oscillator ready

Bit 16 **HSEON**: HSE clock enable

Set and cleared by software.

Cleared by hardware to stop the HSE oscillator when entering Stop or Standby mode. This bit cannot be reset if the HSE oscillator is used directly or indirectly as the system clock.

0: HSE oscillator OFF

1: HSE oscillator ON

Bits 15:8 **HSICAL[7:0]**: Internal high-speed clock calibration

These bits are initialized automatically at startup.

Bits 7:3 **HSITRIM[4:0]**: Internal high-speed clock trimming

These bits provide an additional user-programmable trimming value that is added to the HSICAL[7:0] bits. It can be programmed to adjust to variations in voltage and temperature that influence the frequency of the internal HSI RC.

Bit 2 Reserved, must be kept at reset value.

Bit 1 **HSIRDY**: Internal high-speed clock ready flag

Set by hardware to indicate that the HSI oscillator is stable. After the HSION bit is cleared, HSIRDY goes low after 6 HSI clock cycles.

0: HSI oscillator not ready

1: HSI oscillator ready

Bit 0 **HSION**: Internal high-speed clock enable

Set and cleared by software.

Set by hardware to force the HSI oscillator ON when leaving the Stop or Standby mode or in case of a failure of the HSE oscillator used directly or indirectly as the system clock. This bit cannot be cleared if the HSI is used directly or indirectly as the system clock.

0: HSI oscillator OFF

1: HSI oscillator ON

### 5.3.2 RCC PLL configuration register (RCC\_PLLCFGR)

Address offset: 0x04

Reset value: 0x2400 3010

Access: no wait state, word, half-word and byte access.

This register is used to configure the PLL clock outputs according to the formulas:

- $f_{(VCO \text{ clock})} = f_{(PLL \text{ clock input})} \times (PLL_N / PLL_M)$
- $f_{(PLL \text{ general clock output})} = f_{(VCO \text{ clock})} / PLL_P$
- $f_{(USB \text{ OTG FS, SDMMC, RNG clock output})} = f_{(VCO \text{ clock})} / PLL_Q$

|      |            |      |      |           |    |    |    |      |            |      |      |      |      |           |    |
|------|------------|------|------|-----------|----|----|----|------|------------|------|------|------|------|-----------|----|
| 31   | 30         | 29   | 28   | 27        | 26 | 25 | 24 | 23   | 22         | 21   | 20   | 19   | 18   | 17        | 16 |
| Res. | Res.       | Res. | Res. | PLLQ[3:0] |    |    |    | Res. | PLLSRC     | Res. | Res. | Res. | Res. | PLLP[1:0] |    |
|      |            |      |      | rw        | rw | rw | rw |      | rw         |      |      |      |      | rw        | rw |
| 15   | 14         | 13   | 12   | 11        | 10 | 9  | 8  | 7    | 6          | 5    | 4    | 3    | 2    | 1         | 0  |
| Res. | PLL_N[8:0] |      |      |           |    |    |    |      | PLL_M[5:0] |      |      |      |      |           |    |
|      | rw         | rw   | rw   | rw        | rw | rw | rw | rw   | rw         | rw   | rw   | rw   | rw   | rw        | rw |

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:24 **PLLQ[3:0]**: Main PLL (PLL) division factor for USB OTG FS, SDMMC and random number generator clocks

Set and cleared by software to control the frequency of USB OTG FS clock, the random number generator clock and the SDMMC clock. These bits should be written only if PLL is disabled.

**Caution:** The USB OTG FS requires a 48 MHz clock to work correctly. The SDMMC and the random number generator need a frequency lower than or equal to 48 MHz to work correctly.

USB OTG FS clock frequency = VCO frequency / PLLQ with  $2 \leq PLLQ \leq 15$

0000: PLLQ = 0, wrong configuration

0001: PLLQ = 1, wrong configuration

0010: PLLQ = 2

0011: PLLQ = 3

0100: PLLQ = 4

...

1111: PLLQ = 15

Bit 23 Reserved, must be kept at reset value.

Bit 22 **PLLSRC**: Main PLL(PLL) and audio PLL (PLLI2S) entry clock source

Set and cleared by software to select PLL and PLLI2S clock source. This bit can be written only when PLL and PLLI2S are disabled.

0: HSI clock selected as PLL and PLLI2S clock entry

1: HSE oscillator clock selected as PLL and PLLI2S clock entry

Bits 21:18 Reserved, must be kept at reset value.

Bits 17:16 **PLL\_P[1:0]**: Main PLL (PLL) division factor for main system clock

Set and cleared by software to control the frequency of the general PLL output clock. These bits can be written only if PLL is disabled.

**Caution:** The software has to set these bits correctly not to exceed 216 MHz on this domain.

PLL output clock frequency = VCO frequency / PLL\_P with PLL\_P = 2, 4, 6, or 8

00: PLL\_P = 2

01: PLL\_P = 4

10: PLL\_P = 6

11: PLL\_P = 8

Bits 14:6 **PLL\_N[8:0]**: Main PLL (PLL) multiplication factor for VCO

Set and cleared by software to control the multiplication factor of the VCO. These bits can be written only when PLL is disabled. Only half-word and word accesses are allowed to write these bits.

**Caution:** The software has to set these bits correctly to ensure that the VCO output frequency is between 100 and 432 MHz.

VCO output frequency = VCO input frequency × PLL\_N with  $50 \leq \text{PLL}_N \leq 432$

00000000: PLL\_N = 0, wrong configuration

00000001: PLL\_N = 1, wrong configuration

...

000110010: PLL\_N = 50

...

001100011: PLL\_N = 99

001100100: PLL\_N = 100

...

110110000: PLL\_N = 432

110110001: PLL\_N = 433, wrong configuration

...

111111111: PLL\_N = 511, wrong configuration

*Note: Between 50 and 99, multiplication factors are possible for VCO input frequency higher than 1 MHz. However care must be taken to fulfill the minimum VCO output frequency as specified above.*

Bits 5:0 **PLL\_M[5:0]**: Division factor for the main PLLs (PLL, PLLI2S and PLLSAI) input clock

Set and cleared by software to divide the PLL and PLLI2S input clock before the VCO. These bits can be written only when the PLL and PLLI2S are disabled.

**Caution:** The software has to set these bits correctly to ensure that the VCO input frequency ranges from 1 to 2 MHz. It is recommended to select a frequency of 2 MHz to limit PLL jitter.

VCO input frequency = PLL input clock frequency / PLL\_M with  $2 \leq \text{PLL}_M \leq 63$

000000: PLL\_M = 0, wrong configuration

000001: PLL\_M = 1, wrong configuration

000010: PLL\_M = 2

000011: PLL\_M = 3

000100: PLL\_M = 4

...

111110: PLL\_M = 62

111111: PLL\_M = 63

### 5.3.3 RCC clock configuration register (RCC\_CFGR)

Address offset: 0x08

Reset value: 0x0000 0000

Access:  $0 \leq \text{wait state} \leq 2$ , word, half-word and byte access

1 or 2 wait states inserted only if the access occurs during a clock source switch.

|            |    |               |            |    |               |     |     |            |      |    |             |      |      |     |     |
|------------|----|---------------|------------|----|---------------|-----|-----|------------|------|----|-------------|------|------|-----|-----|

| rw         | rw | rw            | rw         | rw | rw            |     |     | rw         | rw   | rw | rw          | r    | r    | rw  | rw  |

Bits 31:30 **MCO2[1:0]**: Microcontroller clock output 2

Set and cleared by software. Clock source selection may generate glitches on MCO2. It is highly recommended to configure these bits only after reset before enabling the external oscillators and the PLLs.

00: System clock (SYSCLK) selected

01: PLLI2S clock selected

10: HSE oscillator clock selected

11: PLL clock selected

Bits 27:29 **MCO2PRE**: MCO2 prescaler

Set and cleared by software to configure the prescaler of the MCO2. Modification of this prescaler may generate glitches on MCO2. It is highly recommended to change this prescaler only after reset before enabling the external oscillators and the PLLs.

0xx: no division

100: division by 2

101: division by 3

110: division by 4

111: division by 5

Bits 24:26 **MCO1PRE**: MCO1 prescaler

Set and cleared by software to configure the prescaler of the MCO1. Modification of this prescaler may generate glitches on MCO1. It is highly recommended to change this prescaler only after reset before enabling the external oscillators and the PLL.

0xx: no division

100: division by 2

101: division by 3

110: division by 4

111: division by 5

Bit 23 **I2SSRC**: I2S clock selection

Set and cleared by software. This bit allows to select the I2S clock source between the PLLI2S clock and the external clock. It is highly recommended to change this bit only after reset and before enabling the I2S module.

0: PLLI2S clock used as I2S clock source

1: External clock mapped on the I2S\_CKIN pin used as I2S clock source

Bits 22:21 **MCO1**: Microcontroller clock output 1

Set and cleared by software. Clock source selection may generate glitches on MCO1. It is highly recommended to configure these bits only after reset before enabling the external oscillators and PLL.

00: HSI clock selected

01: LSE oscillator selected

10: HSE oscillator clock selected

11: PLL clock selected

Bits 20:16 **RTCPRE**: HSE division factor for RTC clock

Set and cleared by software to divide the HSE clock input clock to generate a 1 MHz clock for RTC.

**Caution:** The software has to set these bits correctly to ensure that the clock supplied to the RTC is 1 MHz. These bits must be configured if needed before selecting the RTC clock source.

00000: no clock

00001: no clock

00010: HSE/2

00011: HSE/3

00100: HSE/4

...

11110: HSE/30

11111: HSE/31

Bits 15:13 **PPRE2**: APB high-speed prescaler (APB2)

Set and cleared by software to control APB high-speed clock division factor.

**Caution:** The software has to set these bits correctly not to exceed 108 MHz on this domain. The clocks are divided with the new prescaler factor from 1 to 16 AHB cycles after PPRE2 write.

0xx: AHB clock not divided

100: AHB clock divided by 2

101: AHB clock divided by 4

110: AHB clock divided by 8

111: AHB clock divided by 16

Bits 12:10 **PPRE1**: APB Low-speed prescaler (APB1)

Set and cleared by software to control APB low-speed clock division factor.

**Caution:** The software has to set these bits correctly not to exceed 54 MHz on this domain. The clocks are divided with the new prescaler factor from 1 to 16 AHB cycles after PPRE1 write.

0xx: AHB clock not divided

100: AHB clock divided by 2

101: AHB clock divided by 4

110: AHB clock divided by 8

111: AHB clock divided by 16

Bits 9:8 Reserved, must be kept at reset value.

Bits 7:4 **HPRE**: AHB prescaler

Set and cleared by software to control AHB clock division factor.

**Caution:** The clocks are divided with the new prescaler factor from 1 to 16 AHB cycles after HPRE write.

**Caution:** The AHB clock frequency must be at least 25 MHz when the Ethernet is used.

0xxx: system clock not divided  
 1000: system clock divided by 2  
 1001: system clock divided by 4  
 1010: system clock divided by 8  
 1011: system clock divided by 16  
 1100: system clock divided by 64  
 1101: system clock divided by 128  
 1110: system clock divided by 256  
 1111: system clock divided by 512

Bits 3:2 **SWS**: System clock switch status

Set and cleared by hardware to indicate which clock source is used as the system clock.

00: HSI oscillator used as the system clock  
 01: HSE oscillator used as the system clock  
 10: PLL used as the system clock  
 11: not applicable

Bits 1:0 **SW**: System clock switch

Set and cleared by software to select the system clock source.

Set by hardware to force the HSI selection when leaving the Stop or Standby mode or in case of failure of the HSE oscillator used directly or indirectly as the system clock.

00: HSI oscillator selected as system clock  
 01: HSE oscillator selected as system clock  
 10: PLL selected as system clock  
 11: not allowed

### 5.3.4 RCC clock interrupt register (RCC\_CIR)

Address offset: 0x0C

Reset value: 0x0000 0000

Access: no wait state, word, half-word and byte access

| 31   | 30              | 29              | 28           | 27           | 26           | 25           | 24           | 23   | 22             | 21             | 20          | 19          | 18          | 17          | 16          |

Bits 31:24 Reserved, must be kept at reset value.

Bit 23 **CSSC**: Clock security system interrupt clear

This bit is set by software to clear the CSSF flag.

0: No effect

1: Clear CSSF flag

Bit 22 **PLLSAIRDYC**: PLLSAI Ready Interrupt Clear

This bit is set by software to clear PLLSAIRDYF flag. It is reset by hardware when the PLLSAIRDYF is cleared.

0: PLLSAIRDYF not cleared

1: PLLSAIRDYF cleared

Bit 21 **PLLI2SRDYC**: PLLI2S ready interrupt clear

This bit is set by software to clear the PLLI2SRDYF flag.

0: No effect

1: PLLI2SRDYF cleared

Bit 20 **PLLRDYC**: Main PLL(PLL) ready interrupt clear

This bit is set by software to clear the PLLRDYF flag.

0: No effect

1: PLLRDYF cleared

Bit 19 **HSERDYC**: HSE ready interrupt clear

This bit is set by software to clear the HSERDYF flag.

0: No effect

1: HSERDYF cleared

Bit 18 **HSIRDYC**: HSI ready interrupt clear

This bit is set software to clear the HSIRDYF flag.

0: No effect

1: HSIRDYF cleared

Bit 17 **LSERDYC**: LSE ready interrupt clear

This bit is set by software to clear the LSERDYF flag.

0: No effect

1: LSERDYF cleared

Bit 16 **LSIRDYC**: LSI ready interrupt clear

This bit is set by software to clear the LSIRDYF flag.

0: No effect

1: LSIRDYF cleared

Bit 15 Reserved, must be kept at reset value.

Bit 14 **PLLSAIRDYIE**: PLLSAI Ready Interrupt Enable

This bit is set and reset by software to enable/disable interrupt caused by PLLSAI lock.

0: PLLSAI lock interrupt disabled

1: PLLSAI lock interrupt enabled

Bit 13 **PLLI2SRDYIE**: PLLI2S ready interrupt enable

This bit is set and cleared by software to enable/disable interrupt caused by PLLI2S lock.

0: PLLI2S lock interrupt disabled

1: PLLI2S lock interrupt enabled

- Bit 12 **PLLRDYIE**: Main PLL (PLL) ready interrupt enable  
This bit is set and cleared by software to enable/disable interrupt caused by PLL lock.  
0: PLL lock interrupt disabled  
1: PLL lock interrupt enabled
- Bit 11 **HSERDYIE**: HSE ready interrupt enable  
This bit is set and cleared by software to enable/disable interrupt caused by the HSE oscillator stabilization.  
0: HSE ready interrupt disabled  
1: HSE ready interrupt enabled
- Bit 10 **HSIRDYIE**: HSI ready interrupt enable  
This bit is set and cleared by software to enable/disable interrupt caused by the HSI oscillator stabilization.  
0: HSI ready interrupt disabled  
1: HSI ready interrupt enabled
- Bit 9 **LSERDYIE**: LSE ready interrupt enable  
This bit is set and cleared by software to enable/disable interrupt caused by the LSE oscillator stabilization.  
0: LSE ready interrupt disabled  
1: LSE ready interrupt enabled
- Bit 8 **LSIRDYIE**: LSI ready interrupt enable  
This bit is set and cleared by software to enable/disable interrupt caused by LSI oscillator stabilization.  
0: LSI ready interrupt disabled  
1: LSI ready interrupt enabled
- Bit 7 **CSSF**: Clock security system interrupt flag  
This bit is set by hardware when a failure is detected in the HSE oscillator.  
It is cleared by software by setting the CSSC bit.  
0: No clock security interrupt caused by HSE clock failure  
1: Clock security interrupt caused by HSE clock failure
- Bit 6 **PLLSAIRDYF**: PLLSAI Ready Interrupt flag  
This bit is set by hardware when the PLLSAI is locked and PLLSAIRDYDIE is set.  
It is cleared by software by setting the PLLSAIRDYC bit.  
0: No clock ready interrupt caused by PLLSAI lock  
1: Clock ready interrupt caused by PLLSAI lock
- Bit 5 **PLLI2SRDYF**: PLLI2S ready interrupt flag  
This bit is set by hardware when the PLLI2S is locked and PLLI2SRDYDIE is set.  
It is cleared by software by setting the PLLI2SRDYC bit.  
0: No clock ready interrupt caused by PLLI2S lock  
1: Clock ready interrupt caused by PLLI2S lock
- Bit 4 **PLLRDYF**: Main PLL (PLL) ready interrupt flag  
This bit is set by hardware when PLL is locked and PLLRDYDIE is set.  
It is cleared by software setting the PLLRDYC bit.  
0: No clock ready interrupt caused by PLL lock  
1: Clock ready interrupt caused by PLL lock

**Bit 3 HSERDYF:** HSE ready interrupt flag

This bit is set by hardware when External High Speed clock becomes stable and HSERDYDIE is set.

It is cleared by software by setting the HSERDYC bit.

0: No clock ready interrupt caused by the HSE oscillator

1: Clock ready interrupt caused by the HSE oscillator

**Bit 2 HSIRDYF:** HSI ready interrupt flag

This bit is set by hardware when the Internal High Speed clock becomes stable and HSIRDYDIE is set.

It is cleared by software by setting the HSIRDYC bit.

0: No clock ready interrupt caused by the HSI oscillator

1: Clock ready interrupt caused by the HSI oscillator

**Bit 1 LSERDYF:** LSE ready interrupt flag

This bit is set by hardware when the External low-speed clock becomes stable and LSERDYDIE is set.

It is cleared by software by setting the LSERDYC bit.

0: No clock ready interrupt caused by the LSE oscillator

1: Clock ready interrupt caused by the LSE oscillator

**Bit 0 LSIRDYF:** LSI ready interrupt flag

This bit is set by hardware when the internal low-speed clock becomes stable and LSIRDYDIE is set.

It is cleared by software by setting the LSIRDYC bit.

0: No clock ready interrupt caused by the LSI oscillator

1: Clock ready interrupt caused by the LSI oscillator

**5.3.5 RCC AHB1 peripheral reset register (RCC\_AHB1RSTR)**

Address offset: 0x10

Reset value: 0x0000 0000

Access: no wait state, word, half-word and byte access.

| 31   | 30   | 29       | 28     | 27   | 26       | 25        | 24      | 23       | 22      | 21      | 20      | 19      | 18      | 17      | 16      |

Bits 31:30 Reserved, must be kept at reset value.

**Bit 29 OTGHSRST:** USB OTG HS module reset

This bit is set and cleared by software.

0: does not reset the USB OTG HS module

1: resets the USB OTG HS module

Bits 28:26 Reserved, must be kept at reset value.

- Bit 25 **ETHMACRST**: Ethernet MAC reset  
This bit is set and cleared by software.  
0: does not reset Ethernet MAC  
1: resets Ethernet MAC
- Bit 24 Reserved, must be kept at reset value.
- Bit 23 **DMA2DRST**: DMA2D reset  
This bit is set and reset by software.  
0: does not reset DMA2D  
1: resets DMA2D
- Bit 22 **DMA2RST**: DMA2 reset  
This bit is set and cleared by software.  
0: does not reset DMA2  
1: resets DMA2
- Bit 21 **DMA1RST**: DMA2 reset  
This bit is set and cleared by software.  
0: does not reset DMA2  
1: resets DMA2
- Bits 20:13 Reserved, must be kept at reset value.
- Bit 12 **CRCRST**: CRC reset  
This bit is set and cleared by software.  
0: does not reset CRC  
1: resets CRC
- Bit 11 Reserved, must be kept at reset value.
- Bit 10 **GPIOKRST**: IO port K reset  
This bit is set and cleared by software.  
0: does not reset IO port K  
1: resets IO port K
- Bit 9 **GPIOJRST**: IO port J reset  
This bit is set and cleared by software.  
0: does not reset IO port J  
1: resets IO port J
- Bit 8 **GPIOIRST**: IO port I reset  
This bit is set and cleared by software.  
0: does not reset IO port I  
1: resets IO port I
- Bit 7 **GPIOHRST**: IO port H reset  
This bit is set and cleared by software.  
0: does not reset IO port H  
1: resets IO port H
- Bit 6 **GPIOGRST**: IO port G reset  
This bit is set and cleared by software.  
0: does not reset IO port G  
1: resets IO port G

- Bit 5 **GPIOFRST**: IO port F reset  
This bit is set and cleared by software.  
0: does not reset IO port F  
1: resets IO port F
- Bit 4 **GPIOERST**: IO port E reset  
This bit is set and cleared by software.  
0: does not reset IO port E  
1: resets IO port E
- Bit 3 **GPIODRST**: IO port D reset  
This bit is set and cleared by software.  
0: does not reset IO port D  
1: resets IO port D
- Bit 2 **GPIOCRST**: IO port C reset  
This bit is set and cleared by software.  
0: does not reset IO port C  
1: resets IO port C
- Bit 1 **GPIOBRST**: IO port B reset  
This bit is set and cleared by software.  
0: does not reset IO port B  
1: resets IO port B
- Bit 0 **GPIOARST**: IO port A reset  
This bit is set and cleared by software.  
0: does not reset IO port A  
1: resets IO port A

### 5.3.6 RCC AHB2 peripheral reset register (RCC\_AHB2RSTR)

Address offset: 0x14

Reset value: 0x0000 0000

Access: no wait state, word, half-word and byte access

|      |      |      |      |      |      |      |      |              |            |             |             |      |      |      |             |

Bits 31:8 Reserved, must be kept at reset value.

Bit 7 **OTGFSRST**: USB OTG FS module reset

Set and cleared by software.

0: does not reset the USB OTG FS module

1: resets the USB OTG FS module

Bit 6 **RNGRST**: Random number generator module reset

Set and cleared by software.

0: does not reset the random number generator module

1: resets the random number generator module

Bit 5 **HASHRST**: Hash module reset

Set and cleared by software.

0: does not reset the HASH module

1: resets the HASH module

Bit 4 **CRYP RST**: Cryptographic module reset

Set and cleared by software.

0: does not reset the cryptographic module

1: resets the cryptographic module

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **DCMIRST**: Camera interface reset

Set and cleared by software.

0: does not reset the Camera interface

1: resets the Camera interface

### 5.3.7 RCC AHB3 peripheral reset register (RCC\_AHB3RSTR)

Address offset: 0x18

Reset value: 0x0000 0000

Access: no wait state, word, half-word and byte access.

|      |      |      |      |      |      |      |      |      |      |      |      |      |      |         |        |

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **QSPIRST**: Quad SPI memory controller reset

Set and cleared by software.

0: does not reset the QUADSPI memory controller

1: resets the QUADSPI memory controller

Bit 0 **FMCRST**: Flexible memory controller module reset

Set and cleared by software.

0: does not reset the FMC module

1: resets the FMC module

### 5.3.8 RCC APB1 peripheral reset register (RCC\_APB1RSTR)

Address offset: 0x20

Reset value: 0x0000 0000

Access: no wait state, word, half-word and byte access.

|          |          |        |         |          |          |            |           |           |           |          |           |           |           |           |             |

- Bit 31 **UART8RST**: UART8 reset  
Set and cleared by software.  
0: does not reset UART8  
1: resets UART8
- Bit 30 **UART7RST**: UART7 reset  
Set and cleared by software.  
0: does not reset UART7  
1: resets UART7
- Bit 29 **DACRST**: DAC reset  
Set and cleared by software.  
0: does not reset the DAC interface  
1: resets the DAC interface
- Bit 28 **PWRRST**: Power interface reset  
Set and cleared by software.  
0: does not reset the power interface  
1: resets the power interface
- Bit 27 **CECRST**: HDMI-CEC reset  
Set and cleared by software.  
0: does not reset HDMI-CEC  
1: resets HDMI-CEC
- Bit 26 **CAN2RST**: CAN2 reset  
Set and cleared by software.  
0: does not reset CAN2  
1: resets CAN2
- Bit 25 **CAN1RST**: CAN1 reset  
Set and cleared by software.  
0: does not reset CAN1  
1: resets CAN1
- Bit 24 **I2C4RST**: I2C4 reset  
Set and cleared by software.  
0: does not reset I2C4  
1: resets I2C4
- Bit 23 **I2C3RST**: I2C3 reset  
Set and cleared by software.  
0: does not reset I2C3  
1: resets I2C3
- Bit 22 **I2C2RST**: I2C2 reset  
Set and cleared by software.  
0: does not reset I2C2  
1: resets I2C2
- Bit 21 **I2C1RST**: I2C1 reset  
Set and cleared by software.  
0: does not reset I2C1  
1: resets I2C1

- Bit 20 **UART5RST**: UART5 reset  
Set and cleared by software.  
0: does not reset UART5  
1: resets UART5
- Bit 19 **UART4RST**: USART4 reset  
Set and cleared by software.  
0: does not reset UART4  
1: resets UART4
- Bit 18 **USART3RST**: USART3 reset  
Set and cleared by software.  
0: does not reset USART3  
1: resets USART3
- Bit 17 **USART2RST**: USART2 reset  
Set and cleared by software.  
0: does not reset USART2  
1: resets USART2
- Bit 16 **SPDIFRXRST**: SPDIFRX reset  
Set and cleared by software.  
0: does not reset SPDIFRX  
1: resets SPDIFRX
- Bit 15 **SPI3RST**: SPI3 reset  
Set and cleared by software.  
0: does not reset SPI3  
1: resets SPI3
- Bit 14 **SPI2RST**: SPI2 reset  
Set and cleared by software.  
0: does not reset SPI2  
1: resets SPI2
- Bits 13:12 Reserved, must be kept at reset value.
- Bit 11 **WWDGRST**: Window watchdog reset  
Set and cleared by software.  
0: does not reset the window watchdog  
1: resets the window watchdog
- Bit 10 Reserved, must be kept at reset value.
- Bit 9 **LPTIM1RST**: Low-power timer 1 reset  
Set and cleared by software.  
0: does not reset LPTMI1  
1: resets LPTMI1
- Bit 8 **TIM14RST**: TIM14 reset  
Set and cleared by software.  
0: does not reset TIM14  
1: resets TIM14
- Bit 7 **TIM13RST**: TIM13 reset  
Set and cleared by software.  
0: does not reset TIM13  
1: resets TIM13

- Bit 6 **TIM12RST**: TIM12 reset  
Set and cleared by software.  
0: does not reset TIM12  
1: resets TIM12
- Bit 5 **TIM7RST**: TIM7 reset  
Set and cleared by software.  
0: does not reset TIM7  
1: resets TIM7
- Bit 4 **TIM6RST**: TIM6 reset  
Set and cleared by software.  
0: does not reset TIM6  
1: resets TIM6
- Bit 3 **TIM5RST**: TIM5 reset  
Set and cleared by software.  
0: does not reset TIM5  
1: resets TIM5
- Bit 2 **TIM4RST**: TIM4 reset  
Set and cleared by software.  
0: does not reset TIM4  
1: resets TIM4
- Bit 1 **TIM3RST**: TIM3 reset  
Set and cleared by software.  
0: does not reset TIM3  
1: resets TIM3
- Bit 0 **TIM2RST**: TIM2 reset  
Set and cleared by software.  
0: does not reset TIM2  
1: resets TIM2

### 5.3.9 RCC APB2 peripheral reset register (RCC\_APB2RSTR)

Address offset: 0x24

Reset value: 0x0000 0000

Access: no wait state, word, half-word and byte access.

| 31   | 30            | 29          | 28          | 27            | 26          | 25   | 24         | 23          | 22          | 21            | 20            | 19   | 18           | 17           | 16          |

Bits 31:27 Reserved, must be kept at reset value.

Bit 26 **LTDCRST**: LTDC reset

This bit is set and reset by software.

0: does not reset LCD-TFT

1: resets LCD-TFT

Bits 27:24 Reserved, must be kept at reset value.

Bit 23 **SAI2RST**: SAI2 reset

This bit is set and cleared by software.

0: does not reset SAI2

1: resets SAI2

Bit 22 **SAI1RST**: SAI1 reset

This bit is set and reset by software.

0: does not reset SAI1

1: resets SAI1

Bit 21 **SPI6RST**: SPI6 reset

This bit is set and cleared by software.

0: does not reset SPI6

1: resets SPI6

Bit 20 **SPI5RST**: SPI5 reset

This bit is set and cleared by software.

0: does not reset SPI5

1: resets SPI5

Bit 19 Reserved, must be kept at reset value.

Bit 18 **TIM11RST**: TIM11 reset

This bit is set and cleared by software.

0: does not reset TIM11

1: resets TIM14

Bit 17 **TIM10RST**: TIM10 reset

This bit is set and cleared by software.

0: does not reset TIM10

1: resets TIM10

- Bit 16 **TIM9RST**: TIM9 reset  
This bit is set and cleared by software.  
0: does not reset TIM9  
1: resets TIM9
- Bit 15 Reserved, must be kept at reset value.
- Bit 14 **SYSCFGRST**: System configuration controller reset  
This bit is set and cleared by software.  
0: does not reset the System configuration controller  
1: resets the System configuration controller
- Bit 13 **SPI4RST**: SPI4 reset  
This bit is set and cleared by software.  
0: does not reset SPI4  
1: resets SPI4
- Bit 12 **SPI1RST**: SPI1 reset  
This bit is set and cleared by software.  
0: does not reset SPI1  
1: resets SPI1
- Bit 11 **SDMMC1RST**: SDMMC1 reset  
This bit is set and cleared by software.  
0: does not reset the SDMMC1 module  
1: resets the SDMMC1 module
- Bits 10:9 Reserved, must be kept at reset value.
- Bit 8 **ADCRST**: ADC interface reset (common to all ADCs)  
This bit is set and cleared by software.  
0: does not reset the ADC interface  
1: resets the ADC interface
- Bits 7:6 Reserved, must be kept at reset value.
- Bit 5 **USART6RST**: USART6 reset  
This bit is set and cleared by software.  
0: does not reset USART6  
1: resets USART6
- Bit 4 **USART1RST**: USART1 reset  
This bit is set and cleared by software.  
0: does not reset USART1  
1: resets USART1
- Bits 3:2 Reserved, must be kept at reset value.
- Bit 1 **TIM8RST**: TIM8 reset  
This bit is set and cleared by software.  
0: does not reset TIM8  
1: resets TIM8
- Bit 0 **TIM1RST**: TIM1 reset  
This bit is set and cleared by software.  
0: does not reset TIM1  
1: resets TIM1

### 5.3.10 RCC AHB1 peripheral clock register (RCC\_AHB1ENR)

Address offset: 0x30

Reset value: 0x0010 0000

Access: no wait state, word, half-word and byte access.

|      |                 |             |                     |                    |                    |              |             |             |             |             |               |            |               |            |            |

Bit 31 Reserved, must be kept at reset value.

Bit 30 **OTGHSULPIEN**: USB OTG HSULPI clock enable

This bit is set and cleared by software.

0: USB OTG HS ULPI clock disabled

1: USB OTG HS ULPI clock enabled

Bit 29 **OTGHSEN**: USB OTG HS clock enable

This bit is set and cleared by software.

0: USB OTG HS clock disabled

1: USB OTG HS clock enabled

Bit 28 **ETHMACPTPEN**: Ethernet PTP clock enable

This bit is set and cleared by software.

0: Ethernet PTP clock disabled

1: Ethernet PTP clock enabled

Bit 27 **ETHMACRXEN**: Ethernet Reception clock enable

This bit is set and cleared by software.

0: Ethernet Reception clock disabled

1: Ethernet Reception clock enabled

Bit 26 **ETHMACTXEN**: Ethernet Transmission clock enable

This bit is set and cleared by software.

0: Ethernet Transmission clock disabled

1: Ethernet Transmission clock enabled

Bit 25 **ETHMACEN**: Ethernet MAC clock enable

This bit is set and cleared by software.

0: Ethernet MAC clock disabled

1: Ethernet MAC clock enabled

Bit 24 Reserved, must be kept at reset value.

Bit 23 **DMA2DEN**: DMA2D clock enable

This bit is set and cleared by software.

0: DMA2D clock disabled

1: DMA2D clock enabled

- Bit 22 **DMA2EN**: DMA2 clock enable  
This bit is set and cleared by software.  
0: DMA2 clock disabled  
1: DMA2 clock enabled
- Bit 21 **DMA1EN**: DMA1 clock enable  
This bit is set and cleared by software.  
0: DMA1 clock disabled  
1: DMA1 clock enabled
- Bit 20 **DTCMRAMEN**: DTCM data RAM clock enable  
This bit is set and cleared by software.  
0: DTCM RAM clock disabled  
1: DTCM RAM clock enabled
- Bit 19 Reserved, must be kept at reset value.
- Bit 18 **BKPSRAMEN**: Backup SRAM interface clock enable  
This bit is set and cleared by software.  
0: Backup SRAM interface clock disabled  
1: Backup SRAM interface clock enabled
- Bits 17:13 Reserved, must be kept at reset value.
- Bit 12 **CRCEN**: CRC clock enable  
This bit is set and cleared by software.  
0: CRC clock disabled  
1: CRC clock enabled
- Bit 11 Reserved, must be kept at reset value.
- Bit 10 **GPIOKEN**: IO port K clock enable  
This bit is set and cleared by software.  
0: IO port K clock disabled  
1: IO port K clock enabled
- Bit 9 **GPIOJEN**: IO port J clock enable  
This bit is set and cleared by software.  
0: IO port J clock disabled  
1: IO port J clock enabled
- Bit 8 **GPIOIEN**: IO port I clock enable  
This bit is set and cleared by software.  
0: IO port I clock disabled  
1: IO port I clock enabled
- Bit 7 **GPIOHEN**: IO port H clock enable  
This bit is set and cleared by software.  
0: IO port H clock disabled  
1: IO port H clock enabled
- Bit 6 **GPIOGEN**: IO port G clock enable  
This bit is set and cleared by software.  
0: IO port G clock disabled  
1: IO port G clock enabled

- Bit 5 **GPIOFEN**: IO port F clock enable  
This bit is set and cleared by software.  
0: IO port F clock disabled  
1: IO port F clock enabled
- Bit 4 **GPIOEEN**: IO port E clock enable  
This bit is set and cleared by software.  
0: IO port E clock disabled  
1: IO port E clock enabled
- Bit 3 **GPIODEN**: IO port D clock enable  
This bit is set and cleared by software.  
0: IO port D clock disabled  
1: IO port D clock enabled
- Bit 2 **GPIOCEN**: IO port C clock enable  
This bit is set and cleared by software.  
0: IO port C clock disabled  
1: IO port C clock enabled
- Bit 1 **GPIOBEN**: IO port B clock enable  
This bit is set and cleared by software.  
0: IO port B clock disabled  
1: IO port B clock enabled
- Bit 0 **GPIOAEN**: IO port A clock enable  
This bit is set and cleared by software.  
0: IO port A clock disabled  
1: IO port A clock enabled

### 5.3.11 RCC AHB2 peripheral clock enable register (RCC\_AHB2ENR)

Address offset: 0x34

Reset value: 0x0000 0000

Access: no wait state, word, half-word and byte access.

|      |      |      |      |      |      |      |      |             |           |            |            |      |      |      |            |

Bits 31:8 Reserved, must be kept at reset value.

- Bit 7 **OTGFSEN**: USB OTG FS clock enable  
This bit is set and cleared by software.  
0: USB OTG FS clock disabled  
1: USB OTG FS clock enabled

- Bit 6 **RNGEN**: Random number generator clock enable  
This bit is set and cleared by software.  
0: Random number generator clock disabled  
1: Random number generator clock enabled

Bit 5 **HASHEN**: Hash modules clock enable

This bit is set and cleared by software.

0: Hash modules clock disabled

1: Hash modules clock enabled

Bit 4 **CRYPEN**: Cryptographic modules clock enable

This bit is set and cleared by software.

0: cryptographic module clock disabled

1: cryptographic module clock enabled

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **DCMIEN**: Camera interface enable

This bit is set and cleared by software.

0: Camera interface clock disabled

1: Camera interface clock enabled

### 5.3.12 RCC AHB3 peripheral clock enable register (RCC\_AHB3ENR)

Address offset: 0x38

Reset value: 0x0000 0000

Access: no wait state, word, half-word and byte access.

|      |      |      |      |      |      |      |      |      |      |      |      |      |      |        |       |

Bit 31 **UART8EN**: UART8 clock enable

This bit is set and cleared by software.

0: UART8 clock disabled

1: UART8 clock enabled

Bit 30 **UART7EN**: UART7 clock enable

This bit is set and cleared by software.

0: UART7 clock disabled

1: UART7 clock enabled

Bit 29 **DACEN**: DAC interface clock enable

This bit is set and cleared by software.

0: DAC interface clock disabled

1: DAC interface clock enable

Bit 28 **PWREN**: Power interface clock enable

This bit is set and cleared by software.

0: Power interface clock disabled

1: Power interface clock enable

Bit 27 **CECEN**: HDMI-CEC clock enable

This bit is set and cleared by software.

0: HDMI-CEC clock disabled

1: HDMI-CEC clock enabled

Bit 26 **CAN2EN**: CAN 2 clock enable

This bit is set and cleared by software.

0: CAN 2 clock disabled

1: CAN 2 clock enabled

Bit 25 **CAN1EN**: CAN 1 clock enable

This bit is set and cleared by software.

0: CAN 1 clock disabled

1: CAN 1 clock enabled

Bit 24 **I2C4**: I2C4 clock enable

This bit is set and cleared by software.

0: I2C4 clock disabled

1: I2C4 clock enabled

Bit 23 **I2C3EN**: I2C3 clock enable

This bit is set and cleared by software.

0: I2C3 clock disabled

1: I2C3 clock enabled

Bit 22 **I2C2EN**: I2C2 clock enable

This bit is set and cleared by software.

0: I2C2 clock disabled

1: I2C2 clock enabled

- Bit 21 **I2C1EN**: I2C1 clock enable  
This bit is set and cleared by software.  
0: I2C1 clock disabled  
1: I2C1 clock enabled
- Bit 20 **UART5EN**: UART5 clock enable  
This bit is set and cleared by software.  
0: UART5 clock disabled  
1: UART5 clock enabled
- Bit 19 **UART4EN**: UART4 clock enable  
This bit is set and cleared by software.  
0: UART4 clock disabled  
1: UART4 clock enabled
- Bit 18 **USART3EN**: USART3 clock enable  
This bit is set and cleared by software.  
0: USART3 clock disabled  
1: USART3 clock enabled
- Bit 17 **USART2EN**: USART2 clock enable  
This bit is set and cleared by software.  
0: USART2 clock disabled  
1: USART2 clock enabled
- Bit 16 **SPDIFRXEN**: SPDIFRX clock enable  
This bit is set and cleared by software.  
0: SPDIFRX clock disabled  
1: SPDIFRX clock enable
- Bit 15 **SPI3EN**: SPI3 clock enable  
This bit is set and cleared by software.  
0: SPI3 clock disabled  
1: SPI3 clock enabled
- Bit 14 **SPI2EN**: SPI2 clock enable  
This bit is set and cleared by software.  
0: SPI2 clock disabled  
1: SPI2 clock enabled
- Bits 13:12 Reserved, must be kept at reset value.
- Bit 11 **WWDGEN**: Window watchdog clock enable  
This bit is set and cleared by software.  
0: Window watchdog clock disabled  
1: Window watchdog clock enabled
- Bit 10 Reserved, must be kept at reset value.
- Bit 9 **LPTIM1EN**: Low-power timer 1 clock enable  
This bit is set and cleared by software.  
0: LPTIM1 clock disabled  
1: LPTIM1 clock enabled
- Bit 8 **TIM14EN**: TIM14 clock enable  
This bit is set and cleared by software.  
0: TIM14 clock disabled  
1: TIM14 clock enabled

- Bit 7 **TIM13EN**: TIM13 clock enable  
This bit is set and cleared by software.  
0: TIM13 clock disabled  
1: TIM13 clock enabled
- Bit 6 **TIM12EN**: TIM12 clock enable  
This bit is set and cleared by software.  
0: TIM12 clock disabled  
1: TIM12 clock enabled
- Bit 5 **TIM7EN**: TIM7 clock enable  
This bit is set and cleared by software.  
0: TIM7 clock disabled  
1: TIM7 clock enabled
- Bit 4 **TIM6EN**: TIM6 clock enable  
This bit is set and cleared by software.  
0: TIM6 clock disabled  
1: TIM6 clock enabled
- Bit 3 **TIM5EN**: TIM5 clock enable  
This bit is set and cleared by software.  
0: TIM5 clock disabled  
1: TIM5 clock enabled
- Bit 2 **TIM4EN**: TIM4 clock enable  
This bit is set and cleared by software.  
0: TIM4 clock disabled  
1: TIM4 clock enabled
- Bit 1 **TIM3EN**: TIM3 clock enable  
This bit is set and cleared by software.  
0: TIM3 clock disabled  
1: TIM3 clock enabled
- Bit 0 **TIM2EN**: TIM2 clock enable  
This bit is set and cleared by software.  
0: TIM2 clock disabled  
1: TIM2 clock enabled

### 5.3.14 RCC APB2 peripheral clock enable register (RCC\_APB2ENR)

Address offset: 0x44

Reset value: 0x0000 0000

Access: no wait state, word, half-word and byte access.

Bits 31:27 Reserved, must be kept at reset value.

Bit 26 **LTDCEN**: LTDC clock enable

This bit is set and cleared by software.

0: LTDC clock disabled

1: LTDC clock enabled

Bits 27: 24 Reserved, must be kept at reset value.

Bit 23 **SAI2EN**: SAI2 clock enable

This bit is set and cleared by software.

0: SAI2 clock disabled

1: SAI2 clock enabled

Bit 22 **SAI1EN**: SAI1 clock enable

This bit is set and cleared by software.

0: SAI1 clock disabled

1: SAI1 clock enabled

Bit 21 **SPI6EN**: SPI6 clock enable

This bit is set and cleared by software.

0: SPI6 clock disabled

1: SPI6 clock enabled

Bit 20 **SPI5EN**: SPI5 clock enable

This bit is set and cleared by software.

0: SPI5 clock disabled

1: SPI5 clock enabled

Bit 18 **TIM11EN**: TIM11 clock enable

This bit is set and cleared by software.

0: TIM11 clock disabled

1: TIM11 clock enabled

Bit 17 **TIM10EN**: TIM10 clock enable

This bit is set and cleared by software.

0: TIM10 clock disabled

1: TIM10 clock enabled

- Bit 16 **TIM9EN**: TIM9 clock enable  
This bit is set and cleared by software.  
0: TIM9 clock disabled  
1: TIM9 clock enabled
- Bit 15 Reserved, must be kept at reset value.
- Bit 14 **SYSCFGEN**: System configuration controller clock enable  
This bit is set and cleared by software.  
0: System configuration controller clock disabled  
1: System configuration controller clock enabled
- Bit 13 **SPI4EN**: SPI4 clock enable  
This bit is set and cleared by software.  
0: SPI4 clock disabled  
1: SPI4 clock enabled
- Bit 12 **SPI1EN**: SPI1 clock enable  
This bit is set and cleared by software.  
0: SPI1 clock disabled  
1: SPI1 clock enabled
- Bit 11 **SDMMC1EN**: SDMMC1 clock enable  
This bit is set and cleared by software.  
0: SDMMC1 module clock disabled  
1: SDMMC1 module clock enabled
- Bit 10 **ADC3EN**: ADC3 clock enable  
This bit is set and cleared by software.  
0: ADC3 clock disabled  
1: ADC3 clock enabled
- Bit 9 **ADC2EN**: ADC2 clock enable  
This bit is set and cleared by software.  
0: ADC2 clock disabled  
1: ADC2 clock enabled
- Bit 8 **ADC1EN**: ADC1 clock enable  
This bit is set and cleared by software.  
0: ADC1 clock disabled  
1: ADC1 clock enabled
- Bits 7:6 Reserved, must be kept at reset value.
- Bit 5 **USART6EN**: USART6 clock enable  
This bit is set and cleared by software.  
0: USART6 clock disabled  
1: USART6 clock enabled
- Bit 4 **USART1EN**: USART1 clock enable  
This bit is set and cleared by software.  
0: USART1 clock disabled  
1: USART1 clock enabled

Bits 3:2 Reserved, must be kept at reset value.

Bit 1 **TIM8EN**: TIM8 clock enable

This bit is set and cleared by software.

0: TIM8 clock disabled

1: TIM8 clock enabled

Bit 0 **TIM1EN**: TIM1 clock enable

This bit is set and cleared by software.

0: TIM1 clock disabled

1: TIM1 clock enabled

### 5.3.15 RCC AHB1 peripheral clock enable in low-power mode register (RCC\_AHB1LPENR)

Address offset: 0x50

Reset value: 0x7EF7 B7FFh

Access: no wait state, word, half-word and byte access.

Bit 31 Reserved, must be kept at reset value.

Bit 30 **OTGHSULPIPEN**: USB OTG HS ULPI clock enable during Sleep mode

This bit is set and cleared by software.

0: USB OTG HS ULPI clock disabled during Sleep mode

1: USB OTG HS ULPI clock enabled during Sleep mode

Bit 29 **OTGHSLPEN**: USB OTG HS clock enable during Sleep mode

This bit is set and cleared by software.

0: USB OTG HS clock disabled during Sleep mode

1: USB OTG HS clock enabled during Sleep mode

Bit 28 **ETHMACPTLPEN**: Ethernet PTP clock enable during Sleep mode

This bit is set and cleared by software.

0: Ethernet PTP clock disabled during Sleep mode

1: Ethernet PTP clock enabled during Sleep mode

Bit 27 **ETHMACRXLPEN**: Ethernet reception clock enable during Sleep mode

This bit is set and cleared by software.

0: Ethernet reception clock disabled during Sleep mode

1: Ethernet reception clock enabled during Sleep mode

Bit 26 **ETHMACTXLPEN**: Ethernet transmission clock enable during Sleep mode

This bit is set and cleared by software.

0: Ethernet transmission clock disabled during sleep mode

1: Ethernet transmission clock enabled during sleep mode

Bit 25 **ETHMACLPEN**: Ethernet MAC clock enable during Sleep mode

This bit is set and cleared by software.

0: Ethernet MAC clock disabled during Sleep mode

1: Ethernet MAC clock enabled during Sleep mode

Bit 24 Reserved, must be kept at reset value.

Bit 23 **DMA2DLPEN**: DMA2D clock enable during Sleep mode

This bit is set and cleared by software.

0: DMA2D clock disabled during Sleep mode

1: DMA2D clock enabled during Sleep mode

- Bit 22 **DMA2LPEN**: DMA2 clock enable during Sleep mode  
This bit is set and cleared by software.  
0: DMA2 clock disabled during Sleep mode  
1: DMA2 clock enabled during Sleep mode
- Bit 21 **DMA1LPEN**: DMA1 clock enable during Sleep mode  
This bit is set and cleared by software.  
0: DMA1 clock disabled during Sleep mode  
1: DMA1 clock enabled during Sleep mode
- Bit 20 **DTCMLPEN**: DTCM RAM interface clock enable during Sleep mode  
This bit is set and cleared by software.  
0: DTCM RAM interface clock disabled during Sleep mode  
1: DTCM RAM interface clock enabled during Sleep mode
- Bit 19 Reserved, must be kept at reset value.
- Bit 18 **BKPSRAMLPEN**: Backup SRAM interface clock enable during Sleep mode  
This bit is set and cleared by software.  
0: Backup SRAM interface clock disabled during Sleep mode  
1: Backup SRAM interface clock enabled during Sleep mode
- Bit 17 **SRAM2LPEN**: SRAM2 interface clock enable during Sleep mode  
This bit is set and cleared by software.  
0: SRAM2 interface clock disabled during Sleep mode  
1: SRAM2 interface clock enabled during Sleep mode
- Bit 16 **SRAM1LPEN**: SRAM1 interface clock enable during Sleep mode  
This bit is set and cleared by software.  
0: SRAM1 interface clock disabled during Sleep mode  
1: SRAM1 interface clock enabled during Sleep mode
- Bit 15 **FLITFLPEN**: Flash interface clock enable during Sleep mode  
This bit is set and cleared by software.  
0: Flash interface clock disabled during Sleep mode  
1: Flash interface clock enabled during Sleep mode
- Bit 14 Reserved, must be kept at reset value.
- Bit 13 **AXILPEN**: AXI to AHB bridge clock enable during Sleep mode  
This bit is set and cleared by software.  
0: AXI to AHB bridge clock disabled during Sleep mode  
1: AXI to AHB bridge clock enabled during Sleep mode
- Bit 12 **CRCLPEN**: CRC clock enable during Sleep mode  
This bit is set and cleared by software.  
0: CRC clock disabled during Sleep mode  
1: CRC clock enabled during Sleep mode
- Bit 11 Reserved, must be kept at reset value.
- Bit 10 **GPIOKLPEN**: IO port K clock enable during Sleep mode  
This bit is set and cleared by software.  
0: IO port K clock disabled during Sleep mode  
1: IO port K clock enabled during Sleep mode

- Bit 9 **GPIOJLPEN**: IO port J clock enable during Sleep mode  
 This bit is set and cleared by software.  
 0: IO port J clock disabled during Sleep mode  
 1: IO port J clock enabled during Sleep mode
- Bit 8 **GPIOILPEN**: IO port I clock enable during Sleep mode  
 This bit is set and cleared by software.  
 0: IO port I clock disabled during Sleep mode  
 1: IO port I clock enabled during Sleep mode
- Bit 7 **GPIOHLPEN**: IO port H clock enable during Sleep mode  
 This bit is set and cleared by software.  
 0: IO port H clock disabled during Sleep mode  
 1: IO port H clock enabled during Sleep mode
- Bit 6 **GPIOGLPEN**: IO port G clock enable during Sleep mode  
 This bit is set and cleared by software.  
 0: IO port G clock disabled during Sleep mode  
 1: IO port G clock enabled during Sleep mode
- Bit 5 **GPIOFLPEN**: IO port F clock enable during Sleep mode  
 This bit is set and cleared by software.  
 0: IO port F clock disabled during Sleep mode  
 1: IO port F clock enabled during Sleep mode
- Bit 4 **GPIOELPEN**: IO port E clock enable during Sleep mode  
 Set and cleared by software.  
 0: IO port E clock disabled during Sleep mode  
 1: IO port E clock enabled during Sleep mode
- Bit 3 **GPIODLPEN**: IO port D clock enable during Sleep mode  
 This bit is set and cleared by software.  
 0: IO port D clock disabled during Sleep mode  
 1: IO port D clock enabled during Sleep mode
- Bit 2 **GPIOCLPEN**: IO port C clock enable during Sleep mode  
 This bit is set and cleared by software.  
 0: IO port C clock disabled during Sleep mode  
 1: IO port C clock enabled during Sleep mode
- Bit 1 **GPIOBLPEN**: IO port B clock enable during Sleep mode  
 This bit is set and cleared by software.  
 0: IO port B clock disabled during Sleep mode  
 1: IO port B clock enabled during Sleep mode
- Bit 0 **GPIOALPEN**: IO port A clock enable during sleep mode  
 This bit is set and cleared by software.  
 0: IO port A clock disabled during Sleep mode  
 1: IO port A clock enabled during Sleep mode

### 5.3.16 RCC AHB2 peripheral clock enable in low-power mode register (RCC\_AHB2LPENR)

Address offset: 0x54

Reset value: 0x0000 00F1

Access: no wait state, word, half-word and byte access.

Bits 31:8 Reserved, must be kept at reset value.

Bit 7 **OTGFSLPEN**: USB OTG FS clock enable during Sleep mode

This bit is set and cleared by software.

0: USB OTG FS clock disabled during Sleep mode

1: USB OTG FS clock enabled during Sleep mode

Bit 6 **RNGLPEN**: Random number generator clock enable during Sleep mode

This bit is set and cleared by software.

0: Random number generator clock disabled during Sleep mode

1: Random number generator clock enabled during Sleep mode

Bit 5 **HASHLPEN**: Hash modules clock enable during Sleep mode

This bit is set and cleared by software.

0: Hash modules clock disabled during Sleep mode

1: Hash modules clock enabled during Sleep mode

Bit 4 **CRYPLPEN**: Cryptography modules clock enable during Sleep mode

This bit is set and cleared by software.

0: cryptography modules clock disabled during Sleep mode

1: cryptography modules clock enabled during Sleep mode

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **DCMILPEN**: Camera interface enable during Sleep mode

This bit is set and cleared by software.

0: Camera interface clock disabled during Sleep mode

1: Camera interface clock enabled during Sleep mode

### 5.3.17 RCC AHB3 peripheral clock enable in low-power mode register (RCC\_AHB3LPENR)

Address offset: 0x58

Reset value: 0x0000 0003

Access: no wait state, word, half-word and byte access.

|      |      |      |      |      |      |      |      |      |      |      |      |      |      |              |             |

Bit 31 **UART8LPEN**: UART8 clock enable during Sleep mode

This bit is set and cleared by software.

0: UART8 clock disabled during Sleep mode

1: UART8 clock enabled during Sleep mode

Bit 30 **UART7LPEN**: UART7 clock enable during Sleep mode

This bit is set and cleared by software.

0: UART7 clock disabled during Sleep mode

1: UART7 clock enabled during Sleep mode

Bit 29 **DACL PEN**: DAC interface clock enable during Sleep mode

This bit is set and cleared by software.

0: DAC interface clock disabled during Sleep mode

1: DAC interface clock enabled during Sleep mode

Bit 28 **PWRLPEN**: Power interface clock enable during Sleep mode

This bit is set and cleared by software.

0: Power interface clock disabled during Sleep mode

1: Power interface clock enabled during Sleep mode

Bit 27 **CECLPEN**: HDMI-CEC clock enable during Sleep mode

This bit is set and cleared by software.

0: HDMI-CEC clock disabled during Sleep mode

1: HDMI-CEC clock enabled during Sleep mode

- Bit 26 **CAN2LPEN**: CAN 2 clock enable during Sleep mode  
This bit is set and cleared by software.  
0: CAN 2 clock disabled during sleep mode  
1: CAN 2 clock enabled during sleep mode
- Bit 25 **CAN1LPEN**: CAN 1 clock enable during Sleep mode  
This bit is set and cleared by software.  
0: CAN 1 clock disabled during Sleep mode  
1: CAN 1 clock enabled during Sleep mode
- Bit 24 **I2C4LPEN**: I2C4 clock enable during Sleep mode  
This bit is set and cleared by software.  
0: I2C4 clock disabled during Sleep mode  
1: I2C4 clock enabled during Sleep mode
- Bit 23 **I2C3LPEN**: I2C3 clock enable during Sleep mode  
This bit is set and cleared by software.  
0: I2C3 clock disabled during Sleep mode  
1: I2C3 clock enabled during Sleep mode
- Bit 22 **I2C2LPEN**: I2C2 clock enable during Sleep mode  
This bit is set and cleared by software.  
0: I2C2 clock disabled during Sleep mode  
1: I2C2 clock enabled during Sleep mode
- Bit 21 **I2C1LPEN**: I2C1 clock enable during Sleep mode  
This bit is set and cleared by software.  
0: I2C1 clock disabled during Sleep mode  
1: I2C1 clock enabled during Sleep mode
- Bit 20 **UART5LPEN**: UART5 clock enable during Sleep mode  
This bit is set and cleared by software.  
0: UART5 clock disabled during Sleep mode  
1: UART5 clock enabled during Sleep mode
- Bit 19 **UART4LPEN**: UART4 clock enable during Sleep mode  
This bit is set and cleared by software.  
0: UART4 clock disabled during Sleep mode  
1: UART4 clock enabled during Sleep mode
- Bit 18 **USART3LPEN**: USART3 clock enable during Sleep mode  
This bit is set and cleared by software.  
0: USART3 clock disabled during Sleep mode  
1: USART3 clock enabled during Sleep mode
- Bit 17 **USART2LPEN**: USART2 clock enable during Sleep mode  
This bit is set and cleared by software.  
0: USART2 clock disabled during Sleep mode  
1: USART2 clock enabled during Sleep mode
- Bit 16 **SPDIFRXLPEN**: SPDIFRX clock enable during Sleep mode  
This bit is set and cleared by software.  
0: SPDIFRX clock disabled during Sleep mode  
1: SPDIFRX clock enabled during Sleep mode

Bit 15 **SPI3LPEN**: SPI3 clock enable during Sleep mode

This bit is set and cleared by software.

0: SPI3 clock disabled during Sleep mode

1: SPI3 clock enabled during Sleep mode

Bit 14 **SPI2LPEN**: SPI2 clock enable during Sleep mode

This bit is set and cleared by software.

0: SPI2 clock disabled during Sleep mode

1: SPI2 clock enabled during Sleep mode

Bits 13:12 Reserved, must be kept at reset value.

Bit 11 **WWDGLPEN**: Window watchdog clock enable during Sleep mode

This bit is set and cleared by software.

0: Window watchdog clock disabled during sleep mode

1: Window watchdog clock enabled during sleep mode

Bit 10 Reserved, must be kept at reset value.

Bit 9 **LPTIM1LPEN**: low-power timer 1 clock enable during Sleep mode

This bit is set and cleared by software.

0: LPTIM1 clock disabled during Sleep mode

1: LPTIM1 clock enabled during Sleep mode

Bit 8 **TIM14LPEN**: TIM14 clock enable during Sleep mode

This bit is set and cleared by software.

0: TIM14 clock disabled during Sleep mode

1: TIM14 clock enabled during Sleep mode

Bit 7 **TIM13LPEN**: TIM13 clock enable during Sleep mode

This bit is set and cleared by software.

0: TIM13 clock disabled during Sleep mode

1: TIM13 clock enabled during Sleep mode

Bit 6 **TIM12LPEN**: TIM12 clock enable during Sleep mode

This bit is set and cleared by software.

0: TIM12 clock disabled during Sleep mode

1: TIM12 clock enabled during Sleep mode

Bit 5 **TIM7LPEN**: TIM7 clock enable during Sleep mode

This bit is set and cleared by software.

0: TIM7 clock disabled during Sleep mode

1: TIM7 clock enabled during Sleep mode

Bit 4 **TIM6LPEN**: TIM6 clock enable during Sleep mode

This bit is set and cleared by software.

0: TIM6 clock disabled during Sleep mode

1: TIM6 clock enabled during Sleep mode

Bit 3 **TIM5LPEN**: TIM5 clock enable during Sleep mode

This bit is set and cleared by software.

0: TIM5 clock disabled during Sleep mode

1: TIM5 clock enabled during Sleep mode

Bit 2 **TIM4LPEN**: TIM4 clock enable during Sleep mode

This bit is set and cleared by software.

0: TIM4 clock disabled during Sleep mode

1: TIM4 clock enabled during Sleep mode

Bit 1 **TIM3LPEN**: TIM3 clock enable during Sleep mode

This bit is set and cleared by software.

0: TIM3 clock disabled during Sleep mode

1: TIM3 clock enabled during Sleep mode

Bit 0 **TIM2LPEN**: TIM2 clock enable during Sleep mode

This bit is set and cleared by software.

0: TIM2 clock disabled during Sleep mode

1: TIM2 clock enabled during Sleep mode

### 5.3.19 RCC APB2 peripheral clock enabled in low-power mode register (RCC\_APB2LPENR)

Address offset: 0x64

Reset value: 0x04F7 7F33h

Access: no wait state, word, half-word and byte access.

Bits 31:27 Reserved, must be kept at reset value.

Bit 26 **LTDC LPEN**: LTDC clock enable during Sleep mode

This bit is set and cleared by software.

0: LTDC clock disabled during Sleep mode

1: LTDC clock enabled during Sleep mode

Bits 25:24 Reserved, must be kept at reset value.

Bit 23 **SAI2 LPEN**: SAI2 clock enable during Sleep mode

This bit is set and cleared by software.

0: SAI2 clock disabled during Sleep mode

1: SAI2 clock enabled during Sleep mode

Bit 22 **SAI1 LPEN**: SAI1 clock enable during Sleep mode

This bit is set and cleared by software.

0: SAI1 clock disabled during Sleep mode

1: SAI1 clock enabled during Sleep mode

Bit 21 **SPI6 LPEN**: SPI6 clock enable during Sleep mode

This bit is set and cleared by software.

0: SPI6 clock disabled during Sleep mode

1: SPI6 clock enabled during Sleep mode

Bit 20 **SPI5 LPEN**: SPI5 clock enable during Sleep mode

This bit is set and cleared by software.

0: SPI5 clock disabled during Sleep mode

1: SPI5 clock enabled during Sleep mode

Bit 19 Reserved, must be kept at reset value.

Bit 18 **TIM11 LPEN**: TIM11 clock enable during Sleep mode

This bit is set and cleared by software.

0: TIM11 clock disabled during Sleep mode

1: TIM11 clock enabled during Sleep mode

Bit 17 **TIM10 LPEN**: TIM10 clock enable during Sleep mode

This bit is set and cleared by software.

0: TIM10 clock disabled during Sleep mode

1: TIM10 clock enabled during Sleep mode

- Bit 16 **TIM9LPEN**: TIM9 clock enable during sleep mode  
This bit is set and cleared by software.  
0: TIM9 clock disabled during Sleep mode  
1: TIM9 clock enabled during Sleep mode
- Bit 15 Reserved, must be kept at reset value.
- Bit 14 **SYSCFGLPEN**: System configuration controller clock enable during Sleep mode  
This bit is set and cleared by software.  
0: System configuration controller clock disabled during Sleep mode  
1: System configuration controller clock enabled during Sleep mode
- Bit 13 **SPI4LPEN**: SPI4 clock enable during Sleep mode  
This bit is set and cleared by software.  
0: SPI4 clock disabled during Sleep mode  
1: SPI4 clock enabled during Sleep mode
- Bit 12 **SPI1LPEN**: SPI1 clock enable during Sleep mode  
This bit is set and cleared by software.  
0: SPI1 clock disabled during Sleep mode  
1: SPI1 clock enabled during Sleep mode
- Bit 11 **SDMMC1LPEN**: SDMMC1 clock enable during Sleep mode  
This bit is set and cleared by software.  
0: SDMMC1 module clock disabled during Sleep mode  
1: SDMMC1 module clock enabled during Sleep mode
- Bit 10 **ADC3LPEN**: ADC 3 clock enable during Sleep mode  
This bit is set and cleared by software.  
0: ADC 3 clock disabled during Sleep mode  
1: ADC 3 clock enabled during Sleep mode
- Bit 9 **ADC2LPEN**: ADC2 clock enable during Sleep mode  
This bit is set and cleared by software.  
0: ADC2 clock disabled during Sleep mode  
1: ADC2 clock enabled during Sleep mode
- Bit 8 **ADC1LPEN**: ADC1 clock enable during Sleep mode  
This bit is set and cleared by software.  
0: ADC1 clock disabled during Sleep mode  
1: ADC1 clock enabled during Sleep mode
- Bits 7:6 Reserved, must be kept at reset value.
- Bit 5 **USART6LPEN**: USART6 clock enable during Sleep mode  
This bit is set and cleared by software.  
0: USART6 clock disabled during Sleep mode  
1: USART6 clock enabled during Sleep mode
- Bit 4 **USART1LPEN**: USART1 clock enable during Sleep mode  
This bit is set and cleared by software.  
0: USART1 clock disabled during Sleep mode  
1: USART1 clock enabled during Sleep mode

Bits 3:2 Reserved, must be kept at reset value.

Bit 1 **TIM8LPEN**: TIM8 clock enable during Sleep mode

This bit is set and cleared by software.

0: TIM8 clock disabled during Sleep mode

1: TIM8 clock enabled during Sleep mode

Bit 0 **TIM1LPEN**: TIM1 clock enable during Sleep mode

This bit is set and cleared by software.

0: TIM1 clock disabled during Sleep mode

1: TIM1 clock enabled during Sleep mode

### 5.3.20 RCC backup domain control register (RCC\_BDCR)

Address offset: 0x70

Reset value: 0x0000 0000, reset by Backup domain reset.

Access:  $0 \leq \text{wait state} \leq 3$ , word, half-word and byte access

Wait states are inserted in case of successive accesses to this register.

The LSEON, LSEBYP, LSEDRV[1:0], RTCSEL and RTCEN bits in the [RCC backup domain control register \(RCC\\_BDCR\)](#) are in the Backup domain. As a result, after Reset, these bits are write-protected and the DBP bit in the [PWR power control register \(PWR\\_CR1\)](#) has to be set before these can be modified. Refer to [Section 5.1.1: System reset on page 132](#) for further information. These bits are only reset after a Backup domain Reset (see [Section 5.1.3: Backup domain reset](#)). Any internal or external Reset will not have any effect on these bits.

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **BDRST**: Backup domain software reset

This bit is set and cleared by software.

0: Reset not activated

1: Resets the entire Backup domain

*Note: The BKPSRAM is not affected by this reset, the only way of resetting the BKPSRAM is through the Flash interface when a protection level change from level 1 to level 0 is requested.*

Bit 15 **RTCEN**: RTC clock enable

This bit is set and cleared by software.

0: RTC clock disabled

1: RTC clock enabled

Bits 14:10 Reserved, must be kept at reset value.

Bits 9:8 **RTCSEL[1:0]**: RTC clock source selection

These bits are set by software to select the clock source for the RTC. Once the RTC clock source has been selected, it cannot be changed anymore unless the Backup domain is reset. The BDRST bit can be used to reset them.

00: No clock

01: LSE oscillator clock used as the RTC clock

10: LSI oscillator clock used as the RTC clock

11: HSE oscillator clock divided by a programmable prescaler (selection through the RTCPRE[4:0] bits in the RCC clock configuration register (RCC\_CFGR)) used as the RTC clock

Bits 7:5 Reserved, must be kept at reset value.

Bits 4:3 **LSEDRV[1:0]**: LSE oscillator drive capability

Set by software to modulate the LSE oscillator's drive capability.

00: Low driving capability

01: Medium high driving capability

10: Medium low driving capability

11: High driving capability

Bit 2 **LSEBYP**: External low-speed oscillator bypass

This bit is set and cleared by software to bypass the oscillator. This bit can be written only when the LSE clock is disabled.

0: LSE oscillator not bypassed

1: LSE oscillator bypassed

Bit 1 **LSERDY**: External low-speed oscillator ready

This bit is set and cleared by hardware to indicate when the external 32 kHz oscillator is stable. After the LSEON bit is cleared, LSERDY goes low after 6 external low-speed oscillator clock cycles.

0: LSE clock not ready

1: LSE clock ready

Bit 0 **LSEON**: External low-speed oscillator enable

This bit is set and cleared by software.

0: LSE clock OFF

1: LSE clock ON

### 5.3.21 RCC clock control & status register (RCC\_CSR)

Address offset: 0x74

Reset value: 0x0E00 0000, reset by system reset, except reset flags by power reset only.

Access:  $0 \leq \text{wait state} \leq 3$ , word, half-word and byte access

Wait states are inserted in case of successive accesses to this register.

| 31           | 30           | 29           | 28          | 27          | 26          | 25          | 24   | 23   | 22   | 21   | 20   | 19   | 18   | 17     | 16    |

**Bit 31 LPWRRSTF:** Low-power reset flag

This bit is set by hardware when a Low-power management reset occurs.

Cleared by writing to the RMVF bit.

0: No Low-power management reset occurred

1: Low-power management reset occurred

For further information on Low-power management reset, refer to [Low-power management reset](#).

**Bit 30 WWDGRSTF:** Window watchdog reset flag

This bit is set by hardware when a window watchdog reset occurs.

Cleared by writing to the RMVF bit.

0: No window watchdog reset occurred

1: Window watchdog reset occurred

**Bit 29 IWDGRSTF:** Independent watchdog reset flag

This bit is set by hardware when an independent watchdog reset from V<sub>DD</sub> domain occurs.

Cleared by writing to the RMVF bit.

0: No watchdog reset occurred

1: Watchdog reset occurred

**Bit 28 SFTRSTF:** Software reset flag

This bit is set by hardware when a software reset occurs.

Cleared by writing to the RMVF bit.

0: No software reset occurred

1: Software reset occurred

**Bit 27 PORRSTF:** POR/PDR reset flag

This bit is set by hardware when a POR/PDR reset occurs.

Cleared by writing to the RMVF bit.

0: No POR/PDR reset occurred

1: POR/PDR reset occurred

**Bit 26 PINRSTF:** PIN reset flag

This bit is set by hardware when a reset from the NRST pin occurs.

Cleared by writing to the RMVF bit.

0: No reset from NRST pin occurred

1: Reset from NRST pin occurred

**Bit 25 BORRSTF:** BOR reset flag

Cleared by software by writing the RMVF bit.

This bit is set by hardware when a POR/PDR or BOR reset occurs.

0: No POR/PDR or BOR reset occurred

1: POR/PDR or BOR reset occurred

**Bit 24 RMVF:** Remove reset flag

This bit is set by software to clear the reset flags.

0: No effect

1: Clear the reset flags

Bits 23:2 Reserved, must be kept at reset value.

Bit 1 **LSIRDY**: Internal low-speed oscillator ready

This bit is set and cleared by hardware to indicate when the internal RC 40 kHz oscillator is stable. After the LSION bit is cleared, LSIRDY goes low after 3 LSI clock cycles.

0: LSI RC oscillator not ready

1: LSI RC oscillator ready

Bit 0 **LSION**: Internal low-speed oscillator enable

This bit is set and cleared by software.

0: LSI RC oscillator OFF

1: LSI RC oscillator ON

### 5.3.22 RCC spread spectrum clock generation register (RCC\_SSCGR)

Address offset: 0x80

Reset value: 0x0000 0000

Access: no wait state, word, half-word and byte access.

The spread spectrum clock generation is available only for the main PLL.

The RCC\_SSCGR register must be written either before the main PLL is enabled or after the main PLL disabled.

**Note:** For full details about PLL spread spectrum clock generation (SSCG) characteristics, refer to the “Electrical characteristics” section in your device datasheet.

Bit 31 **SSCGEN**: Spread spectrum modulation enable

This bit is set and cleared by software.

0: Spread spectrum modulation DISABLE. (To write after clearing CR[24]=PLLON bit)

1: Spread spectrum modulation ENABLE. (To write before setting CR[24]=PLLON bit)

Bit 30 **SPREADSEL**: Spread Select

This bit is set and cleared by software.

To write before to set CR[24]=PLLON bit.

0: Center spread

1: Down spread

Bits 29:28 Reserved, must be kept at reset value.

Bits 27:13 **INCSTEP**: Incrementation step

These bits are set and cleared by software. To write before setting CR[24]=PLLON bit.  
Configuration input for modulation profile amplitude.

Bits 12:0 **MODPER**: Modulation period

These bits are set and cleared by software. To write before setting CR[24]=PLLON bit.  
Configuration input for modulation profile period.

### 5.3.23 RCC PLLI2S configuration register (RCC\_PLLI2SCFGR)

Address offset: 0x84

Reset value: 0x2400 3000

Access: no wait state, word, half-word and byte access.

This register is used to configure the PLLI2S clock outputs according to the formulas:

$$f_{(VCO \text{ clock})} = f_{(PLLI2S \text{ clock input})} \times (PLLI2SN / PLLM)$$

$$f_{(PLLI2S\_P)} = f_{(VCO \text{ clock})} / PLLI2SP$$

$$f_{(PLLI2S\_Q)} = f_{(VCO \text{ clock})} / PLLI2SQ$$

$$f_{(PLLI2S\_R)} = f_{(VCO \text{ clock})} / PLLI2SR$$

|      |              |    |    |              |    |    |    |      |      |      |      |      |      |              |      |

Bit 31 Reserved, must be kept at reset value.

Bits 30:28 **PLLI2SR[2:0]**: PLLI2S division factor for I2S clocks

These bits are set and cleared by software to control the I2S clock frequency. These bits should be written only if the PLLI2S is disabled. The factor must be chosen in accordance with the prescaler values inside the I2S peripherals, to reach 0.3% error when using standard crystals and 0% error with audio crystals. For more information about I2S clock frequency and precision, refer to [Section 32.7.4: Start-up description](#) in the I2S chapter.

**Caution:** The I2Ss requires a frequency lower than or equal to 192 MHz to work correctly.

$I2S\ clock\ frequency = VCO\ frequency / PLLR$  with  $2 \leq PLLR \leq 7$

000: PLLR = 0, wrong configuration

001: PLLR = 1, wrong configuration

010: PLLR = 2

...

111: PLLR = 7

Bits 27:24 **PLLI2SQ[3:0]**: PLLI2S division factor for SAI clock

These bits are set and cleared by software to control the SAI clock frequency. They should be written when the PLLI2S is disabled.

$SAI\ clock\ frequency = VCO\ frequency / PLLI2SQ$  with  $2 \leq PLLI2SQ \leq 15$

0000: PLLI2SQ = 0, wrong configuration

0001: PLLI2SQ = 1, wrong configuration

0010: PLLI2SQ = 2

0011: PLLI2SQ = 3

0100: PLLI2SQ = 4

0101: PLLI2SQ = 5

...

1111: PLLI2SQ = 15

Bits 23:18 Reserved, must be kept at reset value.

Bits 17:16 **PLLI2SP[1:0]**: PLLI2S division factor for SPDIFRX clock

These bits are set and cleared by software to control the SPDIFRX clock. These bits can be written only if the PLLI2S is disabled.

The factor must be chosen in accordance with the prescaler values inside the SPDIF to reach an audio clock close to 44 kHz or 48 kHz according to the SPDIF mode

$SPDIF\ clock\ frequency = VCO\ frequency / PLLI2SP$  with PLLI2S P = 2, 4, 6, or 8

00: PLLI2SP = 2

01: PLLI2SP = 4

10: PLLI2SP = 6

11: PLLI2SP = 8

Bit 15 Reserved, must be kept at reset value.

Bits 14:6 **PLLI2SN[8:0]**: PLLI2S multiplication factor for VCO

These bits are set and cleared by software to control the multiplication factor of the VCO. These bits can be written only when the PLLI2S is disabled. Only half-word and word accesses are allowed to write these bits.

**Caution:** The software has to set these bits correctly to ensure that the VCO output frequency is between 100 and 432 MHz.

VCO output frequency = VCO input frequency  $\times$  PLLI2SN with  $50 \leq \text{PLLI2SN} \leq 432$

00000000: PLLI2SN = 0, wrong configuration

00000001: PLLI2SN = 1, wrong configuration

...

001100010: PLLI2SN = 50

...

001100011: PLLI2SN = 99

001100100: PLLI2SN = 100

001100101: PLLI2SN = 101

001100110: PLLI2SN = 102

...

110110000: PLLI2SN = 432

110110000: PLLI2SN = 433, wrong configuration

...

111111111: PLLI2SN = 511, wrong configuration

*Note: Between 50 and 99, multiplication factors are possible for VCO input frequency higher than 1 MHz. However care must be taken to fulfill the minimum VCO output frequency as specified above.*

Bits 5:0 Reserved, must be kept at reset value.

### 5.3.24 RCC PLLSAI configuration register (RCC\_PLLSAICFGR)

Address offset: 0x88

Reset value: 0x2400 3000

Access: no wait state, word, half-word and byte access.

This register is used to configure the PLLSAI clock outputs according to the formulas:

- $f_{(VCO\ clock)} = f_{(PLLSAI\ clock\ input)} \times (PLLSAIN / PLLM)$
- $f_{(PLLSAI\_P)} = f_{(VCO\ clock)} / PLLSAIP$
- $f_{(PLLSAI\_Q)} = f_{(VCO\ clock)} / PLLSAIQ$
- $f_{(PLLSAI\_R)} = f_{(VCO\ clock)} / PLLSAIR$

|      |              |    |    |              |    |    |    |      |      |      |      |      |      |              |      |

Bit 31 Reserved, must be kept at reset value.

Bits 30:28 **PLLSAIR[2:0]**: PLLSAI division factor for LCD clock

Set and reset by software to control the LCD clock frequency.

These bits should be written when the PLLSAI is disabled.

LCD clock frequency = VCO frequency / PLLSAIR with  $2 \leq PLLSAIR \leq 7$

000: PLLSAIR = 0, wrong configuration

001: PLLSAIR = 1, wrong configuration

010: PLLSAIR = 2

...

111: PLLSAIR = 7

Bits 27:24 **PLLSAIQ[3:0]**: PLLSAI division factor for SAI clock

Set and reset by software to control the frequency of SAI clock.

These bits should be written when the PLLSAI is disabled.

SAI1 clock frequency = VCO frequency / PLLSAIQ with  $2 \leq PLLSAIQ \leq 15$

0000: PLLSAIQ = 0, wrong configuration

0001: PLLSAIQ = 1, wrong configuration

...

0010: PLLSAIQ = 2

0011: PLLSAIQ = 3

0100: PLLSAIQ = 4

0101: PLLSAIQ = 5

...

1111: PLLSAIQ = 15

Bits 23:18 Reserved, must be kept at reset value.

Bits 17:16 **PLLSAIP[1:0]**: PLLSAI division factor for 48MHz clock

Set and reset by software to control the frequency of the PLLSAI output clock (PLLSAI48CLK). This output can be selected for USB, RNG, SDMMC (48 MHz clock). These bits should be written only if the PLLSAI is disabled.

Only half-word and word accesses are allowed to write these bits.

PLLSAI48 output clock frequency = VCO frequency / PLLSAIP with PLLSAI P = 2, 4, 6, or 8

00: PLLSAIP = 2

01: PLLSAIP = 4

10: PLLSAIP = 6

11: PLLSAIP = 8

Bit 15 Reserved, must be kept at reset value.

Bits 14:6 **PLLSAIN[8:0]**: PLLSAI division factor for VCO

Set and reset by software to control the multiplication factor of the VCO.

These bits should be written when the PLLSAI is disabled.

Only half-word and word accesses are allowed to write these bits.

**Caution:** The software has to set these bits correctly to ensure that the VCO output frequency is between 100 and 432 MHz.

VCO output frequency = VCO input frequency x PLLSAIN with  $50 \leq \text{PLLSAIN} \leq 432$

000000000: PLLSAIN = 0, wrong configuration

000000001: PLLSAIN = 1, wrong configuration

.....

001100010: PLLSAIN = 50

...

001100011: PLLSAIN = 99

001100100: PLLSAIN = 100

001100101: PLLSAIN = 101

001100110: PLLSAIN = 102

...

110110000: PLLSAIN = 432

110110000: PLLSAIN = 433, wrong configuration

...

111111111: PLLSAIN = 511, wrong configuration

*Note: Between 50 and 99, multiplication factors are possible for VCO input frequency higher than 1 MHz. However care must be taken to fulfill the minimum VCO output frequency as specified above.*

Bits 5:0 Reserved, must be kept at reset value

### 5.3.25 RCC dedicated clocks configuration register (RCC\_DCKCFGR1)

Address offset: 0x8C

Reset value: 0x0000 0000

Access: no wait state, word, half-word and byte access.

This register allows to configure the timer clock prescalers and the PLLSAI and PLLI2S output clock dividers for SAI and LTDC peripherals according to the following formula:

$$f_{(\text{PLLSAIDIVQ clock output})} = f_{(\text{PLLSAI\_Q})} / \text{PLLSAIDIVQ}$$

$$f_{(\text{PLLSAIDIVR clock output})} = f_{(\text{PLLSAI\_R})} / \text{PLLSAIDIVR}$$

$$f_{(\text{PLLI2SDIVQ clock output})} = f_{(\text{PLLI2S\_Q})} / \text{PLLI2SDIVQ}$$

Bits 31:25 Reserved, must be kept at reset value.

Bit 24 **TIMPRE**: Timers clocks prescalers selection

This bit is set and reset by software to control the clock frequency of all the timers connected to APB1 and APB2 domain.

0: If the APB prescaler (PPRE1, PPRE2 in the RCC\_CFGR register) is configured to a division factor of 1, TIMxCLK = PCLKx. Otherwise, the timer clock frequencies are set to twice to the frequency of the APB domain to which the timers are connected:

$TIMxCLK = 2 \times PCLKx$ .

1: If the APB prescaler (PPRE1, PPRE2 in the RCC\_CFGR register) is configured to a division factor of 1, 2 or 4, TIMxCLK = HCLK. Otherwise, the timer clock frequencies are set to four times to the frequency of the APB domain to which the timers are connected:

$TIMxCLK = 4 \times PCLKx$ .

Bits 23:22 **SAI2SEL[1:0]**: SAI2 clock source selection:

These bits are set and cleared by software to control the SAI2 clock frequency.

They should be written when the PLLSAI and PLLI2S are disabled.

00: SAI2 clock frequency =  $f(PLLSAI\_Q) / PLLSAIDIVQ$

01: SAI2 clock frequency =  $f(PLLI2S\_Q) / PLLI2SDIVQ$

10: SAI2 clock frequency = Alternate function input frequency

11: wrong configuration

Bits 21:20 **SAI1SEL[1:0]**: SAI1 clock source selection

These bits are set and cleared by software to control the SAI1 clock frequency.

They should be written when the PLLSAI and PLLI2S are disabled.

00: SAI1 clock frequency =  $f(PLLSAI\_Q) / PLLSAIDIVQ$

01: SAI1 clock frequency =  $f(PLLI2S\_Q) / PLLI2SDIVQ$

10: SAI1 clock frequency = Alternate function input frequency

11: wrong configuration

Bits 19: 18 Reserved, must be kept at reset value.

Bits 17:16 **PLLSAIDIVR[1:0]**: division factor for LCD\_CLK

These bits are set and cleared by software to control the frequency of LCD\_CLK.

They should be written only if PLLSAI is disabled.

$LCD\_CLK \text{ frequency} = f(PLLSAI\_R) / PLLSAIDIVR$  with  $2 \leq PLLSAIDIVR \leq 16$

00: PLLSAIDIVR = /2

01: PLLSAIDIVR = /4

10: PLLSAIDIVR = /8

11: PLLSAIDIVR = /16

Bits 15: 13 Reserved, must be kept at reset value.

Bits 12:8 **PLLSAIDIVQ[4:0]**: PLLSAI division factor for SAI1 clock

These bits are set and reset by software to control the SAI1 clock frequency.

They should be written only if PLLSAI is disabled.

SAI1 clock frequency =  $f(\text{PLLSAI\_Q}) / \text{PLLSAIDIVQ}$  with  $1 \leq \text{PLLSAIDIVQ} \leq 31$

00000: PLLSAIDIVQ = /1

00001: PLLSAIDIVQ = /2

00010: PLLSAIDIVQ = /3

00011: PLLSAIDIVQ = /4

00100: PLLSAIDIVQ = /5

...

11111: PLLSAIDIVQ = /32

Bits 7:5 Reserved, must be kept at reset value.

Bits 4:0 **PLLI2SDIVQ[4:0]**: PLLI2S division factor for SAI1 clock

These bits are set and reset by software to control the SAI1 clock frequency.

They should be written only if PLLI2S is disabled.

SAI1 clock frequency =  $f(\text{PLLI2S\_Q}) / \text{PLLI2SDIVQ}$  with  $1 \leq \text{PLLI2SDIVQ} \leq 31$

00000: PLLI2SDIVQ = /1

00001: PLLI2SDIVQ = /2

00010: PLLI2SDIVQ = /3

00011: PLLI2SDIVQ = /4

00100: PLLI2SDIVQ = /5

...

11111: PLLI2SDIVQ = /32

### 5.3.26 RCC dedicated clocks configuration register (DCKCFGR2)

Address: 0x90h

Reset value: 0x0000 0000h

Access: no wait state, word, half-word and byte access

This register allows to select the source clock for the 48MHz, SDMMC, HDMI-CEC, LPTIM1, UARTs, USARTs and I2Cs clocks.

- Bits 31:29 Reserved, must be kept at reset value.
- Bit 28 **SDMMCSEL**: SDMMC clock source selection  
Set and reset by software.  
0: 48 MHz clock is selected as SDMMC clock  
1: System clock is selected as SDMMC clock
- Bit 27 **CK48MSEL**: 48MHz clock source selection  
Set and reset by software.  
0: 48MHz clock from PLL is selected  
1: 48MHz clock from PLLSAI is selected.
- Bit 26 **CECSEL**: HDMI-CEC clock source selection  
Set and reset by software.  
0: LSE clock is selected as HDMI-CEC clock  
1: HSI divided by 488 clock is selected as HDMI-CEC clock
- Bits 25:24 **LPTIM1SEL**: Low-power timer 1 clock source selection  
Set and reset by software.  
00: APB1 clock (PCLK1) selected as LPTILM1 clock  
01: LSI clock is selected as LPTILM1 clock  
10: HSI clock is selected as LPTILM1 clock  
11: LSE clock is selected as LPTILM1 clock
- Bits 23:22 **I2C4SEL**: I2C4 clock source selection  
Set and reset by software.  
00: APB1 clock (PCLK1) is selected as I2C4 clock  
01: System clock is selected as I2C4 clock  
10: HSI clock is selected as I2C4 clock  
11: reserved
- Bits 21:20 **I2C3SEL**: I2C3 clock source selection  
Set and reset by software.  
00: APB clock is selected as I2C3 clock  
01: System clock is selected as I2C3 clock  
10: HSI clock is selected as I2C3 clock  
11: reserved
- Bits 19:18 **I2C2SEL**: I2C2 clock source selection  
Set and reset by software.  
00: APB1 clock (PCLK1) is selected as I2C2 clock  
01: System clock is selected as I2C2 clock  
10: HSI clock is selected as I2C2 clock  
11: reserved
- Bits 17:16 **I2C1SEL**: I2C1 clock source selection  
Set and reset by software.  
00: APB clock (PCLK1) is selected as I2C1 clock  
01: System clock is selected as I2C1 clock  
10: HSI clock is selected as I2C1 clock  
11: reserved

- Bits 15:14 **UART8SEL[1:0]**: UART 8 clock source selection  
Set and reset by software.  
00: APB1 clock (PCLK1) is selected as UART 8 clock  
01: System clock is selected as UART 8 clock  
10: HSI clock is selected as UART 8 clock  
11: LSE clock is selected as UART 8 clock
- Bits 13:12 **UART7SEL[1:0]**: UART 7 clock source selection  
Set and reset by software.  
00: APB1 clock (PCLK1) is selected as UART 7 clock  
01: System clock is selected as UART 7 clock  
10: HSI clock is selected as UART 7 clock  
11: LSE clock is selected as UART 7 clock
- Bits 11:10 **USART6SEL[1:0]**: USART 6 clock source selection  
Set and reset by software.  
00: APB2 clock (PCLK2) is selected as USART 6 clock  
01: System clock is selected as USART 6 clock  
10: HSI clock is selected as USART 6 clock  
11: LSE clock is selected as USART 6 clock
- Bits 9:8 **UART5SEL[1:0]**: UART 5 clock source selection  
Set and reset by software.  
00: APB1 clock (PCLK1) is selected as UART 5 clock  
01: System clock is selected as UART 5 clock  
10: HSI clock is selected as UART 5 clock  
11: LSE clock is selected as UART 5 clock
- Bits 7:6 **UART4SEL[1:0]**: UART 4 clock source selection  
Set and reset by software.  
00: APB1 clock (PCLK1) is selected as UART 4 clock  
01: System clock is selected as UART 4 clock  
10: HSI clock is selected as UART 4 clock  
11: LSE clock is selected as UART 4 clock
- Bits 5:4 **USART3SEL[1:0]**: USART 3 clock source selection  
Set and reset by software.  
00: APB1 clock (PCLK1) is selected as USART 3 clock  
01: System clock is selected as USART 3 clock  
10: HSI clock is selected as USART 3 clock  
11: LSE clock is selected as USART 3 clock
- Bits 3:2 **USART2SEL[1:0]**: USART 2 clock source selection  
Set and reset by software.  
00: APB1 clock (PCLK1) is selected as USART 2 clock  
01: System clock is selected as USART 2 clock  
10: HSI clock is selected as USART 2 clock  
11: LSE clock is selected as USART 2 clock
- Bits 1:0 **USART1SEL[1:0]**: USART 1 clock source selection  
Set and reset by software.  
00: APB2 clock (PCLK2) is selected as USART 1 clock  
01: System clock is selected as USART 1 clock  
10: HSI clock is selected as USART 1 clock  
11: LSE clock is selected as USART 1 clock

### 5.3.27 RCC register map

Table 21 gives the register map and reset values.

Table 21. RCC register map and reset values

| Addr. offset | Register name | 31       | 30       | 29          | 28        | 27          | 26         | 25         | 24        | 23       | 22         | 21        | 20       | 19        | 18       | 17        | 16         | 15       | 14       | 13          | 12         | 11       | 10       | 9        | 8        | 7         | 6         | 5          | 4         | 3         | 2        | 1       | 0       |         |

Refer to [Section 2.2.2 on page 69](#) for the register boundary addresses.

## 6 General-purpose I/Os (GPIO)

### 6.1 Introduction

Each general-purpose I/O port has four 32-bit configuration registers (GPIOx\_MODER, GPIOx\_OTYPER, GPIOx\_OSPEEDR and GPIOx\_PUPDR), two 32-bit data registers (GPIOx\_IDR and GPIOx\_ODR) and a 32-bit set/reset register (GPIOx\_BSRR). In addition all GPIOs have a 32-bit locking register (GPIOx\_LCKR) and two 32-bit alternate function selection registers (GPIOx\_AFRH and GPIOx\_AFRL).

### 6.2 GPIO main features

- Output states: push-pull or open drain + pull-up/down
- Output data from output data register (GPIOx\_ODR) or peripheral (alternate function output)
- Speed selection for each I/O
- Input states: floating, pull-up/down, analog
- Input data to input data register (GPIOx\_IDR) or peripheral (alternate function input)
- Bit set and reset register (GPIOx\_BSRR) for bitwise write access to GPIOx\_ODR
- Locking mechanism (GPIOx\_LCKR) provided to freeze the I/O port configurations
- Analog function
- Alternate function selection registers
- Fast toggle capable of changing every two clock cycles
- Highly flexible pin multiplexing allows the use of I/O pins as GPIOs or as one of several peripheral functions

### 6.3 GPIO functional description

Subject to the specific hardware characteristics of each I/O port listed in the datasheet, each port bit of the general-purpose I/O (GPIO) ports can be individually configured by software in several modes:

- Input floating
- Input pull-up
- Input-pull-down
- Analog
- Output open-drain with pull-up or pull-down capability
- Output push-pull with pull-up or pull-down capability
- Alternate function push-pull with pull-up or pull-down capability
- Alternate function open-drain with pull-up or pull-down capability

Each I/O port bit is freely programmable, however the I/O port registers have to be accessed as 32-bit words, half-words or bytes. The purpose of the GPIOx\_BSRR and GPIOx\_BRR registers is to allow atomic read/modify accesses to any of the GPIOx\_ODR registers. In this way, there is no risk of an IRQ occurring between the read and the modify access.

Figure 17 and Figure 18 shows the basic structures of a standard and a 5-Volt tolerant I/O port bit, respectively. Table 22 gives the possible port bit configurations.

**Figure 17. Basic structure of an I/O port bit**

**Figure 18. Basic structure of a 5-Volt tolerant I/O port bit**

1.  $V_{DD\_FT}$  is a potential specific to five-volt tolerant I/Os and different from  $V_{DD}$ .

Table 22. Port bit configuration table<sup>(1)</sup>

| MODE(i)<br>[1:0] | OTYPER(i) | OSPEED(i)<br>[1:0] |   | PUPD(i)<br>[1:0] |   | I/O configuration         |          |
|------------------|-----------|--------------------|---|------------------|---|---------------------------|----------|
| 01               | 0         | SPEED<br>[1:0]     |   | 0                | 0 | GP output                 | PP       |
|                  | 0         |                    |   | 0                | 1 | GP output                 | PP + PU  |
|                  | 0         |                    |   | 1                | 0 | GP output                 | PP + PD  |
|                  | 0         |                    |   | 1                | 1 | Reserved                  |          |
|                  | 1         |                    |   | 0                | 0 | GP output                 | OD       |
|                  | 1         |                    |   | 0                | 1 | GP output                 | OD + PU  |

|                  | x         | x                  | x | 1                | 1 | Reserved (input floating) |          |
| 11               | x         | x                  | x | 0                | 0 | Input/output              | Analog   |
|                  | x         | x                  | x | 0                | 1 | Reserved                  |          |
|                  | x         | x                  | x | 1                | 0 |                           |          |
|                  | x         | x                  | x | 1                | 1 |                           |          |

1. GP = general-purpose, PP = push-pull, PU = pull-up, PD = pull-down, OD = open-drain, AF = alternate function.

### 6.3.1 General-purpose I/O (GPIO)

During and just after reset, the alternate functions are not active and most of the I/O ports are configured in input floating mode.

The debug pins are in AF pull-up/pull-down after reset:

- PA15: JTDI in pull-up
- PA14: JTCK/SWCLK in pull-down
- PA13: JTMS/SWDAT in pull-up
- PB4: NJTRST in pull-up
- PB3: JTDO in floating state

When the pin is configured as output, the value written to the output data register (GPIOx\_ODR) is output on the I/O pin. It is possible to use the output driver in push-pull mode or open-drain mode (only the low level is driven, high level is HI-Z).

The input data register (GPIOx\_IDR) captures the data present on the I/O pin at every AHB clock cycle.

All GPIO pins have weak internal pull-up and pull-down resistors, which can be activated or not depending on the value in the GPIOx\_PUPDR register.

### 6.3.2 I/O pin alternate function multiplexer and mapping

The device I/O pins are connected to on-board peripherals/modules through a multiplexer that allows only one peripheral alternate function (AF) connected to an I/O pin at a time. In this way, there can be no conflict between peripherals available on the same I/O pin.

Each I/O pin has a multiplexer with up to sixteen alternate function inputs (AF0 to AF15) that can be configured through the GPIOx\_AFRL (for pin 0 to 7) and GPIOx\_AFRH (for pin 8 to 15) registers:

- After reset the multiplexer selection is alternate function 0 (AF0). The I/Os are configured in alternate function mode through GPIOx\_MODER register.
- The specific alternate function assignments for each pin are detailed in the device datasheet.
- Cortex-M7 with FPU EVENTOUT is mapped on AF15

In addition to this flexible I/O multiplexing architecture, each peripheral has alternate functions mapped onto different I/O pins to optimize the number of peripherals available in smaller packages.

To use an I/O in a given configuration, the user has to proceed as follows:

- **Debug function:** after each device reset these pins are assigned as alternate function pins immediately usable by the debugger host
- **System function:** MCOx pins have to be configured in alternate function mode.
- **GPIO:** configure the desired I/O as output, input or analog in the GPIOx\_MODER register.
- **Peripheral alternate function:**
  - Connect the I/O to the desired AFx in one of the GPIOx\_AFRL or GPIOx\_AFRH register.
  - Select the type, pull-up/pull-down and output speed via the GPIOx\_OTYPER, GPIOx\_PUPDR and GPIOx\_OSPEEDER registers, respectively.

- Configure the desired I/O as an alternate function in the GPIOx\_MODER register.
- **Additional functions:**
  - For the ADC and DAC, configure the desired I/O in analog mode in the GPIOx\_MODER register and configure the required function in the ADC and DAC registers. For the additional functions like RTC\_OUT, RTC\_TS, RTC\_TAMPx, WKUPx and oscillators, configure the required function in the related RTC, PWR and RCC registers. These functions have priority over the configuration in the standard GPIO registers. For details about I/O control by the RTC, refer to [Section 29.3: RTC functional description on page 915](#).
- **EVENTOUT**
  - Configure the I/O pin used to output the core EVENTOUT signal by connecting it to AF15.

Refer to the “Alternate function mapping” table in the device datasheet for the detailed mapping of the alternate function I/O pins.

### 6.3.3 I/O port control registers

Each of the GPIO ports has four 32-bit memory-mapped control registers (GPIOx\_MODER, GPIOx\_OTYPER, GPIOx\_OSPEEDR, GPIOx\_PUPDR) to configure up to 16 I/Os. The GPIOx\_MODER register is used to select the I/O mode (input, output, AF, analog). The GPIOx\_OTYPER and GPIOx\_OSPEEDR registers are used to select the output type (push-pull or open-drain) and speed. The GPIOx\_PUPDR register is used to select the pull-up/pull-down whatever the I/O direction.

### 6.3.4 I/O port data registers

Each GPIO has two 16-bit memory-mapped data registers: input and output data registers (GPIOx\_IDR and GPIOx\_ODR). GPIOx\_ODR stores the data to be output, it is read/write accessible. The data input through the I/O are stored into the input data register (GPIOx\_IDR), a read-only register.

See [Section 6.4.5: GPIO port input data register \(GPIOx\\_IDR\) \(x = A to K\)](#) and [Section 6.4.6: GPIO port output data register \(GPIOx\\_ODR\) \(x = A to K\)](#) for the register descriptions.

### 6.3.5 I/O data bitwise handling

The bit set reset register (GPIOx\_BSRR) is a 32-bit register which allows the application to set and reset each individual bit in the output data register (GPIOx\_ODR). The bit set reset register has twice the size of GPIOx\_ODR.

To each bit in GPIOx\_ODR, correspond two control bits in GPIOx\_BSRR: BS(i) and BR(i). When written to 1, bit BS(i) **sets** the corresponding ODR(i) bit. When written to 1, bit BR(i) **resets** the ODR(i) corresponding bit.

Writing any bit to 0 in GPIOx\_BSRR does not have any effect on the corresponding bit in GPIOx\_ODR. If there is an attempt to both set and reset a bit in GPIOx\_BSRR, the set action takes priority.

Using the GPIOx\_BSRR register to change the values of individual bits in GPIOx\_ODR is a “one-shot” effect that does not lock the GPIOx\_ODR bits. The GPIOx\_ODR bits can always be accessed directly. The GPIOx\_BSRR register provides a way of performing atomic bitwise handling.

There is no need for the software to disable interrupts when programming the GPIOx\_ODR at bit level: it is possible to modify one or more bits in a single atomic AHB write access.

### 6.3.6 GPIO locking mechanism

It is possible to freeze the GPIO control registers by applying a specific write sequence to the GPIOx\_LCKR register. The frozen registers are GPIOx\_MODER, GPIOx\_OTYPER, GPIOx\_OSPEEDR, GPIOx\_PUPDR, GPIOx\_AFRL and GPIOx\_AFRH.

To write the GPIOx\_LCKR register, a specific write / read sequence has to be applied. When the right LOCK sequence is applied to bit 16 in this register, the value of LCKR[15:0] is used to lock the configuration of the I/Os (during the write sequence the LCKR[15:0] value must be the same). When the LOCK sequence has been applied to a port bit, the value of the port bit can no longer be modified until the next MCU reset or peripheral reset. Each GPIOx\_LCKR bit freezes the corresponding bit in the control registers (GPIOx\_MODER, GPIOx\_OTYPER, GPIOx\_OSPEEDR, GPIOx\_PUPDR, GPIOx\_AFRL and GPIOx\_AFRH).

The LOCK sequence (refer to [Section 6.4.8: GPIO port configuration lock register \(GPIOx\\_LCKR\) \(x = A to K\)](#)) can only be performed using a word (32-bit long) access to the GPIOx\_LCKR register due to the fact that GPIOx\_LCKR bit 16 has to be set at the same time as the [15:0] bits.

For more details refer to LCKR register description in [Section 6.4.8: GPIO port configuration lock register \(GPIOx\\_LCKR\) \(x = A to K\)](#).

### 6.3.7 I/O alternate function input/output

Two registers are provided to select one of the alternate function inputs/outputs available for each I/O. With these registers, the user can connect an alternate function to some other pin as required by the application.

This means that a number of possible peripheral functions are multiplexed on each GPIO using the GPIOx\_AFRL and GPIOx\_AFRH alternate function registers. The application can thus select any one of the possible functions for each I/O. The AF selection signal being common to the alternate function input and alternate function output, a single channel is selected for the alternate function input/output of a given I/O.

To know which functions are multiplexed on each GPIO pin, refer to the device datasheet.

### 6.3.8 External interrupt/wakeup lines

All ports have external interrupt capability. To use external interrupt lines, the port must be configured in input mode. Refer to [Section 11: Extended interrupts and events controller \(EXTI\)](#) [Section 11.3: Wakeup event management](#).

### 6.3.9 Input configuration

When the I/O port is programmed as input:

- The output buffer is disabled
- The Schmitt trigger input is activated
- The pull-up and pull-down resistors are activated depending on the value in the GPIOx\_PUPDR register
- The data present on the I/O pin are sampled into the input data register every AHB clock cycle
- A read access to the input data register provides the I/O state

Figure 19 shows the input configuration of the I/O port bit.

**Figure 19. Input floating/pull up/pull down configurations**

### 6.3.10 Output configuration

When the I/O port is programmed as output:

- The output buffer is enabled:
  - Open drain mode: A “0” in the Output register activates the N-MOS whereas a “1” in the Output register leaves the port in Hi-Z (the P-MOS is never activated)
  - Push-pull mode: A “0” in the Output register activates the N-MOS whereas a “1” in the Output register activates the P-MOS
- The Schmitt trigger input is activated
- The pull-up and pull-down resistors are activated depending on the value in the GPIOx\_PUPDR register
- The data present on the I/O pin are sampled into the input data register every AHB clock cycle
- A read access to the input data register gets the I/O state
- A read access to the output data register gets the last written value

Figure 20 shows the output configuration of the I/O port bit.

Figure 20. Output configuration

### 6.3.11 Alternate function configuration

When the I/O port is programmed as alternate function:

- The output buffer can be configured in open-drain or push-pull mode
- The output buffer is driven by the signals coming from the peripheral (transmitter enable and data)
- The Schmitt trigger input is activated
- The weak pull-up and pull-down resistors are activated or not depending on the value in the GPIOx\_PUPDR register
- The data present on the I/O pin are sampled into the input data register every AHB clock cycle
- A read access to the input data register gets the I/O state

Figure 21 shows the Alternate function configuration of the I/O port bit.

Figure 21. Alternate function configuration

### 6.3.12 Analog configuration

When the I/O port is programmed as analog configuration:

- The output buffer is disabled
- The Schmitt trigger input is deactivated, providing zero consumption for every analog value of the I/O pin. The output of the Schmitt trigger is forced to a constant value (0).
- The weak pull-up and pull-down resistors are disabled by hardware
- Read access to the input data register gets the value “0”

Figure 22 shows the high-impedance, analog-input configuration of the I/O port bits.

**Figure 22. High impedance-analog configuration**

### 6.3.13 Using the HSE or LSE oscillator pins as GPIOs

When the HSE or LSE oscillator is switched OFF (default state after reset), the related oscillator pins can be used as normal GPIOs.

When the HSE or LSE oscillator is switched ON (by setting the HSEON or LSEON bit in the RCC\_CSR register) the oscillator takes control of its associated pins and the GPIO configuration of these pins has no effect.

When the oscillator is configured in a user external clock mode, only the OSC\_IN or OSC32\_IN pin is reserved for clock input and the OSC\_OUT or OSC32\_OUT pin can still be used as normal GPIO.

### 6.3.14 Using the GPIO pins in the backup supply domain

The PC13/PC14/PC15/PI8 GPIO functionality is lost when the core supply domain is powered off (when the device enters Standby mode). In this case, if their GPIO configuration is not bypassed by the RTC configuration, these pins are set in an analog input mode.

## 6.4 GPIO registers

This section gives a detailed description of the GPIO registers.

For a summary of register bits, register address offsets and reset values, refer to [Table 23](#).

The peripheral registers can be written in word, half word or byte mode.

### 6.4.1 GPIO port mode register (GPIOx\_MODER) (x =A to K)

Address offset: 0x00

Reset value:

- 0xA800 0000 for port A
- 0x0000 0280 for port B
- 0x0000 0000 for other ports

|              |    |              |    |              |    |              |    |              |    |              |    |             |    |             |    |
|--------------|----|--------------|----|--------------|----|--------------|----|--------------|----|--------------|----|-------------|----|-------------|----|

Bits 31:0 **MODER[15:0][1:0]**: Port x configuration I/O pin y (y = 15 to 0)

These bits are written by software to configure the I/O mode.

00: Input mode (reset state)

01: General purpose output mode

10: Alternate function mode

11: Analog mode

### 6.4.2 GPIO port output type register (GPIOx\_OTYPER) (x = A to K)

Address offset: 0x04

Reset value: 0x0000 0000

|      |      |      |      |      |      |     |     |     |     |     |     |     |     |     |     |
|------|------|------|------|------|------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| 31   | 30   | 29   | 28   | 27   | 26   | 25  | 24  | 23  | 22  | 21  | 20  | 19  | 18  | 17  | 16  |
| Res  | Res  | Res  | Res  | Res  | Res  | Res | Res | Res | Res | Res | Res | Res | Res | Res | Res |
|      |      |      |      |      |      |     |     |     |     |     |     |     |     |     |     |
| 15   | 14   | 13   | 12   | 11   | 10   | 9   | 8   | 7   | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
| OT15 | OT14 | OT13 | OT12 | OT11 | OT10 | OT9 | OT8 | OT7 | OT6 | OT5 | OT4 | OT3 | OT2 | OT1 | OT0 |
| rw   | rw   | rw   | rw   | rw   | rw   | rw  | rw  | rw  | rw  | rw  | rw  | rw  | rw  | rw  | rw  |

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **OT[15:0]**: Port x configuration I/O pin y (y = 15 to 0)

These bits are written by software to configure the I/O output type.

0: Output push-pull (reset state)

1: Output open-drain

### 6.4.3 GPIO port output speed register (GPIOx\_OSPEEDR) (x = A to K)

Address offset: 0x08

Reset value: 0x0C00 0000 (for port A)

Reset value: 0x0000 00C0 (for port B)

Reset value: 0x0000 0000 (for other ports)

|                    |     |                    |     |                    |     |                    |     |                    |     |                    |     |                   |     |                   |     |
|--------------------|-----|--------------------|-----|--------------------|-----|--------------------|-----|--------------------|-----|--------------------|-----|-------------------|-----|-------------------|-----|

| r/w                | r/w | r/w                | r/w | r/w                | r/w | r/w                | r/w | r/w                | r/w | r/w                | r/w | r/w               | r/w | r/w               | r/w |

Bits 31:0 **OSPEEDR[15:0][1:0]**: Port x configuration I/O pin y (y = 15 to 0)

These bits are written by software to configure the I/O output speed.

00: Low speed

01: Medium speed

10: High speed

11: Very high speed

*Note: Refer to the product datasheets for the values of OSPEEDRy bits versus V<sub>DD</sub> range and external load.*

### 6.4.4 GPIO port pull-up/pull-down register (GPIOx\_PUPDR) (x = A to K)

Address offset: 0x0C

Reset value: 0x6400 0000 (for port A)

Reset value: 0x0000 0100 (for port B)

Reset value: 0x0000 0000 (for other ports)

|              |     |              |     |              |     |              |     |              |     |              |     |             |     |             |     |
|--------------|-----|--------------|-----|--------------|-----|--------------|-----|--------------|-----|--------------|-----|-------------|-----|-------------|-----|

| r/w          | r/w | r/w          | r/w | r/w          | r/w | r/w          | r/w | r/w          | r/w | r/w          | r/w | r/w         | r/w | r/w         | r/w |

Bits 31:0 **PUPDR[15:0][1:0]**: Port x configuration I/O pin y (y = 15 to 0)

These bits are written by software to configure the I/O pull-up or pull-down

00: No pull-up, pull-down

01: Pull-up

10: Pull-down

11: Reserved

### 6.4.5 GPIO port input data register (GPIOx\_IDR) (x = A to K)

Address offset: 0x10

Reset value: 0x0000 XXXX

|       |       |       |       |       |       |      |      |      |      |      |      |      |      |      |      |
|-------|-------|-------|-------|-------|-------|------|------|------|------|------|------|------|------|------|------|
| 31    | 30    | 29    | 28    | 27    | 26    | 25   | 24   | 23   | 22   | 21   | 20   | 19   | 18   | 17   | 16   |
| Res.  | Res.  | Res.  | Res.  | Res.  | Res.  | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. |
|       |       |       |       |       |       |      |      |      |      |      |      |      |      |      |      |
| 15    | 14    | 13    | 12    | 11    | 10    | 9    | 8    | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0    |

| r     | r     | r     | r     | r     | r     | r    | r    | r    | r    | r    | r    | r    | r    | r    | r    |

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **IDR[15:0]**: Port x input data I/O pin y (y = 15 to 0)

These bits are read-only. They contain the input value of the corresponding I/O port.

### 6.4.6 GPIO port output data register (GPIOx\_ODR) (x = A to K)

Address offset: 0x14

Reset value: 0x0000 0000

|       |       |       |       |       |       |      |      |      |      |      |      |      |      |      |      |
|-------|-------|-------|-------|-------|-------|------|------|------|------|------|------|------|------|------|------|
| 31    | 30    | 29    | 28    | 27    | 26    | 25   | 24   | 23   | 22   | 21   | 20   | 19   | 18   | 17   | 16   |
| Res.  | Res.  | Res.  | Res.  | Res.  | Res.  | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. |
|       |       |       |       |       |       |      |      |      |      |      |      |      |      |      |      |
| 15    | 14    | 13    | 12    | 11    | 10    | 9    | 8    | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0    |
| ODR15 | ODR14 | ODR13 | ODR12 | ODR11 | ODR10 | ODR9 | ODR8 | ODR7 | ODR6 | ODR5 | ODR4 | ODR3 | ODR2 | ODR1 | ODR0 |
| rW    | rW    | rW    | rW    | rW    | rW    | rW   | rW   | rW   | rW   | rW   | rW   | rW   | rW   | rW   | rW   |

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **ODR[15:0]**: Port output data I/O pin y (y = 15 to 0)

These bits can be read and written by software.

*Note: For atomic bit set/reset, the ODR bits can be individually set and/or reset by writing to the GPIOx\_BSRR or GPIOx\_BRR registers (x = A..F).*

### 6.4.7 GPIO port bit set/reset register (GPIOx\_BSRR) (x = A to K)

Address offset: 0x18

Reset value: 0x0000 0000

|      |      |      |      |      |      |     |     |     |     |     |     |     |     |     |     |
|------|------|------|------|------|------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| 31   | 30   | 29   | 28   | 27   | 26   | 25  | 24  | 23  | 22  | 21  | 20  | 19  | 18  | 17  | 16  |
| BR15 | BR14 | BR13 | BR12 | BR11 | BR10 | BR9 | BR8 | BR7 | BR6 | BR5 | BR4 | BR3 | BR2 | BR1 | BR0 |
| w    | w    | w    | w    | w    | w    | w   | w   | w   | w   | w   | w   | w   | w   | w   | w   |
| 15   | 14   | 13   | 12   | 11   | 10   | 9   | 8   | 7   | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
| BS15 | BS14 | BS13 | BS12 | BS11 | BS10 | BS9 | BS8 | BS7 | BS6 | BS5 | BS4 | BS3 | BS2 | BS1 | BS0 |
| w    | w    | w    | w    | w    | w    | w   | w   | w   | w   | w   | w   | w   | w   | w   | w   |

Bits 31:16 **BR[15:0]**: Port x reset I/O pin y (y = 15 to 0)

These bits are write-only. A read to these bits returns the value 0x0000.

0: No action on the corresponding ODRx bit

1: Resets the corresponding ODRx bit

*Note: If both BSx and BRx are set, BSx has priority.*

Bits 15:0 **BS[15:0]**: Port x set I/O pin y (y = 15 to 0)

These bits are write-only. A read to these bits returns the value 0x0000.

0: No action on the corresponding ODRx bit

1: Sets the corresponding ODRx bit

#### 6.4.8 GPIO port configuration lock register (GPIOx\_LCKR) (x = A to K)

This register is used to lock the configuration of the port bits when a correct write sequence is applied to bit 16 (LCKK). The value of bits [15:0] is used to lock the configuration of the GPIO. During the write sequence, the value of LCKR[15:0] must not change. When the LOCK sequence has been applied on a port bit, the value of this port bit can no longer be modified until the next MCU reset or peripheral reset.

*Note: A specific write sequence is used to write to the GPIOx\_LCKR register. Only word access (32-bit long) is allowed during this locking sequence.*

Each lock bit freezes a specific configuration register (control and alternate function registers).

Address offset: 0x1C

Reset value: 0x0000 0000

|       |       |       |       |       |       |      |      |      |      |      |      |      |      |      |      |
|-------|-------|-------|-------|-------|-------|------|------|------|------|------|------|------|------|------|------|
| 31    | 30    | 29    | 28    | 27    | 26    | 25   | 24   | 23   | 22   | 21   | 20   | 19   | 18   | 17   | 16   |
| Res.  | Res.  | Res.  | Res.  | Res.  | Res.  | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | LCKK |
|       |       |       |       |       |       |      |      |      |      |      |      |      |      |      | rw   |
| 15    | 14    | 13    | 12    | 11    | 10    | 9    | 8    | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0    |
| LCK15 | LCK14 | LCK13 | LCK12 | LCK11 | LCK10 | LCK9 | LCK8 | LCK7 | LCK6 | LCK5 | LCK4 | LCK3 | LCK2 | LCK1 | LCK0 |
| rw    | rw    | rw    | rw    | rw    | rw    | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   |

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **LCKK**: Lock key

This bit can be read any time. It can only be modified using the lock key write sequence.

0: Port configuration lock key not active

1: Port configuration lock key active. The GPIOx\_LCKR register is locked until the next MCU reset or peripheral reset.

LOCK key write sequence:

WR LCKR[16] = '1' + LCKR[15:0]

WR LCKR[16] = '0' + LCKR[15:0]

WR LCKR[16] = '1' + LCKR[15:0]

RD LCKR

RD LCKR[16] = '1' (this read operation is optional but it confirms that the lock is active)

*Note: During the LOCK key write sequence, the value of LCK[15:0] must not change.*

*Any error in the lock sequence aborts the lock.*

*After the first lock sequence on any bit of the port, any read access on the LCKK bit will return '1' until the next MCU reset or peripheral reset.*

Bits 15:0 **LCK[15:0]**: Port x lock I/O pin y (y = 15 to 0)

These bits are read/write but can only be written when the LCKK bit is '0'.

0: Port configuration not locked

1: Port configuration locked

#### 6.4.9 GPIO alternate function low register (GPIOx\_AFRL) (x = A to K)

Address offset: 0x20

Reset value: 0x0000 0000

|           |    |    |    |           |    |    |    |           |    |    |    |           |    |    |    |
|-----------|----|----|----|-----------|----|----|----|-----------|----|----|----|-----------|----|----|----|
| 31        | 30 | 29 | 28 | 27        | 26 | 25 | 24 | 23        | 22 | 21 | 20 | 19        | 18 | 17 | 16 |

### 6.4.11 GPIO register map

The following table gives the GPIO register map and reset values.

**Table 23. GPIO register map and reset values**

| Offset | Register name                     | 31             | 30   | 29             | 28   | 27             | 26   | 25             | 24   | 23             | 22   | 21             | 20   | 19            | 18   | 17            | 16   | 15            | 14   | 13            | 12   | 11            | 10   | 9             | 8   | 7             | 6   | 5             | 4   | 3             | 2   | 1             | 0   |

Refer to [Section 2.2](#) for the register boundary addresses.

## 7 System configuration controller (SYSCFG)

The system configuration controller is mainly used to:

- Remap the memory areas
- Select the Ethernet PHY interface
- Manage the external interrupt line connection to the GPIOs.

### 7.1 I/O compensation cell

By default the I/O compensation cell is not used. However when the I/O output buffer speed is configured in 50 MHz or 100 MHz mode, it is recommended to use the compensation cell for slew rate control on I/O  $t_{f(IO)out}/t_{r(IO)out}$  commutation to reduce the I/O noise on power supply.

When the compensation cell is enabled, a READY flag is set to indicate that the compensation cell is ready and can be used. The I/O compensation cell can be used only when the supply voltage ranges from 2.4 to 3.6 V.

### 7.2 SYSCFG registers

#### 7.2.1 SYSCFG memory remap register (SYSCFG\_MEMRMP)

This register is used for specific configurations on memory mapping:

- 1bit is used to indicate which option bytes BOOT\_ADD0 or BOOT\_ADD1 defines the boot memory base address.
- Other bits are used to swap FMC SDRAM Banks with FMC NOR/PSRAM bank

Address offset: 0x00

Reset value: 0x0000 0000

| 31   | 30   | 29   | 28   | 27           | 26   | 25   | 24   | 23   | 22   | 21   | 20   | 19   | 18   | 17   | 16       |

Bits 31:12 Reserved, must be kept at reset value.

Bits 11:10 **SWP\_FMC[1:0]**: FMC memory mapping swap

Set and cleared by software. These bits are used to swap the FMC SDRAM banks and FMC NOR/PSRAM in order to enable the code execution from SDRAM Banks without modifying the default MPU attribute

00: No FMC memory mapping swapping

SDRAM bank1 and Bank2 are mapped at 0xC000 0000 and 0xD000 0000 respectively (default mapping)

NOR/RAM is accessible @ 0x60000000 (default mapping)

01: NOR/RAM and SDRAM memory mapping swapped,

SDRAM bank1 and bank2 are mapped at 0x6000 0000 and 0x7000 0000, respectively

NOR/PSRAM bank is mapped at 0xC000 0000

10: Reserved

11: Reserved

Bits 9:1 Reserved, must be kept at reset value.

Bit 0 **MEM\_BOOT**: Memory boot mapping

This bit indicates which option bytes BOOT\_ADD0 or BOOT\_ADD1 defines the boot memory base address.

0: Boot memory base address is defined by BOOT\_ADD0 option byte (Factory Reset value: TCM-FLASH mapped at 0x00200000).

1: Boot memory base address is defined by BOOT\_ADD1 option byte (Factory Reset value: System memory mapped at 0x001 0000).

*Note: Refer to section 2.3: Memory map for details about the boot memory base address selection.*

## 7.2.2 SYSCFG peripheral mode configuration register (SYSCFG\_PMC)

Address offset: 0x04

Reset value: 0x0000 0000

|      |      |      |      |      |      |      |      |              |      |      |      |      |         |      |      |

Bits 31:24 Reserved, must be kept at reset value.

Bit 23 **MII\_RMII\_SEL**: Ethernet PHY interface selection

Set and Cleared by software. These bits control the PHY interface for the Ethernet MAC.

0: MII interface is selected

1: RMII PHY interface is selected

*Note: This configuration must be done while the MAC is under reset and before enabling the MAC clocks.*

Bits 22:19 Reserved, must be kept at reset value.

Bits 18:16 **ADCxDC2**:

0: No effect.

1: Refer to AN4073 on how to use this bit.

*Note: These bits can be set only if the following conditions are met:*

- ADC clock higher or equal to 30 MHz.
- Only one ADCxDC2 bit must be selected if ADC conversions do not start at the same time and the sampling times differ.
- These bits must not be set when the ADCDC1 bit is set in PWR\_CR register.

Bits 15:0 Reserved, must be kept at reset value.

### 7.2.3 SYSCFG external interrupt configuration register 1 (SYSCFG\_EXTICR1)

Address offset: 0x08

Reset value: 0x0000 0000

Refer to [Section 2.2.2 on page 69](#) for the register boundary addresses.

## 8 Direct memory access controller (DMA)

### 8.1 DMA introduction

Direct memory access (DMA) is used in order to provide high-speed data transfer between peripherals and memory and between memory and memory. Data can be quickly moved by DMA without any CPU action. This keeps CPU resources free for other operations.

The DMA controller combines a powerful dual AHB master bus architecture with independent FIFO to optimize the bandwidth of the system, based on a complex bus matrix architecture.

The two DMA controllers (DMA1 and DMA2) have 16 streams in total (8 for each controller), each dedicated to managing memory access requests from one or more peripherals.

Each stream can have up to 8 channels (requests) in total.

Each DMA controller has an arbiter for handling the priority between DMA requests.

### 8.2 DMA main features

The main DMA features are:

- Dual AHB master bus architecture, one dedicated to memory accesses and one dedicated to peripheral accesses
- AHB slave programming interface supporting only 32-bit accesses
- 8 streams for each DMA controller, up to 8 channels (requests) per stream
- Four-word depth 32 first-in, first-out memory buffers (FIFOs) per stream, that can be used in FIFO mode or direct mode:
  - FIFO mode: with threshold level software selectable between 1/4, 1/2 or 3/4 of the FIFO size
  - Direct mode: each DMA request immediately initiates a transfer from/to the memory. When it is configured in direct mode (FIFO disabled), to transfer data in memory-to-peripheral mode, the DMA preloads only one data from the memory to the internal FIFO to ensure an immediate data transfer as soon as a DMA request is triggered by a peripheral.
- Each stream can be configured to be:
  - a regular channel that supports peripheral-to-memory, memory-to-peripheral and memory-to-memory transfers
  - a double buffer channel that also supports double buffering on the memory side
- Priorities between DMA stream requests are software-programmable (4 levels consisting of very high, high, medium, low) or hardware in case of equality (for example, request 0 has priority over request 1)
- Each stream also supports software trigger for memory-to-memory transfers (only available for the DMA2 controller)
- Each stream request can be selected among up to 8 possible channel requests. This selection is software-configurable and allows several peripherals to initiate DMA requests
- The number of data items to be transferred can be managed either by the DMA controller or by the peripheral:

- DMA flow controller: the number of data items to be transferred is software-programmable from 1 to 65535
- Peripheral flow controller: the number of data items to be transferred is unknown and controlled by the source or the destination peripheral that signals the end of the transfer by hardware
- Independent source and destination transfer width (byte, half-word, word): when the data widths of the source and destination are not equal, the DMA automatically packs/unpacks the necessary transfers to optimize the bandwidth. This feature is only available in FIFO mode
- Incrementing or non-incrementing addressing for source and destination
- Supports incremental burst transfers of 4, 8 or 16 beats. The size of the burst is software-configurable, usually equal to half the FIFO size of the peripheral
- Each stream supports circular buffer management
- 5 event flags (DMA half transfer, DMA transfer complete, DMA transfer error, DMA FIFO error, direct mode error) logically ORed together in a single interrupt request for each stream

## 8.3 DMA functional description

### 8.3.1 DMA block diagram

Figure 23 shows the block diagram of a DMA.

Figure 23. DMA block diagram

### 8.3.2 DMA overview

The DMA controller performs direct memory transfer: as an AHB master, it can take the control of the AHB bus matrix to initiate AHB transactions.

It carries out the following transactions:

- peripheral-to-memory
- memory-to-peripheral
- memory-to-memory

The DMA controller provides two AHB master ports: the AHB memory port, intended to be connected to memories and the AHB peripheral port, intended to be connected to peripherals. However, to allow memory-to-memory transfers, the AHB peripheral port must also have access to the memories.

The AHB slave port is used to program the DMA controller (it supports only 32-bit accesses).

**Note:** The DMA1 controller AHB peripheral port is not connected to the bus matrix like in the case of the DMA2 controller, thus only DMA2 streams are able to perform memory-to-memory transfers.

See [Figure 1](#) for the implementation of the system of two DMA controllers.

### 8.3.3 DMA transactions

A DMA transaction consists of a sequence of a given number of data transfers. The number of data items to be transferred and their width (8-bit, 16-bit or 32-bit) are software-programmable.

Each DMA transfer consists of three operations:

- a loading from the peripheral data register or a location in memory, addressed through the DMA\_SxPAR or DMA\_SxM0AR register
- a storage of the data loaded to the peripheral data register or a location in memory addressed through the DMA\_SxPAR or DMA\_SxM0AR register
- a post-decrement of the DMA\_SxNDTR register, containing the number of transactions that still have to be performed

After an event, the peripheral sends a request signal to the DMA controller. The DMA controller serves the request depending on the channel priorities. As soon as the DMA controller accesses the peripheral, an Acknowledge signal is sent to the peripheral by the DMA controller. The peripheral releases its request as soon as it gets the Acknowledge signal from the DMA controller. Once the request has been deasserted by the peripheral, the DMA controller releases the Acknowledge signal. If there are more requests, the peripheral can initiate the next transaction.

### 8.3.4 Channel selection

Each stream is associated with a DMA request that can be selected out of 816 possible channel requests. The selection is controlled by the CHSEL[23:0] bits in the DMA\_SxCR register.

**Figure 24. Channel selection**

The 8 requests from the peripherals (such as TIM, ADC, SPI, I2C) are independently connected to each channel and their connection depends on the product implementation.

[Table 25](#) and [Table 26](#) give examples of DMA request mappings.

**Table 25. DMA1 request mapping**

| Peripheral requests | Stream 0            | Stream 1              | Stream 2            | Stream 3              | Stream 4              | Stream 5  | Stream 6             | Stream 7            |
|---------------------|---------------------|-----------------------|---------------------|-----------------------|-----------------------|-----------|----------------------|---------------------|
| Channel 0           | SPI3_RX             | SPDIFRX_DT            | SPI3_RX             | SPI2_RX               | SPI2_TX               | SPI3_TX   | SPDIFRX_CS           | SPI3_TX             |
| Channel 1           | I2C1_RX             | I2C3_RX               | TIM7_UP             | -                     | TIM7_UP               | I2C1_RX   | I2C1_TX              | I2C1_TX             |
| Channel 2           | TIM4_CH1            | -                     | I2C4_RX             | TIM4_CH2              | -                     | I2C4_RX   | TIM4_UP              | TIM4_CH3            |
| Channel 3           | -                   | TIM2_UP<br>TIM2_CH3   | I2C3_RX             | -                     | I2C3_TX               | TIM2_CH1  | TIM2_CH2<br>TIM2_CH4 | TIM2_UP<br>TIM2_CH4 |
| Channel 4           | UART5_RX            | USART3_RX             | UART4_RX            | USART3_TX             | UART4_TX              | USART2_RX | USART2_TX            | UART5_TX            |
| Channel 5           | UART8_TX            | UART7_TX              | TIM3_CH4<br>TIM3_UP | UART7_RX              | TIM3_CH1<br>TIM3_TRIG | TIM3_CH2  | UART8_RX             | TIM3_CH3            |
| Channel 6           | TIM5_CH3<br>TIM5_UP | TIM5_CH4<br>TIM5_TRIG | TIM5_CH1            | TIM5_CH4<br>TIM5_TRIG | TIM5_CH2              | -         | TIM5_UP              | -                   |
| Channel 7           |                     | TIM6_UP               | I2C2_RX             | I2C2_RX               | USART3_TX             | DAC1      | DAC2                 | I2C2_TX             |

**Table 26. DMA2 request mapping**

| Peripheral requests | Stream 0  | Stream 1  | Stream 2                         | Stream 3 | Stream 4                          | Stream 5  | Stream 6                         | Stream 7                          |
|---------------------|-----------|-----------|----------------------------------|----------|-----------------------------------|-----------|----------------------------------|-----------------------------------|

| Channel 7           | -         | TIM8_UP   | TIM8_CH1                         | TIM8_CH2 | TIM8_CH3                          | SPI5_RX   | SPI5_TX                          | TIM8_CH4<br>TIM8_TRIG<br>TIM8_COM |

### 8.3.5 Arbiter

An arbiter manages the 8 DMA stream requests based on their priority for each of the two AHB master ports (memory and peripheral ports) and launches the peripheral/memory access sequences.

Priorities are managed in two stages:

- Software: each stream priority can be configured in the DMA\_SxCR register. There are four levels:
  - Very high priority
  - High priority
  - Medium priority
  - Low priority
- Hardware: If two requests have the same software priority level, the stream with the lower number takes priority over the stream with the higher number. For example, stream 2 takes priority over stream 4.

### 8.3.6 DMA streams

Each of the 8 DMA controller streams provides a unidirectional transfer link between a source and a destination.

Each stream can be configured to perform:

- Regular type transactions: memory-to-peripherals, peripherals-to-memory or memory-to-memory transfers
- Double-buffer type transactions: double buffer transfers using two memory pointers for the memory (while the DMA is reading/writing from/to a buffer, the application can write/read to/from the other buffer).

The amount of data to be transferred (up to 65535) is programmable and related to the source width of the peripheral that requests the DMA transfer connected to the peripheral AHB port. The register that contains the amount of data items to be transferred is decremented after each transaction.

### 8.3.7 Source, destination and transfer modes

Both source and destination transfers can address peripherals and memories in the entire 4 Gbytes area, at addresses comprised between 0x0000 0000 and 0xFFFF FFFF.

The direction is configured using the DIR[1:0] bits in the DMA\_SxCR register and offers three possibilities: memory-to-peripheral, peripheral-to-memory or memory-to-memory transfers. [Table 27](#) describes the corresponding source and destination addresses.

**Table 27. Source and destination address**

| Bits DIR[1:0] of the DMA_SxCR register | Direction            | Source address | Destination address |
|----------------------------------------|----------------------|----------------|---------------------|
| 00                                     | Peripheral-to-memory | DMA_SxPAR      | DMA_SxM0AR          |
| 01                                     | Memory-to-peripheral | DMA_SxM0AR     | DMA_SxPAR           |
| 10                                     | Memory-to-memory     | DMA_SxPAR      | DMA_SxM0AR          |
| 11                                     | Reserved             | -              | -                   |

When the data width (programmed in the PSIZE or MSIZE bits in the DMA\_SxCR register) is a half-word or a word, respectively, the peripheral or memory address written into the DMA\_SxPAR or DMA\_SxM0AR/M1AR registers has to be aligned on a word or half-word address boundary, respectively.

### Peripheral-to-memory mode

Figure 25 describes this mode.

When this mode is enabled (by setting the bit EN in the DMA\_SxCR register), each time a peripheral request occurs, the stream initiates a transfer from the source to fill the FIFO.

When the threshold level of the FIFO is reached, the contents of the FIFO are drained and stored into the destination.

The transfer stops once the DMA\_SxNDTR register reaches zero, when the peripheral requests the end of transfers (in case of a peripheral flow controller) or when the EN bit in the DMA\_SxCR register is cleared by software.

In direct mode (when the DMDIS value in the DMA\_SxFCR register is '0'), the threshold level of the FIFO is not used: after each single data transfer from the peripheral to the FIFO, the corresponding data are immediately drained and stored into the destination.

The stream has access to the AHB source or destination port only if the arbitration of the corresponding stream is won. This arbitration is performed using the priority defined for each stream using the PL[1:0] bits in the DMA\_SxCR register.

**Figure 25. Peripheral-to-memory mode**

1. For double-buffer mode.

### Memory-to-peripheral mode

Figure 26 describes this mode.

When this mode is enabled (by setting the EN bit in the DMA\_SxCR register), the stream immediately initiates transfers from the source to entirely fill the FIFO.

Each time a peripheral request occurs, the contents of the FIFO are drained and stored into the destination. When the level of the FIFO is lower than or equal to the predefined threshold level, the FIFO is fully reloaded with data from the memory.

The transfer stops once the DMA\_SxNDTR register reaches zero, when the peripheral requests the end of transfers (in case of a peripheral flow controller) or when the EN bit in the DMA\_SxCR register is cleared by software.

In direct mode (when the DMDIS value in the DMA\_SxFCR register is '0'), the threshold level of the FIFO is not used. Once the stream is enabled, the DMA preloads the first data to transfer into an internal FIFO. As soon as the peripheral requests a data transfer, the DMA transfers the preloaded value into the configured destination. It then reloads again the empty internal FIFO with the next data to be transfer. The preloaded data size corresponds to the value of the PSIZE bitfield in the DMA\_SxCR register.

The stream has access to the AHB source or destination port only if the arbitration of the corresponding stream is won. This arbitration is performed using the priority defined for each stream using the PL[1:0] bits in the DMA\_SxCR register.

**Figure 26. Memory-to-peripheral mode**

1. For double-buffer mode.

### Memory-to-memory mode

The DMA channels can also work without being triggered by a request from a peripheral. This is the memory-to-memory mode, described in [Figure 27](#).

When the stream is enabled by setting the Enable bit (EN) in the DMA\_SxCR register, the stream immediately starts to fill the FIFO up to the threshold level. When the threshold level is reached, the FIFO contents are drained and stored into the destination.

The transfer stops once the DMA\_SxNDTR register reaches zero or when the EN bit in the DMA\_SxCR register is cleared by software.

The stream has access to the AHB source or destination port only if the arbitration of the corresponding stream is won. This arbitration is performed using the priority defined for each stream using the PL[1:0] bits in the DMA\_SxCR register.

**Note:** When memory-to-memory mode is used, the circular and direct modes are not allowed. Only the DMA2 controller is able to perform memory-to-memory transfers.

**Figure 27. Memory-to-memory mode**

1. For double-buffer mode.

### 8.3.8 Pointer incrementation

Peripheral and memory pointers can optionally be automatically post-incremented or kept constant after each transfer depending on the PINC and MINC bits in the DMA\_SxCR register.

Disabling the increment mode is useful when the peripheral source or destination data is accessed through a single register.

If the increment mode is enabled, the address of the next transfer is the address of the previous one incremented by 1 (for bytes), 2 (for half-words) or 4 (for words) depending on the data width programmed in the PSIZE or MSIZE bits in the DMA\_SxCR register.

In order to optimize the packing operation, it is possible to fix the increment offset size for the peripheral address whatever the size of the data transferred on the AHB peripheral port. The PINCOS bit in the DMA\_SxCR register is used to align the increment offset size with the data size on the peripheral AHB port, or on a 32-bit address (the address is then incremented by 4). The PINCOS bit has an impact on the AHB peripheral port only.

If the PINCOS bit is set, the address of the following transfer is the address of the previous one incremented by 4 (automatically aligned on a 32-bit address), whatever the PSIZE value. The AHB memory port, however, is not impacted by this operation.

### 8.3.9 Circular mode

The circular mode is available to handle circular buffers and continuous data flows (e.g. ADC scan mode). This feature can be enabled using the CIRC bit in the DMA\_SxCR register.

When the circular mode is activated, the number of data items to be transferred is automatically reloaded with the initial value programmed during the stream configuration phase, and the DMA requests continue to be served.

**Note:** *In the circular mode, it is mandatory to respect the following rule in case of a burst mode configured for memory:*

$DMA\_SxNDTR = \text{Multiple of } ((Mburst\ beat) \times (Msize)/(Psize)), \text{ where:}$

- $(Mburst\ beat) = 4, 8 \text{ or } 16$  (depending on the MBURST bits in the DMA\_SxCR register)
- $((Msize)/(Psize)) = 1, 2, 4, 1/2 \text{ or } 1/4$  (Msize and Psize represent the MSIZE and PSIZE bits in the DMA\_SxCR register. They are byte dependent)
- $DMA\_SxNDTR = \text{Number of data items to transfer on the AHB peripheral port}$

For example: Mburst beat = 8 (INCR8), MSIZE = '00' (byte) and PSIZE = '01' (half-word), in this case: DMA\_SxNDTR must be a multiple of  $(8 \times 1/2 = 4)$ .

*If this formula is not respected, the DMA behavior and data integrity are not guaranteed.*

*NDTR must also be a multiple of the Peripheral burst size multiplied by the peripheral data size, otherwise this could result in a bad DMA behavior.*

### 8.3.10 Double-buffer mode

This mode is available for all the DMA1 and DMA2 streams.

The double-buffer mode is enabled by setting the DBM bit in the DMA\_SxCR register.

A double-buffer stream works as a regular (single buffer) stream with the difference that it has two memory pointers. When the double-buffer mode is enabled, the circular mode is automatically enabled (CIRC bit in DMA\_SxCR is not relevant) and at each end of transaction, the memory pointers are swapped.

In this mode, the DMA controller swaps from one memory target to another at each end of transaction. This allows the software to process one memory area while the second memory area is being filled/used by the DMA transfer. The double-buffer stream can work in both directions (the memory can be either the source or the destination) as described in [Table 28: Source and destination address registers in double-buffer mode \(DBM = 1\)](#).

**Note:** *In double-buffer mode, it is possible to update the base address for the AHB memory port on-the-fly (DMA\_SxM0AR or DMA\_SxM1AR) when the stream is enabled, by respecting the following conditions:*

- *When the CT bit is '0' in the DMA\_SxCR register, the DMA\_SxM1AR register can be written. Attempting to write to this register while CT = '1' sets an error flag (TEIF) and the stream is automatically disabled.*
- *When the CT bit is '1' in the DMA\_SxCR register, the DMA\_SxM0AR register can be written. Attempting to write to this register while CT = '0', sets an error flag (TEIF) and the stream is automatically disabled.*

*To avoid any error condition, it is advised to change the base address as soon as the TCIF flag is asserted because, at this point, the targeted memory must have changed from*

memory 0 to 1 (or from 1 to 0) depending on the value of CT in the DMA\_SxCR register in accordance with one of the two above conditions.

For all the other modes (except the double-buffer mode), the memory address registers are write-protected as soon as the stream is enabled.

**Table 28. Source and destination address registers in double-buffer mode (DBM = 1)**

| Bits DIR[1:0] of the DMA_SxCR register | Direction                  | Source address          | Destination address     |
|----------------------------------------|----------------------------|-------------------------|-------------------------|
| 00                                     | Peripheral-to-memory       | DMA_SxPAR               | DMA_SxM0AR / DMA_SxM1AR |
| 01                                     | Memory-to-peripheral       | DMA_SxM0AR / DMA_SxM1AR | DMA_SxPAR               |
| 10                                     | Not allowed <sup>(1)</sup> |                         |                         |
| 11                                     | Reserved                   | -                       | -                       |

1. When the double-buffer mode is enabled, the circular mode is automatically enabled. Since the memory-to-memory mode is not compatible with the circular mode, when the double-buffer mode is enabled, it is not allowed to configure the memory-to-memory mode.

### 8.3.11 Programmable data width, packing/unpacking, endianness

The number of data items to be transferred has to be programmed into DMA\_SxNDTR (number of data items to transfer bit, NDT) before enabling the stream (except when the flow controller is the peripheral, PFCTRL bit in DMA\_SxCR is set).

When using the internal FIFO, the data widths of the source and destination data are programmable through the PSIZE and MSIZE bits in the DMA\_SxCR register (can be 8-, 16- or 32-bit).

When PSIZE and MSIZE are not equal:

- The data width of the number of data items to transfer, configured in the DMA\_SxNDTR register is equal to the width of the peripheral bus (configured by the PSIZE bits in the DMA\_SxCR register). For instance, in case of peripheral-to-memory, memory-to-peripheral or memory-to-memory transfers and if the PSIZE[1:0] bits are configured for half-word, the number of bytes to be transferred is equal to  $2 \times \text{NDT}$ .
- The DMA controller only copes with little-endian addressing for both source and destination. This is described in [Table 29: Packing/unpacking and endian behavior \(bit PINC = MINC = 1\)](#).

This packing/unpacking procedure may present a risk of data corruption when the operation is interrupted before the data are completely packed/unpacked. So, to ensure data coherence, the stream may be configured to generate burst transfers: in this case, each group of transfers belonging to a burst are indivisible (refer to [Section 8.3.12: Single and burst transfers](#)).

In direct mode (DMDIS = 0 in the DMA\_SxFCR register), the packing/unpacking of data is not possible. In this case, it is not allowed to have different source and destination transfer data widths: both are equal and defined by the PSIZE bits in the DMA\_SxCR register. MSIZE bits are not relevant.

Table 29. Packing/unpacking and endian behavior (bit PINC = MINC = 1)

| AHB memory port width | AHB peripheral port width | Number of data items to transfer (NDT) | Memory transfer number | Memory port address / byte lane | Peripheral transfer number | Peripheral port address / byte lane |                         |
|-----------------------|---------------------------|----------------------------------------|------------------------|---------------------------------|----------------------------|-------------------------------------|-------------------------|
|                       |                           |                                        |                        |                                 |                            | PINCOS = 1                          | PINCOS = 0              |
| 8                     | 8                         | 4                                      | 1                      | 0x0 / B0[7:0]                   | 1                          | 0x0 / B0[7:0]                       | 0x0 / B0[7:0]           |
|                       |                           |                                        | 2                      | 0x1 / B1[7:0]                   | 2                          | 0x4 / B1[7:0]                       | 0x1 / B1[7:0]           |

| 32                    | 32                        | 1                                      | 1                      | 0x0 / B3 B2 B1 B0 [31:0]        | 1                          | 0x0 / B3 B2 B1 B0 [31:0]            | 0x0 / B3 B2 B1 B0[31:0] |

**Note:** Peripheral port may be the source or the destination (it could also be the memory source in the case of memory-to-memory transfer).

PSIZE, MSIZE and NDT[15:0] have to be configured so as to ensure that the last transfer will not be incomplete. This can occur when the data width of the peripheral port (PSIZE bits) is lower than the data width of the memory port (MSIZE bits). This constraint is summarized in [Table 30](#).

Table 30. Restriction on NDT versus PSIZE and MSIZE

| PSIZE[1:0] of DMA_SxCR | MSIZE[1:0] of DMA_SxCR | NDT[15:0] of DMA_SxNDTR |
|------------------------|------------------------|-------------------------|
| 00 (8-bit)             | 01 (16-bit)            | must be a multiple of 2 |
| 00 (8-bit)             | 10 (32-bit)            | must be a multiple of 4 |
| 01 (16-bit)            | 10 (32-bit)            | must be a multiple of 2 |

### 8.3.12 Single and burst transfers

The DMA controller can generate single transfers or incremental burst transfers of 4, 8 or 16 beats.

The size of the burst is configured by software independently for the two AHB ports by using the MBURST[1:0] and PBURST[1:0] bits in the DMA\_SxCR register.

The burst size indicates the number of beats in the burst, not the number of bytes transferred.

To ensure data coherence, each group of transfers that form a burst are indivisible: AHB transfers are locked and the arbiter of the AHB bus matrix does not degrant the DMA master during the sequence of the burst transfer.

Depending on the single or burst configuration, each DMA request initiates a different number of transfers on the AHB peripheral port:

- When the AHB peripheral port is configured for single transfers, each DMA request generates a data transfer of a byte, half-word or word depending on the PSIZE[1:0] bits in the DMA\_SxCR register
- When the AHB peripheral port is configured for burst transfers, each DMA request generates 4,8 or 16 beats of byte, half word or word transfers depending on the PBURST[1:0] and PSIZE[1:0] bits in the DMA\_SxCR register.

The same as above has to be considered for the AHB memory port considering the MBURST and MSIZE bits.

In direct mode, the stream can only generate single transfers and the MBURST[1:0] and PBURST[1:0] bits are forced by hardware.

The address pointers (DMA\_SxPAR or DMA\_SxM0AR registers) must be chosen so as to ensure that all transfers within a burst block are aligned on the address boundary equal to the size of the transfer.

The burst configuration has to be selected in order to respect the AHB protocol, where bursts **must not** cross the 1 Kbyte address boundary because the minimum address space that can be allocated to a single slave is 1 Kbyte. This means that the 1 Kbyte address boundary **must not** be crossed by a burst block transfer, otherwise an AHB error is generated, that is not reported by the DMA registers.

### 8.3.13 FIFO

#### FIFO structure

The FIFO is used to temporarily store data coming from the source before transmitting them to the destination.

Each stream has an independent 4-word FIFO and the threshold level is software-configurable between 1/4, 1/2, 3/4 or full.

To enable the use of the FIFO threshold level, the direct mode must be disabled by setting the DMDIS bit in the DMA\_SxFCR register.

The structure of the FIFO differs depending on the source and destination data widths, and is described in [Figure 28: FIFO structure](#).

Figure 28. FIFO structure

### FIFO threshold and burst configuration

Caution is required when choosing the FIFO threshold (bits FTH[1:0] of the DMA\_SxFCR register) and the size of the memory burst (MBURST[1:0] of the DMA\_SxCR register): The content pointed by the FIFO threshold must exactly match an integer number of memory burst transfers. If this is not in the case, a FIFO error (flag FEIFx of the DMA\_HISR or DMA\_LISR register) is generated when the stream is enabled, then the stream is automatically disabled. The allowed and forbidden configurations are described in [Table 31](#). The forbidden configurations are highlighted in gray in the table.

Table 31. FIFO threshold configurations

| MSIZE | FIFO level | MBURST = INCR4      | MBURST = INCR8      | MBURST = INCR16     |
|-------|------------|---------------------|---------------------|---------------------|
| Byte  | 1/4        | 1 burst of 4 beats  | Forbidden           | Forbidden           |
|       | 1/2        | 2 bursts of 4 beats | 1 burst of 8 beats  |                     |
|       | 3/4        | 3 bursts of 4 beats | Forbidden           |                     |
|       | Full       | 4 bursts of 4 beats | 2 bursts of 8 beats | 1 burst of 16 beats |

Table 31. FIFO threshold configurations (continued)

| MSIZE     | FIFO level | MBURST = INCR4      | MBURST = INCR8     | MBURST = INCR16 |
|-----------|------------|---------------------|--------------------|-----------------|
| Half-word | 1/4        | Forbidden           | Forbidden          | Forbidden       |
|           | 1/2        | 1 burst of 4 beats  |                    |                 |
|           | 3/4        | Forbidden           |                    |                 |
|           | Full       | 2 bursts of 4 beats | 1 burst of 8 beats |                 |
| Word      | 1/4        | Forbidden           | Forbidden          |                 |
|           | 1/2        |                     |                    |                 |
|           | 3/4        |                     |                    |                 |
|           | Full       | 1 burst of 4 beats  |                    |                 |

In all cases, the burst size multiplied by the data size must not exceed the FIFO size (data size can be: 1 (byte), 2 (half-word) or 4 (word)).

Incomplete burst transfer at the end of a DMA transfer may happen if one of the following conditions occurs:

- For the AHB peripheral port configuration: the total number of data items (set in the DMA\_SxNDTR register) is not a multiple of the burst size multiplied by the data size.
- For the AHB memory port configuration: the number of remaining data items in the FIFO to be transferred to the memory is not a multiple of the burst size multiplied by the data size.

In such cases, the remaining data to be transferred is managed in single mode by the DMA, even if a burst transaction is requested during the DMA stream configuration.

**Note:** *When burst transfers are requested on the peripheral AHB port and the FIFO is used (DMDIS = 1 in the DMA\_SxCR register), it is mandatory to respect the following rule to avoid permanent underrun or overrun conditions, depending on the DMA stream direction:*

*If  $(PBURST \times PSIZE) = FIFO\_SIZE$  (4 words),  $FIFO\_Threshold = 3/4$  is forbidden with  $PSIZE = 1, 2$  or  $4$  and  $PBURST = 4, 8$  or  $16$ .*

*This rule ensures that enough FIFO space at a time is free to serve the request from the peripheral.*

### FIFO flush

The FIFO can be flushed when the stream is disabled by resetting the EN bit in the DMA\_SxCR register and when the stream is configured to manage peripheral-to-memory or memory-to-memory transfers. If some data are still present in the FIFO when the stream is disabled, the DMA controller continues transferring the remaining data to the destination (even though stream is effectively disabled). When this flush is completed, the transfer complete status bit (TCIFx) in the DMA\_LISR or DMA\_HISR register is set.

The remaining data counter DMA\_SxNDTR keeps the value in this case to indicate how many data items are currently available in the destination memory.

Note that during the FIFO flush operation, if the number of remaining data items in the FIFO to be transferred to memory (in bytes) is less than the memory data width (for example 2 bytes in FIFO while MSIZE is configured to word), data is sent with the data width set in the MSIZE bit in the DMA\_SxCR register. This means that memory is written with an undesired

value. The software may read the DMA\_SxNDTR register to determine the memory area that contains the good data (start address and last address).

If the number of remaining data items in the FIFO is lower than a burst size (if the MBURST bits in DMA\_SxCR register are set to configure the stream to manage burst on the AHB memory port), single transactions are generated to complete the FIFO flush.

### Direct mode

By default, the FIFO operates in direct mode (DMDIS bit in the DMA\_SxFCR is reset) and the FIFO threshold level is not used. This mode is useful when the system requires an immediate and single transfer to or from the memory after each DMA request.

When the DMA is configured in direct mode (FIFO disabled), to transfer data in memory-to-peripheral mode, the DMA preloads one data from the memory to the internal FIFO to ensure an immediate data transfer as soon as a DMA request is triggered by a peripheral.

To avoid saturating the FIFO, it is recommended to configure the corresponding stream with a high priority.

This mode is restricted to transfers where:

- the source and destination transfer widths are equal and both defined by the PSIZE[1:0] bits in DMA\_SxCR (MSIZE[1:0] bits are not relevant)
- burst transfers are not possible (PBURST[1:0] and MBURST[1:0] bits in DMA\_SxCR are don't care)

Direct mode must not be used when implementing memory-to-memory transfers.

### 8.3.14 DMA transfer completion

Different events can generate an end of transfer by setting the TCIFx bit in the DMA\_LISR or DMA\_HISR status register:

- In DMA flow controller mode:
  - The DMA\_SxNDTR counter has reached zero in the memory-to-peripheral mode.
  - The stream is disabled before the end of transfer (by clearing the EN bit in the DMA\_SxCR register) and (when transfers are peripheral-to-memory or memory-to-memory) all the remaining data have been flushed from the FIFO into the memory.
- In Peripheral flow controller mode:
  - The last external burst or single request has been generated from the peripheral and (when the DMA is operating in peripheral-to-memory mode) the remaining data have been transferred from the FIFO into the memory
  - The stream is disabled by software, and (when the DMA is operating in peripheral-to-memory mode) the remaining data have been transferred from the FIFO into the memory

*Note: The transfer completion is dependent on the remaining data in FIFO to be transferred into memory only in the case of peripheral-to-memory mode. This condition is not applicable in memory-to-peripheral mode.*

If the stream is configured in noncircular mode, after the end of the transfer (that is when the number of data to be transferred reaches zero), the DMA is stopped (EN bit in DMA\_SxCR register is cleared by Hardware) and no DMA request is served unless the software reprograms the stream and re-enables it (by setting the EN bit in the DMA\_SxCR register).

### 8.3.15 DMA transfer suspension

At any time, a DMA transfer can be suspended to be restarted later on or to be definitively disabled before the end of the DMA transfer.

There are two cases:

- The stream disables the transfer with no later-on restart from the point where it was stopped. There is no particular action to do, except to clear the EN bit in the DMA\_SxCR register to disable the stream. The stream may take time to be disabled (ongoing transfer is completed first). The transfer complete interrupt flag (TCIF in the DMA\_LISR or DMA\_HISR register) is set in order to indicate the end of transfer. The value of the EN bit in DMA\_SxCR is now '0' to confirm the stream interruption. The DMA\_SxNDTR register contains the number of remaining data items at the moment when the stream was stopped so that the software can determine how many data items have been transferred before the stream was interrupted.
- The stream suspends the transfer before the number of remaining data items to be transferred in the DMA\_SxNDTR register reaches 0. The aim is to restart the transfer later by re-enabling the stream. In order to restart from the point where the transfer was stopped, the software has to read the DMA\_SxNDTR register after disabling the stream by writing the EN bit in DMA\_SxCR register (and then checking that it is at '0') to know the number of data items already collected. Then:
  - The peripheral and/or memory addresses have to be updated in order to adjust the address pointers
  - The SxNDTR register has to be updated with the remaining number of data items to be transferred (the value read when the stream was disabled)
  - The stream may then be re-enabled to restart the transfer from the point it was stopped

*Note:* A transfer complete interrupt flag (TCIF in DMA\_LISR or DMA\_HISR) is set to indicate the end of transfer due to the stream interruption.

### 8.3.16 Flow controller

The entity that controls the number of data to be transferred is known as the flow controller. This flow controller is configured independently for each stream using the PFCTRL bit in the DMA\_SxCR register.

The flow controller can be:

- The DMA controller: in this case, the number of data items to be transferred is programmed by software into the DMA\_SxNDTR register before the DMA stream is enabled.
- The peripheral source or destination: this is the case when the number of data items to be transferred is unknown. The peripheral indicates by hardware to the DMA controller when the last data are being transferred. This feature is only supported for peripherals that are able to signal the end of the transfer, that is: SDMMC1.

When the peripheral flow controller is used for a given stream, the value written into the DMA\_SxNDTR has no effect on the DMA transfer. Actually, whatever the value written, it will be forced by hardware to 0xFFFF as soon as the stream is enabled, to respect the following schemes:

- Anticipated stream interruption: EN bit in DMA\_SxCR register is reset to 0 by the software to stop the stream before the last data hardware signal (single or burst) is sent by the peripheral. In such a case, the stream is switched off and the FIFO flush is

triggered in the case of a peripheral-to-memory DMA transfer. The TCIFx flag of the corresponding stream is set in the status register to indicate the DMA completion. To know the number of data items transferred during the DMA transfer, read the DMA\_SxNDTR register and apply the following formula:

$$\text{Number\_of\_data\_transferred} = 0xFFFF - \text{DMA\_SxNDTR}$$

- Normal stream interruption due to the reception of a last data hardware signal: the stream is automatically interrupted when the peripheral requests the last transfer (single or burst) and when this transfer is complete. the TCIFx flag of the corresponding stream is set in the status register to indicate the DMA transfer completion. To know the number of data items transferred, read the DMA\_SxNDTR register and apply the same formula as above.
- The DMA\_SxNDTR register reaches 0: the TCIFx flag of the corresponding stream is set in the status register to indicate the forced DMA transfer completion. The stream is automatically switched off even though the last data hardware signal (single or burst) has not been yet asserted. The already transferred data is not lost. This means that a maximum of 65535 data items can be managed by the DMA in a single transaction, even in peripheral flow control mode.

*Note:* When configured in memory-to-memory mode, the DMA is always the flow controller and the PFCTRL bit is forced to 0 by hardware.

The circular mode is forbidden in the peripheral flow controller mode.

### 8.3.17 Summary of the possible DMA configurations

Table 32 summarizes the different possible DMA configurations. The forbidden configurations are highlighted in gray in the table.

**Table 32. Possible DMA configurations**

| DMA transfer mode    | Source              | Destination         | Flow controller | Circular mode | Transfer type | Direct mode | Double-buffer mode |
|----------------------|---------------------|---------------------|-----------------|---------------|---------------|-------------|--------------------|
| Peripheral-to-memory | AHB peripheral port | AHB memory port     | DMA             | Possible      | single        | Possible    | Possible           |
|                      |                     |                     |                 |               | burst         | Forbidden   |                    |
|                      |                     |                     | Peripheral      | Forbidden     | single        | Possible    | Forbidden          |
|                      |                     |                     |                 |               | burst         | Forbidden   |                    |
| Memory-to-peripheral | AHB memory port     | AHB peripheral port | DMA             | Possible      | single        | Possible    | Possible           |
|                      |                     |                     |                 |               | burst         | Forbidden   |                    |
|                      |                     |                     | Peripheral      | Forbidden     | single        | Possible    | Forbidden          |
|                      |                     |                     |                 |               | burst         | Forbidden   |                    |
| Memory-to-memory     | AHB peripheral port | AHB memory port     | DMA only        | Forbidden     | single        | Forbidden   | Forbidden          |
|                      |                     |                     |                 |               | burst         |             |                    |

### 8.3.18 Stream configuration procedure

The following sequence must be followed to configure a DMA stream x (where x is the stream number):

1. If the stream is enabled, disable it by resetting the EN bit in the DMA\_SxCR register, then read this bit in order to confirm that there is no ongoing stream operation. Writing this bit to 0 is not immediately effective since it is actually written to 0 once all the current transfers are finished. When the EN bit is read as 0, this means that the stream is ready to be configured. It is therefore necessary to wait for the EN bit to be cleared before starting any stream configuration. All the stream dedicated bits set in the status register (DMA\_LISR and DMA\_HISR) from the previous data block DMA transfer must be cleared before the stream can be re-enabled.
2. Set the peripheral port register address in the DMA\_SxPAR register. The data is moved from/ to this address to/ from the peripheral port after the peripheral event.
3. Set the memory address in the DMA\_SxMA0R register (and in the DMA\_SxMA1R register in the case of a double-buffer mode). The data is written to or read from this memory after the peripheral event.
4. Configure the total number of data items to be transferred in the DMA\_SxNDTR register. After each peripheral event or each beat of the burst, this value is decremented.
5. Select the DMA channel (request) using CHSEL[2:0] in the DMA\_SxCR register.
6. If the peripheral is intended to be the flow controller and if it supports this feature, set the PFCTRL bit in the DMA\_SxCR register.
7. Configure the stream priority using the PL[1:0] bits in the DMA\_SxCR register.
8. Configure the FIFO usage (enable or disable, threshold in transmission and reception)
9. Configure the data transfer direction, peripheral and memory incremented/fixed mode, single or burst transactions, peripheral and memory data widths, circular mode, double-buffer mode and interrupts after half and/or full transfer, and/or errors in the DMA\_SxCR register.
10. Activate the stream by setting the EN bit in the DMA\_SxCR register.

As soon as the stream is enabled, it can serve any DMA request from the peripheral connected to the stream.

Once half the data have been transferred on the AHB destination port, the half-transfer flag (HTIF) is set and an interrupt is generated if the half-transfer interrupt enable bit (HTIE) is set. At the end of the transfer, the transfer complete flag (TCIF) is set and an interrupt is generated if the transfer complete interrupt enable bit (TCIE) is set.

---

**Warning:** To switch off a peripheral connected to a DMA stream request, it is mandatory to, first, switch off the DMA stream to which the peripheral is connected, then to wait for EN bit = 0. Only then can the peripheral be safely disabled.

---

### 8.3.19 Error management

The DMA controller can detect the following errors:

- **Transfer error:** the transfer error interrupt flag (TEIFx) is set when:
  - a bus error occurs during a DMA read or a write access
  - a write access is requested by software on a memory address register in double-buffer mode whereas the stream is enabled and the current target memory is the one impacted by the write into the memory address register (refer to [Section 8.3.10: Double-buffer mode](#))
- **FIFO error:** the FIFO error interrupt flag (FEIFx) is set if:
  - a FIFO underrun condition is detected
  - a FIFO overrun condition is detected (no detection in memory-to-memory mode because requests and transfers are internally managed by the DMA)
  - the stream is enabled while the FIFO threshold level is not compatible with the size of the memory burst (refer to [Table 31: FIFO threshold configurations](#))
- **Direct mode error:** the direct mode error interrupt flag (DMEIFx) can only be set in the peripheral-to-memory mode while operating in direct mode and when the MINC bit in the DMA\_SxCR register is cleared. This flag is set when a DMA request occurs while the previous data have not yet been fully transferred into the memory (because the memory bus was not granted). In this case, the flag indicates that 2 data items were be transferred successively to the same destination address, which could be an issue if the destination is not able to manage this situation

In direct mode, the FIFO error flag can also be set under the following conditions:

- In the peripheral-to-memory mode, the FIFO can be saturated (overrun) if the memory bus is not granted for several peripheral requests.
- In the memory-to-peripheral mode, an underrun condition may occur if the memory bus has not been granted before a peripheral request occurs.

If the TEIFx or the FEIFx flag is set due to incompatibility between burst size and FIFO threshold level, the faulty stream is automatically disabled through a hardware clear of its EN bit in the corresponding stream configuration register (DMA\_SxCR).

If the DMEIFx or the FEIFx flag is set due to an overrun or underrun condition, the faulty stream is not automatically disabled and it is up to the software to disable or not the stream by resetting the EN bit in the DMA\_SxCR register. This is because there is no data loss when this kind of errors occur.

When the stream's error interrupt flag (TEIF, FEIF, DMEIF) in the DMA\_LISR or DMA\_HISR register is set, an interrupt is generated if the corresponding interrupt enable bit (TEIE, FEIE, DMIE) in the DMA\_SxCR or DMA\_SxFCR register is set.

*Note:*

*When a FIFO overrun or underrun condition occurs, the data is not lost because the peripheral request is not acknowledged by the stream until the overrun or underrun condition is cleared. If this acknowledge takes too much time, the peripheral itself may detect an overrun or underrun condition of its internal buffer and data might be lost.*

## 8.4 DMA interrupts

For each DMA stream, an interrupt can be produced on the following events:

- Half-transfer reached
- Transfer complete
- Transfer error
- FIFO error (overrun, underrun or FIFO level error)
- Direct mode error

Separate interrupt enable control bits are available for flexibility as shown in [Table 33](#).

**Table 33. DMA interrupt requests**

| Interrupt event       | Event flag | Enable control bit |
|-----------------------|------------|--------------------|
| Half-transfer         | HTIF       | HTIE               |
| Transfer complete     | TCIF       | TCIE               |
| Transfer error        | TEIF       | TEIE               |
| FIFO overrun/underrun | FEIF       | FEIE               |
| Direct mode error     | DMEIF      | DMEIE              |

*Note:* Before setting an enable control bit  $EN = 1$ , the corresponding event flag must be cleared, otherwise an interrupt is immediately generated.

## 8.5 DMA registers

The DMA registers have to be accessed by words (32 bits).

### 8.5.1 DMA low interrupt status register (DMA\_LISR)

Address offset: 0x00

Reset value: 0x0000 0000

| 31   | 30   | 29   | 28   | 27    | 26    | 25    | 24     | 23   | 22    | 21    | 20    | 19    | 18     | 17   | 16    |
|------|------|------|------|-------|-------|-------|--------|------|-------|-------|-------|-------|--------|------|-------|
| Res. | Res. | Res. | Res. | TCIF3 | HTIF3 | TEIF3 | DMEIF3 | Res. | FEIF3 | TCIF2 | HTIF2 | TEIF2 | DMEIF2 | Res. | FEIF2 |
|      |      |      |      | r     | r     | r     | r      |      | r     | r     | r     | r     | r      |      | r     |
| 15   | 14   | 13   | 12   | 11    | 10    | 9     | 8      | 7    | 6     | 5     | 4     | 3     | 2      | 1    | 0     |
| Res. | Res. | Res. | Res. | TCIF1 | HTIF1 | TEIF1 | DMEIF1 | Res. | FEIF1 | TCIF0 | HTIF0 | TEIF0 | DMEIF0 | Res. | FEIF0 |
|      |      |      |      | r     | r     | r     | r      |      | r     | r     | r     | r     | r      |      | r     |

Bits 31:28, 15:12 Reserved, must be kept at reset value.

Bits 27, 21, 11, 5 **TCIF[3:0]**: stream x transfer complete interrupt flag (x = 3..0)

This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in the DMA\_LIFCR register.

0: no transfer complete event on stream x

1: a transfer complete event occurred on stream x

Bits 26, 20, 10, 4 **HTIF[3:0]**: stream x half transfer interrupt flag (x = 3..0)

This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in the DMA\_LIFCR register.

0: no half transfer event on stream x

1: a half transfer event occurred on stream x

Bits 25, 19, 9, 3 **TEIF[3:0]**: stream x transfer error interrupt flag (x = 3..0)

This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in the DMA\_LIFCR register.

0: no transfer error on stream x

1: a transfer error occurred on stream x

Bits 24, 18, 8, 2 **DMEIF[3:0]**: stream x direct mode error interrupt flag (x = 3..0)

This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in the DMA\_LIFCR register.

0: No direct mode error on stream x

1: a direct mode error occurred on stream x

Bits 23, 17, 7, 1 Reserved, must be kept at reset value.

Bits 22, 16, 6, 0 **FEIF[3:0]**: stream x FIFO error interrupt flag (x = 3..0)

This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in the DMA\_LIFCR register.

0: no FIFO error event on stream x

1: a FIFO error event occurred on stream x

## 8.5.2 DMA high interrupt status register (DMA\_HISR)

Address offset: 0x04

Reset value: 0x0000 0000

|      |      |      |      |       |       |       |        |      |       |       |       |       |        |      |       |
|------|------|------|------|-------|-------|-------|--------|------|-------|-------|-------|-------|--------|------|-------|
| 31   | 30   | 29   | 28   | 27    | 26    | 25    | 24     | 23   | 22    | 21    | 20    | 19    | 18     | 17   | 16    |

| 15   | 14   | 13   | 12   | 11    | 10    | 9     | 8      | 7    | 6     | 5     | 4     | 3     | 2      | 1    | 0     |
| Res. | Res. | Res. | Res. | TCIF5 | HTIF5 | TEIF5 | DMEIF5 | Res. | FEIF5 | TCIF4 | HTIF4 | TEIF4 | DMEIF4 | Res. | FEIF4 |
|      |      |      |      | r     | r     | r     | r      |      | r     | r     | r     | r     | r      |      | r     |

Bits 31:28, 15:12 Reserved, must be kept at reset value.

Bits 27, 21, 11, 5 **TCIF[7:4]**: stream x transfer complete interrupt flag (x = 7..4)

This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in the DMA\_HIFCR register.

0: no transfer complete event on stream x

1: a transfer complete event occurred on stream x

Bits 26, 20, 10, 4 **HTIF[7:4]**: stream x half transfer interrupt flag (x = 7..4)

This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in the DMA\_HIFCR register.

0: no half transfer event on stream x

1: a half transfer event occurred on stream x

Bits 25, 19, 9, 3 **TEIF[7:4]**: stream x transfer error interrupt flag (x = 7..4)

This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in the DMA\_HIFCR register.

0: no transfer error on stream x

1: a transfer error occurred on stream x

Bits 24, 18, 8, 2 **DMEIF[7:4]**: stream x direct mode error interrupt flag (x = 7..4)

This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in the DMA\_HIFCR register.

0: no direct mode error on stream x

1: a direct mode error occurred on stream x

Bits 23, 17, 7, 1 Reserved, must be kept at reset value.

Bits 22, 16, 6, 0 **FEIF[7:4]**: stream x FIFO error interrupt flag (x = 7..4)

This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in the DMA\_HIFCR register.

0: no FIFO error event on stream x

1: a FIFO error event occurred on stream x

### 8.5.3 DMA low interrupt flag clear register (DMA\_LIFCR)

Address offset: 0x08

Reset value: 0x0000 0000

Bits 31:28, 15:12 Reserved, must be kept at reset value.

Bits 27, 21, 11, 5 **CTCIF[3:0]**: stream x clear transfer complete interrupt flag (x = 3..0)  
Writing 1 to this bit clears the corresponding TCIFx flag in the DMA\_LISR register.

Bits 26, 20, 10, 4 **CHTIF[3:0]**: stream x clear half transfer interrupt flag (x = 3..0)  
Writing 1 to this bit clears the corresponding HTIFx flag in the DMA\_LISR register.

Bits 25, 19, 9, 3 **CTEIF[3:0]**: Stream x clear transfer error interrupt flag (x = 3..0)  
Writing 1 to this bit clears the corresponding TEIFx flag in the DMA\_LISR register.

Bits 24, 18, 8, 2 **CDMEIF[3:0]**: stream x clear direct mode error interrupt flag (x = 3..0)  
Writing 1 to this bit clears the corresponding DMEIFx flag in the DMA\_LISR register.

Bits 23, 17, 7, 1 Reserved, must be kept at reset value.

Bits 22, 16, 6, 0 **CFEIF[3:0]**: stream x clear FIFO error interrupt flag (x = 3..0)  
Writing 1 to this bit clears the corresponding CFEIFx flag in the DMA\_LISR register.

### 8.5.4 DMA high interrupt flag clear register (DMA\_HIFCR)

Address offset: 0x0C

Reset value: 0x0000 0000

Bits 31:28, 15:12 Reserved, must be kept at reset value.

Bits 27, 21, 11, 5 **CTCIF[7:4]**: stream x clear transfer complete interrupt flag (x = 7..4)  
Writing 1 to this bit clears the corresponding TCIFx flag in the DMA\_HISR register.

Bits 26, 20, 10, 4 **CHTIF[7:4]**: stream x clear half transfer interrupt flag (x = 7..4)  
Writing 1 to this bit clears the corresponding HTIFx flag in the DMA\_HISR register.

Bits 25, 19, 9, 3 **CTEIF[7:4]**: stream x clear transfer error interrupt flag (x = 7..4)  
Writing 1 to this bit clears the corresponding TEIFx flag in the DMA\_HISR register.

Bits 24, 18, 8, 2 **CDMEIF[7:4]**: stream x clear direct mode error interrupt flag (x = 7..4)  
Writing 1 to this bit clears the corresponding DMEIFx flag in the DMA\_HISR register.

Bits 23, 17, 7, 1 Reserved, must be kept at reset value.

Bits 22, 16, 6, 0 **CFEIF[7:4]**: stream x clear FIFO error interrupt flag (x = 7..4)  
Writing 1 to this bit clears the corresponding CFEIFx flag in the DMA\_HISR register.

### 8.5.5 DMA stream x configuration register (DMA\_SxCR)

This register is used to configure the concerned stream.

Address offset:  $0x10 + 0x18 * x$ , (x = 0 to 7)

Reset value: 0x0000 0000

|        |            |      |            |            |      |      |             |          |             |        |      |      |      |         |    |

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:25 **CHSEL[2:0]**: channel selection

These bits are set and cleared by software.

000: channel 0 selected

001: channel 1 selected

010: channel 2 selected

011: channel 3 selected

100: channel 4 selected

101: channel 5 selected

110: channel 6 selected

111: channel 7 selected

These bits are protected and can be written only if EN is '0'.

Bits 24:23 **MBURST[1:0]**: memory burst transfer configuration

These bits are set and cleared by software.

00: single transfer

01: INCR4 (incremental burst of 4 beats)

10: INCR8 (incremental burst of 8 beats)

11: INCR16 (incremental burst of 16 beats)

These bits are protected and can be written only if EN is '0'.

In direct mode, these bits are forced to 0x0 by hardware as soon as bit EN= '1'.

Bits 22:21 **PBURST[1:0]**: peripheral burst transfer configuration

These bits are set and cleared by software.

00: single transfer

01: INCR4 (incremental burst of 4 beats)

10: INCR8 (incremental burst of 8 beats)

11: INCR16 (incremental burst of 16 beats)

These bits are protected and can be written only if EN is '0'.

In direct mode, these bits are forced to 0x0 by hardware.

Bit 20 Reserved, must be kept at reset value.

- Bit 19 **CT**: current target (only in double-buffer mode)  
 This bit is set and cleared by hardware. It can also be written by software.  
 0: current target memory is Memory 0 (addressed by the DMA\_SxM0AR pointer)  
 1: current target memory is Memory 1 (addressed by the DMA\_SxM1AR pointer)  
 This bit can be written only if EN is '0' to indicate the target memory area of the first transfer.  
 Once the stream is enabled, this bit operates as a status flag indicating which memory area is the current target.
- Bit 18 **DBM**: double-buffer mode  
 This bit is set and cleared by software.  
 0: no buffer switching at the end of transfer  
 1: memory target switched at the end of the DMA transfer  
 This bit is protected and can be written only if EN is '0'.
- Bits 17:16 **PL[1:0]**: priority level  
 These bits are set and cleared by software.  
 00: low  
 01: medium  
 10: high  
 11: very high  
 These bits are protected and can be written only if EN is '0'.
- Bit 15 **PINCOS**: peripheral increment offset size  
 This bit is set and cleared by software  
 0: The offset size for the peripheral address calculation is linked to the PSIZE  
 1: The offset size for the peripheral address calculation is fixed to 4 (32-bit alignment).  
 This bit has no meaning if bit PINC = '0'.  
 This bit is protected and can be written only if EN = '0'.  
 This bit is forced low by hardware when the stream is enabled (bit EN = '1') if the direct mode is selected or if PBURST are different from "00".
- Bits 14:13 **MSIZE[1:0]**: memory data size  
 These bits are set and cleared by software.  
 00: byte (8-bit)  
 01: half-word (16-bit)  
 10: word (32-bit)  
 11: reserved  
 These bits are protected and can be written only if EN is '0'.  
 In direct mode, MSIZE is forced by hardware to the same value as PSIZE as soon as bit EN = '1'.
- Bits 12:11 **PSIZE[1:0]**: peripheral data size  
 These bits are set and cleared by software.  
 00: byte (8-bit)  
 01: half-word (16-bit)  
 10: word (32-bit)  
 11: reserved  
 These bits are protected and can be written only if EN is '0'.
- Bit 10 **MINC**: memory increment mode  
 This bit is set and cleared by software.  
 0: memory address pointer is fixed  
 1: memory address pointer is incremented after each data transfer (increment is done according to MSIZE)  
 This bit is protected and can be written only if EN is '0'.

**Bit 9 PINC:** peripheral increment mode

This bit is set and cleared by software.

0: peripheral address pointer is fixed

1: peripheral address pointer is incremented after each data transfer (increment is done according to PSIZE)

This bit is protected and can be written only if EN is '0'.

**Bit 8 CIRC:** circular mode

This bit is set and cleared by software and can be cleared by hardware.

0: circular mode disabled

1: circular mode enabled

When the peripheral is the flow controller (bit PFCTRL = 1) and the stream is enabled (bit EN = 1), then this bit is automatically forced by hardware to 0.

It is automatically forced by hardware to 1 if the DBM bit is set, as soon as the stream is enabled (bit EN = '1').

**Bits 7:6 DIR[1:0]:** data transfer direction

These bits are set and cleared by software.

00: peripheral-to-memory

01: memory-to-peripheral

10: memory-to-memory

11: reserved

These bits are protected and can be written only if EN is '0'.

**Bit 5 PFCTRL:** peripheral flow controller

This bit is set and cleared by software.

0: DMA is the flow controller

1: The peripheral is the flow controller

This bit is protected and can be written only if EN is '0'.

When the memory-to-memory mode is selected (bits DIR[1:0]=10), then this bit is automatically forced to 0 by hardware.

**Bit 4 TCIE:** transfer complete interrupt enable

This bit is set and cleared by software.

0: TC interrupt disabled

1: TC interrupt enabled

**Bit 3 HTIE:** half transfer interrupt enable

This bit is set and cleared by software.

0: HT interrupt disabled

1: HT interrupt enabled

**Bit 2 TEIE:** transfer error interrupt enable

This bit is set and cleared by software.

0: TE interrupt disabled

1: TE interrupt enabled

**Bit 1 DMEIE:** direct mode error interrupt enable

This bit is set and cleared by software.

0: DME interrupt disabled

1: DME interrupt enabled

Bit 0 **EN**: stream enable / flag stream ready when read low

This bit is set and cleared by software.

0: stream disabled

1: stream enabled

This bit may be cleared by hardware:

- on a DMA end of transfer (stream ready to be configured)
- if a transfer error occurs on the AHB master buses
- when the FIFO threshold on memory AHB port is not compatible with the size of the burst

When this bit is read as 0, the software is allowed to program the configuration and FIFO bits registers. It is forbidden to write these registers when the EN bit is read as 1.

*Note: Before setting EN bit to '1' to start a new transfer, the event flags corresponding to the stream in DMA\_LISR or DMA\_HISR register must be cleared.*

### 8.5.6 DMA stream x number of data register (DMA\_SxNDTR)

Address offset:  $0x14 + 0x18 * x$ , ( $x = 0$  to 7)

Reset value: 0x0000 0000

|           |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
|-----------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|
| 31        | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21   | 20   | 19   | 18   | 17   | 16   |
| Res.      | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. |
|           |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
| 15        | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0    |
| NDT[15:0] |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
| rw        | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   |

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **NDT[15:0]**: number of data items to transfer (0 up to 65535)

This register can be written only when the stream is disabled. When the stream is enabled, this register is read-only, indicating the remaining data items to be transmitted. This register decrements after each DMA transfer.

Once the transfer is completed, this register can either stay at zero (when the stream is in normal mode) or be reloaded automatically with the previously programmed value in the following cases:

- when the stream is configured in circular mode.
- when the stream is enabled again by setting EN bit to '1'.

If the value of this register is zero, no transaction can be served even if the stream is enabled.

### 8.5.7 DMA stream x peripheral address register (DMA\_SxPAR)

Address offset:  $0x18 + 0x18 * x$ , ( $x = 0$  to  $7$ )

Reset value: 0x0000 0000

|            |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31         | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| PAR[31:16] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rW         | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW |
| 15         | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| PAR[15:0]  |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rW         | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW |

Bits 31:0 **PAR[31:0]**: peripheral address

Base address of the peripheral data register from/to which the data is read/written.

These bits are write-protected and can be written only when bit EN = '0' in the DMA\_SxCR register.

### 8.5.8 DMA stream x memory 0 address register (DMA\_SxM0AR)

Address offset:  $0x1C + 0x18 * x$ , ( $x = 0$  to  $7$ )

Reset value: 0x0000 0000

|            |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31         | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| M0A[31:16] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rW         | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW |
| 15         | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| M0A[15:0]  |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rW         | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW |

Bits 31:0 **M0A[31:0]**: memory 0 address

Base address of memory area 0 from/to which the data is read/written.

These bits are write-protected. They can be written only if:

- the stream is disabled (bit EN = '0' in the DMA\_SxCR register) or
- the stream is enabled (EN = '1' in DMA\_SxCR register) and bit CT = '1' in the DMA\_SxCR register (in double-buffer mode).

### 8.5.9 DMA stream x memory 1 address register (DMA\_SxM1AR)

Address offset:  $0x20 + 0x18 * x$ , ( $x = 0$  to  $7$ )

Reset value: 0x0000 0000

|            |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31         | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| M1A[31:16] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rW         | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW |
| 15         | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| M1A[15:0]  |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rW         | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW |

Bits 31:0 **M1A[31:0]**: memory 1 address (used in case of double-buffer mode)

Base address of memory area 1 from/to which the data is read/written.

This register is used only for the double-buffer mode.

These bits are write-protected. They can be written only if:

- the stream is disabled (bit EN= '0' in the DMA\_SxCR register) or
- the stream is enabled (EN='1' in DMA\_SxCR register) and bit CT = '0' in the DMA\_SxCR register.

### 8.5.10 DMA stream x FIFO control register (DMA\_SxFCR)

Address offset:  $0x24 + 0x24 * x$ , ( $x = 0$  to  $7$ )

Reset value: 0x0000 0021

Bits 31:8 Reserved, must be kept at reset value.

Bit 7 **FEIE**: FIFO error interrupt enable

This bit is set and cleared by software.

0: FE interrupt disabled

1: FE interrupt enabled

Bit 6 Reserved, must be kept at reset value.

Bits 5:3 **FS[2:0]**: FIFO status

These bits are read-only.

000:  $0 < \text{fifo\_level} < 1/4$

001:  $1/4 \leq \text{fifo\_level} < 1/2$

010:  $1/2 \leq \text{fifo\_level} < 3/4$

011:  $3/4 \leq \text{fifo\_level} < \text{full}$

100: FIFO is empty

101: FIFO is full

others: no meaning

These bits are not relevant in the direct mode (DMDIS bit is zero).

Bit 2 **DMDIS**: direct mode disable

This bit is set and cleared by software. It can be set by hardware.

0: direct mode enabled

1: direct mode disabled

This bit is protected and can be written only if EN is '0'.

This bit is set by hardware if the memory-to-memory mode is selected (DIR bit in DMA\_SxCR are "10") and the EN bit in the DMA\_SxCR register is '1' because the direct mode is not allowed in the memory-to-memory configuration.

Bits 1:0 **FTH[1:0]**: FIFO threshold selection

These bits are set and cleared by software.

00: 1/4 full FIFO

01: 1/2 full FIFO

10: 3/4 full FIFO

11: full FIFO

These bits are not used in the direct mode when the DMIS value is zero.

These bits are protected and can be written only if EN is '0'.

## 8.5.11 DMA register map

Table 34 summarizes the DMA registers.

Table 34. DMA register map and reset values

| Offset | Register name | 31        | 30  | 29  | 28  | 27         | 26     | 25     | 24      | 23          | 22     | 21     | 20     | 19     | 18      | 17      | 16     | 15        | 14         | 13  | 12  | 11         | 10     | 9      | 8       | 7    | 6       | 5        | 4      | 3      | 2        | 1    | 0      |       |    |

Refer to [Section 2.2.2 on page 69](#) for the register boundary addresses.

## 9 Chrom-ART Accelerator™ controller (DMA2D)

### 9.1 DMA2D introduction

The Chrom-ART Accelerator™ (DMA2D) is a specialized DMA dedicated to image manipulation. It can perform the following operations:

- Filling a part or the whole of a destination image with a specific color
- Copying a part or the whole of a source image into a part or the whole of a destination image
- Copying a part or the whole of a source image into a part or the whole of a destination image with a pixel format conversion
- Blending a part and/or two complete source images with different pixel format and copy the result into a part or the whole of a destination image with a different color format.

All the classical color coding schemes are supported from 4-bit up to 32-bit per pixel with indexed or direct color mode. The DMA2D has its own dedicated memories for CLUTs (color look-up tables).

### 9.2 DMA2D main features

The main DMA2D features are:

- Single AHB master bus architecture.
- AHB slave programming interface supporting 8/16/32-bit accesses (except for CLUT accesses which are 32-bit).
- User programmable working area size
- User programmable offset for sources and destination areas
- User programmable sources and destination addresses on the whole memory space
- Up to 2 sources with blending operation
- Alpha value can be modified (source value, fixed value or modulated value)
- User programmable source and destination color format
- Up to 11 color formats supported from 4-bit up to 32-bit per pixel with indirect or direct color coding
- 2 internal memories for CLUT storage in indirect color mode
- Automatic CLUT loading or CLUT programming via the CPU
- User programmable CLUT size
- Internal timer to control AHB bandwidth
- 4 operating modes: register-to-memory, memory-to-memory, memory-to-memory with pixel format conversion, and memory-to-memory with pixel format conversion and blending

- Area filling with a fixed color
- Copy from an area to another
- Copy with pixel format conversion between source and destination images
- Copy from two sources with independent color format and blending
- Abort and suspend of DMA2D operations
- Watermark interrupt on a user programmable destination line
- Interrupt generation on bus error or access conflict
- Interrupt generation on process completion

## 9.3 DMA2D functional description

### 9.3.1 General description

The DMA2D controller performs direct memory transfer. As an AHB master, it can take the control of the AHB bus matrix to initiate AHB transactions.

The DMA2D can operate in the following modes:

- Register-to-memory
- Memory-to-memory
- Memory-to-memory with Pixel Format Conversion
- Memory-to-memory with Pixel Format Conversion and Blending

The AHB slave port is used to program the DMA2D controller.

The block diagram of the DMA2D is shown in [Figure 29: DMA2D block diagram](#).

Figure 29. DMA2D block diagram

### 9.3.2 DMA2D control

The DMA2D controller is configured through the DMA2D Control Register (DMA2D\_CR) which allows selecting:

The user application can perform the following operations:

- Select the operating mode
- Enable/disable the DMA2D interrupt
- Start/suspend/abort ongoing data transfers

### 9.3.3 DMA2D foreground and background FIFOs

The DMA2D foreground (FG) FG FIFO and background (BG) FIFO fetch the input data to be copied and/or processed.

The FIFOs fetch the pixels according to the color format defined in their respective pixel format converter (PFC).

They are programmed through a set of control registers:

- DMA2D foreground memory address register (DMA2D\_FGMAR)
- DMA2D foreground offset register (DMA2D\_FGOR)
- DMA2D background memory address register (DMA2D\_BGMAR)
- DMA2D background offset register (DMA2D\_BGBOR)
- DMA2D number of lines register (number of lines and pixel per lines) (DMA2D\_NLR)

When the DMA2D operates in register-to-memory mode, none of the FIFOs is activated.

When the DMA2D operates in memory-to-memory mode (no pixel format conversion nor blending operation), only the FG FIFO is activated and acts as a buffer.

When the DMA2D operates in memory-to-memory operation with pixel format conversion (no blending operation), the BG FIFO is not activated.

### 9.3.4 DMA2D foreground and background pixel format converter (PFC)

DMA2D foreground pixel format converter (PFC) and background pixel format converter perform the pixel format conversion to generate a 32-bit per pixel value. The PFC can also modify the alpha channel.

The first stage of the converter converts the color format. The original color format of the foreground pixel and background pixels are configured through the CM[3:0] bits of the DMA2D\_FGPFCCR and DMA2D\_BGPFCCR, respectively.

The supported input formats are given in [Table 35: Supported color mode in input](#).

**Table 35. Supported color mode in input**

| CM[3:0] | Color mode |
|---------|------------|
| 0000    | ARGB8888   |
| 0001    | RGB888     |
| 0010    | RGB565     |
| 0011    | ARGB1555   |
| 0100    | ARGB4444   |
| 0101    | L8         |
| 0110    | AL44       |
| 0111    | AL88       |
| 1000    | L4         |
| 1001    | A8         |
| 1010    | A4         |

The color format are coded as follows:

- Alpha value field: transparency  
0xFF value corresponds to an opaque pixel and 0x00 to a transparent one.
- R field for Red
- G field for Green
- B field for Blue
- L field: luminance  
This field is the index to a CLUT to retrieve the three/four RGB/ARGB components.

If the original format was direct color mode (ARGB/RGB), then the extension to 8-bit per channel is performed by copying the MSBs into the LSBs. This ensures a perfect linearity of the conversion.

If the original format is indirect color mode (L/AL), a CLUT is required and each pixel format converter is associated with a 256 entry 32-bit CLUT.

If the original format does not include an alpha channel, the alpha value is automatically set to 0xFF (opaque).

For the specific alpha mode A4 and A8, no color information is stored nor indexed. The color to be used for the image generation is fixed and is defined in the DMA2D\_FGCOLR for foreground pixels and in the DMA2D\_BGCOLR register for background pixels.

The order of the fields in the system memory is defined in [Table 36: Data order in memory](#).

**Table 36. Data order in memory**

| Color Mode | @ + 3                                                      | @ + 2                                    | @ + 1                                                      | @ + 0                                    |
|------------|------------------------------------------------------------|------------------------------------------|------------------------------------------------------------|------------------------------------------|
| ARGB8888   | A <sub>0</sub> [7:0]                                       | R <sub>0</sub> [7:0]                     | G <sub>0</sub> [7:0]                                       | B <sub>0</sub> [7:0]                     |
| RGB888     | B <sub>1</sub> [7:0]                                       | R <sub>0</sub> [7:0]                     | G <sub>0</sub> [7:0]                                       | B <sub>0</sub> [7:0]                     |
|            | G <sub>2</sub> [7:0]                                       | B <sub>2</sub> [7:0]                     | R <sub>1</sub> [7:0]                                       | G <sub>1</sub> [7:0]                     |
|            | R <sub>3</sub> [7:0]                                       | G <sub>3</sub> [7:0]                     | B <sub>3</sub> [7:0]                                       | R <sub>2</sub> [7:0]                     |
| RGB565     | R <sub>1</sub> [4:0]G <sub>1</sub> [5:3]                   | G <sub>1</sub> [2:0]B <sub>1</sub> [4:0] | R <sub>0</sub> [4:0]G <sub>0</sub> [5:3]                   | G <sub>0</sub> [2:0]B <sub>0</sub> [4:0] |
| ARGB1555   | A <sub>1</sub> [0]R <sub>1</sub> [4:0]G <sub>1</sub> [4:3] | G <sub>1</sub> [2:0]B <sub>1</sub> [4:0] | A <sub>0</sub> [0]R <sub>0</sub> [4:0]G <sub>0</sub> [4:3] | G <sub>0</sub> [2:0]B <sub>0</sub> [4:0] |
| ARGB4444   | A <sub>1</sub> [3:0]R <sub>1</sub> [3:0]                   | G <sub>1</sub> [3:0]B <sub>1</sub> [3:0] | A <sub>0</sub> [3:0]R <sub>0</sub> [3:0]                   | G <sub>0</sub> [3:0]B <sub>0</sub> [3:0] |
| L8         | L <sub>3</sub> [7:0]                                       | L <sub>2</sub> [7:0]                     | L <sub>1</sub> [7:0]                                       | L <sub>0</sub> [7:0]                     |
| AL44       | A <sub>3</sub> [3:0]L <sub>3</sub> [3:0]                   | A <sub>2</sub> [3:0]L <sub>2</sub> [3:0] | A <sub>1</sub> [3:0]L <sub>1</sub> [3:0]                   | A <sub>0</sub> [3:0]L <sub>0</sub> [3:0] |
| AL88       | A <sub>1</sub> [7:0]                                       | L <sub>1</sub> [7:0]                     | A <sub>0</sub> [7:0]                                       | L <sub>0</sub> [7:0]                     |
| L4         | L <sub>7</sub> [3:0]L <sub>6</sub> [3:0]                   | L <sub>5</sub> [3:0]L <sub>4</sub> [3:0] | L <sub>3</sub> [3:0]L <sub>2</sub> [3:0]                   | L <sub>1</sub> [3:0]L <sub>0</sub> [3:0] |
| A8         | A <sub>3</sub> [7:0]                                       | A <sub>2</sub> [7:0]                     | A <sub>1</sub> [7:0]                                       | A <sub>0</sub> [7:0]                     |
| A4         | A <sub>7</sub> [3:0]A <sub>6</sub> [3:0]                   | A <sub>5</sub> [3:0]A <sub>4</sub> [3:0] | A <sub>3</sub> [3:0]A <sub>2</sub> [3:0]                   | A <sub>1</sub> [3:0]A <sub>0</sub> [3:0] |

The 24-bit RGB888 aligned on 32-bit is supported through the ARGB8888 mode.

Once the 32-bit value is generated, the alpha channel can be modified according to the AM[1:0] field of the DMA2D\_FGPFCCR/DMA2D\_BGPFCCR registers as shown in [Table 37: Alpha mode configuration](#).

The alpha channel can be:

- kept as it is (no modification),
- replaced by the ALPHA[7:0] value of DMA2D\_FGPFCCR/DMA2D\_BGPFCCR,
- or replaced by the original alpha value multiplied by the ALPHA[7:0] value of DMA2D\_FGPFCCR/DMA2D\_BGPFCCR divided by 255.

**Table 37. Alpha mode configuration**

| AM[1:0] | Alpha mode                                                                |
|---------|---------------------------------------------------------------------------|
| 00      | No modification                                                           |
| 01      | Replaced by value in DMA2D_xxPFCCR                                        |
| 10      | Replaced by original value multiplied by the value in DMA2D_xxPFCCR / 255 |
| 11      | Reserved                                                                  |

### 9.3.5 DMA2D foreground and background CLUT interface

The CLUT interface manages the CLUT memory access and the automatic loading of the CLUT.

Three kinds of accesses are possible:

- CLUT read by the PFC during pixel format conversion operation
- CLUT accessed through the AHB slave port when the CPU is reading or writing data into the CLUT
- CLUT written through the AHB master port when an automatic loading of the CLUT is performed

The CLUT memory loading can be done in two different ways:

- Automatic loading  
The following sequence should be followed to load the CLUT:
  - a) Program the CLUT address into the DMA2D\_FGCMAR register (foreground CLUT) or DMA2D\_BGCMAR register (background CLUT)
  - b) Program the CLUT size in the CS[7:0] field of the DMA2D\_FGPFCCR register (foreground CLUT) or DMA2D\_BGPFCCR register (background CLUT).
  - c) Set the START bit of the DMA2D\_FGPFCCR register (foreground CLUT) or DMA2D\_BGPFCCR register (background CLUT) to start the transfer. During this automatic loading process, the CLUT is not accessible by the CPU. If a conflict occurs, a CLUT access error interrupt is raised assuming CAEIE is set to '1' in DMA2D\_CR.
- Manual loading  
The application has to program the CLUT manually through the DMA2D AHB slave port to which the local CLUT memory is mapped. The foreground CLUT is located at address offset 0x0400 and the background CLUT at address offset 0x0800.

The CLUT format can be 24 or 32 bits. It is configured through the CCM bit of the DMA2D\_FGPFCCR register (foreground CLUT) or DMA2D\_BGPFCCR register (background CLUT) as shown in [Table 38: Supported CLUT color mode](#).

Table 38. Supported CLUT color mode

| CCM | CLUT color mode |
|-----|-----------------|
| 0   | 32-bit ARGB8888 |
| 1   | 24-bit RGB888   |

The way the CLUT data are organized in the system memory is specified in [Table 39: CLUT data order in system memory](#).

Table 39. CLUT data order in system memory

| CLUT Color Mode | @ + 3                | @ + 2                | @ + 1                | @ + 0                |
|-----------------|----------------------|----------------------|----------------------|----------------------|
| ARGB8888        | A <sub>0</sub> [7:0] | R <sub>0</sub> [7:0] | G <sub>0</sub> [7:0] | B <sub>0</sub> [7:0] |
| RGB888          | B <sub>1</sub> [7:0] | R <sub>0</sub> [7:0] | G <sub>0</sub> [7:0] | B <sub>0</sub> [7:0] |
|                 | G <sub>2</sub> [7:0] | B <sub>2</sub> [7:0] | R <sub>1</sub> [7:0] | G <sub>1</sub> [7:0] |
|                 | R <sub>3</sub> [7:0] | G <sub>3</sub> [7:0] | B <sub>3</sub> [7:0] | R <sub>2</sub> [7:0] |

### 9.3.6 DMA2D blender

The DMA2D blender blends the source pixels by pair to compute the resulting pixel.

The blending is performed according to the following equation:

$$\text{with } \alpha_{\text{Mult}} = \frac{\alpha_{\text{FG}} \cdot \alpha_{\text{BG}}}{255}$$

$$\alpha_{\text{OUT}} = \alpha_{\text{FG}} + \alpha_{\text{BG}} - \alpha_{\text{Mult}}$$

$$C_{\text{OUT}} = \frac{C_{\text{FG}} \cdot \alpha_{\text{FG}} + C_{\text{BG}} \cdot \alpha_{\text{BG}} - C_{\text{BG}} \cdot \alpha_{\text{Mult}}}{\alpha_{\text{OUT}}} \quad \text{with } C = R \text{ or } G \text{ or } B$$

*Division is rounded to the nearest lower integer*

No configuration register is required by the blender. The blender usage depends on the DMA2D operating mode defined in MODE[1:0] field of the DMA2D\_CR register.

### 9.3.7 DMA2D output PFC

The output PFC performs the pixel format conversion from 32 bits to the output format defined in the CM[2:0] field of the DMA2D output pixel format converter configuration register (DMA2D\_OPFCCR).

The supported output formats are given in [Table 40: Supported color mode in output](#)

Table 40. Supported color mode in output

| CM[2:0] | Color mode |
|---------|------------|
| 000     | ARGB8888   |
| 001     | RGB888     |
| 010     | RGB565     |
| 011     | ARGB1555   |
| 100     | ARGB4444   |

### 9.3.8 DMA2D output FIFO

The output FIFO programs the pixels according to the color format defined in the output PFC.

The destination area is defined through a set of control registers:

- DMA2D output memory address register (DMA2D\_OMAR)
- DMA2D output offset register (DMA2D\_OOR)
- DMA2D number of lines register (number of lines and pixel per lines) (DMA2D\_NLR)

If the DMA2D operates in register-to-memory mode, the configured output rectangle is filled by the color specified in the DMA2D output color register (DMA2D\_OCOLR) which contains a fixed 32-bit, 24-bit or 16-bit value. The format is selected by the CM[2:0] field of the DMA2D\_OPFCCR register.

The data are stored into the memory in the order defined in [Table 41: Data order in memory](#)

Table 41. Data order in memory

| Color Mode | @ + 3                                                      | @ + 2                                    | @ + 1                                                      | @ + 0                                    |
|------------|------------------------------------------------------------|------------------------------------------|------------------------------------------------------------|------------------------------------------|
| ARGB8888   | A <sub>0</sub> [7:0]                                       | R <sub>0</sub> [7:0]                     | G <sub>0</sub> [7:0]                                       | B <sub>0</sub> [7:0]                     |
| RGB888     | B <sub>1</sub> [7:0]                                       | R <sub>0</sub> [7:0]                     | G <sub>0</sub> [7:0]                                       | B <sub>0</sub> [7:0]                     |
|            | G <sub>2</sub> [7:0]                                       | B <sub>2</sub> [7:0]                     | R <sub>1</sub> [7:0]                                       | G <sub>1</sub> [7:0]                     |
|            | R <sub>3</sub> [7:0]                                       | G <sub>3</sub> [7:0]                     | B <sub>3</sub> [7:0]                                       | R <sub>2</sub> [7:0]                     |
| RGB565     | R <sub>1</sub> [4:0]G <sub>1</sub> [5:3]                   | G <sub>1</sub> [2:0]B <sub>1</sub> [4:0] | R <sub>0</sub> [4:0]G <sub>0</sub> [5:3]                   | G <sub>0</sub> [2:0]B <sub>0</sub> [4:0] |
| ARGB1555   | A <sub>1</sub> [0]R <sub>1</sub> [4:0]G <sub>1</sub> [4:3] | G <sub>1</sub> [2:0]B <sub>1</sub> [4:0] | A <sub>0</sub> [0]R <sub>0</sub> [4:0]G <sub>0</sub> [4:3] | G <sub>0</sub> [2:0]B <sub>0</sub> [4:0] |
| ARGB4444   | A <sub>1</sub> [3:0]R <sub>1</sub> [3:0]                   | G <sub>1</sub> [3:0]B <sub>1</sub> [3:0] | A <sub>0</sub> [3:0]R <sub>0</sub> [3:0]                   | G <sub>0</sub> [3:0]B <sub>0</sub> [3:0] |

The RGB888 aligned on 32-bit is supported through the ARGB8888 mode.

### 9.3.9 DMA2D AHB master port timer

An 8-bit timer is embedded into the AHB master port to provide an optional limitation of the bandwidth on the crossbar.

This timer is clocked by the AHB clock and counts a dead time between two consecutive accesses. This limits the bandwidth usage.

The timer enabling and the dead time value are configured through the AHB master port timer configuration register (DMA2D\_AMPTCR).

### 9.3.10 DMA2D transactions

DMA2D transactions consist of a sequence of a given number of data transfers. The number of data and the width can be programmed by software.

Each DMA2D data transfer is composed of up to 4 steps:

1. Data loading from the memory location pointed by the DMA2D\_FGMAR register and pixel format conversion as defined in DMA2D\_FGCR.
2. Data loading from a memory location pointed by the DMA2D\_BGMAR register and pixel format conversion as defined in DMA2D\_BGCR.
3. Blending of all retrieved pixels according to the alpha channels resulting of the PFC operation on alpha values.
4. Pixel format conversion of the resulting pixels according to the DMA2D\_OCR register and programming of the data to the memory location addressed through the DMA2D\_OMAR register.

### 9.3.11 DMA2D configuration

Both source and destination data transfers can target peripherals and memories in the whole 4 Gbyte memory area, at addresses ranging between 0x0000 0000 and 0xFFFF FFFF.

The DMA2D can operate in any of the four following modes selected through MODE[1:0] bits of the DMA2D\_CR register:

- Register-to-memory
- Memory-to-memory
- Memory-to-memory with PFC
- Memory-to-memory with PFC and blending

#### Register-to-memory

The register-to-memory mode is used to fill a user defined area with a predefined color.

The color format is set in the DMA2D\_OPFCCR.

The DMA2D does not perform any data fetching from any source. It just writes the color defined in the DMA2D\_OCOLR register to the area located at the address pointed by the DMA2D\_OMAR and defined in the DMA2D\_NLR and DMA2D\_OOR.

#### Memory-to-memory

In memory-to-memory mode, the DMA2D does not perform any graphical data transformation. The foreground input FIFO acts as a buffer and the data are transferred from the source memory location defined in DMA2D\_FGMAR to the destination memory location pointed by DMA2D\_OMAR.

The color mode programmed in the CM[3:0] bits of the DMA2D\_FGPFCCR register defines the number of bits per pixel for both input and output.

The size of the area to be transferred is defined by the DMA2D\_NLR and DMA2D\_FGOR registers for the source, and by DMA2D\_NLR and DMA2D\_OOR registers for the destination.

### Memory-to-memory with PFC

In this mode, the DMA2D performs a pixel format conversion of the source data and stores them in the destination memory location.

The size of the areas to be transferred are defined by the DMA2D\_NLR and DMA2D\_FGOR registers for the source, and by DMA2D\_NLR and DMA2D\_OOR registers for the destination.

Data are fetched from the location defined in the DMA2D\_FGMAR register and processed by the foreground PFC. The original pixel format is configured through the DMA2D\_FGPFCCR register.

If the original pixel format is direct color mode, then the color channels are all expanded to 8 bits.

If the pixel format is indirect color mode, the associated CLUT has to be loaded into the CLUT memory.

The CLUT loading can be done automatically by following the sequence below:

1. Set the CLUT address into the DMA2D\_FGCMAR.
2. Set the CLUT size in the CS[7:0] bits of the DMA2D\_FGPFCCR register.
3. Set the CLUT format (24 or 32 bits) in the CCM bit of the DMA2D\_FGPFCCR register.
4. Start the CLUT loading by setting the START bit of the DMA2D\_FGPFCCR register.

Once the CLUT loading is complete, the CTCIF flag of the DMA2D\_IFR register is raised, and an interrupt is generated if the CTCIE bit is set in DMA2D\_CR. The automatic CLUT loading process can not work in parallel with classical DMA2D transfers.

The CLUT can also be filled by the CPU or by any other master through the APB port. The access to the CLUT is not possible when a DMA2D transfer is ongoing and uses the CLUT (indirect color format).

In parallel to the color conversion process, the alpha value can be added or changed depending on the value programmed in the DMA2D\_FGPFCCR register. If the original image does not have an alpha channel, a default alpha value of 0xFF is automatically added to obtain a fully opaque pixel. The alpha value can be modified according to the AM[1:0] bits of the DMA2D\_FGPFCCR register:

- It can be unchanged.
- It can be replaced by the value defined in the ALPHA[7:0] value of the DMA2D\_FGPFCCR register.
- It can be replaced by the original value multiplied by the ALPHA[7:0] value of the DMA2D\_FGPFCCR register divided by 255.

The resulting 32-bit data are encoded by the OUT PFC into the format specified by the CM[2:0] field of the DMA2D\_OPFCCR register. The output pixel format cannot be the indirect mode since no CLUT generation process is supported.

The processed data are written into the destination memory location pointed by DMA2D\_OMAR.

### Memory-to-memory with PFC and blending

In this mode, 2 sources are fetched in the foreground FIFO and background FIFO from the memory locations defined by DMA2D\_FGMAR and DMA2D\_BGMAR.

The two pixel format converters have to be configured as described in the memory-to-memory mode. Their configurations can be different as each pixel format converter are independent and have their own CLUT memory.

Once each pixel has been converted into 32 bits by their respective PFCs, they are blended according to the equation below:

$$\text{with } \alpha_{\text{Mult}} = \frac{\alpha_{\text{FG}} \cdot \alpha_{\text{BG}}}{255}$$

$$\alpha_{\text{OUT}} = \alpha_{\text{FG}} + \alpha_{\text{BG}} - \alpha_{\text{Mult}}$$

$$C_{\text{OUT}} = \frac{C_{\text{FG}} \cdot \alpha_{\text{FG}} + C_{\text{BG}} \cdot \alpha_{\text{BG}} - C_{\text{BG}} \cdot \alpha_{\text{Mult}}}{\alpha_{\text{OUT}}} \quad \text{with } C = R \text{ or } G \text{ or } B$$

*Division are rounded to the nearest lower integer*

The resulting 32-bit pixel value is encoded by the output PFC according to the specified output format, and the data are written into the destination memory location pointed by DMA2D\_OMAR.

### Configuration error detection

The DMA2D checks that the configuration is correct before any transfer. The configuration error interrupt flag is set by hardware when a wrong configuration is detected when a new transfer/automatic loading starts. An interrupt is then generated if the CEIE bit of the DMA2D\_CR is set.

The wrong configurations that can be detected are listed below:

- Foreground CLUT automatic loading: MA bits of DMA2D\_FGCMAR are not aligned with CCM of DMA2D\_FGPFCCR.
- Background CLUT automatic loading: MA bits of DMA2D\_BGCMAR are not aligned with CCM of DMA2D\_BGPFCCR
- Memory transfer (except in register-to-memory mode): MA bits of DMA2D\_FGMAR are not aligned with CM of DMA2D\_FGPFCCR
- Memory transfer (except in register-to-memory mode): CM bits of DMA2D\_FGPFCCR are invalid
- Memory transfer (except in register-to-memory mode): PL bits of DMA2D\_NLR are odd while CM of DMA2D\_FGPFCCR is A4 or L4
- Memory transfer (except in register-to-memory mode): LO bits of DMA2D\_FGOR are odd while CM of DMA2D\_FGPFCCR is A4 or L4
- Memory transfer (only in blending mode): MA bits of DMA2D\_BGMAR are not aligned with the CM of DMA2D\_BGPFCCR
- Memory transfer: (only in blending mode) CM bits of DMA2D\_BGPFCCR are invalid
- Memory transfer (only in blending mode): PL bits of DMA2D\_NLR odd while CM of DMA2D\_BGPFCCR is A4 or L4

- Memory transfer (only in blending mode): LO bits of DMA2D\_BGOR are odd while CM of DMA2D\_BGPFCCR is A4 or L4
- Memory transfer (except in memory to memory mode): MA bits of DMA2D\_OMAR are not aligned with CM bits of DMA2D\_OPFCCR.
- Memory transfer (except in memory to memory mode): CM bits of DMA2D\_OPFCCR are invalid
- Memory transfer: NL bits of DMA2D\_NLR = 0
- Memory transfer: PL bits of DMA2D\_NLR = 0

### 9.3.12 DMA2D transfer control (start, suspend, abort and completion)

Once the DMA2D is configured, the transfer can be launched by setting the START bit of the DMA2D\_CR register. Once the transfer is completed, the START bit is automatically reset and the TCIF flag of the DMA2D\_ISR register is raised. An interrupt can be generated if the TCIE bit of the DMA2D\_CR is set.

The user application can suspend the DMA2D at any time by setting the SUSP bit of the DMA2D\_CR register. The transaction can then be aborted by setting the ABORT bit of the DMA2D\_CR register or can be restarted by resetting the SUSP bit of the DMA2D\_CR register.

The user application can abort at any time an ongoing transaction by setting the ABORT bit of the DMA2D\_CR register. In this case, the TCIF flag is not raised.

Automatic CLUT transfers can also be aborted or suspended by using the ABORT or the SUSP bit of the DMA2D\_CR register.

### 9.3.13 Watermark

A watermark can be programmed to generate an interrupt when the last pixel of a given line has been written to the destination memory area.

The line number is defined in the LW[15:0] field of the DMA2D\_LWR register.

When the last pixel of this line has been transferred, the TWIF flag of the DMA2D\_ISR register is raised and an interrupt is generated if the TWIE bit of the DMA2D\_CR is set.

### 9.3.14 Error management

Two kind of errors can be triggered:

- AHB master port errors signaled by the TEIF flag of the DMA2D\_ISR register.
- Conflicts caused by CLUT access (CPU trying to access the CLUT while a CLUT loading or a DMA2D transfer is ongoing) signalled by the CAEIF flag of the DMA2D\_ISR register.

Both flags are associated to their own interrupt enable flag in the DMA2D\_CR register to generate an interrupt if need be (TEIE and CAEIE).

### 9.3.15 AHB dead time

To limit the AHB bandwidth usage, a dead time between two consecutive AHB accesses can be programmed.

This feature can be enabled by setting the EN bit in the DMA2D\_AMTCR register.

The dead time value is stored in the DT[7:0] field of the DMA2D\_AMTCR register. This value represents the guaranteed minimum number of cycles between two consecutive transactions on the AHB bus.

The update of the dead time value while the DMA2D is running will be taken into account for the next AHB transfer.

## 9.4 DMA2D interrupts

An interrupt can be generated on the following events:

- Configuration error
- CLUT transfer complete
- CLUT access error
- Transfer watermark reached
- Transfer complete
- Transfer error

Separate interrupt enable bits are available for flexibility.

**Table 42. DMA2D interrupt requests**

| Interrupt event        | Event flag | Enable control bit |
|------------------------|------------|--------------------|
| Configuration error    | CEIF       | CEIE               |
| CLUT transfer complete | CTCIF      | CTCIE              |
| CLUT access error      | CAEIF      | CAEIE              |
| Transfer watermark     | TWF        | TWIE               |
| Transfer complete      | TCIF       | TCIE               |
| Transfer error         | TEIF       | TEIE               |

## 9.5 DMA2D registers

### 9.5.1 DMA2D control register (DMA2D\_CR)

Address offset: 0x0000

Reset value: 0x0000 0000

|      |      |      |       |       |      |      |      |      |      |      |      |      |       |           |       |

| Res. | Res. | Res. | Res.  | Res.  | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res.  | MODE[1:0] |       |
|      |      |      |       |       |      |      |      |      |      |      |      |      |       | rw        | rw    |
| 15   | 14   | 13   | 12    | 11    | 10   | 9    | 8    | 7    | 6    | 5    | 4    | 3    | 2     | 1         | 0     |
| Res. | Res. | CEIE | CTCIE | CAEIE | TWIE | TCIE | TEIE | Res. | Res. | Res. | Res. | Res. | ABORT | SUSP      | START |
|      |      | rw   | rw    | rw    | rw   | rw   | rw   |      |      |      |      |      | rs    | rw        | rs    |

Bits 31:18 Reserved, must be kept at reset value

Bits 17:16 **MODE[1:0]**: DMA2D mode

These bits are set and cleared by software. They cannot be modified while a transfer is ongoing.

00: Memory-to-memory (FG fetch only)

01: Memory-to-memory with PFC (FG fetch only with FG PFC active)

10: Memory-to-memory with blending (FG and BG fetch with PFC and blending)

11: Register-to-memory (no FG nor BG, only output stage active)

Bits 15:14 Reserved, must be kept at reset value

Bit 13 **CEIE**: Configuration Error Interrupt Enable

This bit is set and cleared by software.

0: CE interrupt disable

1: CE interrupt enable

Bit 12 **CTCIE**: CLUT transfer complete interrupt enable

This bit is set and cleared by software.

0: CTC interrupt disable

1: CTC interrupt enable

Bit 11 **CAEIE**: CLUT access error interrupt enable

This bit is set and cleared by software.

0: CAE interrupt disable

1: CAE interrupt enable

Bit 10 **TWIE**: Transfer watermark interrupt enable

This bit is set and cleared by software.

0: TW interrupt disable

1: TW interrupt enable

Bit 9 **TCIE**: Transfer complete interrupt enable

This bit is set and cleared by software.

0: TC interrupt disable

1: TC interrupt enable

Bit 8 **TEIE**: Transfer error interrupt enable

This bit is set and cleared by software.

0: TE interrupt disable

1: TE interrupt enable

Bits 7:3 Reserved, must be kept at reset value

Bit 2 **ABORT**: Abort

This bit can be used to abort the current transfer. This bit is set by software and is automatically reset by hardware when the START bit is reset.

0: No transfer abort requested

1: Transfer abort requested

Bit 1 **SUSP**: Suspend

This bit can be used to suspend the current transfer. This bit is set and reset by software. It is automatically reset by hardware when the START bit is reset.

0: Transfer not suspended

1: Transfer suspended

Bit 0 **START**: Start

This bit can be used to launch the DMA2D according to the parameters loaded in the various configuration registers. This bit is automatically reset by the following events:

- At the end of the transfer
- When the data transfer is aborted by the user application by setting the ABORT bit in DMA2D\_CR
- When a data transfer error occurs
- When the data transfer has not started due to a configuration error or another transfer operation already ongoing (automatic CLUT loading).

## 9.5.2 DMA2D Interrupt Status Register (DMA2D\_ISR)

Address offset: 0x0004

Reset value: 0x0000 0000

|      |      |      |      |      |      |      |      |      |      |      |       |       |      |      |      |
|------|------|------|------|------|------|------|------|------|------|------|-------|-------|------|------|------|

|      |      |      |      |      |      |      |      |      |      |      |       |       |      |      |      |
| 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5    | 4     | 3     | 2    | 1    | 0    |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | CEIF | CTCIF | CAEIF | TWIF | TCIF | TEIF |
|      |      |      |      |      |      |      |      |      |      | r    | r     | r     | r    | r    | r    |

Bits 31:6 Reserved, must be kept at reset value

Bit 5 **CEIF**: Configuration error interrupt flag

This bit is set when the START bit of DMA2D\_CR, DMA2DFGPFCCR or DMA2D\_BGPFCCR is set and a wrong configuration has been programmed.

Bit 4 **CTCIF**: CLUT transfer complete interrupt flag

This bit is set when the CLUT copy from a system memory area to the internal DMA2D memory is complete.

Bit 3 **CAEIF**: CLUT access error interrupt flag

This bit is set when the CPU accesses the CLUT while the CLUT is being automatically copied from a system memory to the internal DMA2D.

Bit 2 **TWIF**: Transfer watermark interrupt flag

This bit is set when the last pixel of the watermarked line has been transferred.

Bit 1 **TCIF**: Transfer complete interrupt flag

This bit is set when a DMA2D transfer operation is complete (data transfer only).

Bit 0 **TEIF**: Transfer error interrupt flag

This bit is set when an error occurs during a DMA transfer (data transfer or automatic CLUT loading).

### 9.5.3 DMA2D interrupt flag clear register (DMA2D\_IFCR)

Address offset: 0x0008

Reset value: 0x0000 0000

|      |      |      |      |      |      |      |      |      |      |       |        |        |       |       |       |
|------|------|------|------|------|------|------|------|------|------|-------|--------|--------|-------|-------|-------|
| 31   | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21    | 20     | 19     | 18    | 17    | 16    |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res.  | Res.   | Res.   | Res.  | Res.  | Res.  |
|      |      |      |      |      |      |      |      |      |      |       |        |        |       |       |       |
| 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5     | 4      | 3      | 2     | 1     | 0     |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | CCEIF | CCTCIF | CAECIF | CTWIF | CTCIF | CTEIF |
|      |      |      |      |      |      |      |      |      |      | rc_w1 | rc_w1  | rc_w1  | rc_w1 | rc_w1 | rc_w1 |

Bits 31:6 Reserved, must be kept at reset value

Bit 5 **CCEIF**: Clear configuration error interrupt flag

Programming this bit to 1 clears the CEIF flag in the DMA2D\_ISR register

Bit 4 **CCTCIF**: Clear CLUT transfer complete interrupt flag

Programming this bit to 1 clears the CTCIF flag in the DMA2D\_ISR register

Bit 3 **CAECIF**: Clear CLUT access error interrupt flag

Programming this bit to 1 clears the CAEIF flag in the DMA2D\_ISR register

Bit 2 **CTWIF**: Clear transfer watermark interrupt flag

Programming this bit to 1 clears the TWIF flag in the DMA2D\_ISR register

Bit 1 **CTCIF**: Clear transfer complete interrupt flag

Programming this bit to 1 clears the TCIF flag in the DMA2D\_ISR register

Bit 0 **CTEIF**: Clear Transfer error interrupt flag

Programming this bit to 1 clears the TEIF flag in the DMA2D\_ISR register

### 9.5.4 DMA2D foreground memory address register (DMA2D\_FGMAR)

Address offset: 0x000C

Reset value: 0x0000 0000

|           |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|-----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31        | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| MA[31:16] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rW        | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW |
| 15        | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| MA[15:0]  |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rW        | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW |

Bits 31:0 **MA[31: 0]**: Memory address

Address of the data used for the foreground image. This register can only be written when data transfers are disabled. Once the data transfer has started, this register is read-only.

The address alignment must match the image format selected e.g. a 32-bit per pixel format must be 32-bit aligned, a 16-bit per pixel format must be 16-bit aligned and a 4-bit per pixel format must be 8-bit aligned.

### 9.5.5 DMA2D foreground offset register (DMA2D\_FGOR)

Address offset: 0x0010

Reset value: 0x0000 0000

|      |      |          |      |      |      |      |      |      |      |      |      |      |      |      |      |
|------|------|----------|------|------|------|------|------|------|------|------|------|------|------|------|------|
| 31   | 30   | 29       | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21   | 20   | 19   | 18   | 17   | 16   |
| Res. | Res. | Res.     | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. |
|      |      |          |      |      |      |      |      |      |      |      |      |      |      |      |      |
| 15   | 14   | 13       | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0    |
| Res. | Res. | LO[13:0] |      |      |      |      |      |      |      |      |      |      |      |      |      |
|      |      | rW       | rW   | rW   | rW   | rW   | rW   | rW   | rW   | rW   | rW   | rW   | rW   | rW   | rW   |

Bits 31:14 Reserved, must be kept at reset value

Bits 13:0 **LO[13: 0]**: Line offset

Line offset used for the foreground expressed in pixel. This value is used to generate the address. It is added at the end of each line to determine the starting address of the next line.

These bits can only be written when data transfers are disabled. Once a data transfer has started, they become read-only.

If the image format is 4-bit per pixel, the line offset must be even.

### 9.5.6 DMA2D background memory address register (DMA2D\_BGMAR)

Address offset: 0x0014

Reset value: 0x0000 0000

|           |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|-----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31        | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| MA[31:16] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw        | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |
| 15        | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| MA[15:0]  |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw        | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 31: 0 **MA[31: 0]**: Memory address

Address of the data used for the background image. This register can only be written when data transfers are disabled. Once a data transfer has started, this register is read-only.

The address alignment must match the image format selected e.g. a 32-bit per pixel format must be 32-bit aligned, a 16-bit per pixel format must be 16-bit aligned and a 4-bit per pixel format must be 8-bit aligned.

### 9.5.7 DMA2D background offset register (DMA2D\_BGOR)

Address offset: 0x0018

Reset value: 0x0000 0000

|      |      |          |      |      |      |      |      |      |      |      |      |      |      |      |      |
|------|------|----------|------|------|------|------|------|------|------|------|------|------|------|------|------|
| 31   | 30   | 29       | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21   | 20   | 19   | 18   | 17   | 16   |
| Res. | Res. | Res.     | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. |
|      |      |          |      |      |      |      |      |      |      |      |      |      |      |      |      |
| 15   | 14   | 13       | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0    |
| Res. | Res. | LO[13:0] |      |      |      |      |      |      |      |      |      |      |      |      |      |
|      |      | rw       | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   |

Bits 31:14 Reserved, must be kept at reset value

Bits 13:0 **LO[13: 0]**: Line offset

Line offset used for the background image (expressed in pixel). This value is used for the address generation. It is added at the end of each line to determine the starting address of the next line.

These bits can only be written when data transfers are disabled. Once data transfer has started, they become read-only.

If the image format is 4-bit per pixel, the line offset must be even.

### 9.5.8 DMA2D foreground PFC control register (DMA2D\_FGPFCCR)

Address offset: 0x001C

Reset value: 0x0000 0000

|            |    |    |    |    |    |    |    |      |      |       |      |         |      |         |    |

| CS[7:0]    |    |    |    |    |    |    |    | Res. | Res. | START | CCM  | CM[3:0] |      |         |    |
| rw         | rw | rw | rw | rw | rw | rw | rw |      |      | rs    | rw   | rw      | rw   | rw      | rw |

Bits 31:24 **ALPHA[7: 0]**: Alpha value

These bits define a fixed alpha channel value which can replace the original alpha value or be multiplied by the original alpha value according to the alpha mode selected through the AM[1:0] bits.

These bits can only be written when data transfers are disabled. Once a transfer has started, they become read-only.

Bits 23:18 Reserved, must be kept at reset value

Bits 17:16 **AM[1: 0]**: Alpha mode

These bits select the alpha channel value to be used for the foreground image. They can only be written data the transfer are disabled. Once the transfer has started, they become read-only.

00: No modification of the foreground image alpha channel value

01: Replace original foreground image alpha channel value by ALPHA[7: 0]

10: Replace original foreground image alpha channel value by ALPHA[7:0] multiplied with original alpha channel value

other configurations are meaningless

Bits 15:8 **CS[7: 0]**: CLUT size

These bits define the size of the CLUT used for the foreground image. Once the CLUT transfer has started, this field is read-only.

The number of CLUT entries is equal to CS[7:0] + 1.

Bits 7:6 Reserved, must be kept at reset value

Bit 5 **START**: Start

This bit can be set to start the automatic loading of the CLUT. It is automatically reset:

- at the end of the transfer
- when the transfer is aborted by the user application by setting the ABORT bit in DMA2D\_CR
- when a transfer error occurs
- when the transfer has not started due to a configuration error or another transfer operation already ongoing (data transfer or automatic background CLUT transfer).

Bit 4 **CCM**: CLUT color mode

This bit defines the color format of the CLUT. It can only be written when the transfer is disabled. Once the CLUT transfer has started, this bit is read-only.

0: ARGB8888

1: RGB888

others: meaningless

Bits 3:0 **CM[3: 0]**: Color mode

These bits defines the color format of the foreground image. They can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

0000: ARGB8888

0001: RGB888

0010: RGB565

0011: ARGB1555

0100: ARGB4444

0101: L8

0110: AL44

0111: AL88

1000: L4

1001: A8

1010: A4

others: meaningless

### 9.5.9 DMA2D foreground color register (DMA2D\_FGCOLR)

Address offset: 0x0020

Reset value: 0x0000 0000

Bits 31:24 Reserved, must be kept at reset value

Bits 23:16 **RED[7: 0]**: Red Value

These bits defines the red value for the A4 or A8 mode of the foreground image. They can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

Bits 15:8 **GREEN[7: 0]**: Green Value

These bits defines the green value for the A4 or A8 mode of the foreground image. They can only be written when data transfers are disabled. Once the transfer has started, They are read-only.

Bits 7:0 **BLUE[7: 0]**: Blue Value

These bits defines the blue value for the A4 or A8 mode of the foreground image. They can only be written when data transfers are disabled. Once the transfer has started, They are read-only.

### 9.5.10 DMA2D background PFC control register (DMA2D\_BGPFCCR)

Address offset: 0x0024

Reset value: 0x0000 0000

|            |    |    |    |    |    |    |    |      |      |       |      |         |      |         |    |

Bits 31:24 **ALPHA[7: 0]**: Alpha value

These bits define a fixed alpha channel value which can replace the original alpha value or be multiplied with the original alpha value according to the alpha mode selected with bits AM[1: 0]. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

Bits 23:18 Reserved, must be kept at reset value

Bits 17:16 **AM[1: 0]**: Alpha mode

These bits define which alpha channel value to be used for the background image. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

00: No modification of the foreground image alpha channel value

01: Replace original background image alpha channel value by ALPHA[7: 0]

10: Replace original background image alpha channel value by ALPHA[7:0] multiplied with original alpha channel value

others: meaningless

Bits 15:8 **CS[7: 0]**: CLUT size

These bits define the size of the CLUT used for the BG. Once the CLUT transfer has started, this field is read-only.

The number of CLUT entries is equal to CS[7:0] + 1.

Bits 7:6 Reserved, must be kept at reset value

Bit 5 **START**: Start

This bit is set to start the automatic loading of the CLUT. This bit is automatically reset:

- at the end of the transfer
- when the transfer is aborted by the user application by setting the ABORT bit in the DMA2D\_CR
- when a transfer error occurs
- when the transfer has not started due to a configuration error or another transfer operation already on going (data transfer or automatic foreground CLUT transfer).

Bit 4 **CCM**: CLUT Color mode

These bits define the color format of the CLUT. This register can only be written when the transfer is disabled. Once the CLUT transfer has started, this bit is read-only.

0: ARGB8888

1: RGB888

others: meaningless

Bits 3:0 **CM[3: 0]**: Color mode

These bits define the color format of the foreground image. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

0000: ARGB8888

0001: RGB888

0010: RGB565

0011: ARGB1555

Bits 31:24 **ALPHA[7: 0]**: Alpha Channel Value

These bits define the alpha channel of the output color. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

Bits 23:16 **RED[7: 0]**: Red Value

These bits define the red value of the output image. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

Bits 15:8 **GREEN[7: 0]**: Green Value

These bits define the green value of the output image. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

Bits 7:0 **BLUE[7: 0]**: Blue Value

These bits define the blue value of the output image. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

9.5.16 DMA2D output memory address register (DMA2D\_OMAR)

Address offset: 0x003C

Reset value: 0x0000 0000

|           |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

| MA[15:0]  |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw        | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 31: 0 **MA[31: 0]**: Memory Address

Address of the data used for the output FIFO. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

The address alignment must match the image format selected e.g. a 32-bit per pixel format must be 32-bit aligned and a 16-bit per pixel format must be 16-bit aligned.

### 9.5.17 DMA2D output offset register (DMA2D\_OOR)

Address offset: 0x0040

Reset value: 0x0000 0000

|      |      |          |      |      |      |      |      |      |      |      |      |      |      |      |      |

Bits 31:14 Reserved, must be kept at reset value

Bits 13:0 **LO[13: 0]**: Line Offset

Line offset used for the output (expressed in pixels). This value is used for the address generation. It is added at the end of each line to determine the starting address of the next line. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

### 9.5.18 DMA2D number of line register (DMA2D\_NLR)

Address offset: 0x0044

Reset value: 0x0000 0000

Bits 31:30 Reserved, must be kept at reset value

Bits 29:16 **PL[13: 0]**: Pixel per lines

Number of pixels per lines of the area to be transferred. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.  
If any of the input image format is 4-bit per pixel, pixel per lines must be even.

Bits 15:0 **NL[15: 0]**: Number of lines

Number of lines of the area to be transferred. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

### 9.5.19 DMA2D line watermark register (DMA2D\_LWR)

Address offset: 0x0048

Reset value: 0x0000 0000

|          |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |

Bits 31:16 Reserved, must be kept at reset value

Bits 15:0 **LW[15:0]**: Line watermark

These bits allow to configure the line watermark for interrupt generation.

An interrupt is raised when the last pixel of the watermarked line has been transferred.

These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

### 9.5.20 DMA2D AHB master timer configuration register (DMA2D\_AMTCR)

Address offset: 0x004C

Reset value: 0x0000 0000

|         |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |

Bits 31:16 Reserved

Bits 15:8 **DT[7: 0]**: Dead Time

Dead time value in the AHB clock cycle inserted between two consecutive accesses on the AHB master port. These bits represent the minimum guaranteed number of cycles between two consecutive AHB accesses.

Bits 7:1 Reserved

Bit 0 **EN**: Enable

Enables the dead time functionality.

## 9.5.21 DMA2D register map

The following table summarizes the DMA2D registers. Refer to [Section 2.2.2 on page 69](#) for the DMA2D register base address.

**Table 43. DMA2D register map and reset values**

| Offset | Register      | 31         | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23       | 22   | 21   | 20   | 19   | 18   | 17        | 16         | 15   | 14   | 13       | 12   | 11    | 10    | 9         | 8    | 7    | 6     | 5    | 4       | 3      | 2      | 1       | 0     |       |  |  |  |  |   |

## 10 Nested vectored interrupt controller (NVIC)

### 10.1 NVIC features

The nested vector interrupt controller NVIC includes the following features:

- up to 98 maskable interrupt channels for STM32F75xxx and STM32F74xxx (not including the 16 interrupt lines of Cortex<sup>®</sup>-M7 with FPU)
- 16 programmable priority levels (4 bits of interrupt priority are used)
- low-latency exception and interrupt handling
- power management control
- implementation of system control registers

The NVIC and the processor core interface are closely coupled, which enables low latency interrupt processing and efficient processing of late arriving interrupts.

All interrupts including the core exceptions are managed by the NVIC. For more information on exceptions and NVIC programming, refer to programming manual PMxxxx.

#### 10.1.1 SysTick calibration value register

The SysTick calibration value is fixed to 18750, which gives a reference time base of 1 ms with the SysTick clock set to 18.75 MHz (HCLK/8, with HCLK set to 150 MHz).

#### 10.1.2 Interrupt and exception vectors

See [Table 44](#), for the vector table for the STM32F75xxx and STM32F74xxx devices.

**Table 44. STM32F75xxx and STM32F74xxx vector table**

## 11 Extended interrupts and events controller (EXTI)

The external interrupt/event controller consists of up to 24 edge detectors for generating event/interrupt requests. Each input line can be independently configured to select the type (interrupt or event) and the corresponding trigger event (rising or falling or both). Each line can also be masked independently. A pending register maintains the status line of the interrupt requests.

### 11.1 EXTI main features

The main features of the EXTI controller are the following:

- independent trigger and mask on each interrupt/event line
- dedicated status bit for each interrupt line
- generation of up to 24 software event/interrupt requests
- detection of external signals with a pulse width lower than the APB2 clock period. Refer to the electrical characteristics section of the STM32F75xxx and STM32F74xxx datasheets for details on this parameter.

### 11.2 EXTI block diagram

Figure 30 shows the block diagram.

Figure 30. External interrupt/event controller block diagram

## 11.3 Wakeup event management

The STM32F75xxx and STM32F74xxx devices are able to handle external or internal events in order to wake up the core (WFE). The wakeup event can be generated either by:

- enabling an interrupt in the peripheral control register but not in the NVIC, and enabling the SEVONPEND bit in the Cortex<sup>®</sup>-M7 System Control register. When the MCU resumes from WFE, the peripheral interrupt pending bit and the peripheral NVIC IRQ channel pending bit (in the NVIC interrupt clear pending register) have to be cleared.
- or configuring an external or internal EXTI line in event mode. When the CPU resumes from WFE, it is not necessary to clear the peripheral interrupt pending bit or the NVIC IRQ channel pending bit as the pending bit corresponding to the event line is not set.

To use an external line as a wakeup event, refer to [Section 11.4: Functional description](#).

## 11.4 Functional description

To generate the interrupt, the interrupt line should be configured and enabled. This is done by programming the two trigger registers with the desired edge detection and by enabling the interrupt request by writing a '1' to the corresponding bit in the interrupt mask register. When the selected edge occurs on the external interrupt line, an interrupt request is generated. The pending bit corresponding to the interrupt line is also set. This request is reset by writing a '1' in the pending register.

To generate the event, the event line should be configured and enabled. This is done by programming the two trigger registers with the desired edge detection and by enabling the event request by writing a '1' to the corresponding bit in the event mask register. When the selected edge occurs on the event line, an event pulse is generated. The pending bit corresponding to the event line is not set.

An interrupt/event request can also be generated by software by writing a '1' in the software interrupt/event register.

## 11.5 Hardware interrupt selection

To configure a line as interrupt sources, use the following procedure:

1. Configure the corresponding mask bit (EXTI\_IMR)
2. Configure the Trigger selection bits of the interrupt lines (EXTI\_RTISR and EXTI\_FTISR)
3. Configure the enable and mask bits that control the NVIC IRQ channel mapped to the external interrupt controller (EXTI) so that an interrupt coming from one of the 24 lines can be correctly acknowledged.

## 11.6 Hardware event selection

To configure a line as event sources, use the following procedure:

1. Configure the corresponding mask bit (EXTI\_EMR)
2. Configure the Trigger selection bits of the event line (EXTI\_RTISR and EXTI\_FTISR)

## 11.7 Software interrupt/event selection

The line can be configured as software interrupt/event line. The following is the procedure to generate a software interrupt.

1. Configure the corresponding mask bit (EXTI\_IMR, EXTI\_EMR)
2. Set the required bit in the software interrupt register (EXTI\_SWIER)

## 11.8 External interrupt/event line mapping

Up to 168 GPIOs are connected to the 16 external interrupt/event lines in the following manner:

**Figure 31. External interrupt/event GPIO mapping**

The eight other EXTI lines are connected as follows:

- EXTI line 16 is connected to the PVD output
- EXTI line 17 is connected to the RTC Alarm event
- EXTI line 18 is connected to the USB OTG FS Wakeup event
- EXTI line 19 is connected to the Ethernet Wakeup event
- EXTI line 20 is connected to the USB OTG HS (configured in FS) Wakeup event
- EXTI line 21 is connected to the RTC Tamper and TimeStamp events
- EXTI line 22 is connected to the RTC Wakeup event
- EXTI line 23 is connected to the LPTIM1 asynchronous event

## 11.9 EXTI registers

Refer to [Section 1.2 on page 62](#) for a list of abbreviations used in register descriptions.

### 11.9.1 Interrupt mask register (EXTI\_IMR)

Address offset: 0x00

Reset value: 0x0000 0000

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:0 **SWIERx**: Software Interrupt on line x

If interrupt are enabled on line x in the EXTI\_IMR register, writing '1' to SWIERx bit when it is set at '0' sets the corresponding pending bit in the EXTI\_PR register, thus resulting in an interrupt request generation.

This bit is cleared by clearing the corresponding bit in EXTI\_PR (by writing a 1 to the bit).

### 11.9.6 Pending register (EXTI\_PR)

Address offset: 0x14

Reset value: undefined

Refer to [Section 2.2.2 on page 69](#) for the register boundary addresses.

## 12 Cyclic redundancy check calculation unit (CRC)

### 12.1 Introduction

The CRC (cyclic redundancy check) calculation unit is used to get a CRC code from 8-, 16- or 32-bit data word and a generator polynomial.

Among other applications, CRC-based techniques are used to verify data transmission or storage integrity. In the scope of the functional safety standards, they offer a means of verifying the Flash memory integrity. The CRC calculation unit helps compute a signature of the software during runtime, to be compared with a reference signature generated at link time and stored at a given memory location.

### 12.2 CRC main features

- Uses CRC-32 (Ethernet) polynomial: 0x4C11DB7  
$$X^{32} + X^{26} + X^{23} + X^{22} + X^{16} + X^{12} + X^{11} + X^{10} + X^8 + X^7 + X^5 + X^4 + X^2 + X + 1$$
- Alternatively, uses fully programmable polynomial with programmable size (7, 8, 16, 32 bits)
- Handles 8-, 16-, 32-bit data size
- Programmable CRC initial value
- Single input/output 32-bit data register
- Input buffer to avoid bus stall during calculation
- CRC computation done in 4 AHB clock cycles (HCLK) for the 32-bit data size
- General-purpose 8-bit register (can be used for temporary storage)
- Reversibility option on I/O data

## 12.3 CRC functional description

### 12.3.1 CRC block diagram

Figure 32. CRC calculation unit block diagram

### 12.3.2 CRC internal signals

Table 46. CRC internal input/output signals

| Signal name | Signal type   | Description |
|-------------|---------------|-------------|
| crc_hclk    | Digital input | AHB clock   |

### 12.3.3 CRC operation

The CRC calculation unit has a single 32-bit read/write data register (CRC\_DR). It is used to input new data (write access), and holds the result of the previous CRC calculation (read access).

Each write operation to the data register creates a combination of the previous CRC value (stored in CRC\_DR) and the new one. CRC computation is done on the whole 32-bit data word or byte by byte depending on the format of the data being written.

The CRC\_DR register can be accessed by word, right-aligned half-word and right-aligned byte. For the other registers only 32-bit access is allowed.

The duration of the computation depends on data width:

- 4 AHB clock cycles for 32-bit
- 2 AHB clock cycles for 16-bit
- 1 AHB clock cycles for 8-bit

An input buffer allows to immediately write a second data without waiting for any wait states due to the previous CRC calculation.

The data size can be dynamically adjusted to minimize the number of write accesses for a given number of bytes. For instance, a CRC for 5 bytes can be computed with a word write followed by a byte write.

The input data can be reversed, to manage the various endianness schemes. The reversing operation can be performed on 8 bits, 16 bits and 32 bits depending on the REV\_IN[1:0] bits in the CRC\_CR register.

For example: input data 0x1A2B3C4D is used for CRC calculation as:

- 0x58D43CB2 with bit-reversal done by byte
- 0xD458B23C with bit-reversal done by half-word
- 0xB23CD458 with bit-reversal done on the full word

The output data can also be reversed by setting the REV\_OUT bit in the CRC\_CR register.

The operation is done at bit level: for example, output data 0x11223344 is converted into 0x22CC4488.

The CRC calculator can be initialized to a programmable value using the RESET control bit in the CRC\_CR register (the default value is 0xFFFFFFFF).

The initial CRC value can be programmed with the CRC\_INIT register. The CRC\_DR register is automatically initialized upon CRC\_INIT register write access.

The CRC\_IDR register can be used to hold a temporary value related to CRC calculation. It is not affected by the RESET bit in the CRC\_CR register.

### Polynomial programmability

The polynomial coefficients are fully programmable through the CRC\_POL register, and the polynomial size can be configured to be 7, 8, 16 or 32 bits by programming the POLYSIZE[1:0] bits in the CRC\_CR register. Even polynomials are not supported.

If the CRC data is less than 32-bit, its value can be read from the least significant bits of the CRC\_DR register.

To obtain a reliable CRC calculation, the change on-fly of the polynomial value or size can not be performed during a CRC calculation. As a result, if a CRC calculation is ongoing, the application must either reset it or perform a CRC\_DR read before changing the polynomial.

The default polynomial value is the CRC-32 (Ethernet) polynomial: 0x4C11DB7.

## 12.4 CRC registers

### 12.4.1 Data register (CRC\_DR)

Address offset: 0x00

Reset value: 0xFFFF FFFF

|           |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|-----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31        | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| DR[31:16] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw        | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |
| 15        | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| DR[15:0]  |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw        | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 31:0 **DR[31:0]**: Data register bits

This register is used to write new data to the CRC calculator.

It holds the previous CRC calculation result when it is read.

If the data size is less than 32 bits, the least significant bits are used to write/read the correct value.

### 12.4.2 Independent data register (CRC\_IDR)

Address offset: 0x04

Reset value: 0x0000 0000

|      |      |      |      |      |      |      |      |          |      |      |      |      |      |      |      |
|------|------|------|------|------|------|------|------|----------|------|------|------|------|------|------|------|
| 31   | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23       | 22   | 21   | 20   | 19   | 18   | 17   | 16   |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res.     | Res. | Res. | Res. | Res. | Res. | Res. | Res. |
| 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7        | 6    | 5    | 4    | 3    | 2    | 1    | 0    |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | IDR[7:0] |      |      |      |      |      |      |      |
|      |      |      |      |      |      |      |      | rw       |      |      |      |      |      |      |      |

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **IDR[7:0]**: General-purpose 8-bit data register bits

These bits can be used as a temporary storage location for one byte.

This register is not affected by CRC resets generated by the RESET bit in the CRC\_CR register

### 12.4.3 Control register (CRC\_CR)

Address offset: 0x08

Reset value: 0x0000 0000

|      |      |      |      |      |      |      |      |         |             |      |               |      |      |      |       |
|------|------|------|------|------|------|------|------|---------|-------------|------|---------------|------|------|------|-------|
| 31   | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23      | 22          | 21   | 20            | 19   | 18   | 17   | 16    |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res.    | Res.        | Res. | Res.          | Res. | Res. | Res. | Res.  |
|      |      |      |      |      |      |      |      |         |             |      |               |      |      |      |       |
| 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7       | 6           | 5    | 4             | 3    | 2    | 1    | 0     |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | REV_OUT | REV_IN[1:0] |      | POLYSIZE[1:0] |      | Res. | Res. | RESET |
|      |      |      |      |      |      |      |      | rw      | rw          | rw   | rw            | rw   |      |      | rs    |

Bits 31:8 Reserved, must be kept at reset value.

Bit 7 **REV\_OUT**: Reverse output data

This bit controls the reversal of the bit order of the output data.

0: Bit order not affected

1: Bit-reversed output format

Bits 6:5 **REV\_IN[1:0]**: Reverse input data

These bits control the reversal of the bit order of the input data

00: Bit order not affected

01: Bit reversal done by byte

10: Bit reversal done by half-word

11: Bit reversal done by word

Bits 4:3 **POLYSIZE[1:0]**: Polynomial size

These bits control the size of the polynomial.

00: 32 bit polynomial

01: 16 bit polynomial

10: 8 bit polynomial

11: 7 bit polynomial

Bits 2:1 Reserved, must be kept at reset value.

Bit 0 **RESET**: RESET bit

This bit is set by software to reset the CRC calculation unit and set the data register to the value stored in the CRC\_INIT register. This bit can only be set, it is automatically cleared by hardware

### 12.4.4 Initial CRC value (CRC\_INIT)

Address offset: 0x10

Reset value: 0xFFFF FFFF

|                 |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|-----------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31              | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| CRC_INIT[31:16] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw              | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |
| 15              | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| CRC_INIT[15:0]  |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw              | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 31:0 **CRC\_INIT[31:0]**: Programmable initial CRC value

This register is used to write the CRC initial value.

### 12.4.5 CRC polynomial (CRC\_POL)

Address offset: 0x14

Reset value: 0x04C1 1DB7

|            |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31         | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| POL[31:16] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rW         | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW |
| 15         | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| POL[15:0]  |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rW         | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW |

Bits 31:0 **POL[31:0]**: Programmable polynomial

This register is used to write the coefficients of the polynomial to be used for CRC calculation.

If the polynomial size is less than 32 bits, the least significant bits have to be used to program the correct value.

### 12.4.6 CRC register map

Table 47. CRC register map and reset values

| Offset | Register name | 31                      | 30  | 29  | 28  | 27  | 26  | 25  | 24  | 23  | 22  | 21  | 20  | 19  | 18  | 17  | 16  | 15  | 14  | 13  | 12  | 11  | 10  | 9   | 8   | 7        | 6           | 5 | 4             | 3 | 2   | 1   | 0     |   |  |  |

| 0x10   | CRC_INIT      | CRC_INIT[31:0]          |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |          |             |   |               |   |     |     |       |   |  |  |
|        | Reset value   | 1                       | 1   | 1   | 1   | 1   | 1   | 1   | 1   | 1   | 1   | 1   | 1   | 1   | 1   | 1   | 1   | 1   | 1   | 1   | 1   | 1   | 1   | 1   | 1   | 1        | 1           | 1 | 1             | 1 | 1   | 1   | 1     |   |  |  |
| 0x14   | CRC_POL       | Polynomial coefficients |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |          |             |   |               |   |     |     |       |   |  |  |
|        | Reset value   | 0x04C11DB7              |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |          |             |   |               |   |     |     |       |   |  |  |

Refer to [Section 2.2.2 on page 69](#) for the register boundary addresses.

## 13 Flexible memory controller (FMC)

The Flexible memory controller (FMC) includes three memory controllers:

- The NOR/PSRAM memory controller
- The NAND memory controller
- The Synchronous DRAM (SDRAM/Mobile LPDDR SDRAM) controller

### 13.1 FMC main features

The FMC functional block makes the interface with: synchronous and asynchronous static memories, SDRAM memories, and NAND Flash memory. Its main purposes are:

- to translate AHB transactions into the appropriate external device protocol
- to meet the access time requirements of the external memory devices

All external memories share the addresses, data and control signals with the controller. Each external device is accessed by means of a unique chip select. The FMC performs only one access at a time to an external device.

The main features of the FMC controller are the following:

- Interface with static-memory mapped devices including:
  - Static random access memory (SRAM)
  - NOR Flash memory/OneNAND Flash memory
  - PSRAM (4 memory banks)
  - NAND Flash memory with ECC hardware to check up to 8 Kbytes of data
- Interface with synchronous DRAM (SDRAM/Mobile LPDDR SDRAM) memories
- Interface with parallel LCD modules, supporting Intel 8080 and Motorola 6800 modes.
- Burst mode support for faster access to synchronous devices such as NOR Flash memory, PSRAM and SDRAM)
- Programmable continuous clock output for asynchronous and synchronous accesses
- 8-, 16- or 32-bit wide data bus
- Independent chip select control for each memory bank
- Independent configuration for each memory bank
- Write enable and byte lane select outputs for use with PSRAM, SRAM and SDRAM devices
- External asynchronous wait control
- Write FIFO with 16 x32-bit depth
- Cacheable Read FIFO with 6 x32-bit depth (6 x14-bit address tag) for SDRAM controller.

The Write FIFO is common to all memory controllers and consists of:

- a Write Data FIFO which stores the AHB data to be written to the memory (up to 32 bits) plus one bit for the AHB transfer (burst or not sequential mode)
- a Write Address FIFO which stores the AHB address (up to 28 bits) plus the AHB data size (up to 2 bits). When operating in burst mode, only the start address is stored except when crossing a page boundary (for PSRAM and SDRAM). In this case, the AHB burst is broken into two FIFO entries.

The Write FIFO can be disabled by setting the WFDIS bit in the FMC\_BCR1 register.

At startup the FMC pins must be configured by the user application. The FMC I/O pins which are not used by the application can be used for other purposes.

The FMC registers that define the external device type and associated characteristics are usually set at boot time and do not change until the next reset or power-up. However, the settings can be changed at any time.

## 13.2 FMC block diagram

The FMC consists of the following main blocks:

- The AHB interface (including the FMC configuration registers)
- The NOR Flash/PSRAM/SRAM controller
- The SDRAM controller
- The NAND Flash controller

The block diagram is shown in the figure below.

**Figure 33. FMC block diagram**

## 13.3 AHB interface

The AHB slave interface allows internal CPUs and other bus master peripherals to access the external memories.

AHB transactions are translated into the external device protocol. In particular, if the selected external memory is 16- or 8-bit wide, 32-bit wide transactions on the AHB are split into consecutive 16- or 8-bit accesses. The FMC chip select (FMC\_NEx) does not toggle between the consecutive accesses except in case of Access mode D when the Extended mode is enabled.

The FMC generates an AHB error in the following conditions:

- When reading or writing to an FMC bank (Bank 1 to 4) which is not enabled.
- When reading or writing to the NOR Flash bank while the FACCEN bit is reset in the FMC\_BCRx register.
- When writing to a write protected SDRAM bank (WP bit set in the SDRAM\_SDCRx register).
- When the SDRAM address range is violated (access to reserved address range)

The effect of an AHB error depends on the AHB master which has attempted the R/W access:

- If the access has been attempted by the Cortex®-M7 CPU, a hard fault interrupt is generated.
- If the access has been performed by a DMA controller, a DMA transfer error is generated and the corresponding DMA channel is automatically disabled.

The AHB clock (HCLK) is the reference clock for the FMC.

### 13.3.1 Supported memories and transactions

#### General transaction rules

The requested AHB transaction data size can be 8-, 16- or 32-bit wide whereas the accessed external device has a fixed data width. This may lead to inconsistent transfers.

Therefore, some simple transaction rules must be followed:

- AHB transaction size and memory data size are equal  
There is no issue in this case.
- AHB transaction size is greater than the memory size:  
In this case, the FMC splits the AHB transaction into smaller consecutive memory accesses to meet the external data width. The FMC chip select (FMC\_NEx) does not toggle between the consecutive accesses.
- AHB transaction size is smaller than the memory size:  
The transfer may or not be consistent depending on the type of external device:
  - Accesses to devices that have the byte select feature (SRAM, ROM, PSRAM, SDRAM)  
In this case, the FMC allows read/write transactions and accesses the right data through its byte lanes NBL[3:0].  
Bytes to be written are addressed by NBL[3:0].  
All memory bytes are read (NBL[3:0] are driven low during read transaction) and the useless ones are discarded.
  - Accesses to devices that do not have the byte select feature (NOR and NAND Flash memories)  
This situation occurs when a byte access is requested to a 16-bit wide Flash memory. Since the device cannot be accessed in Byte mode (only 16-bit words can be read/written from/to the Flash memory), Write transactions and Read transactions are allowed (the controller reads the entire 16-bit memory word and uses only the required byte).

### Wrap support for NOR Flash/PSRAM and SDRAM

The synchronous memories must be configured in Linear burst mode of undefined length as not all masters can issue a wrap transactions.

If a master generates an AHB wrap transaction:

- The read is splitted into two linear burst transactions.
- The write is splitted into two linear burst transactions if the write fifo is enabled and into several linear burst transactions if the write fifo is disabled.

### Configuration registers

The FMC can be configured through a set of registers. Refer to [Section 13.5.6](#), for a detailed description of the NOR Flash/PSRAM controller registers. Refer to [Section 13.6.7](#), for a detailed description of the NAND Flash registers and to [Section 13.7.5](#) for a detailed description of the SDRAM controller registers.

## 13.4 External device address mapping

From the FMC point of view, the external memory is divided into fixed-size banks of 256 Mbytes each (see [Figure 34](#)):

- Bank 1 used to address up to 4 NOR Flash memory or PSRAM devices. This bank is split into 4 NOR/PSRAM subbanks with 4 dedicated chip selects, as follows:
  - Bank 1 - NOR/PSRAM 1
  - Bank 1 - NOR/PSRAM 2
  - Bank 1 - NOR/PSRAM 3
  - Bank 1 - NOR/PSRAM 4
- Bank 3 used to address NAND Flash memory devices. The MPU memory attribute for this space must be reconfigured by software to Device.
- Bank 4 and 5 used to address SDRAM devices (1 device per bank).

For each bank the type of memory to be used can be configured by the user application through the Configuration register.

**Figure 34. FMC memory banks**

### 13.4.1 NOR/PSRAM address mapping

HADDR[27:26] bits are used to select one of the four memory banks as shown in [Table 48](#).

Table 48. NOR/PSRAM bank selection

| HADDR[27:26] <sup>(1)</sup> | Selected bank        |
|-----------------------------|----------------------|
| 00                          | Bank 1 - NOR/PSRAM 1 |
| 01                          | Bank 1 - NOR/PSRAM 2 |
| 10                          | Bank 1 - NOR/PSRAM 3 |
| 11                          | Bank 1 - NOR/PSRAM 4 |

1. HADDR are internal AHB address lines that are translated to external memory.

The HADDR[25:0] bits contain the external memory address. Since HADDR is a byte address whereas the memory is addressed at word level, the address actually issued to the memory varies according to the memory data width, as shown in the following table.

Table 49. NOR/PSRAM External memory address

| Memory width <sup>(1)</sup> | Data address issued to the memory | Maximum memory capacity (bits) |
|-----------------------------|-----------------------------------|--------------------------------|
| 8-bit                       | HADDR[25:0]                       | 64 Mbytes x 8 = 512 Mbit       |
| 16-bit                      | HADDR[25:1] >> 1                  | 64 Mbytes/2 x 16 = 512 Mbit    |
| 32-bit                      | HADDR[25:2] >> 2                  | 64 Mbytes/4 x 32 = 512 Mbit    |

1. In case of a 16-bit external memory width, the FMC will internally use HADDR[25:1] to generate the address for external memory FMC\_A[24:0]. In case of a 32-bit memory width, the FMC will internally use HADDR[25:2] to generate the external address. Whatever the external memory width, FMC\_A[0] should be connected to external memory address A[0].

### 13.4.2 NAND Flash memory address mapping

The NAND bank is divided into memory areas as indicated in [Table 50](#).

Table 50. NAND memory mapping and timing registers

| Start address | End address | FMC bank            | Memory space | Timing register |
|---------------|-------------|---------------------|--------------|-----------------|
| 0x8800 0000   | 0x8BFF FFFF | Bank 3 - NAND Flash | Attribute    | FMC_PATT (0x8C) |
| 0x8000 0000   | 0x83FF FFFF |                     | Common       | FMC_PMEM (0x88) |

For NAND Flash memory, the common and attribute memory spaces are subdivided into three sections (see in [Table 51](#) below) located in the lower 256 Kbytes:

- Data section (first 64 Kbytes in the common/attribute memory space)
- Command section (second 64 Kbytes in the common / attribute memory space)
- Address section (next 128 Kbytes in the common / attribute memory space)

Table 51. NAND bank selection

| Section name    | HADDR[17:16] | Address range     |
|-----------------|--------------|-------------------|
| Address section | 1X           | 0x020000-0x03FFFF |
| Command section | 01           | 0x010000-0x01FFFF |
| Data section    | 00           | 0x000000-0x0FFFFF |

The application software uses the 3 sections to access the NAND Flash memory:

- **To sending a command to NAND Flash memory**, the software must write the command value to any memory location in the command section.
- **To specify the NAND Flash address that must be read or written**, the software must write the address value to any memory location in the address section. Since an address can be 4 or 5 bytes long (depending on the actual memory size), several consecutive write operations to the address section are required to specify the full address.
- **To read or write data**, the software reads or writes the data from/to any memory location in the data section.

Since the NAND Flash memory automatically increments addresses, there is no need to increment the address of the data section to access consecutive memory locations.

### 13.4.3 SDRAM address mapping

The HADDR[28] bit (internal AHB address line 28) is used to select one of the two memory banks as indicated in [Table 52](#).

**Table 52. SDRAM bank selection**

| HADDR[28] | Selected bank | Control register | Timing register |
|-----------|---------------|------------------|-----------------|
| 0         | SDRAM Bank1   | FMC_SDCR1        | FMC_SDTR1       |
| 1         | SDRAM Bank2   | FMC_SDCR2        | FMC_SDTR2       |

The following table shows SDRAM mapping for a 13-bit row, a 11-bit column and a 4 internal bank configuration.

**Table 53. SDRAM address mapping**

| Memory width <sup>(1)</sup> | Internal bank | Row address  | Column address <sup>(2)</sup> | Maximum memory capacity (Mbytes) |
|-----------------------------|---------------|--------------|-------------------------------|----------------------------------|
| 8-bit                       | HADDR[25:24]  | HADDR[23:11] | HADDR[10:0]                   | 64 Mbytes:<br>4 x 8K x 2K        |
| 16-bit                      | HADDR[26:25]  | HADDR[24:12] | HADDR[11:1]                   | 128 Mbytes:<br>4 x 8K x 2K x 2   |
| 32-bit                      | HADDR[27:26]  | HADDR[25:13] | HADDR[12:2]                   | 256 Mbytes:<br>4 x 8K x 2K x 4   |

1. When interfacing with a 16-bit memory, the FMC internally uses the HADDR[11:1] internal AHB address lines to generate the external address. Whatever the memory width, FMC\_A[0] has to be connected to the external memory address A[0].
2. The AutoPrecharge is not supported. FMC\_A[10] must be connected to the external memory address A[10] but it will be always driven 'low'.

The HADDR[27:0] bits are translated to external SDRAM address depending on the SDRAM controller configuration:

- Data size: 8, 16 or 32 bits
- Row size: 11, 12 or 13 bits
- Column size: 8, 9, 10 or 11 bits
- Number of internal banks: two or four internal banks

The following tables show the SDRAM address mapping versus the SDRAM controller configuration.

**Table 54. SDRAM address mapping with 8-bit data bus width<sup>(1)(2)</sup>**

| Row size configuration        | HADDR(AHB Internal Address Lines) |    |    |            |            |            |            |            |           |           |    |    |    |    |    |              |              |             |             |             |   |   |   |   |   |   |   |   |  |  |  |  |
|-------------------------------|-----------------------------------|----|----|------------|------------|------------|------------|------------|-----------|-----------|----|----|----|----|----|--------------|--------------|-------------|-------------|-------------|---|---|---|---|---|---|---|---|--|--|--|--|
|                               | 27                                | 26 | 25 | 24         | 23         | 22         | 21         | 20         | 19        | 18        | 17 | 16 | 15 | 14 | 13 | 12           | 11           | 10          | 9           | 8           | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |  |  |  |  |

|                               | Res.                              |    |    | Bank [1:0] |            | Row[12:0]  |            |            |           |           |    |    |    |    |    | Column[10:0] |              |             |             |             |   |   |   |   |   |   |   |   |  |  |  |  |

1. BANK[1:0] are the Bank Address BA[1:0]. When only 2 internal banks are used, BA1 must always be set to '0'.

2. Access to Reserved (Res.) address range generates an AHB error.

**Table 55. SDRAM address mapping with 16-bit data bus width<sup>(1)(2)</sup>**

| Row size Configuration        | HADDR(AHB address Lines) |            |            |            |            |            |            |           |           |    |    |    |    |              |              |              |             |             |             |   |     |     |     |     |     |                    |   |   |

1. BANK[1:0] are the Bank Address BA[1:0]. When only 2 internal banks are used, BA1 must always be set to '0'.

2. Access to Reserved space (Res.) generates an AHB error.

3. BM[1:0]: is the byte mask for 32-bit access.

## 13.5 NOR Flash/PSRAM controller

The FMC generates the appropriate signal timings to drive the following types of memories:

- Asynchronous SRAM and ROM
  - 8 bits
  - 16 bits
  - 32 bits
- PSRAM (CellularRAM™)
  - Asynchronous mode
  - Burst mode for synchronous accesses
  - Multiplexed or non-multiplexed
- NOR Flash memory
  - Asynchronous mode
  - Burst mode for synchronous accesses
  - Multiplexed or non-multiplexed

The FMC outputs a unique chip select signal, NE[4:1], per bank. All the other signals (addresses, data and control) are shared.

The FMC supports a wide range of devices through a programmable timings among which:

- Programmable wait states (up to 15)
- Programmable bus turnaround cycles (up to 15)
- Programmable output enable and write enable delays (up to 15)
- Independent read and write timings and protocol to support the widest variety of memories and timings
- Programmable continuous clock (FMC\_CLK) output.

The FMC Clock (FMC\_CLK) is a submultiple of the HCLK clock. It can be delivered to the selected external device either during synchronous accesses only or during asynchronous and synchronous accesses depending on the CCKEN bit configuration in the FMC\_BCR1 register:

- If the CCKEN bit is reset, the FMC generates the clock (CLK) only during synchronous accesses (Read/write transactions).
- If the CCKEN bit is set, the FMC generates a continuous clock during asynchronous and synchronous accesses. To generate the FMC\_CLK continuous clock, Bank 1 must be configured in Synchronous mode (see [Section 13.5.6: NOR/PSRAM controller registers](#)). Since the same clock is used for all synchronous memories, when a continuous output clock is generated and synchronous accesses are performed, the AHB data size has to be the same as the memory data width (MWID) otherwise the FMC\_CLK frequency will be changed depending on AHB data transaction (refer to [Section 13.5.5: Synchronous transactions](#) for FMC\_CLK divider ratio formula).

The size of each bank is fixed and equal to 64 Mbytes. Each bank is configured through dedicated registers (see [Section 13.5.6: NOR/PSRAM controller registers](#)).

The programmable memory parameters include access times (see [Table 57](#)) and support for wait management (for PSRAM and NOR Flash accessed in Burst mode).

**Table 57. Programmable NOR/PSRAM access parameters**

| Parameter          | Function                                                                         | Access mode                               | Unit                     | Min. | Max. |
|--------------------|----------------------------------------------------------------------------------|-------------------------------------------|--------------------------|------|------|
| Address setup      | Duration of the address setup phase                                              | Asynchronous                              | AHB clock cycle (HCLK)   | 0    | 15   |
| Address hold       | Duration of the address hold phase                                               | Asynchronous, muxed I/Os                  | AHB clock cycle (HCLK)   | 1    | 15   |
| Data setup         | Duration of the data setup phase                                                 | Asynchronous                              | AHB clock cycle (HCLK)   | 1    | 256  |
| Burst turn         | Duration of the bus turnaround phase                                             | Asynchronous and synchronous read / write | AHB clock cycle (HCLK)   | 0    | 15   |
| Clock divide ratio | Number of AHB clock cycles (HCLK) to build one memory clock cycle (CLK)          | Synchronous                               | AHB clock cycle (HCLK)   | 2    | 16   |
| Data latency       | Number of clock cycles to issue to the memory before the first data of the burst | Synchronous                               | Memory clock cycle (CLK) | 2    | 17   |

### 13.5.1 External memory interface signals

[Table 58](#), [Table 59](#) and [Table 60](#) list the signals that are typically used to interface with NOR Flash memory, SRAM and PSRAM.

*Note:* The prefix “N” identifies the signals that are active low.

#### NOR Flash memory, non-multiplexed I/Os

**Table 58. Non-multiplexed I/O NOR Flash memory**

| FMC signal name | I/O | Function                                                                            |
|-----------------|-----|-------------------------------------------------------------------------------------|
| CLK             | O   | Clock (for synchronous access)                                                      |
| A[25:0]         | O   | Address bus                                                                         |
| D[31:0]         | I/O | Bidirectional data bus                                                              |
| NE[x]           | O   | Chip select, x = 1..4                                                               |
| NOE             | O   | Output enable                                                                       |
| NWE             | O   | Write enable                                                                        |
| NL(=NADV)       | O   | Latch enable (this signal is called address valid, NADV, by some NOR Flash devices) |
| NWAIT           | I   | NOR Flash wait input signal to the FMC                                              |

The maximum capacity is 512 Mbits (26 address lines).

#### NOR Flash memory, 16-bit multiplexed I/Os

**Table 59. 16-bit multiplexed I/O NOR Flash memory**

| FMC signal name | I/O | Function                                                                                                                        |
|-----------------|-----|---------------------------------------------------------------------------------------------------------------------------------|
| CLK             | O   | Clock (for synchronous access)                                                                                                  |
| A[25:16]        | O   | Address bus                                                                                                                     |
| AD[15:0]        | I/O | 16-bit multiplexed, bidirectional address/data bus (the 16-bit address A[15:0] and data D[15:0] are multiplexed on the databus) |
| NE[x]           | O   | Chip select, x = 1..4                                                                                                           |
| NOE             | O   | Output enable                                                                                                                   |
| NWE             | O   | Write enable                                                                                                                    |
| NL(=NADV)       | O   | Latch enable (this signal is called address valid, NADV, by some NOR Flash devices)                                             |
| NWAIT           | I   | NOR Flash wait input signal to the FMC                                                                                          |

The maximum capacity is 512 Mbits.

**PSRAM/SRAM, non-multiplexed I/Os****Table 60. Non-multiplexed I/Os PSRAM/SRAM**

| FMC signal name | I/O | Function                                                                 |
|-----------------|-----|--------------------------------------------------------------------------|
| CLK             | O   | Clock (only for PSRAM synchronous access)                                |
| A[25:0]         | O   | Address bus                                                              |
| D[31:0]         | I/O | Data bidirectional bus                                                   |
| NE[x]           | O   | Chip select, x = 1..4 (called NCE by PSRAM (CellularRAM™ i.e. CRAM))     |
| NOE             | O   | Output enable                                                            |
| NWE             | O   | Write enable                                                             |
| NL(= NADV)      | O   | Address valid only for PSRAM input (memory signal name: NADV)            |
| NWAIT           | I   | PSRAM wait input signal to the FMC                                       |
| NBL[3:0]        | O   | Byte lane output. Byte 0 to Byte 3 control (Upper and lower byte enable) |

The maximum capacity is 512 Mbits.

**PSRAM, 16-bit multiplexed I/Os****Table 61. 16-Bit multiplexed I/O PSRAM**

| FMC signal name | I/O | Function                                                                                                                        |
|-----------------|-----|---------------------------------------------------------------------------------------------------------------------------------|
| CLK             | O   | Clock (for synchronous access)                                                                                                  |
| A[25:16]        | O   | Address bus                                                                                                                     |
| AD[15:0]        | I/O | 16-bit multiplexed, bidirectional address/data bus (the 16-bit address A[15:0] and data D[15:0] are multiplexed on the databus) |
| NE[x]           | O   | Chip select, x = 1..4 (called NCE by PSRAM (CellularRAM™ i.e. CRAM))                                                            |
| NOE             | O   | Output enable                                                                                                                   |
| NWE             | O   | Write enable                                                                                                                    |
| NL(= NADV)      | O   | Address valid PSRAM input (memory signal name: NADV)                                                                            |
| NWAIT           | I   | PSRAM wait input signal to the FMC                                                                                              |
| NBL[1:0]        | O   | Byte lane output. Byte 0 and Byte 1 control (upper and lower byte enable)                                                       |

The maximum capacity is 512 Mbits (26 address lines).

**13.5.2 Supported memories and transactions**

[Table 62](#) below shows an example of the supported devices, access modes and transactions when the memory data bus is 16-bit wide for NOR Flash memory, PSRAM and SRAM. The transactions not allowed (or not supported) by the FMC are shown in gray in this example.

Table 62. NOR Flash/PSRAM: example of supported memories and transactions

| Device                                               | Mode              | R/W | AHB data size | Memory data size | Allowed/not allowed | Comments                                                |
|------------------------------------------------------|-------------------|-----|---------------|------------------|---------------------|---------------------------------------------------------|
| NOR Flash<br>(muxed I/Os and nonmuxed I/Os)          | Asynchronous      | R   | 8             | 16               | Y                   | -                                                       |
|                                                      | Asynchronous      | W   | 8             | 16               | N                   | -                                                       |
|                                                      | Asynchronous      | R   | 16            | 16               | Y                   | -                                                       |
|                                                      | Asynchronous      | W   | 16            | 16               | Y                   | -                                                       |
|                                                      | Asynchronous      | R   | 32            | 16               | Y                   | Split into 2 FMC accesses                               |
|                                                      | Asynchronous      | W   | 32            | 16               | Y                   | Split into 2 FMC accesses                               |
|                                                      | Asynchronous page | R   | -             | 16               | N                   | Mode is not supported                                   |
|                                                      | Synchronous       | R   | 8             | 16               | N                   | -                                                       |
|                                                      | Synchronous       | R   | 16            | 16               | Y                   | -                                                       |
|                                                      | Synchronous       | R   | 32            | 16               | Y                   | -                                                       |
| PSRAM<br>(multiplexed I/Os and non-multiplexed I/Os) | Asynchronous      | R   | 8             | 16               | Y                   | -                                                       |
|                                                      | Asynchronous      | W   | 8             | 16               | Y                   | Use of byte lanes NBL[1:0]                              |
|                                                      | Asynchronous      | R   | 16            | 16               | Y                   | -                                                       |

### 13.5.3 General timing rules

#### Signals synchronization

- All controller output signals change on the rising edge of the internal clock (HCLK)
- In Synchronous mode (read or write), all output signals change on the rising edge of HCLK. Whatever the CLKDIV value, all outputs change as follows:
  - NOEL/NWEL/ NEL/NADV L/ NADV H /NBLL/ Address valid outputs change on the falling edge of FMC\_CLK clock.
  - NOEH/ NWEH / NEH/ NOEH/NBLH/ Address invalid outputs change on the rising edge of FMC\_CLK clock.

### 13.5.4 NOR Flash/PSRAM controller asynchronous transactions

#### Asynchronous static memories (NOR Flash, PSRAM, SRAM)

- Signals are synchronized by the internal clock HCLK. This clock is not issued to the memory
- The FMC always samples the data before de-asserting the NOE signal. This guarantees that the memory data hold timing constraint is met (minimum Chip Enable high to data transition is usually 0 ns)
- If the Extended mode is enabled (EXTMOD bit is set in the FMC\_BCRx register), up to four extended modes (A, B, C and D) are available. It is possible to mix A, B, C and D modes for read and write operations. For example, read operation can be performed in mode A and write in mode B.
- If the Extended mode is disabled (EXTMOD bit is reset in the FMC\_BCRx register), the FMC can operate in Mode1 or Mode2 as follows:
  - Mode 1 is the default mode when SRAM/PSRAM memory type is selected (MTYP = 0x0 or 0x01 in the FMC\_BCRx register)
  - Mode 2 is the default mode when NOR memory type is selected (MTYP = 0x10 in the FMC\_BCRx register).

**Mode 1 - SRAM/PSRAM (CRAM)**

The next figures show the read and write transactions for the supported modes followed by the required configuration of FMC\_BCRx, and FMC\_BTRx/FMC\_BWTRx registers.

**Figure 35. Mode1 read access waveforms****Figure 36. Mode1 write access waveforms**

The one HCLK cycle at the end of the write transaction helps guarantee the address and data hold time after the NWE rising edge. Due to the presence of this HCLK cycle, the DATAST value must be greater than zero (DATAST > 0).

**Table 63. FMC\_BCRx bit fields**

| Bit number | Bit name   | Value to set                                                       |
|------------|------------|--------------------------------------------------------------------|
| 31:22      | Reserved   | 0x000                                                              |
| 21         | WFDIS      | As needed                                                          |
| 20         | CCLKEN     | As needed                                                          |

### WAIT management in asynchronous accesses

If the asynchronous memory asserts the WAIT signal to indicate that it is not yet ready to accept or to provide data, the ASYNCWAIT bit has to be set in FMC\_BCRx register.

If the WAIT signal is active (high or low depending on the WAITPOL bit), the second access phase (Data setup phase), programmed by the DATAST bits, is extended until WAIT becomes inactive. Unlike the data setup phase, the first access phases (Address setup and Address hold phases), programmed by the ADDSET and ADDHLD bits, are not WAIT sensitive and so they are not prolonged.

The data setup phase must be programmed so that WAIT can be detected 4 HCLK cycles before the end of the memory transaction. The following cases must be considered:

1. The memory asserts the WAIT signal aligned to NOE/NWE which toggles:  

$$\text{DATAST} \geq (4 \times \text{HCLK}) + \text{max\_wait\_assertion\_time}$$
2. The memory asserts the WAIT signal aligned to NEx (or NOE/NWE not toggling):  
 if

$$\text{max\_wait\_assertion\_time} > \text{address\_phase} + \text{hold\_phase}$$

then:

$$\text{DATAST} \geq (4 \times \text{HCLK}) + (\text{max\_wait\_assertion\_time} - \text{address\_phase} - \text{hold\_phase})$$

otherwise

$$\text{DATAST} \geq 4 \times \text{HCLK}$$

where max\_wait\_assertion\_time is the maximum time taken by the memory to assert the WAIT signal once NEx/NOE/NWE is low.

Figure 48 and Figure 49 show the number of HCLK clock cycles that are added to the memory access phase after WAIT is released by the asynchronous memory (independently of the above cases).

**Figure 48. Asynchronous wait during a read access waveforms**

1. N WAIT polarity depends on WAITPOL bit setting in FMC\_BCRx register.

1. NWAIT polarity depends on WAITPOL bit setting in FMC\_BCRx register.

### 13.5.5 Synchronous transactions

The memory clock, FMC\_CLK, is a submultiple of HCLK. It depends on the value of CLKDIV and the MWID/ AHB data size, following the formula given below:

$$\text{FMC\_CLK divider ratio} = \max(\text{CLKDIV} + 1, \text{MWID}(\text{AHB data size}))$$

If MWID is 16 or 8-bit, the FMC\_CLK divider ratio is always defined by the programmed CLKDIV value.

If MWID is 32-bit, the FMC\_CLK divider ratio depends also on AHB data size.

Example:

- If CLKDIV=1, MWID = 32 bits, AHB data size=8 bits, FMC\_CLK=HCLK/4.
- If CLKDIV=1, MWID = 16 bits, AHB data size=8 bits, FMC\_CLK=HCLK/2.

NOR Flash memories specify a minimum time from NADV assertion to CLK high. To meet this constraint, the FMC does not issue the clock to the memory during the first internal clock cycle of the synchronous access (before NADV assertion). This guarantees that the rising edge of the memory clock occurs in the middle of the NADV low pulse.

#### Data latency versus NOR memory latency

The data latency is the number of cycles to wait before sampling the data. The DATLAT value must be consistent with the latency value specified in the NOR Flash configuration register. The FMC does not include the clock cycle when NADV is low in the data latency count.

**Caution:** Some NOR Flash memories include the NADV Low cycle in the data latency count, so that the exact relation between the NOR Flash latency and the FMC DATLAT parameter can be either:

- NOR Flash latency = (DATLAT + 2) CLK clock cycles
- or NOR Flash latency = (DATLAT + 3) CLK clock cycles

Some recent memories assert NWAIT during the latency phase. In such cases DATLAT can be set to its minimum value. As a result, the FMC samples the data and waits long enough to evaluate if the data are valid. Thus the FMC detects when the memory exits latency and real data are processed.

Other memories do not assert NWAIT during latency. In this case the latency must be set correctly for both the FMC and the memory, otherwise invalid data are mistaken for good data, or valid data are lost in the initial phase of the memory access.

### Single-burst transfer

When the selected bank is configured in Burst mode for synchronous accesses, if for example an AHB single-burst transaction is requested on 16-bit memories, the FMC performs a burst transaction of length 1 (if the AHB transfer is 16 bits), or length 2 (if the AHB transfer is 32 bits) and de-assert the chip select signal when the last data is strobed.

Such transfers are not the most efficient in terms of cycles compared to asynchronous read operations. Nevertheless, a random asynchronous access would first require to re-program the memory access mode, which would altogether last longer.

### Cross boundary page for CellularRAM™ 1.5

CellularRAM™ 1.5 does not allow burst access to cross the page boundary. The FMC controller allows to split automatically the burst access when the memory page size is reached by configuring the CPSIZE bits in the FMC\_BCR1 register following the memory page size.

### Wait management

For synchronous NOR Flash memories, NWAIT is evaluated after the programmed latency period, which corresponds to (DATLAT+2) CLK clock cycles.

If NWAIT is active (low level when WAITPOL = 0, high level when WAITPOL = 1), wait states are inserted until NWAIT is inactive (high level when WAITPOL = 0, low level when WAITPOL = 1).

When NWAIT is inactive, the data is considered valid either immediately (bit WAITCFG = 1) or on the next clock edge (bit WAITCFG = 0).

During wait-state insertion via the NWAIT signal, the controller continues to send clock pulses to the memory, keeping the chip select and output enable signals valid. It does not consider the data as valid.

In Burst mode, there are two timing configurations for the NOR Flash NWAIT signal:

- The Flash memory asserts the NWAIT signal one data cycle before the wait state (default after reset).
- The Flash memory asserts the NWAIT signal during the wait state

The FMC supports both NOR Flash wait state configurations, for each chip select, thanks to the WAITCFG bit in the FMC\_BCRx registers (x = 0..3).

Figure 50. Wait configuration waveforms

**Figure 51. Synchronous multiplexed read mode waveforms - NOR, PSRAM (CRAM)**

1. Byte lane outputs (NBL are not shown; for NOR access, they are held high, and, for PSRAM (CRAM) access, they are held low.

Table 80. FMC\_BTRx bit fields

| Bit number | Bit name | Value to set                                                             |
|------------|----------|--------------------------------------------------------------------------|
| 31:30      | Reserved | 0x0                                                                      |
| 29:28      | ACCMOD   | 0x0                                                                      |
| 27-24      | DATLAT   | Data latency                                                             |
| 27-24      | DATLAT   | Data latency                                                             |
| 23-20      | CLKDIV   | 0x0 to get CLK = HCLK (Not supported)<br>0x1 to get CLK = 2 × HCLK<br>.. |
| 19-16      | BUSTURN  | Time between NEx high to NEx low (BUSTURN HCLK).                         |
| 15-8       | DATAST   | Don't care                                                               |
| 7-4        | ADDHLD   | Don't care                                                               |
| 3-0        | ADDSET   | Don't care                                                               |

**Figure 52. Synchronous multiplexed write mode waveforms - PSRAM (CRAM)**

1. The memory must issue NWAIT signal one cycle in advance, accordingly WAITCFG must be programmed to 0.
2. Byte Lane (NBL) outputs are not shown, they are held low while NEx is active.

**Table 81. FMC\_BCRx bit fields**

| Bit number | Bit name  | Value to set                                                                   |
|------------|-----------|--------------------------------------------------------------------------------|
| 31:22      | Reserved  | 0x000                                                                          |
| 21         | WFDIS     | As needed                                                                      |
| 20         | CCLKEN    | As needed                                                                      |
| 19         | CBURSTRW  | 0x1                                                                            |
| 18:16      | CPSIZE    | As needed (0x1 for CRAM 1.5)                                                   |
| 15         | ASYNCWAIT | 0x0                                                                            |
| 14         | EXTMOD    | 0x0                                                                            |
| 13         | WAITEN    | To be set to 1 if the memory supports this feature, to be kept at 0 otherwise. |

**Table 81. FMC\_BCRx bit fields (continued)**

| Bit number | Bit name | Value to set                    |
|------------|----------|---------------------------------|

| 3-0        | ADDSET   | Don't care                                                         |

### 13.5.6 NOR/PSRAM controller registers

#### SRAM/NOR-Flash chip-select control register for bank x (FMC\_BCRx) (x = 1 to 4)

Address offset:  $8 * (x - 1)$ , (x = 1 to 4)

Reset value: Bank 1: 0x0000 30DB

Reset value: Bank 2: 0x0000 30D2

Reset value: Bank 3: 0x0000 30D2

Reset value: Bank 4: 0x0000 30D2

This register contains the control information of each memory bank, used for SRAMs, PSRAM and NOR Flash memories.

|               |            |            |      |             |      |             |             |      |            |           |            |              |             |           |           |

| rw            | rw         | rw         | rw   | rw          |      | rw          | rw          |      | rw         | rw        | rw         | rw           | rw          | rw        | rw        |

Bits 31:22 Reserved, must be kept at reset value.

##### Bit 21 **WFDIS**: Write FIFO Disable

This bit disables the Write FIFO used by the FMC controller.

0: Write FIFO enabled (Default after reset)

1: Write FIFO disabled

*Note: The WFDIS bit of the FMC\_BCR2..4 registers is don't care. It is only enabled through the FMC\_BCR1 register.*

##### Bit 20 **CCLKEN**: Continuous Clock Enable.

This bit enables the FMC\_CLK clock output to external memory devices.

0: The FMC\_CLK is only generated during the synchronous memory access (read/write transaction). The FMC\_CLK clock ratio is specified by the programmed CLKDIV value in the FMC\_BCRx register (default after reset).

1: The FMC\_CLK is generated continuously during asynchronous and synchronous access. The FMC\_CLK clock is activated when the CCLKEN is set.

*Note: The CCLKEN bit of the FMC\_BCR2..4 registers is don't care. It is only enabled through the FMC\_BCR1 register. Bank 1 must be configured in Synchronous mode to generate the FMC\_CLK continuous clock.*

*Note: If CCLKEN bit is set, the FMC\_CLK clock ratio is specified by CLKDIV value in the FMC\_BTR1 register. CLKDIV in FMC\_BWTR1 is don't care.*

*Note: If the Synchronous mode is used and CCLKEN bit is set, the synchronous memories connected to other banks than Bank 1 are clocked by the same clock (the CLKDIV value in the FMC\_BTR2..4 and FMC\_BWTR2..4 registers for other banks has no effect.)*

Bit 19 **CBURSTRW**: Write burst enable.

For PSRAM (CRAM) operating in Burst mode, the bit enables synchronous accesses during write operations. The enable bit for synchronous read accesses is the BURSTEN bit in the FMC\_BCRx register.

0: Write operations are always performed in Asynchronous mode

1: Write operations are performed in Synchronous mode.

Bits 18:16 **CPSIZE[2:0]**: CRAM page size.

These are used for CellularRAM™ 1.5 which does not allow burst access to cross the address boundaries between pages. When these bits are configured, the FMC controller splits automatically the burst access when the memory page size is reached (refer to memory datasheet for page size).

000: No burst split when crossing page boundary (default after reset)

001: 128 bytes

010: 256 bytes

011: 512 bytes

100: 1024 bytes

Others: reserved

Bit 15 **ASYNCAWAIT**: Wait signal during asynchronous transfers

This bit enables/disables the FMC to use the wait signal even during an asynchronous protocol.

0: NWAIT signal is not taken in to account when running an asynchronous protocol (default after reset)

1: NWAIT signal is taken in to account when running an asynchronous protocol

Bit 14 **EXTMOD**: Extended mode enable.

This bit enables the FMC to program the write timings for non multiplexed asynchronous accesses inside the FMC\_BWTR register, thus resulting in different timings for read and write operations.

0: values inside FMC\_BWTR register are not taken into account (default after reset)

1: values inside FMC\_BWTR register are taken into account

*Note: When the Extended mode is disabled, the FMC can operate in Mode1 or Mode2 as follows:*

- Mode 1 is the default mode when the SRAM/PSRAM memory type is selected (MTYP = 0x0 or 0x01)
- Mode 2 is the default mode when the NOR memory type is selected (MTYP = 0x10).

Bit 13 **WAITEN**: Wait enable bit.

This bit enables/disables wait-state insertion via the NWAIT signal when accessing the memory in Synchronous mode.

0: NWAIT signal is disabled (its level not taken into account, no wait state inserted after the programmed Flash latency period)

1: NWAIT signal is enabled (its level is taken into account after the programmed latency period to insert wait states if asserted) (default after reset)

Bit 12 **WREN**: Write enable bit.

This bit indicates whether write operations are enabled/disabled in the bank by the FMC:

0: Write operations are disabled in the bank by the FMC, an AHB error is reported,

1: Write operations are enabled for the bank by the FMC (default after reset).

Bit 11 **WAITCFG**: Wait timing configuration.

The NWAIT signal indicates whether the data from the memory are valid or if a wait state must be inserted when accessing the memory in Synchronous mode. This configuration bit determines if NWAIT is asserted by the memory one clock cycle before the wait state or during the wait state:

0: NWAIT signal is active one data cycle before wait state (default after reset),

1: NWAIT signal is active during wait state (not used for PSRAM).

Bit 10 Reserved, must be kept at reset value.

Bit 9 **WAITPOL**: Wait signal polarity bit.

Defines the polarity of the wait signal from memory used for either in Synchronous or Asynchronous mode:

- 0: NWAIT active low (default after reset),
- 1: NWAIT active high.

Bit 8 **BURSTEN**: Burst enable bit.

This bit enables/disables synchronous accesses during read operations. It is valid only for synchronous memories operating in Burst mode:

- 0: Burst mode disabled (default after reset). Read accesses are performed in Asynchronous mode.
- 1: Burst mode enable. Read accesses are performed in Synchronous mode.

Bit 7 Reserved, must be kept at reset value.

Bit 6 **FACCEN**: Flash access enable

Enables NOR Flash memory access operations.

- 0: Corresponding NOR Flash memory access is disabled
- 1: Corresponding NOR Flash memory access is enabled (default after reset)

Bits 5:4 **MWID[1:0]**: Memory data bus width.

Defines the external memory device width, valid for all type of memories.

- 00: 8 bits
- 01: 16 bits (default after reset)
- 10: 32 bits
- 11: reserved

Bits 3:2 **MTYP[1:0]**: Memory type.

Defines the type of external memory attached to the corresponding memory bank:

- 00: SRAM (default after reset for Bank 2...4)
- 01: PSRAM (CRAM)
- 10: NOR Flash/OneNAND Flash (default after reset for Bank 1)
- 11: reserved

Bit 1 **MUXEN**: Address/data multiplexing enable bit.

When this bit is set, the address and data values are multiplexed on the data bus, valid only with NOR and PSRAM memories:

- 0: Address/Data non multiplexed
- 1: Address/Data multiplexed on databus (default after reset)

Bit 0 **MBKEN**: Memory bank enable bit.

Enables the memory bank. After reset Bank1 is enabled, all others are disabled. Accessing a disabled bank causes an ERROR on AHB bus.

- 0: Corresponding memory bank is disabled
- 1: Corresponding memory bank is enabled

### SRAM/NOR-Flash chip-select timing register for bank x (FMC\_BTRx)

Address offset:  $0x04 + 8 * (x - 1)$ , ( $x = 1$  to  $4$ )

Reset value: 0x0FFF FFFF

This register contains the control information of each memory bank, used for SRAMs, PSRAM and NOR Flash memories. If the EXTMOD bit is set in the FMC\_BCRx register, then this register is partitioned for write and read access, that is, 2 registers are available: one to configure read accesses (this register) and one to configure write accesses (FMC\_BWTRx registers).

Bits 31:30 Reserved, must be kept at reset value.

Bits 29:28 **ACCMOD[1:0]**: Access mode

Specifies the asynchronous access modes as shown in the timing diagrams. These bits are taken into account only when the EXTMOD bit in the FMC\_BCRx register is 1.

00: Access mode A

01: Access mode B

10: Access mode C

11: Access mode D

Bits 27:24 **DATLAT[3:0]**: (see note below bit descriptions): Data latency for synchronous memory

For synchronous access with read/write Burst mode enabled (BURSTEN / CBURSTWR bits set), defines the number of memory clock cycles (+2) to issue to the memory before reading/writing the first data:

This timing parameter is not expressed in HCLK periods, but in FMC\_CLK periods.

For asynchronous access, this value is don't care.

0000: Data latency of 2 CLK clock cycles for first burst access

1111: Data latency of 17 CLK clock cycles for first burst access (default value after reset)

Bits 23:20 **CLKDIV[3:0]**: Clock divide ratio (for FMC\_CLK signal)

Defines the period of FMC\_CLK clock output signal, expressed in number of HCLK cycles:

0000: Reserved

0001: FMC\_CLK period = 2 × HCLK periods

0010: FMC\_CLK period = 3 × HCLK periods

1111: FMC\_CLK period = 16 × HCLK periods (default value after reset)

In asynchronous NOR Flash, SRAM or PSRAM accesses, this value is don't care.

*Note: Refer to [Section 13.5.5: Synchronous transactions](#) for FMC\_CLK divider ratio formula)*

Bits 19:16 **BUSTURN[3:0]**: Bus turnaround phase duration

These bits are written by software to add a delay at the end of a write-to-read (and read-to-write) transaction. This delay allows to match the minimum time between consecutive transactions (tEHEL from NEx high to NEx low) and the maximum time needed by the memory to free the data bus after a read access (tEHQZ). The programmed bus turnaround delay is inserted between an asynchronous read (muxed or mode D) or write transaction and any other asynchronous /synchronous read or write to or from a static bank. The bank can be the same or different in case of read, in case of write the bank can be different except for muxed or mode D.

In some cases, whatever the programmed BUSTURN values, the bus turnaround delay is fixed as follows:

- The bus turnaround delay is not inserted between two consecutive asynchronous write transfers to the same static memory bank except for muxed and D modes.
- There is a bus turnaround delay of 1 HCLK clock cycle between:
  - Two consecutive asynchronous read transfers to the same static memory bank except for muxed and D modes.
  - An asynchronous read to an asynchronous or synchronous write to any static bank or dynamic bank except for muxed and D modes.
  - An asynchronous (modes 1, 2, A, B or C) read and a read from another static bank.
- There is a bus turnaround delay of 2 HCLK clock cycle between:
  - Two consecutive synchronous writes (burst or single) to the same bank.
  - A synchronous write (burst or single) access and an asynchronous write or read transfer to or from static memory bank (the bank can be the same or different for the case of read).
  - Two consecutive synchronous reads (burst or single) followed by any synchronous/asynchronous read or write from/to another static memory bank.
- There is a bus turnaround delay of 3 HCLK clock cycle between:
  - Two consecutive synchronous writes (burst or single) to different static bank.
  - A synchronous write (burst or single) access and a synchronous read from the same or a different bank.

0000: BUSTURN phase duration = 0 HCLK clock cycle added

...

1111: BUSTURN phase duration = 15 x HCLK clock cycles added (default value after reset)

Bits 15:8 **DATAST[7:0]**: Data-phase duration

These bits are written by software to define the duration of the data phase (refer to [Figure 35](#) to [Figure 47](#)), used in asynchronous accesses:

0000 0000: Reserved

0000 0001: DATAST phase duration = 1 x HCLK clock cycles

0000 0010: DATAST phase duration = 2 x HCLK clock cycles

...

1111 1111: DATAST phase duration = 255 x HCLK clock cycles (default value after reset)

For each memory type and access mode data-phase duration, refer to the respective figure ([Figure 35](#) to [Figure 47](#)).

Example: Mode1, write access, DATAST=1: Data-phase duration= DATAST+1 = 2 HCLK clock cycles.

*Note: In synchronous accesses, this value is don't care.*

Bits 7:4 **ADDHLD[3:0]**: Address-hold phase duration

These bits are written by software to define the duration of the *address hold* phase (refer to [Figure 35](#) to [Figure 47](#)), used in mode D or multiplexed accesses:

0000: Reserved

0001: ADDHLD phase duration =  $1 \times \text{HCLK}$  clock cycle

0010: ADDHLD phase duration =  $2 \times \text{HCLK}$  clock cycle

...

1111: ADDHLD phase duration =  $15 \times \text{HCLK}$  clock cycles (default value after reset)

For each access mode address-hold phase duration, refer to the respective figure ([Figure 35](#) to [Figure 47](#)).

*Note: In synchronous accesses, this value is not used, the address hold phase is always 1 memory clock period duration.*

Bits 3:0 **ADDSET[3:0]**: Address setup phase duration

These bits are written by software to define the duration of the *address setup* phase (refer to [Figure 35](#) to [Figure 47](#)), used in SRAMs, ROMs, asynchronous NOR Flash and PSRAM:

0000: ADDSET phase duration =  $0 \times \text{HCLK}$  clock cycle

...

1111: ADDSET phase duration =  $15 \times \text{HCLK}$  clock cycles (default value after reset)

For each access mode address setup phase duration, refer to the respective figure ([Figure 35](#) to [Figure 47](#)).

*Note: In synchronous accesses, this value is don't care.*

*In Muxed mode or Mode D, the minimum value for ADDSET is 1.*

*In mode 1 and PSRAM memory, the minimum value for ADDSET is 1.*

*Note: PSRAMs (CRAMs) have a variable latency due to internal refresh. Therefore these memories issue the NWAIT signal during the whole latency phase to prolong the latency as needed.*

*With PSRAMs (CRAMs) the filled DATLAT must be set to 0, so that the FMC exits its latency phase soon and starts sampling NWAIT from memory, then starts to read or write when the memory is ready.*

*This method can be used also with the latest generation of synchronous Flash memories that issue the NWAIT signal, unlike older Flash memories (check the datasheet of the specific Flash memory being used).*

#### SRAM/NOR-Flash write timing registers 1..4 (FMC\_BWTR1..4)

Address offset:  $0x104 + 8 * (x - 1)$ ,  $x = 1...4$

Reset value: 0x0FFF FFFF

This register contains the control information of each memory bank. It is used for SRAMs, PSRAMs and NOR Flash memories. When the EXTMOD bit is set in the FMC\_BCRx register, then this register is active for write access.

|            |      |             |    |      |      |      |      |             |      |      |      |              |    |    |    |

| rw         | rw   | rw          | rw | rw   | rw   | rw   | rw   | rw          | rw   | rw   | rw   | rw           | rw | rw | rw |

Bits 31:30 Reserved, must be kept at reset value.

Bits 29:28 **ACCMOD[1:0]**: Access mode.

Specifies the asynchronous access modes as shown in the next timing diagrams. These bits are taken into account only when the EXTMOD bit in the FMC\_BCRx register is 1.

00: Access mode A

01: Access mode B

10: Access mode C

11: Access mode D

Bits 27:20 Reserved, must be kept at reset value.

Bits 19:16 **BUSTURN[3:0]**: Bus turnaround phase duration

The programmed bus turnaround delay is inserted between an asynchronous write transfer and any other asynchronous /synchronous read or write transfer to or from a static bank. The bank can be the same or different in case of read, in case of write the bank can be different except for muxed or mode D.

In some cases, whatever the programmed BUSTURN values, the bus turnaround delay is fixed as follows:

- The bus turnaround delay is not inserted between two consecutive asynchronous write transfers to the same static memory bank except for muxed and D modes.
- There is a bus turnaround delay of 2 HCLK clock cycle between:
  - Two consecutive synchronous writes (burst or single) to the same bank.
  - A synchronous write (burst or single) transfer and an asynchronous write or read transfer to or from static memory bank.
- There is a bus turnaround delay of 3 HCLK clock cycle between:
  - Two consecutive synchronous writes (burst or single) to different static bank.
  - A synchronous write (burst or single) transfer and a synchronous read from the same or a different bank.

0000: BUSTURN phase duration = 0 HCLK clock cycle added

...

1111: BUSTURN phase duration = 15 HCLK clock cycles added (default value after reset)

Bits 15:8 **DATAST[7:0]**: Data-phase duration.

These bits are written by software to define the duration of the data phase (refer to [Figure 35](#) to [Figure 47](#)), used in asynchronous SRAM, PSRAM and NOR Flash memory accesses:

0000 0000: Reserved

0000 0001: DATAST phase duration = 1 × HCLK clock cycles

0000 0010: DATAST phase duration = 2 × HCLK clock cycles

...

1111 1111: DATAST phase duration = 255 × HCLK clock cycles (default value after reset)

Bits 7:4 **ADDHLD[3:0]**: Address-hold phase duration.

These bits are written by software to define the duration of the *address hold* phase (refer to [Figure 44](#) to [Figure 47](#)), used in asynchronous multiplexed accesses:

0000: Reserved

0001: ADDHLD phase duration = 1 × HCLK clock cycle

0010: ADDHLD phase duration = 2 × HCLK clock cycle

...

1111: ADDHLD phase duration = 15 × HCLK clock cycles (default value after reset)

*Note: In synchronous NOR Flash accesses, this value is not used, the address hold phase is always 1 Flash clock period duration.*

Bits 3:0 **ADDSET[3:0]**: Address setup phase duration.

These bits are written by software to define the duration of the *address setup* phase in HCLK cycles (refer to [Figure 35](#) to [Figure 47](#)), used in asynchronous accesses:

0000: ADDSET phase duration = 0 × HCLK clock cycle

...

1111: ADDSET phase duration = 15 × HCLK clock cycles (default value after reset)

*Note:* In synchronous accesses, this value is not used, the address setup phase is always 1 Flash clock period duration. In muxed mode, the minimum ADDSET value is 1.

## 13.6 NAND Flash controller

The FMC generates the appropriate signal timings to drive the following types of device:

- 8- and 16-bit NAND Flash memories

The NAND bank is configured through dedicated registers ([Section 13.6.7](#)). The programmable memory parameters include access timings (shown in [Table 83](#)) and ECC configuration.

**Table 83. Programmable NAND Flash access parameters**

| Parameter             | Function                                                                                                                                                | Access mode | Unit                   | Min. | Max. |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|-------------|------------------------|------|------|
| Memory setup time     | Number of clock cycles (HCLK) required to set up the address before the command assertion                                                               | Read/Write  | AHB clock cycle (HCLK) | 1    | 255  |
| Memory wait           | Minimum duration (in HCLK clock cycles) of the command assertion                                                                                        | Read/Write  | AHB clock cycle (HCLK) | 2    | 255  |
| Memory hold           | Number of clock cycles (HCLK) during which the address must be held (as well as the data if a write access is performed) after the command de-assertion | Read/Write  | AHB clock cycle (HCLK) | 1    | 254  |
| Memory databus high-Z | Number of clock cycles (HCLK) during which the data bus is kept in high-Z state after a write access has started                                        | Write       | AHB clock cycle (HCLK) | 1    | 255  |

### 13.6.1 External memory interface signals

The following tables list the signals that are typically used to interface NAND Flash memory.

*Note:* The prefix “N” identifies the signals which are active low.

#### 8-bit NAND Flash memory

**Table 84. 8-bit NAND Flash**

| FMC signal name | I/O | Function                                     |
|-----------------|-----|----------------------------------------------|
| A[17]           | O   | NAND Flash address latch enable (ALE) signal |
| A[16]           | O   | NAND Flash command latch enable (CLE) signal |

Table 84. 8-bit NAND Flash (continued)

| FMC signal name | I/O | Function                                             |
|-----------------|-----|------------------------------------------------------|
| D[7:0]          | I/O | 8-bit multiplexed, bidirectional address/data bus    |
| NCE             | O   | Chip select                                          |
| NOE(= NRE)      | O   | Output enable (memory signal name: read enable, NRE) |
| NWE             | O   | Write enable                                         |
| NWAIT/INT       | I   | NAND Flash ready/busy input signal to the FMC        |

Theoretically, there is no capacity limitation as the FMC can manage as many address cycles as needed.

### 16-bit NAND Flash memory

Table 85. 16-bit NAND Flash

| FMC signal name | I/O | Function                                             |
|-----------------|-----|------------------------------------------------------|
| A[17]           | O   | NAND Flash address latch enable (ALE) signal         |
| A[16]           | O   | NAND Flash command latch enable (CLE) signal         |
| D[15:0]         | I/O | 16-bit multiplexed, bidirectional address/data bus   |
| NCE             | O   | Chip select                                          |
| NOE(= NRE)      | O   | Output enable (memory signal name: read enable, NRE) |
| NWE             | O   | Write enable                                         |
| NWAIT/INT       | I   | NAND Flash ready/busy input signal to the FMC        |

*Theoretically, there is no capacity limitation as the FMC can manage as many address cycles as needed.*

### 13.6.2 NAND Flash supported memories and transactions

*Table 86 shows the supported devices, access modes and transactions. Transactions not allowed (or not supported) by the NAND Flash controller are shown in gray.*

**Table 86. Supported memories and transactions**

| Device      | Mode         | R/W | AHB data size | Memory data size | Allowed/<br>not allowed | Comments                  |
|-------------|--------------|-----|---------------|------------------|-------------------------|---------------------------|
| NAND 8-bit  | Asynchronous | R   | 8             | 8                | Y                       | -                         |
|             | Asynchronous | W   | 8             | 8                | Y                       | -                         |
|             | Asynchronous | R   | 16            | 8                | Y                       | Split into 2 FMC accesses |
|             | Asynchronous | W   | 16            | 8                | Y                       | Split into 2 FMC accesses |
|             | Asynchronous | R   | 32            | 8                | Y                       | Split into 4 FMC accesses |
|             | Asynchronous | W   | 32            | 8                | Y                       | Split into 4 FMC accesses |
| NAND 16-bit | Asynchronous | R   | 8             | 16               | Y                       | -                         |
|             | Asynchronous | W   | 8             | 16               | N                       | -                         |
|             | Asynchronous | R   | 16            | 16               | Y                       | -                         |
|             | Asynchronous | W   | 16            | 16               | Y                       | -                         |
|             | Asynchronous | R   | 32            | 16               | Y                       | Split into 2 FMC accesses |
|             | Asynchronous | W   | 32            | 16               | Y                       | Split into 2 FMC accesses |

### 13.6.3 Timing diagrams for NAND Flash memory

The NAND Flash memory bank is managed through a set of registers:

- Control register: FMC\_PCR
- Interrupt status register: FMC\_SR
- ECC register: FMC\_ECCR
- Timing register for Common memory space: FMC\_PMEM
- Timing register for Attribute memory space: FMC\_PATT

Each timing configuration register contains three parameters used to define number of HCLK cycles for the three phases of any NAND Flash access, plus one parameter that defines the timing for starting driving the data bus when a write access is performed.

*Figure 53* shows the timing parameter definitions for common memory accesses, knowing that Attribute memory space access timings are similar.

Figure 53. NAND Flash controller waveforms for common memory access

1. NOE remains high (inactive) during write accesses. NWE remains high (inactive) during read accesses.
2. For write access, the hold phase delay is (MEMHOLD) HCLK cycles and for read access is (MEMHOLD + 2) HCLK cycles.

### 13.6.4 NAND Flash operations

The command latch enable (CLE) and address latch enable (ALE) signals of the NAND Flash memory device are driven by address signals from the FMC controller. This means that to send a command or an address to the NAND Flash memory, the CPU has to perform a write to a specific address in its memory space.

A typical page read operation from the NAND Flash device requires the following steps:

1. Program and enable the corresponding memory bank by configuring the FMC\_PCR and FMC\_PMEM (and for some devices, FMC\_PATT, see [Section 13.6.5: NAND Flash prewait functionality](#)) registers according to the characteristics of the NAND Flash memory (PWID bits for the data bus width of the NAND Flash, PTYP = 1, PWAITEN = 0 or 1 as needed, see [Section 13.4.2: NAND Flash memory address mapping](#) for timing configuration).
2. The CPU performs a byte write to the common memory space, with data byte equal to one Flash command byte (for example 0x00 for Samsung NAND Flash devices). The LE input of the NAND Flash memory is active during the write strobe (low pulse on NWE), thus the written byte is interpreted as a command by the NAND Flash memory. Once the command is latched by the memory device, it does not need to be written again for the following page read operations.
3. The CPU can send the start address (STARTAD) for a read operation by writing four bytes (or three for smaller capacity devices), STARTAD[7:0], STARTAD[16:9], STARTAD[24:17] and finally STARTAD[25] (for 64 Mb x 8 bit NAND Flash memories) in the common memory or attribute space. The ALE input of the NAND Flash device is active during the write strobe (low pulse on NWE), thus the written bytes are interpreted as the start address for read operations. Using the attribute memory space makes it possible to use a different timing configuration of the FMC, which can be used to implement the prewait functionality needed by some NAND Flash memories (see

details in [Section 13.6.5: NAND Flash prewait functionality](#)).

4. The controller waits for the NAND Flash memory to be ready (R/NB signal high), before starting a new access to the same or another memory bank. While waiting, the controller holds the NCE signal active (low).
5. The CPU can then perform byte read operations from the common memory space to read the NAND Flash page (data field + Spare field) byte by byte.
6. The next NAND Flash page can be read without any CPU command or address write operation. This can be done in three different ways:
  - by simply performing the operation described in step 5
  - a new random address can be accessed by restarting the operation at step 3
  - a new command can be sent to the NAND Flash device by restarting at step 2

### 13.6.5 NAND Flash prewait functionality

Some NAND Flash devices require that, after writing the last part of the address, the controller waits for the R/NB signal to go low. (see [Figure 54](#)).

**Figure 54. Access to non 'CE don't care' NAND-Flash**

1. CPU wrote byte 0x00 at address 0x7001 0000.
2. CPU wrote byte A7~A0 at address 0x7002 0000.
3. CPU wrote byte A16~A9 at address 0x7002 0000.
4. CPU wrote byte A24~A17 at address 0x7002 0000.
5. CPU wrote byte A25 at address 0x7802 0000: FMC performs a write access using FMC\_PATT timing definition, where  $ATTHOLD \geq 7$  (providing that  $(7+1) \times HCLK = 112 \text{ ns} > t_{WB} \text{ max}$ ). This guarantees that NCE remains low until R/NB goes low and high again (only requested for NAND Flash memories where NCE is not don't care).

When this functionality is required, it can be ensured by programming the MEMHOLD value to meet the  $t_{WB}$  timing. However any CPU read access to the NAND Flash memory has a hold delay of (MEMHOLD + 2) HCLK cycles and CPU write access has a hold delay of (MEMHOLD) HCLK cycles inserted between the rising edge of the NWE signal and the next access.

To cope with this timing constraint, the attribute memory space can be used by programming its timing register with an ATTHOLD value that meets the  $t_{WB}$  timing, and by keeping the MEMHOLD value at its minimum value. The CPU must then use the common memory space for all NAND Flash read and write accesses, except when writing the last address byte to the NAND Flash device, where the CPU must write to the attribute memory space.

### 13.6.6 Computation of the error correction code (ECC) in NAND Flash memory

The FMC NAND Card controller includes two error correction code computation hardware blocks, one per memory bank. They reduce the host CPU workload when processing the ECC by software.

These two ECC blocks are identical and associated with Bank 2 and Bank 3. As a consequence, no hardware ECC computation is available for memories connected to Bank 4.

The ECC algorithm implemented in the FMC can perform 1-bit error correction and 2-bit error detection per 256, 512, 1 024, 2 048, 4 096 or 8 192 bytes read or written from/to the NAND Flash memory. It is based on the Hamming coding algorithm and consists in calculating the row and column parity.

The ECC modules monitor the NAND Flash data bus and read/write signals (NCE and NWE) each time the NAND Flash memory bank is active.

The ECC operates as follows:

- When accessing NAND Flash memory bank 2 or bank 3, the data present on the D[15:0] bus is latched and used for ECC computation.
- When accessing any other address in NAND Flash memory, the ECC logic is idle, and does not perform any operation. As a result, write operations to define commands or addresses to the NAND Flash memory are not taken into account for ECC computation.

Once the desired number of bytes has been read/written from/to the NAND Flash memory by the host CPU, the FMC\_ECCR registers must be read to retrieve the computed value. Once read, they should be cleared by resetting the ECCEN bit to '0'. To compute a new data block, the ECCEN bit must be set to one in the FMC\_PCR registers.

To perform an ECC computation:

1. Enable the ECCEN bit in the FMC\_PCR register.
2. Write data to the NAND Flash memory page. While the NAND page is written, the ECC block computes the ECC value.
3. Read the ECC value available in the FMC\_ECCR register and store it in a variable.
4. Clear the ECCEN bit and then enable it in the FMC\_PCR register before reading back the written data from the NAND page. While the NAND page is read, the ECC block computes the ECC value.
5. Read the new ECC value available in the FMC\_ECCR register.
6. If the two ECC values are the same, no correction is required, otherwise there is an ECC error and the software correction routine returns information on whether the error can be corrected or not.

### 13.6.7 NAND Flash controller registers

#### NAND Flash control registers (FMC\_PCR)

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:17 **ECCPS[2:0]**: ECC page size.

Defines the page size for the extended ECC:

000: 256 bytes

001: 512 bytes

010: 1024 bytes

011: 2048 bytes

100: 4096 bytes

101: 8192 bytes

Bits 16:13 **TAR[3:0]**: ALE to RE delay.

Sets time from ALE low to RE low in number of AHB clock cycles (HCLK).

Time is:  $t_{ar} = (TAR + SET + 2) \times THCLK$  where THCLK is the HCLK clock period

0000: 1 HCLK cycle (default)

1111: 16 HCLK cycles

*Note: SET is MEMSET or ATTSET according to the addressed space.*

Bits 12:9 **TCLR[3:0]**: CLE to RE delay.

Sets time from CLE low to RE low in number of AHB clock cycles (HCLK).

Time is  $t_{clr} = (TCLR + SET + 2) \times THCLK$  where THCLK is the HCLK clock period

0000: 1 HCLK cycle (default)

1111: 16 HCLK cycles

*Note: SET is MEMSET or ATTSET according to the addressed space.*

Bits 8:7 Reserved, must be kept at reset value.

Bit 6 **ECCEN**: ECC computation logic enable bit

0: ECC logic is disabled and reset (default after reset),

1: ECC logic is enabled.

Bits 5:4 **PWID[1:0]**: Data bus width.

Defines the external memory device width.

00: 8 bits

01: 16 bits (default after reset).

10: reserved.

11: reserved.

Bit 3 **PTYP**: Memory type.

Defines the type of device attached to the corresponding memory bank:

0: Reserved, must be kept at reset value

1: NAND Flash (default after reset)

Bit 2 **PBKEN**: NAND Flash memory bank enable bit.

Enables the memory bank. Accessing a disabled memory bank causes an ERROR on AHB bus

0: Corresponding memory bank is disabled (default after reset)

1: Corresponding memory bank is enabled

Bit 1 **PWAITEN**: Wait feature enable bit.

Enables the Wait feature for the NAND Flash memory bank:

0: disabled

1: enabled

Bit 0 Reserved, must be kept at reset value.

### FIFO status and interrupt register (FMC\_SR)

Address offset: 0x84

Reset value: 0x0000 0040

This register contains information about the FIFO status and interrupt. The FMC features a FIFO that is used when writing to memories to transfer up to 16 words of data from the AHB.

This is used to quickly write to the FIFO and free the AHB for transactions to peripherals other than the FMC, while the FMC is draining its FIFO into the memory. One of these register bits indicates the status of the FIFO, for ECC purposes.

The ECC is calculated while the data are written to the memory. To read the correct ECC, the software must consequently wait until the FIFO is empty.

|      |      |      |      |      |      |      |      |      | r     | rw   | rw   | rw   | rw   | rw   | rw   |

Bits 31:7 Reserved, must be kept at reset value.

Bit 6 **FEMPT**: FIFO empty.

Read-only bit that provides the status of the FIFO

0: FIFO not empty

1: FIFO empty

Bit 5 **IFEN**: Interrupt falling edge detection enable bit

0: Interrupt falling edge detection request disabled

1: Interrupt falling edge detection request enabled

Bit 4 **ILEN**: Interrupt high-level detection enable bit

0: Interrupt high-level detection request disabled

1: Interrupt high-level detection request enabled

Bit 3 **IREN**: Interrupt rising edge detection enable bit

0: Interrupt rising edge detection request disabled

1: Interrupt rising edge detection request enabled

Bit 2 **IFS**: Interrupt falling edge status

The flag is set by hardware and reset by software.

0: No interrupt falling edge occurred

1: Interrupt falling edge occurred

*Note: If this bit is written by software to 1 it will be set.*

Bit 1 **ILS**: Interrupt high-level status

The flag is set by hardware and reset by software.

0: No Interrupt high-level occurred

1: Interrupt high-level occurred

Bit 0 **IRS**: Interrupt rising edge status

The flag is set by hardware and reset by software.

0: No interrupt rising edge occurred

1: Interrupt rising edge occurred

*Note: If this bit is written by software to 1 it will be set.*

## Common memory space timing register 2..4 (FMC\_PMEM)

Address offset: Address: 0x88

Reset value: 0xFCFC FCFC

The FMC\_PMEM read/write register contains the timing information for NAND Flash memory bank. This information is used to access either the common memory space of the NAND Flash for command, address write access and data read/write access.

|              |    |    |    |    |    |    |    |              |    |    |    |    |    |    |    |
|--------------|----|----|----|----|----|----|----|--------------|----|----|----|----|----|----|----|
| 31           | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23           | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| MEMHIZ[7:0]  |    |    |    |    |    |    |    | MEMHOLD[7:0] |    |    |    |    |    |    |    |
| rw           | rw | rw | rw | rw | rw | rw | rw | rw           | rw | rw | rw | rw | rw | rw | rw |
| 15           | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7            | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| MEMWAIT[7:0] |    |    |    |    |    |    |    | MEMSET[7:0]  |    |    |    |    |    |    |    |
| rw           | rw | rw | rw | rw | rw | rw | rw | rw           | rw | rw | rw | rw | rw | rw | rw |

Bits 31:24 **MEMHIZ[7:0]**: Common memory x data bus Hi-Z time

Defines the number of HCLK clock cycles during which the data bus is kept Hi-Z after the start of a NAND Flash write access to common memory space on socket. This is only valid for write transactions:

0000 0000: 1 HCLK cycle

1111 1110: 255 HCLK cycles

1111 1111: reserved.

Bits 23:16 **MEMHOLD[7:0]**: Common memory hold time

Defines the number of HCLK clock cycles for write access and HCLK (+2) clock cycles for read access during which the address is held (and data for write accesses) after the command is deasserted (NWE, NOE), for NAND Flash read or write access to common memory space on socket x:

0000 0000: reserved.

0000 0001: 1 HCLK cycle for write access / 3 HCLK cycles for read access

1111 1110: 254 HCLK cycles for write access / 256 HCLK cycles for read access

1111 1111: reserved.

Bits 15:8 **MEMWAIT[7:0]**: Common memory wait time

Defines the minimum number of HCLK (+1) clock cycles to assert the command (NWE, NOE), for NAND Flash read or write access to common memory space on socket. The duration of command assertion is extended if the wait signal (NWAIT) is active (low) at the end of the programmed value of HCLK:

0000 0000: reserved

0000 0001: 2HCLK cycles (+ wait cycle introduced by deasserting NWAIT)

1111 1110: 255 HCLK cycles (+ wait cycle introduced by deasserting NWAIT)

1111 1111: reserved.

Bits 7:0 **MEMSET[7:0]**: Common memory x setup time

Defines the number of HCLK (+1) clock cycles to set up the address before the command assertion (NWE, NOE), for NAND Flash read or write access to common memory space on socket x:

0000 0000: 1 HCLK cycle

1111 1110: 255 HCLK cycles

1111 1111: reserved

### Attribute memory space timing registers (FMC\_PATT)

Address offset: 0x8C

Reset value: 0xFCFC FCFC

The FMC\_PATT read/write register contains the timing information for NAND Flash memory bank. It is used for 8-bit accesses to the attribute memory space of the NAND Flash for the last address write access if the timing must differ from that of previous accesses (for Ready/Busy management, refer to [Section 13.6.5: NAND Flash prewait functionality](#)).

|              |    |    |    |    |    |    |    |               |    |    |    |    |    |    |    |
|--------------|----|----|----|----|----|----|----|---------------|----|----|----|----|----|----|----|
| 31           | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23            | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| ATTTHIZ[7:0] |    |    |    |    |    |    |    | ATTTHOLD[7:0] |    |    |    |    |    |    |    |
| rw           | rw | rw | rw | rw | rw | rw | rw | rw            | rw | rw | rw | rw | rw | rw | rw |
| 15           | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7             | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| ATTWAIT[7:0] |    |    |    |    |    |    |    | ATTSET[7:0]   |    |    |    |    |    |    |    |
| rw           | rw | rw | rw | rw | rw | rw | rw | rw            | rw | rw | rw | rw | rw | rw | rw |

Bits 31:24 **ATTTHIZ[7:0]**: Attribute memory data bus Hi-Z time

Defines the number of HCLK clock cycles during which the data bus is kept in Hi-Z after the start of a NAND Flash write access to attribute memory space on socket. Only valid for writ transaction:

0000 0000: 0 HCLK cycle

1111 1110: 255 HCLK cycles

1111 1111: reserved.

Bits 23:16 **ATTTHOLD[7:0]**: Attribute memory hold time

Defines the number of HCLK clock cycles for write access and HCLK (+2) clock cycles for read access during which the address is held (and data for write access) after the command deassertion (NWE, NOE), for NAND Flash read or write access to attribute memory space on socket:

0000 0000: reserved

0000 0001: 1 HCLK cycle for write access / 3 HCLK cycles for read access

1111 1110: 254 HCLK cycles for write access / 256 HCLK cycles for read access

1111 1111: reserved.

Bits 15:8 **ATTWAIT[7:0]**: Attribute memory wait time

Defines the minimum number of HCLK (+1) clock cycles to assert the command (NWE, NOE), for NAND Flash read or write access to attribute memory space on socket x. The duration for command assertion is extended if the wait signal (NWAIT) is active (low) at the end of the programmed value of HCLK:

0000 0000: reserved

0000 0001: 2 HCLK cycles (+ wait cycle introduced by deassertion of NWAIT)

1111 1110: 255 HCLK cycles (+ wait cycle introduced by deasserting NWAIT)

1111 1111: reserved.

Bits 7:0 **ATTSET[7:0]**: Attribute memory setup time

Defines the number of HCLK (+1) clock cycles to set up address before the command assertion (NWE, NOE), for NAND Flash read or write access to attribute memory space on socket:

0000 0000: 1 HCLK cycle

1111 1110: 255 HCLK cycles

1111 1111: reserved.

**ECC result registers (FMC\_ECCR)**

Address offset: 0x94

Reset value: 0x0000 0000

This register contains the current error correction code value computed by the ECC computation modules of the FMC NAND controller. When the CPU reads the data from a NAND Flash memory page at the correct address (refer to [Section 13.6.6: Computation of the error correction code \(ECC\) in NAND Flash memory](#)), the data read/written from/to the NAND Flash memory are processed automatically by the ECC computation module. When X bytes have been read (according to the ECCPS field in the FMC\_PCR registers), the CPU must read the computed ECC value from the FMC\_ECC registers. It then verifies if these computed parity data are the same as the parity value recorded in the spare area, to determine whether a page is valid, and, to correct it otherwise. The FMC\_ECCR register should be cleared after being read by setting the ECCEN bit to '0'. To compute a new data block, the ECCEN bit must be set to '1'.

|            |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|

| 101        | 8192               | ECC[31:0] |

## 13.7 SDRAM controller

### 13.7.1 SDRAM controller main features

The main features of the SDRAM controller are the following:

- Two SDRAM banks with independent configuration
- 8-bit, 16-bit, 32-bit data bus width
- 13-bits Address Row, 11-bits Address Column, 4 internal banks: 4x16Mx32bit (256 MB), 4x16Mx16bit (128 MB), 4x16Mx8bit (64 MB)
- Word, half-word, byte access
- SDRAM clock can be HCLK/2 or HCLK/3
- Automatic row and bank boundary management
- Multibank ping-pong access
- Programmable timing parameters
- Automatic Refresh operation with programmable Refresh rate
- Self-refresh mode
- Power-down mode
- SDRAM power-up initialization by software
- CAS latency of 1,2,3
- Cacheable Read FIFO with depth of 6 lines x32-bit (6 x14-bit address tag)

### 13.7.2 SDRAM External memory interface signals

At startup, the SDRAM I/O pins used to interface the FMC SDRAM controller with the external SDRAM devices must be configured by the user application. The SDRAM controller I/O pins which are not used by the application, can be used for other purposes.

**Table 88. SDRAM signals**

| SDRAM signal | I/O type | Description                                                            | Alternate function |
|--------------|----------|------------------------------------------------------------------------|--------------------|
| SDCLK        | O        | SDRAM clock                                                            | -                  |

### 13.7.3 SDRAM controller functional description

All SDRAM controller outputs (signals, address and data) change on the falling edge of the memory clock (FMC\_SDCLK).

#### SDRAM initialization

The initialization sequence is managed by software. If the two banks are used, the initialization sequence must be generated simultaneously to Bank 1 and Bank 2 by setting the Target Bank bits CTB1 and CTB2 in the FMC\_SDCMR register:

1. Program the memory device features into the FMC\_SDCRx register. The SDRAM clock frequency, RBURST and RPIPE must be programmed in the FMC\_SDCR1 register.
2. Program the memory device timing into the FMC\_SDTRx register. The TRP and TRC timings must be programmed in the FMC\_SDTR1 register.
3. Set MODE bits to '001' and configure the Target Bank bits (CTB1 and/or CTB2) in the FMC\_SDCMR register to start delivering the clock to the memory (SDCKE is driven high).
4. Wait during the prescribed delay period. Typical delay is around 100  $\mu$ s (refer to the SDRAM datasheet for the required delay after power-up).
5. Set MODE bits to '010' and configure the Target Bank bits (CTB1 and/or CTB2) in the FMC\_SDCMR register to issue a "Precharge All" command.
6. Set MODE bits to '011', and configure the Target Bank bits (CTB1 and/or CTB2) as well as the number of consecutive Auto-refresh commands (NRFS) in the FMC\_SDCMR register. Refer to the SDRAM datasheet for the number of Auto-refresh commands that should be issued. Typical number is 8.
7. Configure the MRD field according to the SDRAM device, set the MODE bits to '100', and configure the Target Bank bits (CTB1 and/or CTB2) in the FMC\_SDCMR register to issue a "Load Mode Register" command in order to program the SDRAM device. In particular:
  - a) the CAS latency must be selected following configured value in FMC\_SDCR1/2 registers
  - b) the Burst Length (BL) of 1 must be selected by configuring the M[2:0] bits to 000 in the mode register. Refer to SDRAM device datasheet.

If the Mode Register is not the same for both SDRAM banks, this step has to be repeated twice, once for each bank, and the Target Bank bits set accordingly.

8. Program the refresh rate in the FMC\_SDRTR register  
The refresh rate corresponds to the delay between refresh cycles. Its value must be adapted to SDRAM devices.
9. For mobile SDRAM devices, to program the extended mode register it should be done once the SDRAM device is initialized: First, a dummy read access should be performed while BA1=1 and BA=0 (refer to SDRAM address mapping section for BA[1:0] address mapping) in order to select the extended mode register instead of the load mode register and then program the needed value.

At this stage the SDRAM device is ready to accept commands. If a system reset occurs during an ongoing SDRAM access, the data bus might still be driven by the SDRAM device. Therefore the SDRAM device must be first reinitialized after reset before issuing any new access by the NOR Flash/PSRAM/SRAM or NAND Flash controller.

**Note:** If two SDRAM devices are connected to the FMC, all the accesses performed at the same time to both devices by the Command Mode register (Load Mode Register command) are issued using the timing parameters configured for SDRAM Bank 1 (TMRD and TRAS timings) in the FMC\_SDTR1 register.

### SDRAM controller write cycle

The SDRAM controller accepts single and burst write requests and translates them into single memory accesses. In both cases, the SDRAM controller keeps track of the active row for each bank to be able to perform consecutive write accesses to different banks (Multibank ping-pong access).

Before performing any write access, the SDRAM bank write protection must be disabled by clearing the WP bit in the FMC\_SDCRx register.

**Figure 55. Burst write SDRAM access waveforms**

The SDRAM controller always checks the next access.

- If the next access is in the same row or in another active row, the write operation is carried out,
- if the next access targets another row (not active), the SDRAM controller generates a precharge command, activates the new row and initiates a write command.

### SDRAM controller read cycle

The SDRAM controller accepts single and burst read requests and translates them into single memory accesses. In both cases, the SDRAM controller keeps track of the active row in each bank to be able to perform consecutive read accesses in different banks (Multibank ping-pong access).

Figure 56. Burst read SDRAM access

The FMC SDRAM controller features a Cacheable read FIFO (6 lines x 32 bits). It is used to store data read in advance during the CAS latency period and the RPIPE delay following the below formula. The RBURST bit must be set in the FMC\_SDCR1 register to anticipate the next read access.

Number for anticipated data = CAS latency + 1 + (RPIPE delay)/2

Examples:

- CAS latency = 3, RPIPE delay = 0: Four data (not committed) are stored in the FIFO.
- CAS latency = 3, RPIPE delay = 2: Five data (not committed) are stored in the FIFO.

The read FIFO features a 14-bit address tag to each line to identify its content: 11 bits for the column address, 2 bits to select the internal bank and the active row, and 1 bit to select the SDRAM device

When the end of the row is reached in advance during an AHB burst read, the data read in advance (not committed) are not stored in the read FIFO. For single read access, data are correctly stored in the FIFO.

Each time a read request occurs, the SDRAM controller checks:

- If the address matches one of the address tags, data are directly read from the FIFO and the corresponding address tag/ line content is cleared and the remaining data in the FIFO are compacted to avoid empty lines.
- Otherwise, a new read command is issued to the memory and the FIFO is updated with new data. If the FIFO is full, the older data are lost.

**Figure 57. Logic diagram of Read access with RBURST bit set (CAS=1, RPIPE=0)**

During a write access or a Precharge command, the read FIFO is flushed and ready to be filled with new data.

After the first read request, if the current access was not performed to a row boundary, the SDRAM controller anticipates the next read access during the CAS latency period and the RPIPE delay (if configured). This is done by incrementing the memory address. The following condition must be met:

- RBURST control bit should be set to '1' in the FMC\_SDCR1 register.

The address management depends on the next AHB request:

- Next AHB request is sequential (AHB Burst)  
In this case, the SDRAM controller increments the address.
- Next AHB request is not sequential
  - If the new read request targets the same row or another active row, the new address is passed to the memory and the master is stalled for the CAS latency period, waiting for the new data from memory.
  - If the new read request does not target an active row, the SDRAM controller generates a Precharge command, activates the new row, and initiates a read command.

If the RURST is reset, the read FIFO is not used.

### Row and bank boundary management

When a read or write access crosses a row boundary, if the next read or write access is sequential and the current access was performed to a row boundary, the SDRAM controller executes the following operations:

1. Precharge of the active row,
2. Activation of the new row
3. Start of a read/write command.

At a row boundary, the automatic activation of the next row is supported for all columns and data bus width configurations.

If necessary, the SDRAM controller inserts additional clock cycles between the following commands:

- Between Precharge and Active commands to match TRP parameter (only if the next access is in a different row in the same bank),
- Between Active and Read commands to match the TRCD parameter.

These parameters are defined into the FMC\_SDTRx register.

Refer to [Figure 55](#) and [Figure 56](#) for read and burst write access crossing a row boundary.

Figure 58. Read access crossing row boundary

Figure 59. Write access crossing row boundary

If the next access is sequential and the current access crosses a bank boundary, the SDRAM controller activates the first row in the next bank and initiates a new read/write command. Two cases are possible:

- If the current bank is not the last one, the active row in the new bank must be precharged. At a bank boundary, the automatic activation of the next row is supported for all rows/columns and data bus width configuration.
- If the current bank is the last one, the automatic activation of the next row is supported only when addressing 13-bit rows, 11-bit columns, 4 internal banks and 32-bit data bus SDRAM devices. Otherwise, the SDRAM address range is violated and an AHB error is generated.
- In case of 13-bit row address, 11-bit column address, 4 internal banks and bus width 32-bit SDRAM memories, at boundary bank, the SDRAM controller continues to read/write from the second SDRAM device (assuming it has been initialized):
  - a) The SDRAM controller activates the first row (after precharging the active row, if there is already an active row in the first internal bank, and initiates a new read/write command.
  - b) If the first row is already activated, the SDRAM controller just initiates a read/write command.

### SDRAM controller refresh cycle

The Auto-refresh command is used to refresh the SDRAM device content. The SDRAM controller periodically issues auto-refresh commands. An internal counter is loaded with the COUNT value in the register FMC\_SDRTR. This value defines the number of memory clock cycles between the refresh cycles (refresh rate). When this counter reaches zero, an internal pulse is generated.

If a memory access is ongoing, the auto-refresh request is delayed. However, if the memory access and the auto-refresh requests are generated simultaneously, the auto-refresh request takes precedence.

If the memory access occurs during an auto-refresh operation, the request is buffered and processed when the auto-refresh is complete.

If a new auto-refresh request occurs while the previous one was not served, the RE (Refresh Error) bit is set in the Status register. An Interrupt is generated if it has been enabled (REIE = '1').

If SDRAM lines are not in idle state (not all row are closed), the SDRAM controller generates a PALL (Precharge ALL) command before the auto-refresh.

If the Auto-refresh command is generated by the FMC\_SDCMR Command Mode register (Mode bits = '011'), a PALL command (Mode bits = '010') must be issued first.

### 13.7.4 Low-power modes

Two low-power modes are available:

- Self-refresh mode  
The auto-refresh cycles are performed by the SDRAM device itself to retain data without external clocking.
- Power-down mode  
The auto-refresh cycles are performed by the SDRAM controller.

### Self-refresh mode

This mode is selected by setting the MODE bits to '101' and by configuring the Target Bank bits (CTB1 and/or CTB2) in the FMC\_SDCMR register.

The SDRAM clock stops running after a TRAS delay and the internal refresh timer stops counting only if one of the following conditions is met:

- A Self-refresh command is issued to both devices
- One of the devices is not activated (SDRAM bank is not initialized).

Before entering Self-Refresh mode, the SDRAM controller automatically issues a PALL command.

If the Write data FIFO is not empty, all data are sent to the memory before activating the Self-refresh mode and the BUSY status flag remains set.

In Self-refresh mode, all SDRAM device inputs become don't care except for SDCKE which remains low.

The SDRAM device must remain in Self-refresh mode for a minimum period of time of TRAS and can remain in Self-refresh mode for an indefinite period beyond that. To guarantee this minimum period, the BUSY status flag remains high after the Self-refresh activation during a TRAS delay.

As soon as an SDRAM device is selected, the SDRAM controller generates a sequence of commands to exit from Self-refresh mode. After the memory access, the selected device remains in Normal mode.

To exit from Self-refresh, the MODE bits must be set to '000' (Normal mode) and the Target Bank bits (CTB1 and/or CTB2) must be configured in the FMC\_SDCMR register.

Figure 60. Self-refresh mode

### Power-down mode

This mode is selected by setting the MODE bits to '110' and by configuring the Target Bank bits (CTB1 and/or CTB2) in the FMC\_SDCMR register.

Figure 61. Power-down mode

If the Write data FIFO is not empty, all data are sent to the memory before activating the Power-down mode.

As soon as an SDRAM device is selected, the SDRAM controller exits from the Power-down mode. After the memory access, the selected SDRAM device remains in Normal mode.

During Power-down mode, all SDRAM device input and output buffers are deactivated except for the SDCKE which remains low.

The SDRAM device cannot remain in Power-down mode longer than the refresh period and cannot perform the Auto-refresh cycles by itself. Therefore, the SDRAM controller carries out the refresh operation by executing the operations below:

1. Exit from Power-down mode and drive the SDCKE high
2. Generate the PALL command only if a row was active during Power-down mode
3. Generate the auto-refresh command
4. Drive SDCKE low again to return to Power-down mode.

To exit from Power-down mode, the MODE bits must be set to '000' (Normal mode) and the Target Bank bits (CTB1 and/or CTB2) must be configured in the FMC\_SDCMR register.

### 13.7.5 SDRAM controller registers

#### SDRAM Control registers 1,2 (FMC\_SDCR1,2)

Address offset:  $0x140 + 4 * (x - 1)$ ,  $x = 1, 2$

Reset value: 0x0000 02D0

This register contains the control parameters for each SDRAM memory bank

|      |            |      |        |       |      |      |      |      |      |      |      |      |      |      |      |
|------|------------|------|--------|-------|------|------|------|------|------|------|------|------|------|------|------|
| 31   | 30         | 29   | 28     | 27    | 26   | 25   | 24   | 23   | 22   | 21   | 20   | 19   | 18   | 17   | 16   |
| Res. | Res.       | Res. | Res.   | Res.  | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. |
|      |            |      |        |       |      |      |      |      |      |      |      |      |      |      |      |
| 15   | 14         | 13   | 12     | 11    | 10   | 9    | 8    | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0    |
| Res. | RPIPE[1:0] |      | RBURST | SDCLK |      | WP   | CAS  |      | NB   | MWID |      | NR   |      | NC   |      |
|      | rw         | rw   | rw     | rw    | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   |

Bits 31:15 Reserved, must be kept at reset value.

Bits 14:13 **RPIPE[1:0]**: Read pipe

These bits define the delay, in HCLK clock cycles, for reading data after CAS latency.

00: No HCLK clock cycle delay

01: One HCLK clock cycle delay

10: Two HCLK clock cycle delay

11: reserved.

*Note: The corresponding bits in the FMC\_SDCR2 register is read only.*

Bit 12 **RBURST**: Burst read

This bit enables Burst read mode. The SDRAM controller anticipates the next read commands during the CAS latency and stores data in the Read FIFO.

0: single read requests are not managed as bursts

1: single read requests are always managed as bursts

*Note: The corresponding bit in the FMC\_SDCR2 register is don't care.*

Bits 11:10 **SDCLK[1:0]**: SDRAM clock configuration

These bits define the SDRAM clock period for both SDRAM banks and allow disabling the clock before changing the frequency. In this case the SDRAM must be re-initialized.

00: SDCLK clock disabled

01: reserved

10: SDCLK period = 2 x HCLK periods

11: SDCLK period = 3 x HCLK periods

*Note: The corresponding bits in the FMC\_SDCR2 register are don't care.*

Bit 9 **WP**: Write protection

This bit enables write mode access to the SDRAM bank.

0: Write accesses allowed

1: Write accesses ignored

Bits 8:7 **CAS[1:0]**: CAS Latency

This bits sets the SDRAM CAS latency in number of memory clock cycles

00: reserved.

01: 1 cycle

10: 2 cycles

11: 3 cycles

Bit 6 **NB**: Number of internal banks

This bit sets the number of internal banks.

0: Two internal Banks

1: Four internal Banks

Bits 5:4 **MWID[1:0]**: Memory data bus width.

These bits define the memory device width.

00: 8 bits

01: 16 bits

10: 32 bits

11: reserved.

Bits 3:2 **NR[1:0]**: Number of row address bits

These bits define the number of bits of a row address.

00: 11 bit

01: 12 bits

10: 13 bits

11: reserved.

Bits 1:0 **NC[1:0]**: Number of column address bits

These bits define the number of bits of a column address.

00: 8 bits

01: 9 bits

10: 10 bits

11: 11 bits.

**Note:** Before modifying the *RBURST* or *RPIPE* settings or disabling the *SDCLK* clock, the user must first send a *PALL* command to make sure ongoing operations are complete.

### SDRAM Timing registers 1,2 (FMC\_SDTR1,2)

Address offset:  $0x148 + 4 * (x - 1)$ ,  $x = 1,2$

Reset value: 0x0FFF FFFF

This register contains the timing parameters of each SDRAM bank

|      |      |      |      |      |    |    |    |      |    |    |    |      |    |    |    |
|------|------|------|------|------|----|----|----|------|----|----|----|------|----|----|----|
| 31   | 30   | 29   | 28   | 27   | 26 | 25 | 24 | 23   | 22 | 21 | 20 | 19   | 18 | 17 | 16 |
| Res. | Res. | Res. | Res. | TRCD |    |    |    | TRP  |    |    |    | TWR  |    |    |    |
|      |      |      |      | rw   | rw | rw | rw | rw   | rw | rw | rw | rw   | rw | rw | rw |
| 15   | 14   | 13   | 12   | 11   | 10 | 9  | 8  | 7    | 6  | 5  | 4  | 3    | 2  | 1  | 0  |
| TRC  |      |      |      | TRAS |    |    |    | TXSR |    |    |    | TMRD |    |    |    |
| rw   | rw   | rw   | rw   | rw   | rw | rw | rw | rw   | rw | rw | rw | rw   | rw | rw | rw |

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:24 **TRCD[3:0]**: Row to column delay

These bits define the delay between the Activate command and a Read/Write command in number of memory clock cycles.

0000: 1 cycle.

0001: 2 cycles

....

1111: 16 cycles

Bits 23:20 **TRP[3:0]**: Row precharge delay

These bits define the delay between a Precharge command and another command in number of memory clock cycles. The TRP timing is only configured in the FMC\_SDTR1 register. If two SDRAM devices are used, the TRP must be programmed with the timing of the slowest device.

0000: 1 cycle

0001: 2 cycles

....

1111: 16 cycles

*Note: The corresponding bits in the FMC\_SDTR2 register are don't care.*

Bits 19:16 **TWR[3:0]**: Recovery delay

These bits define the delay between a Write and a Precharge command in number of memory clock cycles.

0000: 1 cycle

0001: 2 cycles

....

1111: 16 cycles

*Note: TWR must be programmed to match the write recovery time ( $t_{WR}$ ) defined in the SDRAM datasheet, and to guarantee that:*

$$TWR \geq TRAS - TRCD \text{ and } TWR \geq TRC - TRCD - TRP$$

*Example: TRAS= 4 cycles, TRCD= 2 cycles. So, TWR >= 2 cycles. TWR must be programmed to 0x1.*

*If two SDRAM devices are used, the FMC\_SDTR1 and FMC\_SDTR2 must be programmed with the same TWR timing corresponding to the slowest SDRAM device.*

*If only one SDRAM device is used, the TWR timing must be kept at reset value (0xF) for the not used bank.*

Bits 15:12 **TRC[3:0]**: Row cycle delay

These bits define the delay between the Refresh command and the Activate command, as well as the delay between two consecutive Refresh commands. It is expressed in number of memory clock cycles. The TRC timing is only configured in the FMC\_SDTR1 register. If two SDRAM devices are used, the TRC must be programmed with the timings of the slowest device.

0000: 1 cycle

0001: 2 cycles

....

1111: 16 cycles

*Note: TRC must match the TRC and TRFC (Auto Refresh period) timings defined in the SDRAM device datasheet.*

*Note: The corresponding bits in the FMC\_SDTR2 register are don't care.*

Bits 11:8 **TRAS[3:0]**: Self refresh time

These bits define the minimum Self-refresh period in number of memory clock cycles.

0000: 1 cycle

0001: 2 cycles

....

1111: 16 cycles

Bits 7:4 **TXSR[3:0]**: Exit Self-refresh delay

These bits define the delay from releasing the Self-refresh command to issuing the Activate command in number of memory clock cycles.

0000: 1 cycle

0001: 2 cycles

....

1111: 16 cycles

*Note: If two SDRAM devices are used, the FMC\_SDTR1 and FMC\_SDTR2 must be programmed with the same TXSR timing corresponding to the slowest SDRAM device.*

Bits 3:0 **TMRD[3:0]**: Load Mode Register to Active

These bits define the delay between a Load Mode Register command and an Active or Refresh command in number of memory clock cycles.

0000: 1 cycle

0001: 2 cycles

....

1111: 16 cycles

*Note: If two SDRAM devices are connected, all the accesses performed simultaneously to both devices by the Command Mode register (Load Mode Register command) are issued using the timing parameters configured for Bank 1 (TMRD and TRAS timings) in the FMC\_SDTR1 register.*

*The TRP and TRC timings are only configured in the FMC\_SDTR1 register. If two SDRAM devices are used, the TRP and TRC timings must be programmed with the timings of the slowest device.*

**SDRAM Command Mode register (FMC\_SDCMR)**

Address offset: 0x150

Reset value: 0x0000 0000

This register contains the command issued when the SDRAM device is accessed. This register is used to initialize the SDRAM device, and to activate the Self-refresh and the Power-down modes. As soon as the MODE field is written, the command will be issued only to one or to both SDRAM banks according to CTB1 and CTB2 command bits. This register is the same for both SDRAM banks.

|      |      |      |      |      |      |      |      |      |      |     |      |      |      |    |    |
|------|------|------|------|------|------|------|------|------|------|-----|------|------|------|----|----|
| 31   | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21  | 20   | 19   | 18   | 17 | 16 |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | MRD |      |      |      |    |    |
|      |      |      |      |      |      |      |      |      |      | rw  | rw   | rw   | rw   | rw | rw |
| 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5   | 4    | 3    | 2    | 1  | 0  |
| MRD  |      |      |      |      |      |      | NRFS |      |      |     | CTB1 | CTB2 | MODE |    |    |
| rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw  | rw   | rw   | rw   | rw | rw |

Bits 31:22 Reserved, must be kept at reset value.

Bits 21:9 **MRD[12:0]**: Mode Register definition

This 13-bit field defines the SDRAM Mode Register content. The Mode Register is programmed using the Load Mode Register command.

Bits 8:5 **NRFS[3:0]**: Number of Auto-refresh

These bits define the number of consecutive Auto-refresh commands issued when MODE = '011'.

0000: 1 Auto-refresh cycle

0001: 2 Auto-refresh cycles

....

1110: 15 Auto-refresh cycles

1111: 16 Auto-refresh cycles

Bit 4 **CTB1**: Command Target Bank 1

This bit indicates whether the command will be issued to SDRAM Bank 1 or not.

0: Command not issued to SDRAM Bank 1

1: Command issued to SDRAM Bank 1

Bit 3 **CTB2**: Command Target Bank 2

This bit indicates whether the command will be issued to SDRAM Bank 2 or not.

0: Command not issued to SDRAM Bank 2

1: Command issued to SDRAM Bank 2

Bits 2:0 **MODE[2:0]**: Command mode

These bits define the command issued to the SDRAM device.

000: Normal Mode

001: Clock Configuration Enable

010: PALL ("All Bank Precharge") command

011: Auto-refresh command

100: Load Mode Register

101: Self-refresh command

110: Power-down command

111: Reserved

*Note: When a command is issued, at least one Command Target Bank bit ( CTB1 or CTB2) must be set otherwise the command will be ignored.*

*Note: If two SDRAM banks are used, the Auto-refresh and PALL command must be issued simultaneously to the two devices with CTB1 and CTB2 bits set otherwise the command will be ignored.*

*Note: If only one SDRAM bank is used and a command is issued with it's associated CTB bit set, the other CTB bit of the the unused bank must be kept to 0.*

### SDRAM Refresh Timer register (FMC\_SDRTR)

Address offset: 0x154

Reset value: 0x0000 0000

This register sets the refresh rate in number of SDCLK clock cycles between the refresh cycles by configuring the Refresh Timer Count value.

$$\text{Refresh rate} = (\text{COUNT} + 1) \times \text{SDRAM clock frequency}$$

$$\text{COUNT} = (\text{SDRAM refresh period} / \text{Number of rows}) - 20$$

### Example

$$\text{Refresh rate} = 64 \text{ ms} / (8196 \text{ rows}) = 7.81 \mu\text{s}$$

where 64 ms is the SDRAM refresh period.

$$7.81\mu\text{s} \times 60\text{MHz} = 468.6$$

The refresh rate must be increased by 20 SDRAM clock cycles (as in the above example) to obtain a safe margin if an internal refresh request occurs when a read request has been accepted. It corresponds to a COUNT value of '0000111000000' (448).

This 13-bit field is loaded into a timer which is decremented using the SDRAM clock. This timer generates a refresh pulse when zero is reached. The COUNT value must be set at least to 41 SDRAM clock cycles.

As soon as the FMC\_SDRTR register is programmed, the timer starts counting. If the value programmed in the register is '0', no refresh is carried out. This register must not be reprogrammed after the initialization procedure to avoid modifying the refresh rate.

Each time a refresh pulse is generated, this 13-bit COUNT field is reloaded into the counter.

If a memory access is in progress, the Auto-refresh request is delayed. However, if the memory access and Auto-refresh requests are generated simultaneously, the Auto-refresh takes precedence. If the memory access occurs during a refresh operation, the request is buffered to be processed when the refresh is complete.

This register is common to SDRAM bank 1 and bank 2.

Bits 31: 15 Reserved, must be kept at reset value.

Bit 14 **REIE**: RES Interrupt Enable

0: Interrupt is disabled

1: An Interrupt is generated if RE = 1

Bits 13:1 **COUNT[12:0]**: Refresh Timer Count

This 13-bit field defines the refresh rate of the SDRAM device. It is expressed in number of memory clock cycles. It must be set at least to 41 SDRAM clock cycles (0x29).

Refresh rate = (COUNT + 1) x SDRAM frequency clock

COUNT = (SDRAM refresh period / Number of rows) - 20

Bit 0 **CRE**: Clear Refresh error flag

This bit is used to clear the Refresh Error Flag (RE) in the Status Register.

0: no effect

1: Refresh Error flag is cleared

**Note:** *The programmed COUNT value must not be equal to the sum of the following timings: TWR+TRP+TRC+TRCD+4 memory clock cycles.*

### SDRAM Status register (FMC\_SDSR)

Address offset: 0x158

Reset value: 0x0000 0000

Bits 31:5 Reserved, must be kept at reset value.

Bit 5 **BUSY**: Busy status

This bit defines the status of the SDRAM controller after a Command Mode request

0: SDRAM Controller is ready to accept a new request

1: SDRAM Controller is not ready to accept a new request

Bits 4:3 **MODES2[1:0]**: Status Mode for Bank 2

This bit defines the Status Mode of SDRAM Bank 2.

00: Normal Mode

01: Self-refresh mode

10: Power-down mode

Bits 2:1 **MODES1[1:0]**: Status Mode for Bank 1

This bit defines the Status Mode of SDRAM Bank 1.

00: Normal Mode

01: Self-refresh mode

10: Power-down mode

Bit 0 **RE**: Refresh error flag

0: No refresh error has been detected

1: A refresh error has been detected

An interrupt is generated if REIE = 1 and RE = 1

Refer to [Section 2.2.2 on page 69](#) for the register boundary addresses.

## 14 Quad-SPI interface (QUADSPI)

### 14.1 Introduction

The QUADSPI is a specialized communication interface targeting single, dual or quad SPI Flash memories. It can operate in any of the three following modes:

- indirect mode: all the operations are performed using the QUADSPI registers
- status polling mode: the external Flash memory status register is periodically read and an interrupt can be generated in case of flag setting
- memory-mapped mode: the external Flash memory is mapped to the microcontroller address space and is seen by the system as if it was an internal memory

Both throughput and capacity can be increased two-fold using dual-flash mode, where two Quad-SPI Flash memories are accessed simultaneously.

### 14.2 QUADSPI main features

- Three functional modes: indirect, status-polling, and memory-mapped
- Dual-flash mode, where 8 bits can be sent/received simultaneously by accessing two Flash memories in parallel.
- SDR and DDR support
- Fully programmable opcode for both indirect and memory mapped mode
- Fully programmable frame format for both indirect and memory mapped mode
- Integrated FIFO for reception and transmission
- 8, 16, and 32-bit data accesses are allowed
- DMA channel for indirect mode operations
- Interrupt generation on FIFO threshold, timeout, operation complete, and access error

### 14.3 QUADSPI functional description

#### 14.3.1 QUADSPI block diagram

Figure 62. QUADSPI block diagram when dual-flash mode is disabled

Figure 63. QUADSPI block diagram when dual-flash mode is enabled

### 14.3.2 QUADSPI pins

[Table 90](#) lists the QUADSPI pins, six for interfacing with a single Flash memory, or 10 to 11 for interfacing with two Flash memories (FLASH 1 and FLASH 2) in dual-flash mode.

Table 90. QUADSPI pins

| Signal name | Signal type          | Description                                                                                                      |
|-------------|----------------------|------------------------------------------------------------------------------------------------------------------|
| CLK         | Digital output       | Clock to FLASH 1 and FLASH 2                                                                                     |
| BK1_IO0/SO  | Digital input/output | Bidirectional IO in dual/quad modes or serial output in single mode, for FLASH 1                                 |
| BK1_IO1/SI  | Digital input/output | Bidirectional IO in dual/quad modes or serial input in single mode, for FLASH 1                                  |
| BK1_IO2     | Digital input/output | Bidirectional IO in quad mode, for FLASH 1                                                                       |
| BK1_IO3     | Digital input/output | Bidirectional IO in quad mode, for FLASH 1                                                                       |
| BK2_IO0/SO  | Digital input/output | Bidirectional IO in dual/quad modes or serial output in single mode, for FLASH 2                                 |
| BK2_IO1/SI  | Digital input/output | Bidirectional IO in dual/quad modes or serial input in single mode, for FLASH 2                                  |
| BK2_IO2     | Digital input/output | Bidirectional IO in quad mode, for FLASH 2                                                                       |
| BK2_IO3     | Digital input/output | Bidirectional IO in quad mode, for FLASH 2                                                                       |
| BK1_nCS     | Digital output       | Chip select (active low) for FLASH 1. Can also be used for FLASH 2 if QUADSPI is always used in dual-flash mode. |
| BK2_nCS     | Digital output       | Chip select (active low) for FLASH 2. Can also be used for FLASH 1 if QUADSPI is always used in dual-flash mode. |

The QUADSPI communicates with the Flash memory using commands. Each command can include 5 phases: instruction, address, alternate byte, dummy, data. Any of these phases can be configured to be skipped, but at least one of the instruction, address, alternate byte, or data phase must be present.

**Figure 64. An example of a read command in quad mode**

During this phase, an 8-bit instruction, configured in INSTRUCTION field of QUADSPI\_CCR[7:0] register, is sent to the Flash memory, specifying the type of operation to be performed.

When IMODE = 00, the instruction phase is skipped, and the command sequence starts with the address phase, if present.

In the address phase, 1-4 bytes are sent to the Flash memory to indicate the address of the operation. The number of address bytes to be sent is configured in the ADSSIZE[1:0] field of QUADSPI\_CCR[13:12] register. In indirect and automatic-polling modes, the address bytes to be sent are specified in the ADDRESS[31:0] field of QUADSPI\_AR register, while in memory-mapped mode the address is given directly via the AHB (from the Cortex® or from a DMA).

When **ADMODE** = 00, the address phase is skipped, and the command sequence proceeds directly to the next phase, if any.

### Alternate-bytes phase

In the alternate-bytes phase, 1-4 bytes are sent to the Flash memory, generally to control the mode of operation. The number of alternate bytes to be sent is configured in the ABSIZE[1:0] field of QUADSPI\_CCR[17:16] register. The bytes to be sent are specified in the QUADSPI\_ABR register.

The alternate-bytes phase can send 1 bit at a time (over SO in single SPI mode), 2 bits at a time (over IO0/IO1 in dual SPI mode), or 4 bits at a time (over IO0/IO1/IO2/IO3 in quad SPI mode). This can be configured using the ABMODE[1:0] field of QUADSPI\_CCR[15:14] register.

When ABMODE = 00, the alternate-bytes phase is skipped, and the command sequence proceeds directly to the next phase, if any.

There may be times when only a single nibble needs to be sent during the alternate-byte phase rather than a full byte, such as when dual-mode is used and only two cycles are used for the alternate bytes. In this case, firmware can use quad-mode (ABMODE = 11) and send a byte with bits 7 and 3 of ALTERNATE set to '1' (keeping the IO3 line high), and bits 6 and 2 set to '0' (keeping the IO2 line low). In this case the upper two bits of the nibble to be sent are placed in bits 4:3 of ALTERNATE while the lower two bits are placed in bits 1 and 0. For example, if the nibble 2 (0010) is to be sent over IO0/IO1, then ALTERNATE should be set to 0x8A (1000\_1010).

### Dummy-cycles phase

In the dummy-cycles phase, 1-31 cycles are given without any data being sent or received, in order to allow the Flash memory the time to prepare for the data phase when higher clock frequencies are used. The number of cycles given during this phase is specified in the DCYC[4:0] field of QUADSPI\_CCR[22:18] register. In both SDR and DDR modes, the duration is specified as a number of full CLK cycles.

When DCYC is zero, the dummy-cycles phase is skipped, and the command sequence proceeds directly to the data phase, if present.

The operating mode of the dummy-cycles phase is determined by DMODE.

In order to assure enough "turn-around" time for changing the data signals from output mode to input mode, there must be at least one dummy cycle when using dual or quad mode to receive data from the Flash memory.

### Data phase

During the data phase, any number of bytes can be sent to, or received from the Flash memory.

In indirect and automatic-polling modes, the number of bytes to be sent/received is specified in the QUADSPI\_DLR register.

In indirect write mode the data to be sent to the Flash memory must be written to the QUADSPI\_DR register, while in indirect read mode the data received from the Flash memory is obtained by reading from the QUADSPI\_DR register.

In memory-mapped mode, the data which is read is sent back directly over the AHB to the Cortex or to a DMA.

The data phase can send/receive 1 bit at a time (over SO/SI in single SPI mode), 2 bits at a time (over IO0/IO1 in dual SPI mode), or 4 bits at a time (over IO0/IO1/IO2/IO3 in quad SPI mode).

mode). This can be configured using the ABMODE[1:0] field of QUADSPI\_CCR[15:14] register.

When DMODE = 00, the data phase is skipped, and the command sequence finishes immediately by raising nCS. This configuration must only be used in only indirect write mode.

### 14.3.4 QUADSPI signal interface protocol modes

#### Single SPI mode

Legacy SPI mode allows just a single bit to be sent/received serially. In this mode, data is sent to the Flash memory over the SO signal (whose I/O shared with IO0). Data received from the Flash memory arrives via SI (whose I/O shared with IO1).

The different phases can each be configured separately to use this single bit mode by setting the IMODE/ADMODE/ABMODE/DMODE fields (in QUADSPI\_CCR) to 01.

In each phase which is configured in single mode:

- IO0 (SO) is in output mode
- IO1 (SI) is in input mode (high impedance)
- IO2 is in output mode and forced to '0' (to deactivate the "write protect" function)
- IO3 is in output mode and forced to '1' (to deactivate the "hold" function)

This is the case even for the dummy phase if DMODE = 01.

#### Dual SPI mode

In dual SPI mode, two bits are sent/received simultaneously over the IO0/IO1 signals.

The different phases can each be configured separately to use dual SPI mode by setting the IMODE/ADMODE/ABMODE/DMODE fields of QUADSPI\_CCR register to 10.

In each phase which is configured in dual mode:

- IO0/IO1 are at high-impedance (input) during the data phase for read operations, and outputs in all other cases
- IO2 is in output mode and forced to '0'
- IO3 is in output mode and forced to '1'

In the dummy phase when DMODE = 01, IO0/IO1 are always high-impedance.

#### Quad SPI mode

In quad SPI mode, four bits are sent/received simultaneously over the IO0/IO1/IO2/IO3 signals.

The different phases can each be configured separately to use quad SPI mode by setting the IMODE/ADMODE/ABMODE/DMODE fields of QUADSPI\_CCR register to 11.

In each phase which is configured in quad mode, IO0/IO1/IO2/IO3 are all are at high-impedance (input) during the data phase for read operations, and outputs in all other cases.

In the dummy phase when DMODE = 11, IO0/IO1/IO2/IO3 are all high-impedance.

IO2 and IO3 are used only in Quad SPI mode. If none of the phases are configured to use Quad SPI mode, then the pins corresponding to IO2 and IO3 can be used for other functions even while QUADSPI is active.

### SDR mode

By default, the DDRM bit (QUADSPI\_CCR[31]) is 0 and the QUADSPI operates in single data rate (SDR) mode.

In SDR mode, when the QUADSPI is driving the IO0/SO, IO1, IO2, IO3 signals, these signals transition only with the falling edge of CLK.

When receiving data in SDR mode, the QUADSPI assumes that the Flash memories also send the data using CLK's falling edge. By default (when SSHIFT = 0), the signals are sampled using the following (rising) edge of CLK.

### DDR mode

When the DDRM bit (QUADSPI\_CCR[31]) is set to 1, the QUADSPI operates in double data rate (DDR) mode.

In DDR mode, when the QUADSPI is driving the IO0/SO, IO1, IO2, IO3 signals in the address/alternate-byte/data phases, a bit is sent on each of the falling and rising edges of CLK.

The instruction phase is not affected by DDRM. The instruction is always sent using CLK's falling edge.

When receiving data in DDR mode, the QUADSPI assumes that the Flash memories also send the data using both rising and falling CLK edges. When DDRM = 1, firmware must clear SSHIFT bit (bit 4 of QUADSPI\_CR). Thus, the signals are sampled one half of a CLK cycle later (on the following, opposite edge) of CLK.

**Figure 65. An example of a DDR command in quad mode**

### Dual-flash mode

When the DFM bit (bit 6 of QUADSPI\_CR) is 1, the QUADSPI is in dual-flash mode, where two external quad SPI Flash memories (FLASH 1 and FLASH 2) are used in order to send/receive 8 bits (or 16 bits in DDR mode) every cycle, effectively doubling the throughput as well as the capacity.

Each of the Flash memories use the same CLK and optionally the same nCS signals, but each have separate IO0, IO1, IO2, and IO3 signals.

Dual-flash mode can be used in conjunction with single-bit, dual-bit, and quad-bit modes, as well as with either SDR or DDR mode.

The Flash memory size, as specified in FSIZE[4:0] (QUADSPI\_DCR[20:16]), should reflect the total Flash memory capacity, which is double the size of one individual component.

If address X is even, then the byte which the QUADSPI gives for address X is the byte at the address X/2 of FLASH 1, and the byte which the QUADSPI gives for address X+1 is the byte at the address X/2 of FLASH 2. In other words, bytes at even addresses are all stored in FLASH 1 and bytes at odd addresses are all stored in FLASH 2.

When reading the Flash memories status registers in dual-flash mode, twice as many bytes should be read compared to doing the same read in single-flash mode. This means that if each Flash memory gives 8 valid bits after the instruction for fetching the status register, then the QUADSPI must be configured with a data length of 2 bytes (16 bits), and the QUADSPI will receive one byte from each Flash memory. If each Flash memory gives a status of 16 bits, then the QUADSPI must be configured to read 4 bytes to get all the status bits of both Flash memories in dual-flash mode. The least-significant byte of the result (in the data register) is the least-significant byte of FLASH 1 status register, while the next byte is the least-significant byte of FLASH 2 status register. Then, the third byte of the data register is FLASH 1 second byte, while the forth byte is FLASH 2 second byte (in the case that the Flash memories have 16-bit status registers).

An even number of bytes must always be accessed in dual-flash mode. For this reason, bit 0 of the data length field (QUADSPI\_DLR[0]) is stuck at 1 when DRM = 1.

In dual-flash mode, the behavior of FLASH 1 interface signals are basically the same as in normal mode. FLASH 2 interface signals have exactly the same waveforms as FLASH 1 during the instruction, address, alternate-byte, and dummy-cycles phases. In other words, each Flash memory always receives the same instruction and the same address. Then, during the data phase, the BK1\_IOx and BK2\_IOx buses are both transferring data in parallel, but the data that are sent to (or received from) FLASH 1 are distinct from those of FLASH 2.

### 14.3.5 QUADSPI indirect mode

When in indirect mode, commands are started by writing to QUADSPI registers and data is transferred by writing or reading the data register, in the same way as for other communication peripherals.

When FMODE = 00 (QUADSPI\_CCR[27:26]), the QUADSPI is in indirect write mode, where bytes are sent to the Flash memory during the data phase. Data are provided by writing to the data register (QUADSPI\_DR).

When FMODE = 01, the QUADSPI is in indirect read mode, where bytes are received from the Flash memory during the data phase. Data are recovered by reading QUADSPI\_DR.

The number of bytes to be read/written is specified in the data length register (QUADSPI\_DLR). If QUADSPI\_DLR = 0xFFFF\_FFFF (all 1's), then the data length is considered undefined and the QUADSPI simply continues to transfer data until the end of Flash memory (as defined by FSIZE) is reached. If no bytes are to be transferred, DMODE (QUADSPI\_CCR[25:24]) should be set to 00.

If QUADSPI\_DLR = 0xFFFF\_FFFF and FSIZE = 0x1F (max value indicating a 4GB Flash memory), then in this special case the transfers continue indefinitely, stopping only after an abort request or after the QUADSPI is disabled. After the last memory address is read (at address 0xFFFF\_FFFF), reading continues with address = 0x0000\_0000.

When the programmed number of bytes to be transmitted or received is reached, TCF is set and an interrupt is generated if TCIE = 1. In the case of undefined number of data, the TCF

is set when the limit of the external SPI memory is reached according to the Flash memory size defined in the QUADSPI\_CR.

### Triggering the start of a command

Essentially, a command starts as soon as firmware gives the last information that is necessary for this command. Depending on the QUADSPI configuration, there are three different ways to trigger the start of a command in indirect mode. The commands starts immediately after:

1. a write is performed to INSTRUCTION[7:0] (QUADSPI\_CCR), if no address is necessary (when ADMODE = 00) and if no data needs to be provided by the firmware (when FMODE = 01 or DMODE = 00)
2. a write is performed to ADDRESS[31:0] (QUADSPI\_AR), if an address is necessary (when ADMODE != 00) and if no data needs to be provided by the firmware (when FMODE = 01 or DMODE = 00)
3. a write is performed to DATA[31:0] (QUADSPI\_DR), if an address is necessary (when ADMODE != 00) and if data needs to be provided by the firmware (when FMODE = 00 and DMODE != 00)

Writes to the alternate byte register (QUADSPI\_ABR) never trigger the communication start. If alternate bytes are required, they must be programmed before.

As soon as a command is started, the BUSY bit (bit 5 of QUADSPI\_SR) is automatically set.

### FIFO and data management

In indirect mode, data go through a 32-byte FIFO which is internal to the QUADSPI. FLEVEL[5:0] (QUADSPI\_SR[13:8]) indicates how many bytes are currently being held in the FIFO.

In indirect write mode (FMODE = 00), firmware adds data to the FIFO when it writes QUADSPI\_DR. Word writes add 4 bytes to the FIFO, halfword writes add 2 bytes, and byte writes add only 1 byte. If firmware adds too many bytes to the FIFO (more than is indicated by DL[31:0]), the extra bytes are flushed from the FIFO at the end of the write operation (when TCF is set).

Byte/halfword accesses to QUADSPI\_DR must be done only to the least significant byte/halfword of the 32-bit register.

FTHRES[3:0] is used to define a FIFO threshold. When the threshold is reached, the FTF (FIFO threshold flag) is set. In indirect read mode, FTF is set when the number of valid bytes to be read from the FIFO is above the threshold. FTF is also set if there are data in the FIFO after the last byte is read from the Flash memory, regardless of the FTHRES setting. In indirect write mode, FTF is set when the number of empty bytes in the FIFO is above the threshold.

If FTIE = 1, there is an interrupt when FTF is set. If DMAEN = 1, a DMA transfer is initiated when FTF is set. FTF is cleared by HW as soon as the threshold condition is no longer true (after enough data has been transferred by the CPU or DMA).

In indirect read mode, when the FIFO becomes full, the QUADSPI temporarily stops reading bytes from the Flash memory to avoid an overrun. Note that the reading of the Flash memory does not restart until 4 bytes become vacant in the FIFO (when FLEVEL ≤ 28). Thus, when FTHRES ≥ 29, the application must take care to read enough bytes to assure that the QUADSPI starts retrieving data from the Flash memory again. Otherwise, the FTF flag stays at '0' as long as 28 < FLEVEL < FTHRES.

### 14.3.6 QUADSPI status flag polling mode

In automatic-polling mode, the QUADSPI periodically starts a command to read a defined number of status bytes (up to 4). The received bytes can be masked to isolate some status bits and an interrupt can be generated when the selected bits have a defined value.

The accesses to the Flash memory begin in the same way as in indirect read mode: if no address is required (AMODE = 00), accesses begin as soon as the QUADSPI\_CCR is written. Otherwise, if an address is required, the first access begins when QUADSPI\_AR is written. BUSY goes high at this point and stays high even between the periodic accesses.

The contents of MASK[31:0] (QUADSPI\_PSMAR) are used to mask the data from the Flash memory in automatic-polling mode. If the MASK[n] = 0, then bit n of the result is masked and not considered. If MASK[n] = 1, and the content of bit[n] is the same as MATCH[n] (QUADSPI\_PSMAR), then there is a match for bit n.

If the polling match mode bit (PMM, bit 23 of QUADSPI\_CR) is 0, then “AND” match mode is activated. This means status match flag (SMF) is set only when there is a match on all of the unmasked bits.

If PMM = 1, then “OR” match mode is activated. This means SMF is set if there is a match on any of the unmasked bits.

An interrupt is called when SMF is set if SMIE = 1.

If the automatic-polling-mode-stop (APMS) bit is set, operation stops and BUSY goes to 0 as soon as a match is detected. Otherwise, BUSY stays at ‘1’ and the periodic accesses continue until there is an abort or the QUADSPI is disabled (EN = 0).

The data register (QUADSPI\_DR) contains the latest received status bytes (the FIFO is deactivated). The content of the data register is not affected by the masking used in the matching logic. The FTF status bit is set as soon as a new reading of the status is complete, and FTF is cleared as soon as the data is read.

### 14.3.7 QUADSPI memory-mapped mode

When configured in memory-mapped mode, the external SPI device is seen as an internal memory.

It is forbidden to access QUADSPI Flash bank area before having properly configured and enabled the QUADSPI peripheral.

No more than 256MB can be addressed even if the Flash memory capacity is larger.

If an access is made to an address outside of the range defined by FSIZE but still within the 256MB range, then a bus error is given. The effect of this error depends on the bus master that attempted the access:

- If it is the Cortex<sup>®</sup> CPU, bus fault exception is generated when enabled (or a hard fault exception when bus fault is disabled)
- If it is a DMA, a DMA transfer error is generated and the corresponding DMA channel is automatically disabled.

Byte, halfword, and word access types are all supported.

Support for execute in place (XIP) operation is implemented, where the QUADSPI anticipates the next microcontroller access and loads in advance the byte at the following address. If the subsequent access is indeed made at a continuous address, the access will be completed faster since the value is already prefetched.

By default, the QUADSPI never stops its prefetch operation, keeping the previous read operation active with nCS maintained low, even if no access to the Flash memory occurs for a long time. Since Flash memories tend to consume more when nCS is held low, the application might want to activate the timeout counter (TCEN = 1, bit 3 of QUADSPI\_CR) so that nCS is released after a period of TIMEOUT[15:0] (QUADSPI\_LPTR) cycles have elapsed without any access since when the FIFO becomes full with prefetch data.

BUSY goes high as soon as the first memory-mapped access occurs. Because of the prefetch operations, BUSY does not fall until there is a timeout, there is an abort, or the peripheral is disabled.

### 14.3.8 QUADSPI Flash memory configuration

The device configuration register (QUADSPI\_DCR) can be used to specify the characteristics of the external SPI Flash memory.

The FSIZE[4:0] field defines the size of external memory using the following formula:

$$\text{Number of bytes in Flash memory} = 2^{[FSIZE+1]}$$

FSIZE+1 is effectively the number of address bits required to address the Flash memory. The Flash memory capacity can be up to 4GB (addressed using 32 bits) in indirect mode, but the addressable space in memory-mapped mode is limited to 256MB.

If DFM = 1, FSIZE indicates the total capacity of the two Flash memories together.

When the QUADSPI executes two commands, one immediately after the other, it raises the chip select signal (nCS) high between the two commands for only one CLK cycle by default. If the Flash memory requires more time between commands, the chip select high time (CSHT) field can be used to specify the minimum number of CLK cycles (up to 8) that nCS must remain high.

The clock mode (CKMODE) bit indicates the CLK signal logic level in between commands (when nCS = 1).

### 14.3.9 QUADSPI delayed data sampling

By default, the QUADSPI samples the data driven by the Flash memory one half of a CLK cycle after the Flash memory drives the signal.

In case of external signal delays, it may be beneficial to sample the data later. Using the SSHIFT bit (bit 4 of QUADSPI\_CR), the sampling of the data can be shifted by half of a CLK cycle.

Clock shifting is not supported in DDR mode: the SSHIFT bit must be clear when DDRM bit is set.

### 14.3.10 QUADSPI configuration

The QUADSPI configuration is done in two phases:

- QUADSPI IP configuration
- QUADSPI Flash memory configuration

Once configured and enabled, the QUADSPI can be used in one of its three operating modes: indirect mode, status-polling mode, or memory-mapped mode.

QUADSPI IP configuration

The QUADSPI IP is configured using the QUADSPI\_CR. The user shall configure the clock prescaler division factor and the sample shifting settings for the incoming data.

DDR mode can be set through the DDRM bit. Once enabled, the address and the alternate bytes are sent on both clock edges and the data are sent/received on both clock edges. Regardless of the DDRM bit setting, instructions are always sent in SDR mode.

The DMA requests are enabled setting the DMAEN bit. In case of interrupt usage, their respective enable bit can be also set during this phase.

FIFO level for either DMA request generation or interrupt generation is programmed in the FTHRES bits.

If timeout counter is needed, the TCEN bit can be set and the timeout value programmed in the QUADSPI\_LPTR register.

Dual-flash mode can be activated by setting DFM to 1.

### QUADSPI Flash memory configuration

The parameters related to the targeted external Flash memory are configured through the QUADSPI\_DCR register. The user shall program the Flash memory size in the FSIZE bits, the Chip Select minimum high time in the CSHT bits, and the functional mode (Mode 0 or Mode 3) in the MODE bit.

#### 14.3.11 QUADSPI usage

The operating mode is selected using FMODE[1:0] (QUADSPI\_CCR[27:26]).

##### Indirect mode procedure

When FMODE is programmed to 00, indirect write mode is selected and data can be sent to the Flash memory. With FMODE = 01, indirect read mode is selected where data can be read from the Flash memory.

When the QUADSPI is used in indirect mode, the frames are constructed in the following way:

1. Specify a number of data bytes to read or write in the QUADSPI\_DLR.
2. Specify the frame format, mode and instruction code in the QUADSPI\_CCR.
3. Specify optional alternate byte to be sent right after the address phase in the QUADSPI\_ABR.
4. Specify the operating mode in the QUADSPI\_CR. If FMODE = 00 (indirect write mode) and DMAEN = 1, then QUADSPI\_AR should be specified before QUADSPI\_CR, because otherwise QUADSPI\_DR might be written by the DMA before QUADSPI\_AR is updated (if the DMA controller has already been enabled)
5. Specify the targeted address in the QUADSPI\_AR.
6. Read/Write the data from/to the FIFO through the QUADSPI\_DR.

When writing the control register (QUADSPI\_CR) the user specifies the following settings:

- The enable bit (EN) set to '1'
- The DMA enable bit (DMAEN) for transferring data to/from RAM
- Timeout counter enable bit (TCEN)
- Sample shift setting (SSHIFT)
- FIFO threshold level (FTRHES) to indicate when the FTF flag should be set
- Interrupt enables
- Automatic polling mode parameters: match mode and stop mode (valid when FMODE = 11)
- Clock prescaler

When writing the communication configuration register (QUADSPI\_CCR) the user specifies the following parameters:

- The instruction byte through the INSTRUCTION bits
- The way the instruction has to be sent through the IMODE bits (1/2/4 lines)
- The way the address has to be sent through the ADMODE bits (None/1/2/4 lines)
- The address size (8/16/24/32-bit) through the ADSIZE bits
- The way the alternate bytes have to be sent through the ABMODE (None/1/2/4 lines)
- The alternate bytes number (1/2/3/4) through the ABSIZE bits
- The presence or not of dummy bytes through the DBMODE bit
- The number of dummy bytes through the DCYC bits
- The way the data have to be sent/received (None/1/2/4 lines) through the DMODE bits

If neither the address register (QUADSPI\_AR) nor the data register (QUADSPI\_DR) need to be updated for a particular command, then the command sequence starts as soon as QUADSPI\_CCR is written. This is the case when both ADMODE and DMODE are 00, or if just ADMODE = 00 when in indirect read mode (FMODE = 01).

When an address is required (ADMODE is not 00) and the data register does not need to be written (when FMODE = 01 or DMODE = 00), the command sequence starts as soon as the address is updated with a write to QUADSPI\_AR.

In case of data transmission (FMODE = 00 and DMODE! = 00), the communication start is triggered by a write in the FIFO through QUADSPI\_DR.

### Status flag polling mode

The status flag polling mode is enabled setting the FMODE field (QUADSPI\_CCR[27:26]) to 10. In this mode, the programmed frame will be sent and the data retrieved periodically.

The maximum amount of data read in each frame is 4 bytes. If more data is requested in QUADSPI\_DLR, it will be ignored and only 4 bytes will be read.

The periodicity is specified in the QUADSPI\_PISR register.

Once the status data has been retrieved, it can internally be processed in order to:

- set the status match flag and generate an interrupt if enabled
- stop automatically the periodic retrieving of the status bytes

The received value can be masked with the value stored in the QUADSPI\_PSMKR and ORed or ANDed with the value stored in the QUADSPI\_PSMAR.

In case of match, the status match flag is set and an interrupt is generated if enabled, and the QUADSPI can be automatically stopped if the AMPS bit is set.

In any case, the latest retrieved value is available in the QUADSPI\_DR.

### Memory-mapped mode

In memory-mapped mode, the external Flash memory is seen as internal memory but with some latency during accesses. Only read operations are allowed to the external Flash memory in this mode.

Memory-mapped mode is entered by setting the FMODE to 11 in the QUADSPI\_CCR register.

The programmed instruction and frame is sent when a master is accessing the memory mapped space.

The FIFO is used as a prefetch buffer to anticipate linear reads. Any access to QUADSPI\_DR in this mode returns zero.

The data length register (QUADSPI\_DLR) has no meaning in memory-mapped mode.

### 14.3.12 Sending the instruction only once

Some Flash memories (e.g. Winbound) might provide a mode where an instruction must be sent only with the first command sequence, while subsequent commands start directly with the address. One can take advantage of such a feature using the SIOO bit (QUADSPI\_CCR[28]).

SIOO is valid for all functional modes (indirect, automatic polling, and memory-mapped). If the SIOO bit is set, the instruction is sent only for the first command following a write to QUADSPI\_CCR. Subsequent command sequences skip the instruction phase, until there is a write to QUADSPI\_CCR.

SIOO has no effect when IMODE = 00 (no instruction).

### 14.3.13 QUADSPI error management

An error can be generated in the following case:

- In indirect mode or status flag polling mode when a wrong address has been programmed in the QUADSPI\_AR (according to the Flash memory size defined by FSIZE[4:0] in the QUADSPI\_DCR): this will set the TEF and an interrupt is generated if enabled.
- Also in indirect mode, if the address plus the data length exceeds the Flash memory size, TEF will be set as soon as the access is triggered.
- In memory-mapped mode, when an out of range access is done by a master or when the QUADSPI is disabled: this will generate a bus error as a response to the faulty bus master request.
- When a master is accessing the memory mapped space while the memory mapped mode is disabled: this will generate a bus error as a response to the faulty bus master request.

### 14.3.14 QUADSPI busy bit and abort functionality

Once the QUADSPI starts an operation with the Flash memory, the BUSY bit is automatically set in the QUADSPI\_SR.

In indirect mode, the BUSY bit is reset once the QUADSPI has completed the requested command sequence and the FIFO is empty.

In automatic-polling mode, BUSY goes low only after the last periodic access is complete, due to a match when APMS = 1, or due to an abort.

After the first access in memory-mapped mode, BUSY goes low only on a timeout event or on an abort.

Any operation can be aborted by setting the ABORT bit in the QUADSPI\_CR. Once the abort is completed, the BUSY bit and the ABORT bit are automatically reset, and the FIFO is flushed.

*Note: Some Flash memories might misbehave if a write operation to a status registers is aborted.*

### 14.3.15 nCS behavior

By default, nCS is high, deselecting the external Flash memory. nCS falls before an operation begins and rises as soon as it finishes.

When CKMODE = 0 ("mode0", where CLK stays low when no operation is in progress) nCS falls one CLK cycle before an operation first rising CLK edge, and nCS rises one CLK cycle after the operation final rising CLK edge, as shown in [Figure 66](#).

**Figure 66. nCS when CKMODE = 0 (T = CLK period)**

When CKMODE=1 ("mode3", where CLK goes high when no operation is in progress) and DDRM=0 (SDR mode), nCS still falls one CLK cycle before an operation first rising CLK edge, and nCS rises one CLK cycle after the operation final rising CLK edge, as shown in [Figure 67](#).

**Figure 67. nCS when CKMODE = 1 in SDR mode (T = CLK period)**

When CKMODE = 1 ("mode3") and DDRM = 1 (DDR mode), nCS falls one CLK cycle before an operation first rising CLK edge, and nCS rises one CLK cycle after the operation final active rising CLK edge, as shown in [Figure 68](#). Because DDR operations must finish with a falling edge, CLK is low when nCS rises, and CLK rises back up one half of a CLK cycle afterwards.

**Figure 68. nCS when CKMODE = 1 in DDR mode (T = CLK period)**

When the FIFO stays full in a read operation or if the FIFO stays empty in a write operation, the operation stalls and CLK stays low until firmware services the FIFO. If an abort occurs when an operation is stalled, nCS rises just after the abort is requested and then CLK rises one half of a CLK cycle later, as shown in [Figure 69](#).

**Figure 69. nCS when CKMODE = 1 with an abort (T = CLK period)**

When not in dual-flash mode (DFM = 0), only FLASH 1 is accessed and thus the BK2\_nCS stays high. In dual-flash mode, BK2\_nCS behaves exactly the same as BK1\_nCS. Thus, if there is a FLASH 2 and if the application always stays in dual-flash mode, then FLASH 2 may use BK1\_nCS and the pin outputting BK2\_nCS can be used for other functions.

## 14.4 QUADSPI interrupts

An interrupt can be produced on the following events:

- Timeout
- Status match
- FIFO threshold
- Transfer complete
- Transfer error

Separate interrupt enable bits are available for flexibility.

**Table 91. QUADSPI interrupt requests**

| Interrupt event   | Event flag | Enable control bit |
|-------------------|------------|--------------------|
| Timeout           | TOF        | TOIE               |
| Status match      | SMF        | SMIE               |
| FIFO threshold    | FTF        | FTIE               |
| Transfer complete | TCF        | TCIE               |
| Transfer error    | TEF        | TEIE               |

## 14.5 QUADSPI registers

### 14.5.1 QUADSPI control register (QUADSPI\_CR)

Address offset: 0x0000

Reset value: 0x0000 0000

|                |      |      |             |     |     |     |     |      |      |      |        |      |       |       |      |
|----------------|------|------|-------------|-----|-----|-----|-----|------|------|------|--------|------|-------|-------|------|
| 31             | 30   | 29   | 28          | 27  | 26  | 25  | 24  | 23   | 22   | 21   | 20     | 19   | 18    | 17    | 16   |
| PRESCALER[7:0] |      |      |             |     |     |     |     | PMM  | APMS | Res. | TOIE   | SMIE | FTIE  | TCIE  | TEIE |
| r/w            | r/w  | r/w  | r/w         | r/w | r/w | r/w | r/w | r/w  | r/w  |      | r/w    | r/w  | r/w   | r/w   | r/w  |
| 15             | 14   | 13   | 12          | 11  | 10  | 9   | 8   | 7    | 6    | 5    | 4      | 3    | 2     | 1     | 0    |
| Res.           | Res. | Res. | FTHRES[4:0] |     |     |     |     | FSEL | DFM  | Res. | SSHIFT | TCEN | DMAEN | ABORT | EN   |
|                |      |      | r/w         | r/w | r/w | r/w | r/w | r/w  | r/w  |      | r/w    | r/w  | r/w   | r/w   | r/w  |

Bits 31:24 **PRESCALER[7:0]**: Clock prescaler

This field defines the scaler factor for generating CLK based on the AHB clock (value+1).

0:  $F_{CLK} = F_{AHB}$ , AHB clock used directly as QUADSPI CLK (prescaler bypassed)

1:  $F_{CLK} = F_{AHB}/2$

2:  $F_{CLK} = F_{AHB}/3$

...

255:  $F_{CLK} = F_{AHB}/256$

For odd clock division factors, CLK's duty cycle is not 50%. The clock signal remains low one cycle longer than it stays high.

This field can be modified only when BUSY = 0.

Bit 23 **PMM**: Polling match mode

This bit indicates which method should be used for determining a “match” during automatic polling mode.

0: AND match mode. SMF is set if all the unmasked bits received from the Flash memory match the corresponding bits in the match register.

1: OR match mode. SMF is set if any one of the unmasked bits received from the Flash memory matches its corresponding bit in the match register.

This bit can be modified only when BUSY = 0.

Bit 22 **APMS**: Automatic poll mode stop

This bit determines if automatic polling is stopped after a match.

0: Automatic polling mode is stopped only by abort or by disabling the QUADSPI.

1: Automatic polling mode stops as soon as there is a match.

This bit can be modified only when BUSY = 0.

Bit 21 Reserved, must be kept at reset value.

Bit 20 **TOIE**: TimeOut interrupt enable

This bit enables the TimeOut interrupt.

0: Interrupt disable

1: Interrupt enabled

Bit 19 **SMIE**: Status match interrupt enable

This bit enables the status match interrupt.

0: Interrupt disable

1: Interrupt enabled

Bit 18 **FTIE**: FIFO threshold interrupt enable

This bit enables the FIFO threshold interrupt.

0: Interrupt disabled

1: Interrupt enabled

Bit 17 **TCIE**: Transfer complete interrupt enable

This bit enables the transfer complete interrupt.

0: Interrupt disabled

1: Interrupt enabled

Bit 16 **TEIE**: Transfer error interrupt enable

This bit enables the transfer error interrupt.

0: Interrupt disable

1: Interrupt enabled

Bits 15:13 Reserved, must be kept at reset value.

Bits 12:8 **FTHRES[4:0]** FIFO threshold level

Defines, in indirect mode, the threshold number of bytes in the FIFO that will cause the FIFO threshold flag (FTF, QUADSPI\_SR[2]) to be set.

In indirect write mode (FMODE = 00):

0: FTF is set if there are 1 or more free bytes available to be written to in the FIFO

1: FTF is set if there are 2 or more free bytes available to be written to in the FIFO

...

31: FTF is set if there are 32 free bytes available to be written to in the FIFO

In indirect read mode (FMODE = 01):

0: FTF is set if there are 1 or more valid bytes that can be read from the FIFO

1: FTF is set if there are 2 or more valid bytes that can be read from the FIFO

...

31: FTF is set if there are 32 valid bytes that can be read from the FIFO

If DMAEN = 1, then the DMA controller for the corresponding channel must be disabled before changing the FTHRES value.

Bit 7 **FSEL**: Flash memory selection

This bit selects the Flash memory to be addressed in single flash mode (when DFM = 0).

0: FLASH 1 selected

1: FLASH 2 selected

This bit can be modified only when BUSY = 0.

This bit is ignored when DFM = 1.

Bit 6 **DFM**: Dual-flash mode

This bit activates dual-flash mode, where two external Flash memories are used simultaneously to double throughput and capacity.

0: Dual-flash mode disabled

1: Dual-flash mode enabled

This bit can be modified only when BUSY = 0.

Bit 5 Reserved, must be kept at reset value.

**Bit 4 SSHIFT:** Sample shift

By default, the QUADSPI samples data 1/2 of a CLK cycle after the data is driven by the Flash memory. This bit allows the data is to be sampled later in order to account for external signal delays.

0: No shift

1: 1/2 cycle shift

Firmware must assure that SSHIFT = 0 when in DDR mode (when DDRM = 1).

This field can be modified only when BUSY = 0.

**Bit 3 TCEN:** Timeout counter enable

This bit is valid only when memory-mapped mode (FMODE = 11) is selected. Activating this bit causes the chip select (nCS) to be released (and thus reduces consumption) if there has not been an access after a certain amount of time, where this time is defined by TIMEOUT[15:0] (QUADSPI\_LPTR).

Enable the timeout counter.

By default, the QUADSPI never stops its prefetch operation, keeping the previous read operation active with nCS maintained low, even if no access to the Flash memory occurs for a long time. Since Flash memories tend to consume more when nCS is held low, the application might want to activate the timeout counter (TCEN = 1, bit 3 of QUADSPI\_CR) so that nCS is released after a period of TIMEOUT[15:0] (QUADSPI\_LPTR) cycles have elapsed without an access since when the FIFO becomes full with prefetch data.

0: Timeout counter is disabled, and thus the chip select (nCS) remains active indefinitely after an access in memory-mapped mode.

1: Timeout counter is enabled, and thus the chip select is released in memory-mapped mode after TIMEOUT[15:0] cycles of Flash memory inactivity.

This bit can be modified only when BUSY = 0.

**Bit 2 DMAEN:** DMA enable

In indirect mode, DMA can be used to input or output data via the QUADSPI\_DR register. DMA transfers are initiated when the FIFO threshold flag, FTF, is set.

0: DMA is disabled for indirect mode

1: DMA is enabled for indirect mode

**Bit 1 ABORT:** Abort request

This bit aborts the on-going command sequence. It is automatically reset once the abort is complete.

This bit stops the current transfer.

In polling mode or memory-mapped mode, this bit also reset the APM bit or the DM bit.

0: No abort requested

1: Abort requested

**Bit 0 EN:** Enable

Enable the QUADSPI.

0: QUADSPI is disabled

1: QUADSPI is enabled

## 14.5.2 QUADSPI device configuration register (QUADSPI\_DCR)

Address offset: 0x0004

Reset value: 0x0000 0000

|      |      |      |      |      |           |      |      |      |      |      |            |      |      |      |         |
|------|------|------|------|------|-----------|------|------|------|------|------|------------|------|------|------|---------|
| 31   | 30   | 29   | 28   | 27   | 26        | 25   | 24   | 23   | 22   | 21   | 20         | 19   | 18   | 17   | 16      |
| Res. | Res. | Res. | Res. | Res. | Res.      | Res. | Res. | Res. | Res. | Res. | FSIZE[4:0] |      |      |      |         |
|      |      |      |      |      |           |      |      |      |      |      | rw         | rw   | rw   | rw   | rw      |
| 15   | 14   | 13   | 12   | 11   | 10        | 9    | 8    | 7    | 6    | 5    | 4          | 3    | 2    | 1    | 0       |
| Res. | Res. | Res. | Res. | Res. | CSHT[2:0] |      |      | Res. | Res. | Res. | Res.       | Res. | Res. | Res. | CK MODE |
|      |      |      |      |      | rw        | rw   | rw   |      |      |      |            |      |      |      | rw      |

Bits 31:21 Reserved, must be kept at reset value.

Bits 20:16 **FSIZE[4:0]**: Flash memory size

This field defines the size of external memory using the following formula:

Number of bytes in Flash memory =  $2^{[FSIZE+1]}$

FSIZE+1 is effectively the number of address bits required to address the Flash memory. The Flash memory capacity can be up to 4GB (addressed using 32 bits) in indirect mode, but the addressable space in memory-mapped mode is limited to 256MB.

If DFM = 1, FSIZE indicates the total capacity of the two Flash memories together.

This field can be modified only when BUSY = 0.

Bits 15:11 Reserved, must be kept at reset value.

Bits 10:8 **CSHT[2:0]**: Chip select high time

CSHT+1 defines the minimum number of CLK cycles which the chip select (nCS) must remain high between commands issued to the Flash memory.

0: nCS stays high for at least 1 cycle between Flash memory commands

1: nCS stays high for at least 2 cycles between Flash memory commands

...

7: nCS stays high for at least 8 cycles between Flash memory commands

This field can be modified only when BUSY = 0.

Bits 7:1 Reserved, must be kept at reset value.

Bit 0 **CKMODE**: Mode 0 / mode 3

This bit indicates the level that CLK takes between commands (when nCS = 1).

0: CLK must stay low while nCS is high (chip select released). This is referred to as mode 0.

1: CLK must stay high while nCS is high (chip select released). This is referred to as mode 3.

This field can be modified only when BUSY = 0.

### 14.5.3 QUADSPI status register (QUADSPI\_SR)

Address offset: 0x0008

Reset value: 0x0000 0000

|      |      |             |      |      |      |      |      |      |      |      |      |      |      |      |      |
|------|------|-------------|------|------|------|------|------|------|------|------|------|------|------|------|------|
| 31   | 30   | 29          | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21   | 20   | 19   | 18   | 17   | 16   |
| Res. | Res. | Res.        | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. |
| 15   | 14   | 13          | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0    |
| Res. | Res. | FLEVEL[5:0] |      |      |      |      |      | Res. | Res. | BUSY | TOF  | SMF  | FTF  | TCF  | TEF  |
|      |      | r           | r    | r    | r    | r    | r    |      |      | r    | r    | r    | r    | r    | r    |

Bits 31:14 Reserved, must be kept at reset value.

Bits 13:8 **FLEVEL[5:0]**: FIFO level

This field gives the number of valid bytes which are being held in the FIFO. FLEVEL = 0 when the FIFO is empty, and 32 when it is full. In memory-mapped mode and in automatic status polling mode, FLEVEL is zero.

Bits 7:6 Reserved, must be kept at reset value.

Bit 5 **BUSY**: Busy

This bit is set when an operation is on going. This bit clears automatically when the operation with the Flash memory is finished and the FIFO is empty.

Bit 4 **TOF**: Timeout flag

This bit is set when timeout occurs. It is cleared by writing 1 to CTOF.

Bit 3 **SMF**: Status match flag

This bit is set in automatic polling mode when the unmasked received data matches the corresponding bits in the match register (QUADSPI\_PSMAR). It is cleared by writing 1 to CSMF.

Bit 2 **FTF**: FIFO threshold flag

In indirect mode, this bit is set when the FIFO threshold has been reached, or if there is any data left in the FIFO after reads from the Flash memory are complete. It is cleared automatically as soon as threshold condition is no longer true.

In automatic polling mode this bit is set every time the status register is read, and the bit is cleared when the data register is read.

Bit 1 **TCF**: Transfer complete flag

This bit is set in indirect mode when the programmed number of data has been transferred or in any mode when the transfer has been aborted. It is cleared by writing 1 to CTCF.

Bit 0 **TEF**: Transfer error flag

This bit is set in indirect mode when an invalid address is being accessed in indirect mode. It is cleared by writing 1 to CTEF.

#### 14.5.4 QUADSPI flag clear register (QUADSPI\_FCR)

| 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0    |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | CTOF | CSMF | Res. | CTCF | CTEF |
|      |      |      |      |      |      |      |      |      |      |      | w    | w    |      | w    | w    |

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 **CTOF**: Clear timeout flag

Writing 1 clears the TOF flag in the QUADSPI\_SR register

Bit 3 **CSMF**: Clear status match flag

Writing 1 clears the SMF flag in the QUADSPI\_SR register

Bit 2 Reserved, must be kept at reset value.

Bit 1 **CTCF**: Clear transfer complete flag

Writing 1 clears the TCF flag in the QUADSPI\_SR register

Bit 0 **CTEF**: Clear transfer error flag

Writing 1 clears the TEF flag in the QUADSPI\_SR register

#### 14.5.5 QUADSPI data length register (QUADSPI\_DLR)

Address offset: 0x0010

Reset value: 0x0000 0000

|           |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|-----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31        | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| DL[31:16] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rW        | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW |
| 15        | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| DL[15:0]  |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rW        | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW |

Bits 31:0 **DL[31:0]**: Data length

Number of data to be retrieved (value+1) in indirect and status-polling modes. A value no greater than 3 (indicating 4 bytes) should be used for status-polling mode.

All 1s in indirect mode means undefined length, where QUADSPI will continue until the end of memory, as defined by FSIZE.

0x0000\_0000: 1 byte is to be transferred

0x0000\_0001: 2 bytes are to be transferred

0x0000\_0002: 3 bytes are to be transferred

0x0000\_0003: 4 bytes are to be transferred

...

0xFFFF\_FFFD: 4,294,967,294 (4G-2) bytes are to be transferred

0xFFFF\_FFFE: 4,294,967,295 (4G-1) bytes are to be transferred

0xFFFF\_FFFF: undefined length -- all bytes until the end of Flash memory (as defined by FSIZE) are to be transferred. Continue reading indefinitely if FSIZE = 0x1F.

DL[0] is stuck at '1' in dual-flash mode (DFM = 1) even when '0' is written to this bit, thus assuring that each access transfers an even number of bytes.

This field has no effect when in memory-mapped mode (FMODE = 10).

This field can be written only when BUSY = 0.

### 14.5.6 QUADSPI communication configuration register (QUADSPI\_CCR)

Address offset: 0x0014

Reset value: 0x0000 0000

|             |      |             |      |             |    |            |    |                  |           |    |    |    |             |    |    |
|-------------|------|-------------|------|-------------|----|------------|----|------------------|-----------|----|----|----|-------------|----|----|
| 31          | 30   | 29          | 28   | 27          | 26 | 25         | 24 | 23               | 22        | 21 | 20 | 19 | 18          | 17 | 16 |
| DDRM        | DHHC | Res.        | SIOO | FMODE[1:0]  |    | DMODE[1:0] |    | Res.             | DCYC[4:0] |    |    |    | ABSIZE[1:0] |    |    |
| rw          | rw   |             | rw   | rw          | rw | rw         | rw |                  | rw        | rw | rw | rw | rw          | rw | rw |
| 15          | 14   | 13          | 12   | 11          | 10 | 9          | 8  | 7                | 6         | 5  | 4  | 3  | 2           | 1  | 0  |
| ABMODE[1:0] |      | ADSIZE[1:0] |      | ADMODE[1:0] |    | IMODE[1:0] |    | INSTRUCTION[7:0] |           |    |    |    |             |    |    |
| rw          | rw   | rw          | rw   | rw          | rw | rw         | rw | rw               | rw        | rw | rw | rw | rw          | rw | rw |

Bit 31 **DDRM**: Double data rate mode

This bit sets the DDR mode for the address, alternate byte and data phase:

0: DDR Mode disabled

1: DDR Mode enabled

This field can be written only when BUSY = 0.

Bit 30 **DHHC**: DDR hold

Delay the data output by 1/4 of the QUADSPI output clock cycle in DDR mode:

0: Delay the data output using analog delay

1: Delay the data output by 1/4 of a QUADSPI output clock cycle.

This feature is only active in DDR mode.

This field can be written only when BUSY = 0.

Bit 29 Reserved, must be kept at reset value.

Bit 28 **SIOO**: Send instruction only once mode

See [Section 14.3.12: Sending the instruction only once on page 396](#). This bit has no effect when IMODE = 00.

0: Send instruction on every transaction

1: Send instruction only for the first command

This field can be written only when BUSY = 0.

Bits 27:26 **FMODE[1:0]**: Functional mode

This field defines the QUADSPI functional mode of operation.

00: Indirect write mode

01: Indirect read mode

10: Automatic polling mode

11: Memory-mapped mode

If DMAEN = 1 already, then the DMA controller for the corresponding channel must be disabled before changing the FMODE value.

This field can be written only when BUSY = 0.

Bits 25:24 **DMODE[1:0]**: Data mode

This field defines the data phase's mode of operation:

00: No data

01: Data on a single line

10: Data on two lines

11: Data on four lines

This field also determines the dummy phase mode of operation.

This field can be written only when BUSY = 0.

Bit 23 Reserved, must be kept at reset value.

Bits 22:18 **DCYC[4:0]**: Number of dummy cycles

This field defines the duration of the dummy phase. In both SDR and DDR modes, it specifies a number of CLK cycles (0-31).

This field can be written only when BUSY = 0.

Bits 17:16 **ABSIZE[1:0]**: Alternate bytes size

This bit defines alternate bytes size:

00: 8-bit alternate byte

01: 16-bit alternate bytes

10: 24-bit alternate bytes

11: 32-bit alternate bytes

This field can be written only when BUSY = 0.

Bits 15:14 **ABMODE[1:0]**: Alternate bytes mode

This field defines the alternate-bytes phase mode of operation:

00: No alternate bytes

01: Alternate bytes on a single line

10: Alternate bytes on two lines

11: Alternate bytes on four lines

This field can be written only when BUSY = 0.

Bits 13:12 **ADSIZE[1:0]**: Address size

This bit defines address size:

- 00: 8-bit address
- 01: 16-bit address
- 10: 24-bit address
- 11: 32-bit address

This field can be written only when BUSY = 0.

Bits 11:10 **ADMODE[1:0]**: Address mode

This field defines the address phase mode of operation:

- 00: No address
- 01: Address on a single line
- 10: Address on two lines
- 11: Address on four lines

This field can be written only when BUSY = 0.

Bits 9:8 **IMODE[1:0]**: Instruction mode

This field defines the instruction phase mode of operation:

- 00: No instruction
- 01: Instruction on a single line
- 10: Instruction on two lines
- 11: Instruction on four lines

This field can be written only when BUSY = 0.

Bits 7:0 **INSTRUCTION[7:0]**: Instruction

Instruction to be send to the external SPI device.

This field can be written only when BUSY = 0.

### 14.5.7 QUADSPI address register (QUADSPI\_AR)

Address offset: 0x0018

Reset value: 0x0000 0000

|                |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|----------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31             | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| ADDRESS[31:16] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rW             | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW |
| 15             | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| ADDRESS[15:0]  |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rW             | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW |

Bits 31:0 **ADDRESS[31:0]**: Address

Address to be send to the external Flash memory

Writes to this field are ignored when BUSY = 0 or when FMODE = 11 (memory-mapped mode).

In dual flash mode, ADDRESS[0] is automatically stuck to '0' as the address should always be even

### 14.5.8 QUADSPI alternate bytes registers (QUADSPI\_ABR)

Address offset: 0x001C

Reset value: 0x0000 0000

|                  |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|------------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31               | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| ALTERNATE[31:16] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rW               | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW |
| 15               | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| ALTERNATE[15:0]  |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rW               | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW |

Bits 31:0 **ALTERNATE[31:0]**: Alternate Bytes

Optional data to be send to the external SPI device right after the address.

This field can be written only when BUSY = 0.

### 14.5.9 QUADSPI data register (QUADSPI\_DR)

Address offset: 0x0020

Reset value: 0x0000 0000

|             |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|-------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31          | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| DATA[31:16] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rW          | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW |
| 15          | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| DATA[15:0]  |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rW          | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW |

Bits 31:0 **DATA[31:0]**: Data

Data to be sent/received to/from the external SPI device.

In indirect write mode, data written to this register is stored on the FIFO before it is sent to the Flash memory during the data phase. If the FIFO is too full, a write operation is stalled until the FIFO has enough space to accept the amount of data being written.

In indirect read mode, reading this register gives (via the FIFO) the data which was received from the Flash memory. If the FIFO does not have as many bytes as requested by the read operation and if BUSY=1, the read operation is stalled until enough data is present or until the transfer is complete, whichever happens first.

In automatic polling mode, this register contains the last data read from the Flash memory (without masking).

Word, halfword, and byte accesses to this register are supported. In indirect write mode, a byte write adds 1 byte to the FIFO, a halfword write 2, and a word write 4. Similarly, in indirect read mode, a byte read removes 1 byte from the FIFO, a halfword read 2, and a word read 4. Accesses in indirect mode must be aligned to the bottom of this register: a byte read must read DATA[7:0] and a halfword read must read DATA[15:0].

### 14.5.10 QUADSPI polling status mask register (QUADSPI\_PSMKR)

Address offset: 0x0024

Reset value: 0x0000 0000

|             |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|-------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31          | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| MASK[31:16] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw          | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |
| 15          | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| MASK[15:0]  |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw          | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 31:0 **MASK[31:0]**: Status mask

Mask to be applied to the status bytes received in polling mode.

For bit n:

0: Bit n of the data received in automatic polling mode is masked and its value is not considered in the matching logic

1: Bit n of the data received in automatic polling mode is unmasked and its value is considered in the matching logic

This field can be written only when BUSY = 0.

### 14.5.11 QUADSPI polling status match register (QUADSPI\_PSMAR)

Address offset: 0x0028

Reset value: 0x0000 0000

|              |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|--------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31           | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| MATCH[31:16] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw           | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |
| 15           | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| MATCH[15:0]  |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw           | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 31:0 **MATCH[31:0]**: Status match

Value to be compared with the masked status register to get a match.

This field can be written only when BUSY = 0.

### 14.5.12 QUADSPI polling interval register (QUADSPI\_PIR)

Address offset: 0x002C

Reset value: 0x0000 0000

|                |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
|----------------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|
| 31             | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21   | 20   | 19   | 18   | 17   | 16   |
| Res.           | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. |
|                |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
| 15             | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0    |
| INTERVAL[15:0] |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
| rw             | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   |

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **INTERVAL[15:0]**: Polling interval

Number of CLK cycles between to read during automatic polling phases.

This field can be written only when BUSY = 0.

### 14.5.13 QUADSPI low-power timeout register (QUADSPI\_LPTR)

Address offset: 0x0030

Reset value: 0x0000 0000

|               |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
|---------------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|
| 31            | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21   | 20   | 19   | 18   | 17   | 16   |
| Res.          | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. |
|               |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
| 15            | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0    |
| TIMEOUT[15:0] |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
| rw            | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   |

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **TIMEOUT[15:0]**: Timeout period

After each access in memory-mapped mode, the QUADSPI prefetches the subsequent bytes and holds these bytes in the FIFO. This field indicates how many CLK cycles the QUADSPI waits after the FIFO becomes full until it raises nCS, putting the Flash memory in a lower-consumption state.

This field can be written only when BUSY = 0.

**Table 92. QUADSPI register map and reset values**

Refer to [Section 2.2.2 on page 69](#) for the register boundary addresses.

## 15 Analog-to-digital converter (ADC)

### 15.1 ADC introduction

The 12-bit ADC is a successive approximation analog-to-digital converter. It has up to 19 multiplexed channels allowing it to measure signals from 16 external sources, two internal sources, and the  $V_{BAT}$  channel. The A/D conversion of the channels can be performed in single, continuous, scan or discontinuous mode. The result of the ADC is stored into a left- or right-aligned 16-bit data register.

The analog watchdog feature allows the application to detect if the input voltage goes beyond the user-defined, higher or lower thresholds.

### 15.2 ADC main features

- 12-bit, 10-bit, 8-bit or 6-bit configurable resolution
- Interrupt generation at the end of conversion, end of injected conversion, and in case of analog watchdog or overrun events
- Single and continuous conversion modes
- Scan mode for automatic conversion of channel 0 to channel 'n'
- Data alignment with in-built data coherency
- Channel-wise programmable sampling time
- External trigger option with configurable polarity for both regular and injected conversions
- Discontinuous mode
- Dual/Triple mode (on devices with 2 ADCs or more)
- Configurable DMA data storage in Dual/Triple ADC mode
- Configurable delay between conversions in Dual/Triple interleaved mode
- ADC supply requirements: 2.4 V to 3.6 V at full speed and down to 1.8 V at slower speed
- ADC input range:  $V_{REF-} \leq V_{IN} \leq V_{REF+}$
- DMA request generation during regular channel conversion

*Figure 70* shows the block diagram of the ADC.

*Note:*  $V_{REF-}$ , if available (depending on package), must be tied to  $V_{SSA}$ .

### 15.3 ADC functional description

*Figure 70* shows a single ADC block diagram and *Table 93* gives the ADC pin description.

Figure 70. Single ADC block diagram

MS35935V2

Table 93. ADC pins

| Name          | Signal type                      | Remarks                                                                                                                                                                       |
|---------------|----------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $V_{REF+}$    | Input, analog reference positive | The higher/positive reference voltage for the ADC, $1.8\text{ V} \leq V_{REF+} \leq V_{DDA}$                                                                                  |
| $V_{DDA}$     | Input, analog supply             | Analog power supply equal to $V_{DD}$ and $2.4\text{ V} \leq V_{DDA} \leq V_{DD}$ (3.6 V) for full speed<br>$1.8\text{ V} \leq V_{DDA} \leq V_{DD}$ (3.6 V) for reduced speed |
| $V_{REF-}$    | Input, analog reference negative | The lower/negative reference voltage for the ADC, $V_{REF-} = V_{SSA}$                                                                                                        |
| $V_{SSA}$     | Input, analog supply ground      | Ground for analog power supply equal to $V_{SS}$                                                                                                                              |
| ADCx_IN[15:0] | Analog input signals             | 16 analog input channels                                                                                                                                                      |

### 15.3.1 ADC on-off control

The ADC is powered on by setting the ADON bit in the ADC\_CR2 register. When the ADON bit is set for the first time, it wakes up the ADC from the Power-down mode.

The conversion starts when either the SWSTART or the JSWSTART bit is set.

The user can stop conversion and put the ADC in power down mode by clearing the ADON bit. In this mode the ADC consumes almost no power (only a few  $\mu\text{A}$ ).

### 15.3.2 ADC1/2 and ADC3 connectivity

ADC1, ADC2 and ADC3 are tightly coupled and share some external channels as described in [Figure 71](#), [Figure 72](#) and [Figure 73](#).

Figure 71. ADC1 connectivity

Figure 72. ADC2 connectivity

Figure 73. ADC3 connectivity

### 15.3.3 ADC clock

The ADC features two clock schemes:

- Clock for the analog circuitry: ADCCLK, common to all ADCs  
This clock is generated from the APB2 clock divided by a programmable prescaler that allows the ADC to work at  $f_{PCLK2}/2$ ,  $/4$ ,  $/6$  or  $/8$ . Refer to the datasheets for the maximum value of ADCCLK.
- Clock for the digital interface (used for registers read/write access)  
This clock is equal to the APB2 clock. The digital interface clock can be enabled/disabled individually for each ADC through the RCC APB2 peripheral clock enable register (RCC\_APB2ENR).

### 15.3.4 Channel selection

There are 16 multiplexed channels. It is possible to organize the conversions in two groups: regular and injected. A group consists of a sequence of conversions that can be done on any channel and in any order. For instance, it is possible to implement the conversion sequence in the following order: ADC\_IN3, ADC\_IN8, ADC\_IN2, ADC\_IN2, ADC\_IN0, ADC\_IN2, ADC\_IN2, ADC\_IN15.

- A **regular group** is composed of up to 16 conversions. The regular channels and their order in the conversion sequence must be selected in the ADC\_SQRx registers. The total number of conversions in the regular group must be written in the L[3:0] bits in the ADC\_SQR1 register.
- An **injected group** is composed of up to 4 conversions. The injected channels and their order in the conversion sequence must be selected in the ADC\_JSQR register. The total number of conversions in the injected group must be written in the L[1:0] bits in the ADC\_JSQR register.

If the ADC\_SQRx or ADC\_JSQR registers are modified during a conversion, the current conversion is reset and a new start pulse is sent to the ADC to convert the newly chosen group.

#### Temperature sensor, $V_{REFINT}$ and $V_{BAT}$ internal channels

- The temperature sensor is internally connected to ADC1\_IN18 channel which is shared with VBAT. Only one conversion, temperature sensor or VBAT, must be selected at a time. When the temperature sensor and VBAT conversion are set simultaneously, only the VBAT conversion is performed.

The internal reference voltage VREFINT is connected to ADC1\_IN17.

The  $V_{BAT}$  channel is connected to ADC1\_IN18 channel. It can also be converted as an injected or regular channel.

*Note: The temperature sensor,  $V_{REFINT}$  and the  $V_{BAT}$  channel are available only on the master ADC1 peripheral.*

### 15.3.5 Single conversion mode

In Single conversion mode the ADC does one conversion. This mode is started with the CONT bit at 0 by either:

- setting the SWSTART bit in the ADC\_CR2 register (for a regular channel only)
- setting the JSWSTART bit (for an injected channel)
- external trigger (for a regular or injected channel)

Once the conversion of the selected channel is complete:

- If a regular channel was converted:
  - The converted data are stored into the 16-bit ADC\_DR register
  - The EOC (end of conversion) flag is set
  - An interrupt is generated if the EOCIE bit is set
- If an injected channel was converted:
  - The converted data are stored into the 16-bit ADC\_JDR1 register
  - The JEOC (end of conversion injected) flag is set
  - An interrupt is generated if the JEOCIE bit is set

Then the ADC stops.

### 15.3.6 Continuous conversion mode

In continuous conversion mode, the ADC starts a new conversion as soon as it finishes one. This mode is started with the CONT bit at 1 either by external trigger or by setting the SWSTRT bit in the ADC\_CR2 register (for regular channels only).

After each conversion:

- If a regular group of channels was converted:
  - The last converted data are stored into the 16-bit ADC\_DR register
  - The EOC (end of conversion) flag is set
  - An interrupt is generated if the EOCIE bit is set

*Note:* *Injected channels cannot be converted continuously. The only exception is when an injected channel is configured to be converted automatically after regular channels in continuous mode (using JAUTO bit), refer to [Auto-injection](#) section).*

### 15.3.7 Timing diagram

As shown in [Figure 74](#), the ADC needs a stabilization time of  $t_{\text{STAB}}$  before it starts converting accurately. After the start of the ADC conversion and after 15 clock cycles, the EOC flag is set and the 16-bit ADC data register contains the result of the conversion.

Figure 74. Timing diagram

### 15.3.8 Analog watchdog

The AWD analog watchdog status bit is set if the analog voltage converted by the ADC is below a lower threshold or above a higher threshold. These thresholds are programmed in the 12 least significant bits of the ADC\_HTR and ADC\_LTR 16-bit registers. An interrupt can be enabled by using the AWDIE bit in the ADC\_CR1 register.

The threshold value is independent of the alignment selected by the ALIGN bit in the ADC\_CR2 register. The analog voltage is compared to the lower and higher thresholds before alignment.

Table 94 shows how the ADC\_CR1 register should be configured to enable the analog watchdog on one or more channels.

Figure 75. Analog watchdog's guarded area

Table 94. Analog watchdog channel selection

| Channels guarded by the analog watchdog | ADC_CR1 register control bits (x = don't care) |           |            |
|-----------------------------------------|------------------------------------------------|-----------|------------|
|                                         | AWDSGL bit                                     | AWDEN bit | JAWDEN bit |
| None                                    | x                                              | 0         | 0          |
| All injected channels                   | 0                                              | 0         | 1          |

Table 94. Analog watchdog channel selection (continued)

| Channels guarded by the analog watchdog           | ADC_CR1 register control bits (x = don't care) |           |            |
|---------------------------------------------------|------------------------------------------------|-----------|------------|
|                                                   | AWDSGL bit                                     | AWDEN bit | JAWDEN bit |
| All regular channels                              | 0                                              | 1         | 0          |
| All regular and injected channels                 | 0                                              | 1         | 1          |
| Single <sup>(1)</sup> injected channel            | 1                                              | 0         | 1          |
| Single <sup>(1)</sup> regular channel             | 1                                              | 1         | 0          |
| Single <sup>(1)</sup> regular or injected channel | 1                                              | 1         | 1          |

1. Selected by the AWDCH[4:0] bits

### 15.3.9 Scan mode

This mode is used to scan a group of analog channels.

The Scan mode is selected by setting the SCAN bit in the ADC\_CR1 register. Once this bit has been set, the ADC scans all the channels selected in the ADC\_SQRx registers (for regular channels) or in the ADC\_JSQR register (for injected channels). A single conversion is performed for each channel of the group. After each end of conversion, the next channel in the group is converted automatically. If the CONT bit is set, regular channel conversion does not stop at the last selected channel in the group but continues again from the first selected channel.

If the DMA bit is set, the direct memory access (DMA) controller is used to transfer the data converted from the regular group of channels (stored in the ADC\_DR register) to SRAM after each regular channel conversion.

The EOC bit is set in the ADC\_SR register:

- At the end of each regular group sequence if the EOCS bit is cleared to 0
- At the end of each regular channel conversion if the EOCS bit is set to 1

The data converted from an injected channel are always stored into the ADC\_JDRx registers.

### 15.3.10 Injected channel management

#### Triggered injection

To use triggered injection, the JAUTO bit must be cleared in the ADC\_CR1 register.

1. Start the conversion of a group of regular channels either by external trigger or by setting the SWSTART bit in the ADC\_CR2 register.
2. If an external injected trigger occurs or if the JSWSTART bit is set during the conversion of a regular group of channels, the current conversion is reset and the injected channel sequence switches to Scan-once mode.
3. Then, the regular conversion of the regular group of channels is resumed from the last interrupted regular conversion.

If a regular event occurs during an injected conversion, the injected conversion is not interrupted but the regular sequence is executed at the end of the injected sequence. [Figure 76](#) shows the corresponding timing diagram.

**Note:** When using triggered injection, one must ensure that the interval between trigger events is longer than the injection sequence. For instance, if the sequence length is 30 ADC clock cycles (that is two conversions with a sampling time of 3 clock periods), the minimum interval between triggers must be 31 ADC clock cycles.

### Auto-injection

If the JAUTO bit is set, then the channels in the injected group are automatically converted after the regular group of channels. This can be used to convert a sequence of up to 20 conversions programmed in the ADC\_SQRx and ADC\_JSQR registers.

In this mode, external trigger on injected channels must be disabled.

If the CONT bit is also set in addition to the JAUTO bit, regular channels followed by injected channels are continuously converted.

**Note:** It is not possible to use both the auto-injected and discontinuous modes simultaneously.

**Figure 76. Injected conversion latency**

1. The maximum latency value can be found in the electrical characteristics of the STM32F75xxx and STM32F74xxx datasheets.

## 15.3.11 Discontinuous mode

### Regular group

This mode is enabled by setting the DISCEN bit in the ADC\_CR1 register. It can be used to convert a short sequence of  $n$  conversions ( $n \leq 8$ ) that is part of the sequence of conversions selected in the ADC\_SQRx registers. The value of  $n$  is specified by writing to the DISCNUM[2:0] bits in the ADC\_CR1 register.

When an external trigger occurs, it starts the next  $n$  conversions selected in the ADC\_SQRx registers until all the conversions in the sequence are done. The total sequence length is defined by the L[3:0] bits in the ADC\_SQR1 register.

Example:

- $n = 3$ , channels to be converted = 0, 1, 2, 3, 6, 7, 9, 10
- 1st trigger: sequence converted 0, 1, 2. An EOC event is generated at each conversion.
- 2nd trigger: sequence converted 3, 6, 7. An EOC event is generated at each conversion
- 3rd trigger: sequence converted 9, 10. An EOC event is generated at each conversion
- 4th trigger: sequence converted 0, 1, 2. An EOC event is generated at each conversion

**Note:** *When a regular group is converted in discontinuous mode, no rollover occurs.*

*When all subgroups are converted, the next trigger starts the conversion of the first subgroup. In the example above, the 4th trigger reconverts the channels 0, 1 and 2 in the 1st subgroup.*

### Injected group

This mode is enabled by setting the JDISCEN bit in the ADC\_CR1 register. It can be used to convert the sequence selected in the ADC\_JSQR register, channel by channel, after an external trigger event.

When an external trigger occurs, it starts the next channel conversions selected in the ADC\_JSQR registers until all the conversions in the sequence are done. The total sequence length is defined by the JL[1:0] bits in the ADC\_JSQR register.

Example:

- $n = 1$ , channels to be converted = 1, 2, 3
- 1st trigger: channel 1 converted
- 2nd trigger: channel 2 converted
- 3rd trigger: channel 3 converted and JEOC event generated
- 4th trigger: channel 1

**Note:** *When all injected channels are converted, the next trigger starts the conversion of the first injected channel. In the example above, the 4th trigger reconverts the 1st injected channel 1.*

*It is not possible to use both the auto-injected and discontinuous modes simultaneously.*

*Discontinuous mode must not be set for regular and injected groups at the same time. Discontinuous mode must be enabled only for the conversion of one group.*

## 15.4 Data alignment

The ALIGN bit in the ADC\_CR2 register selects the alignment of the data stored after conversion. Data can be right- or left-aligned as shown in [Figure 77](#) and [Figure 78](#).

The converted data value from the injected group of channels is decreased by the user-defined offset written in the ADC\_JOFRx registers so the result can be a negative value. The SEXT bit represents the extended sign value.

For channels in a regular group, no offset is subtracted so only twelve bits are significant.

**Figure 77. Right alignment of 12-bit data****Figure 78. Left alignment of 12-bit data**

Special case: when left-aligned, the data are aligned on a half-word basis except when the resolution is set to 6-bit. In that case, the data are aligned on a byte basis as shown in [Figure 79](#).

**Figure 79. Left alignment of 6-bit data**

## 15.5 Channel-wise programmable sampling time

The ADC samples the input voltage for a number of ADCCLK cycles that can be modified using the SMP[2:0] bits in the ADC\_SMPR1 and ADC\_SMPR2 registers. Each channel can be sampled with a different sampling time.

The total conversion time is calculated as follows:

$$T_{\text{conv}} = \text{Sampling time} + 12 \text{ cycles}$$

Example:

With ADCCLK = 30 MHz and sampling time = 3 cycles:

$$T_{\text{conv}} = 3 + 12 = 15 \text{ cycles} = 0.5 \mu\text{s} \text{ with APB2 at 60 MHz}$$

## 15.6 Conversion on external trigger and trigger polarity

Conversion can be triggered by an external event (e.g. timer capture, EXTI line). If the EXTEN[1:0] control bits (for a regular conversion) or JEXTEN[1:0] bits (for an injected conversion) are different from “0b00”, then external events are able to trigger a conversion with the selected polarity. [Table 95](#) provides the correspondence between the EXTEN[1:0] and JEXTEN[1:0] values and the trigger polarity.

**Table 95. Configuring the trigger polarity**

| Source                                         | EXTEN[1:0] / JEXTEN[1:0] |
|------------------------------------------------|--------------------------|
| Trigger detection disabled                     | 00                       |
| Detection on the rising edge                   | 01                       |
| Detection on the falling edge                  | 10                       |
| Detection on both the rising and falling edges | 11                       |

*Note:* The polarity of the external trigger can be changed on the fly.

The EXTSEL[3:0] and JEXTSEL[3:0] control bits are used to select which out of 16 possible events can trigger conversion for the regular and injected groups.

[Table 96](#) gives the possible external trigger for regular conversion.

**Table 96. External trigger for regular channels**

| Source       | Type                                | EXTSEL[3:0] |
|--------------|-------------------------------------|-------------|
| TIM1_CH1     | Internal signal from on-chip timers | 0000        |
| TIM1_CH2     |                                     | 0001        |
| TIM1_CH3     |                                     | 0010        |
| TIM2_CH2     |                                     | 0011        |
| TIM5_TRGO    |                                     | 0100        |
| TIM4_CH4     |                                     | 0101        |
| TIM3_CH4     |                                     | 0110        |
| TIM8_TRGO    |                                     | 0111        |
| TIM8_TRGO(2) |                                     | 1000        |
| TIM1_TRGO    |                                     | 1001        |
| TIM1_TRGO(2) |                                     | 1010        |
| TIM2_TRGO    |                                     | 1011        |
| TIM4_TRGO    |                                     | 1100        |
| TIM6_TRGO    |                                     | 1101        |
| EXTI line11  | External pin                        | 1111        |

Table 97 gives the possible external trigger for injected conversion.

**Table 97. External trigger for injected channels**

| Source       | Connection type                     | JEXTSEL[3:0] |
|--------------|-------------------------------------|--------------|
| TIM1_TRGO    | Internal signal from on-chip timers | 0000         |
| TIM1_CH4     |                                     | 0001         |
| TIM2_TRGO    |                                     | 0010         |

| TIM6_TRGO    |                                     | 1110         |

Software source trigger events can be generated by setting SWSTART (for regular conversion) or JSWSTART (for injected conversion) in ADC\_CR2.

A regular group conversion can be interrupted by an injected trigger.

*Note: The trigger selection can be changed on the fly. However, when the selection changes, there is a time frame of 1 APB clock cycle during which the trigger detection is disabled. This is to avoid spurious detection during transitions.*

## 15.7 Fast conversion mode

It is possible to perform faster conversion by reducing the ADC resolution. The RES bits are used to select the number of bits available in the data register. The minimum conversion time for each resolution is then as follows:

- 12 bits:  $3 + 12 = 15$  ADCCLK cycles
- 10 bits:  $3 + 10 = 13$  ADCCLK cycles
- 8 bits:  $3 + 8 = 11$  ADCCLK cycles
- 6 bits:  $3 + 6 = 9$  ADCCLK cycles

## 15.8 Data management

### 15.8.1 Using the DMA

Since converted regular channel values are stored into a unique data register, it is useful to use DMA for conversion of more than one regular channel. This avoids the loss of the data already stored in the ADC\_DR register.

When the DMA mode is enabled (DMA bit set to 1 in the ADC\_CR2 register), after each conversion of a regular channel, a DMA request is generated. This allows the transfer of the converted data from the ADC\_DR register to the destination location selected by the software.

Despite this, if data are lost (overflow), the OVR bit in the ADC\_SR register is set and an interrupt is generated (if the OVRIE enable bit is set). DMA transfers are then disabled and DMA requests are no longer accepted. In this case, if a DMA request is made, the regular conversion in progress is aborted and further regular triggers are ignored. It is then necessary to clear the OVR flag and the DMAEN bit in the used DMA stream, and to re-initialize both the DMA and the ADC to have the wanted converted channel data transferred to the right memory location. Only then can the conversion be resumed and the data transfer, enabled again. Injected channel conversions are not impacted by overflow errors.

When OVR = 1 in DMA mode, the DMA requests are blocked after the last valid data have been transferred, which means that all the data transferred to the RAM can be considered as valid.

At the end of the last DMA transfer (number of transfers configured in the DMA controller's DMA\_SxNTR register):

- No new DMA request is issued to the DMA controller if the DDS bit is cleared to 0 in the ADC\_CR2 register (this avoids generating an overflow error). However the DMA bit is not cleared by hardware. It must be written to 0, then to 1 to start a new transfer.
- Requests can continue to be generated if the DDS bit is set to 1. This allows configuring the DMA in double-buffer circular mode.

To recover the ADC from OVR state when the DMA is used, follow the steps below:

1. Reinitialize the DMA (adjust destination address and NDTR counter)
2. Clear the ADC OVR bit in ADC\_SR register
3. Trigger the ADC to start the conversion.

### 15.8.2 Managing a sequence of conversions without using the DMA

If the conversions are slow enough, the conversion sequence can be handled by the software. In this case the EOCS bit must be set in the ADC\_CR2 register for the EOC status bit to be set at the end of each conversion, and not only at the end of the sequence. When EOCS = 1, overflow detection is automatically enabled. Thus, each time a conversion is complete, EOC is set and the ADC\_DR register can be read. The overflow management is the same as when the DMA is used.

To recover the ADC from OVR state when the EOCS is set, follow the steps below:

1. Clear the ADC OVR bit in ADC\_SR register
2. Trigger the ADC to start the conversion.

### 15.8.3 Conversions without DMA and without overrun detection

It may be useful to let the ADC convert one or more channels without reading the data each time (if there is an analog watchdog for instance). For that, the DMA must be disabled (DMA = 0) and the EOC bit must be set at the end of a sequence only (EOCS = 0). In this configuration, overrun detection is disabled.

## 15.9 Multi ADC mode

In devices with two ADCs or more, the Dual (with two ADCs) and Triple (with three ADCs) ADC modes can be used (see [Figure 80](#)).

In multi ADC mode, the start of conversion is triggered alternately or simultaneously by the ADC1 master to the ADC2 and ADC3 slaves, depending on the mode selected by the MULTI[4:0] bits in the ADC\_CCR register.

*Note:* In multi ADC mode, when configuring conversion trigger by an external event, the application must set trigger by the master only and disable trigger by slaves to prevent spurious triggers that would start unwanted slave conversions.

The four possible modes below are implemented:

- Injected simultaneous mode
- Regular simultaneous mode
- Interleaved mode
- Alternate trigger mode

It is also possible to use the previous modes combined in the following ways:

- Injected simultaneous mode + Regular simultaneous mode
- Regular simultaneous mode + Alternate trigger mode

*Note:* In multi ADC mode, the converted data can be read on the multi-mode data register (ADC\_CDR). The status bits can be read in the multi-mode status register (ADC\_CSR).

Figure 80. Multi ADC block diagram<sup>(1)</sup>

1. Although external triggers are present on ADC2 and ADC3 they are not shown in this diagram.
2. In the Dual ADC mode, the ADC3 slave part is not present.
3. In Triple ADC mode, the ADC common data register (ADC\_CDR) contains the ADC1, ADC2 and ADC3's regular converted data. All 32 register bits are used according to a selected storage order.  
In Dual ADC mode, the ADC common data register (ADC\_CDR) contains both the ADC1 and ADC2's regular converted data. All 32 register bits are used.

- DMA requests in Multi ADC mode:  
In Multi ADC mode the DMA may be configured to transfer converted data in three different modes. In all cases, the DMA streams to use are those connected to the ADC:
  - **DMA mode 1:** On each DMA request (one data item is available), a half-word representing an ADC-converted data item is transferred.  
In Dual ADC mode, ADC1 data are transferred on the first request, ADC2 data are transferred on the second request and so on.  
In Triple ADC mode, ADC1 data are transferred on the first request, ADC2 data are transferred on the second request and ADC3 data are transferred on the third request; the sequence is repeated. So the DMA first transfers ADC1 data followed by ADC2 data followed by ADC3 data and so on.  
DMA mode 1 is used in regular simultaneous triple mode.  
**Example:**  
Regular simultaneous triple mode: 3 consecutive DMA requests are generated (one for each converted data item)  
1st request: ADC\_CDR[31:0] = ADC1\_DR[15:0]  
2nd request: ADC\_CDR[31:0] = ADC2\_DR[15:0]  
3rd request: ADC\_CDR[31:0] = ADC3\_DR[15:0]  
4th request: ADC\_CDR[31:0] = ADC1\_DR[15:0]
  - **DMA mode 2:** On each DMA request (two data items are available) two half-words representing two ADC-converted data items are transferred as a word.  
In Dual ADC mode, both ADC2 and ADC1 data are transferred on the first request (ADC2 data take the upper half-word and ADC1 data take the lower half-word) and so on.  
In Triple ADC mode, three DMA requests are generated. On the first request, both ADC2 and ADC1 data are transferred (ADC2 data take the upper half-word and ADC1 data take the lower half-word). On the second request, both ADC1 and ADC3 data are transferred (ADC1 data take the upper half-word and ADC3 data take the lower half-word). On the third request, both ADC3 and ADC2 data are transferred (ADC3 data take the upper half-word and ADC2 data take the lower half-word) and so on.  
DMA mode 2 is used in interleaved mode and in regular simultaneous mode (for Dual ADC mode only).  
**Example:**
    - a) Interleaved dual mode: a DMA request is generated each time 2 data items are available:  
1st request: ADC\_CDR[31:0] = ADC2\_DR[15:0] | ADC1\_DR[15:0]  
2nd request: ADC\_CDR[31:0] = ADC2\_DR[15:0] | ADC1\_DR[15:0]
    - b) Interleaved triple mode: a DMA request is generated each time 2 data items are available  
1st request: ADC\_CDR[31:0] = ADC2\_DR[15:0] | ADC1\_DR[15:0]  
2nd request: ADC\_CDR[31:0] = ADC1\_DR[15:0] | ADC3\_DR[15:0]  
3rd request: ADC\_CDR[31:0] = ADC3\_DR[15:0] | ADC2\_DR[15:0]  
4th request: ADC\_CDR[31:0] = ADC2\_DR[15:0] | ADC1\_DR[15:0]

- **DMA mode 3:** This mode is similar to the DMA mode 2. The only differences are that the on each DMA request (two data items are available) two bytes representing two ADC converted data items are transferred as a half-word. The data transfer order is similar to that of the DMA mode 2.

DMA mode 3 is used in interleaved mode in 6-bit and 8-bit resolutions.

**Example:**

- a) Interleaved dual mode: a DMA request is generated each time 2 data items are available  
 1st request: `ADC_CDR[15:0] = ADC2_DR[7:0] | ADC1_DR[7:0]`  
 2nd request: `ADC_CDR[15:0] = ADC2_DR[7:0] | ADC1_DR[7:0]`
- b) Interleaved triple mode: a DMA request is generated each time 2 data items are available  
 1st request: `ADC_CDR[15:0] = ADC2_DR[7:0] | ADC1_DR[7:0]`  
 2nd request: `ADC_CDR[15:0] = ADC1_DR[7:0] | ADC3_DR[15:0]`  
 3rd request: `ADC_CDR[15:0] = ADC3_DR[7:0] | ADC2_DR[7:0]`  
 4th request: `ADC_CDR[15:0] = ADC2_DR[7:0] | ADC1_DR[7:0]`

**Overflow detection:** If an overflow is detected on one of the concerned ADCs (ADC1 and ADC2 in dual and triple modes, ADC3 in triple mode only), the DMA requests are no longer issued to ensure that all the data transferred to the RAM are valid. It may happen that the EOC bit corresponding to one ADC remains set because the data register of this ADC contains valid data.

### 15.9.1 Injected simultaneous mode

This mode converts an injected group of channels. The external trigger source comes from the injected group multiplexer of ADC1 (selected by the JEXTSEL[3:0] bits in the ADC1\_CR2 register). A simultaneous trigger is provided to ADC2 and ADC3.

*Note: Do not convert the same channel on the two/three ADCs (no overlapping sampling times for the two/three ADCs when converting the same channel).*

*In simultaneous mode, one must convert sequences with the same length or ensure that the interval between triggers is longer than the longer of the 2 sequences (Dual ADC mode) /3 sequences (Triple ADC mode). Otherwise, the ADC with the shortest sequence may restart while the ADC with the longest sequence is completing the previous conversions.*

*Regular conversions can be performed on one or all ADCs. In that case, they are independent of each other and are interrupted when an injected event occurs. They are resumed at the end of the injected conversion group.*

### Dual ADC mode

At the end of conversion event on ADC1 or ADC2:

- The converted data are stored into the ADC\_JDRx registers of each ADC interface.
- A JEOC interrupt is generated (if enabled on one of the two ADC interfaces) when the ADC1/ADC2's injected channels have all been converted.

**Figure 81. Injected simultaneous mode on 4 channels: dual ADC mode**

### Triple ADC mode

At the end of conversion event on ADC1, ADC2 or ADC3:

- The converted data are stored into the ADC\_JDRx registers of each ADC interface.
- A JEOC interrupt is generated (if enabled on one of the three ADC interfaces) when the ADC1/ADC2/ADC3's injected channels have all been converted.

**Figure 82. Injected simultaneous mode on 4 channels: triple ADC mode**

## 15.9.2 Regular simultaneous mode

This mode is performed on a regular group of channels. The external trigger source comes from the regular group multiplexer of ADC1 (selected by the EXTSEL[3:0] bits in the ADC1\_CR2 register). A simultaneous trigger is provided to ADC2 and ADC3.

**Note:** *Do not convert the same channel on the two/three ADCs (no overlapping sampling times for the two/three ADCs when converting the same channel).*

*In regular simultaneous mode, one must convert sequences with the same length or ensure that the interval between triggers is longer than the long conversion time of the 2 sequences (Dual ADC mode) /3 sequences (Triple ADC mode). Otherwise, the ADC with the shortest sequence may restart while the ADC with the longest sequence is completing the previous conversions.*

*Injected conversions must be disabled.*

### Dual ADC mode

At the end of conversion event on ADC1 or ADC2:

- A 32-bit DMA transfer request is generated (if DMA[1:0] bits in the ADC\_CCR register are equal to 0b10). This request transfers the ADC2 converted data stored in the upper half-word of the ADC\_CDR 32-bit register to the SRAM and then the ADC1 converted data stored in the lower half-word of ADC\_CCR to the SRAM.
- An EOC interrupt is generated (if enabled on one of the two ADC interfaces) when the ADC1/ADC2's regular channels have all been converted.

**Figure 83. Regular simultaneous mode on 16 channels: dual ADC mode**

### Triple ADC mode

At the end of conversion event on ADC1, ADC2 or ADC3:

- Three 32-bit DMA transfer requests are generated (if DMA[1:0] bits in the ADC\_CCR register are equal to 0b01). Three transfers then take place from the ADC\_CDR 32-bit register to SRAM: first the ADC1 converted data, then the ADC2 converted data and finally the ADC3 converted data. The process is repeated for each new three conversions.
- An EOC interrupt is generated (if enabled on one of the three ADC interfaces) when the ADC1/ADC2/ADC3's regular channels are have all been converted.

**Figure 84. Regular simultaneous mode on 16 channels: triple ADC mode**

## 15.9.3 Interleaved mode

This mode can be started only on a regular group (usually one channel). The external trigger source comes from the regular channel multiplexer of ADC1.

### Dual ADC mode

After an external trigger occurs:

- ADC1 starts immediately
- ADC2 starts after a delay of several-ADC clock cycles

The minimum delay which separates 2 conversions in interleaved mode is configured in the DELAY bits in the ADC\_CCR register. However, an ADC cannot start a conversion if the complementary ADC is still sampling its input (only one ADC can sample the input signal at a given time). In this case, the delay becomes the sampling time + 2 ADC clock cycles. For instance, if DELAY = 5 clock cycles and the sampling takes 15 clock cycles on both ADCs, then 17 clock cycles will separate conversions on ADC1 and ADC2).

If the CONT bit is set on both ADC1 and ADC2, the selected regular channels of both ADCs are continuously converted.

**Note:** *If the conversion sequence is interrupted (for instance when DMA end of transfer occurs), the multi-ADC sequencer must be reset by configuring it in independent mode first (bits DUAL[4:0] = 00000) before reprogramming the interleaved mode.*

After an EOC interrupt is generated by ADC2 (if enabled through the EOCIE bit) a 32-bit DMA transfer request is generated (if the DMA[1:0] bits in ADC\_CCR are equal to 0b10). This request first transfers the ADC2 converted data stored in the upper half-word of the ADC\_CDR 32-bit register into SRAM, then the ADC1 converted data stored in the register's lower half-word into SRAM.

**Figure 85. Interleaved mode on 1 channel in continuous conversion mode: dual ADC mode**

### Triple ADC mode

After an external trigger occurs:

- ADC1 starts immediately and
- ADC2 starts after a delay of several ADC clock cycles
- ADC3 starts after a delay of several ADC clock cycles referred to the ADC2 conversion

The minimum delay which separates 2 conversions in interleaved mode is configured in the DELAY bits in the ADC\_CCR register. However, an ADC cannot start a conversion if the complementary ADC is still sampling its input (only one ADC can sample the input signal at a given time). In this case, the delay becomes the sampling time + 2 ADC clock cycles. For instance, if DELAY = 5 clock cycles and the sampling takes 15 clock cycles on the three ADCs, then 17 clock cycles will separate the conversions on ADC1, ADC2 and ADC3).

If the CONT bit is set on ADC1, ADC2 and ADC3, the selected regular channels of all ADCs are continuously converted.

**Note:** *If the conversion sequence is interrupted (for instance when DMA end of transfer occurs), the multi-ADC sequencer must be reset by configuring it in independent mode first (bits DUAL[4:0] = 00000) before reprogramming the interleaved mode.*

In this mode a DMA request is generated each time 2 data items are available, (if the DMA[1:0] bits in the ADC\_CCR register are equal to 0b10). The request first transfers the

first converted data stored in the lower half-word of the ADC\_CDR 32-bit register to SRAM, then it transfers the second converted data stored in ADC\_CDR's upper half-word to SRAM. The sequence is the following:

- 1st request: ADC\_CDR[31:0] = ADC2\_DR[15:0] | ADC1\_DR[15:0]
- 2nd request: ADC\_CDR[31:0] = ADC1\_DR[15:0] | ADC3\_DR[15:0]
- 3rd request: ADC\_CDR[31:0] = ADC3\_DR[15:0] | ADC2\_DR[15:0]
- 4th request: ADC\_CDR[31:0] = ADC2\_DR[15:0] | ADC1\_DR[15:0], ...

**Figure 86. Interleaved mode on 1 channel in continuous conversion mode: triple ADC mode**

### 15.9.4 Alternate trigger mode

This mode can be started only on an injected group. The source of external trigger comes from the injected group multiplexer of ADC1.

**Note:** *Regular conversions can be enabled on one or all ADCs. In this case the regular conversions are independent of each other. A regular conversion is interrupted when the ADC has to perform an injected conversion. It is resumed when the injected conversion is finished.*

*If the conversion sequence is interrupted (for instance when DMA end of transfer occurs), the multi-ADC sequencer must be reset by configuring it in independent mode first (bits DUAL[4:0] = 00000) before reprogramming the interleaved mode.*

*The time interval between 2 trigger events must be greater than or equal to 1 ADC clock period. The minimum time interval between 2 trigger events that start conversions on the same ADC is the same as in the single ADC mode.*

#### Dual ADC mode

- When the 1st trigger occurs, all injected ADC1 channels in the group are converted
- When the 2nd trigger occurs, all injected ADC2 channels in the group are converted
- and so on

A JEOP interrupt, if enabled, is generated after all injected ADC1 channels in the group have been converted.

A JEOC interrupt, if enabled, is generated after all injected ADC2 channels in the group have been converted.

If another external trigger occurs after all injected channels in the group have been converted then the alternate trigger process restarts by converting the injected ADC1 channels in the group.

**Figure 87. Alternate trigger: injected group of each ADC**

If the injected discontinuous mode is enabled for both ADC1 and ADC2:

- When the 1st trigger occurs, the first injected ADC1 channel is converted.
- When the 2nd trigger occurs, the first injected ADC2 channel are converted
- and so on

A JEOC interrupt, if enabled, is generated after all injected ADC1 channels in the group have been converted.

A JEOC interrupt, if enabled, is generated after all injected ADC2 channels in the group have been converted.

If another external trigger occurs after all injected channels in the group have been converted then the alternate trigger process restarts.

**Figure 88. Alternate trigger: 4 injected channels (each ADC) in discontinuous mode**

### Triple ADC mode

- When the 1st trigger occurs, all injected ADC1 channels in the group are converted.
- When the 2nd trigger occurs, all injected ADC2 channels in the group are converted.
- When the 3rd trigger occurs, all injected ADC3 channels in the group are converted.
- and so on

A JEOC interrupt, if enabled, is generated after all injected ADC1 channels in the group have been converted.

A JEOC interrupt, if enabled, is generated after all injected ADC2 channels in the group have been converted.

A JEOC interrupt, if enabled, is generated after all injected ADC3 channels in the group have been converted.

If another external trigger occurs after all injected channels in the group have been converted then the alternate trigger process restarts by converting the injected ADC1 channels in the group.

**Figure 89. Alternate trigger: injected group of each ADC**

### 15.9.5 Combined regular/injected simultaneous mode

It is possible to interrupt the simultaneous conversion of a regular group to start the simultaneous conversion of an injected group.

**Note:** *In combined regular/injected simultaneous mode, one must convert sequences with the same length or ensure that the interval between triggers is longer than the long conversion time of the 2 sequences (Dual ADC mode) / 3 sequences (Triple ADC mode). Otherwise, the ADC with the shortest sequence may restart while the ADC with the longest sequence is completing the previous conversions.*

### 15.9.6 Combined regular simultaneous + alternate trigger mode

It is possible to interrupt the simultaneous conversion of a regular group to start the alternate trigger conversion of an injected group. [Figure 90](#) shows the behavior of an alternate trigger interrupting a simultaneous regular conversion.

The injected alternate conversion is immediately started after the injected event. If regular conversion is already running, in order to ensure synchronization after the injected conversion, the regular conversion of all (master/slave) ADCs is stopped and resumed synchronously at the end of the injected conversion.

**Note:** *In combined regular simultaneous + alternate trigger mode, one must convert sequences with the same length or ensure that the interval between triggers is longer than the long conversion time of the 2 sequences (Dual ADC mode) / 3 sequences (Triple ADC mode).*

Otherwise, the ADC with the shortest sequence may restart while the ADC with the longest sequence is completing the previous conversions.

If the conversion sequence is interrupted (for instance when DMA end of transfer occurs), the multi-ADC sequencer must be reset by configuring it in independent mode first (bits  $DUAL[4:0] = 00000$ ) before reprogramming the interleaved mode.

**Figure 90. Alternate + regular simultaneous**

If a trigger occurs during an injected conversion that has interrupted a regular conversion, it is ignored. [Figure 91](#) shows the behavior in this case (2nd trigger is ignored).

**Figure 91. Case of trigger occurring during injected conversion**

## 15.10 Temperature sensor

The temperature sensor can be used to measure the ambient temperature ( $T_A$ ) of the device.

- On STM32F75xxx and STM32F74xxx devices, the temperature sensor is internally connected to the same input channel, ADC1\_IN18, as VBAT: ADC1\_IN18 is used to convert the sensor output voltage or VBAT into a digital value. Only one conversion, temperature sensor or VBAT, must be selected at a time. When the temperature sensor and the VBAT conversion are set simultaneously, only the VBAT conversion is performed.

Figure 92 shows the block diagram of the temperature sensor.

When not in use, the sensor can be put in power down mode.

**Note:** The *TSVREFE* bit must be set to enable the conversion of both internal channels: the *ADC1\_IN18* (temperature sensor) and the *ADC1\_IN17* (*VREFINT*).

### Main features

- Supported temperature range:  $-40$  to  $125$  °C
- Precision:  $\pm 1.5$  °C

**Figure 92. Temperature sensor and  $V_{REFINT}$  channel block diagram**

1.  $V_{SENSE}$  is input to *ADC1\_IN18*.

## Reading the temperature

To use the sensor:

3. Select ADC1\_IN18 input channel.
4. Select a sampling time greater than the minimum sampling time specified in the datasheet.
5. Set the TSVREFE bit in the ADC\_CCR register to wake up the temperature sensor from power down mode
6. Start the ADC conversion by setting the SWSTART bit (or by external trigger)
7. Read the resulting  $V_{SENSE}$  data in the ADC data register
8. Calculate the temperature using the following formula:  

$$\text{Temperature (in } ^\circ\text{C)} = \{(V_{SENSE} - V_{25}) / \text{Avg\_Slope}\} + 25$$
 Where:
  - $V_{25} = V_{SENSE}$  value for  $25^\circ\text{C}$
  - Avg\_Slope = average slope of the temperature vs.  $V_{SENSE}$  curve (given in mV/ $^\circ\text{C}$  or  $\mu\text{V}/^\circ\text{C}$ )

Refer to the datasheet electrical characteristics section for the actual values of  $V_{25}$  and Avg\_Slope.

**Note:** *The sensor has a startup time after waking from power down mode before it can output  $V_{SENSE}$  at the correct level. The ADC also has a startup time after power-on, so to minimize the delay, the ADON and TSVREFE bits should be set at the same time.*

The temperature sensor output voltage changes linearly with temperature. The offset of this linear function depends on each chip due to process variation (up to  $45^\circ\text{C}$  from one chip to another).

The internal temperature sensor is more suited for applications that detect temperature variations instead of absolute temperatures. If accurate temperature reading is required, an external temperature sensor should be used.

## 15.11 Battery charge monitoring

The VBATE bit in the ADC\_CCR register is used to switch to the battery voltage. As the  $V_{BAT}$  voltage could be higher than  $V_{DDA}$ , to ensure the correct operation of the ADC, the  $V_{BAT}$  pin is internally connected to a bridge divider.

When the VBATE is set, the bridge is automatically enabled to connect:

- $V_{BAT}/4$  to the ADC1\_IN18 input channel

**Note:** *The VBAT and temperature sensor are connected to the same ADC internal channel (ADC1\_IN18). Only one conversion, either temperature sensor or VBAT, must be selected at a time. When both conversion are enabled simultaneously, only the VBAT conversion is performed.*

## 15.12 ADC interrupts

An interrupt can be produced on the end of conversion for regular and injected groups, when the analog watchdog status bit is set and when the overrun status bit is set. Separate interrupt enable bits are available for flexibility.

Two other flags are present in the ADC\_SR register, but there is no interrupt associated with them:

- JSTRT (Start of conversion for channels of an injected group)
- STRT (Start of conversion for channels of a regular group)

**Table 98. ADC interrupts**

| Interrupt event                        | Event flag | Enable control bit |
|----------------------------------------|------------|--------------------|
| End of conversion of a regular group   | EOC        | EOCIE              |
| End of conversion of an injected group | JEOC       | JEOCIE             |
| Analog watchdog status bit is set      | AWD        | AWDIE              |
| Overrun                                | OVR        | OVRIE              |

## 15.13 ADC registers

Refer to [Section 1.2 on page 62](#) for a list of abbreviations used in register descriptions.

The peripheral registers must be written at word level (32 bits). Read accesses can be done by bytes (8 bits), half-words (16 bits) or words (32 bits).

### 15.13.1 ADC status register (ADC\_SR)

Address offset: 0x00

Reset value: 0x0000 0000

Bits 31:6 Reserved, must be kept at reset value.

Bit 5 **OVR**: Overrun

This bit is set by hardware when data are lost (either in single mode or in dual/triple mode). It is cleared by software. Overrun detection is enabled only when DMA = 1 or EOCS = 1.

0: No overrun occurred  
1: Overrun has occurred

Bit 4 **STRT**: Regular channel start flag

This bit is set by hardware when regular channel conversion starts. It is cleared by software.

0: No regular channel conversion started  
1: Regular channel conversion has started

Bit 3 **JSTRT**: Injected channel start flag

This bit is set by hardware when injected group conversion starts. It is cleared by software.

0: No injected group conversion started  
1: Injected group conversion has started

Bit 2 **JEOC**: Injected channel end of conversion

This bit is set by hardware at the end of the conversion of all injected channels in the group. It is cleared by software.

0: Conversion is not complete  
1: Conversion complete

Bit 1 **EOC**: Regular channel end of conversion

This bit is set by hardware at the end of the conversion of a regular group of channels. It is cleared by software or by reading the ADC\_DR register.

0: Conversion not complete (EOCS=0), or sequence of conversions not complete (EOCS=1)  
1: Conversion complete (EOCS=0), or sequence of conversions complete (EOCS=1)

Bit 0 **AWD**: Analog watchdog flag

This bit is set by hardware when the converted voltage crosses the values programmed in the ADC\_LTR and ADC\_HTR registers. It is cleared by software.

0: No analog watchdog event occurred  
1: Analog watchdog event occurred

### 15.13.2 ADC control register 1 (ADC\_CR1)

Address offset: 0x04

Reset value: 0x0000 0000

Bits 31:27 Reserved, must be kept at reset value.

Bit 26 **OVRIE**: Overrun interrupt enable

This bit is set and cleared by software to enable/disable the Overrun interrupt.

0: Overrun interrupt disabled

1: Overrun interrupt enabled. An interrupt is generated when the OVR bit is set.

Bits 25:24 **RES[1:0]**: Resolution

These bits are written by software to select the resolution of the conversion.

00: 12-bit (minimum 15 ADCCLK cycles)

01: 10-bit (minimum 13 ADCCLK cycles)

10: 8-bit (minimum 11 ADCCLK cycles)

11: 6-bit (minimum 9 ADCCLK cycles)

Bit 23 **AWDEN**: Analog watchdog enable on regular channels

This bit is set and cleared by software.

0: Analog watchdog disabled on regular channels

1: Analog watchdog enabled on regular channels

Bit 22 **JAWDEN**: Analog watchdog enable on injected channels

This bit is set and cleared by software.

0: Analog watchdog disabled on injected channels

1: Analog watchdog enabled on injected channels

Bits 21:16 Reserved, must be kept at reset value.

Bits 15:13 **DISCNUM[2:0]**: Discontinuous mode channel count

These bits are written by software to define the number of regular channels to be converted in discontinuous mode, after receiving an external trigger.

000: 1 channel

001: 2 channels

...

111: 8 channels

Bit 12 **JDISCEN**: Discontinuous mode on injected channels

This bit is set and cleared by software to enable/disable discontinuous mode on the injected channels of a group.

0: Discontinuous mode on injected channels disabled

1: Discontinuous mode on injected channels enabled

- Bit 11 **DISCEN**: Discontinuous mode on regular channels  
 This bit is set and cleared by software to enable/disable Discontinuous mode on regular channels.  
 0: Discontinuous mode on regular channels disabled  
 1: Discontinuous mode on regular channels enabled
- Bit 10 **JAUTO**: Automatic injected group conversion  
 This bit is set and cleared by software to enable/disable automatic injected group conversion after regular group conversion.  
 0: Automatic injected group conversion disabled  
 1: Automatic injected group conversion enabled
- Bit 9 **AWDSGL**: Enable the watchdog on a single channel in scan mode  
 This bit is set and cleared by software to enable/disable the analog watchdog on the channel identified by the AWDCH[4:0] bits.  
 0: Analog watchdog enabled on all channels  
 1: Analog watchdog enabled on a single channel
- Bit 8 **SCAN**: Scan mode  
 This bit is set and cleared by software to enable/disable the Scan mode. In Scan mode, the inputs selected through the ADC\_SQRx or ADC\_JSQRx registers are converted.  
 0: Scan mode disabled  
 1: Scan mode enabled  
*Note: An EOC interrupt is generated if the EOCIE bit is set:*  
 – At the end of each regular group sequence if the EOCS bit is cleared to 0  
 – At the end of each regular channel conversion if the EOCS bit is set to 1  
*Note: A JEOC interrupt is generated only on the end of conversion of the last channel if the JEOCIE bit is set.*
- Bit 7 **JEOCIE**: Interrupt enable for injected channels  
 This bit is set and cleared by software to enable/disable the end of conversion interrupt for injected channels.  
 0: JEOC interrupt disabled  
 1: JEOC interrupt enabled. An interrupt is generated when the JEOC bit is set.
- Bit 6 **AWDIE**: Analog watchdog interrupt enable  
 This bit is set and cleared by software to enable/disable the analog watchdog interrupt.  
 0: Analog watchdog interrupt disabled  
 1: Analog watchdog interrupt enabled
- Bit 5 **EOCIE**: Interrupt enable for EOC  
 This bit is set and cleared by software to enable/disable the end of conversion interrupt.  
 0: EOC interrupt disabled  
 1: EOC interrupt enabled. An interrupt is generated when the EOC bit is set.
- Bits 4:0 **AWDCH[4:0]**: Analog watchdog channel select bits  
 These bits are set and cleared by software. They select the input channel to be guarded by the analog watchdog.  
*Note:* 00000: ADC analog input Channel0  
 00001: ADC analog input Channel1  
 ...  
 01111: ADC analog input Channel15  
 10000: ADC analog input Channel16  
 10001: ADC analog input Channel17  
 10010: ADC analog input Channel18  
 Other values reserved

### 15.13.3 ADC control register 2 (ADC\_CR2)

Bit 31 Reserved, must be kept at reset value.

Bit 30 **SWSTART**: Start conversion of regular channels

This bit is set by software to start conversion and cleared by hardware as soon as the conversion starts.

0: Reset state

1: Starts conversion of regular channels

*Note: This bit can be set only when ADON = 1 otherwise no conversion is launched.*

Bits 29:28 **EXTEN**: External trigger enable for regular channels

These bits are set and cleared by software to select the external trigger polarity and enable the trigger of a regular group.

00: Trigger detection disabled

01: Trigger detection on the rising edge

10: Trigger detection on the falling edge

11: Trigger detection on both the rising and falling edges

Bits 27:24 **EXTSEL[3:0]**: External event select for regular group

These bits select the external event used to trigger the start of conversion of a regular group:

0000: Timer 1 CH1

0001: Timer 1 CH2

0010: Timer 1 CH3

0011: Timer 2 CH2

0100: Timer 5 TRGO

1001: Timer 1 TRGO

1010: Timer 1 TRGO(2)

1011: Timer 2 TRGO

1100: Timer 4 TRGO

1101: Timer 6 TRGO

1110: Reserved

1111: EXTI line11

Bit 23 Reserved, must be kept at reset value.

Bit 22 **JSWSTART**: Start conversion of injected channels

This bit is set by software and cleared by hardware as soon as the conversion starts.

0: Reset state

1: Starts conversion of injected channels

This bit can be set only when ADON = 1 otherwise no conversion is launched.

Bits 21:20 **JEXTEN**: External trigger enable for injected channels

These bits are set and cleared by software to select the external trigger polarity and enable the trigger of an injected group.

00: Trigger detection disabled

01: Trigger detection on the rising edge

10: Trigger detection on the falling edge

11: Trigger detection on both the rising and falling edges

Bits 19:16 **JEXTSEL[3:0]**: External event select for injected group

These bits select the external event used to trigger the start of conversion of an injected group.

0000: Timer 1 TRGO

0001: Timer 1 CH4

0010: Timer 2 TRGO

0011: Timer 2 CH1

0100: Timer 3 CH4

0101: Timer4 TRGO

0110: Reserved

0111: Timer 8 CH4

1000: Timer 1 TRGO(2)

1001: Timer 8 TRGO

1010: Timer 8 TRGO(2)

1011: Timer 3 CH3

1100: Timer 5 TRGO

1101: Timer 3 CH1

1110: Timer 6 TRGO

1111: Reserved

Bits 15:12 Reserved, must be kept at reset value.

Bit 11 **ALIGN**: Data alignment

This bit is set and cleared by software. Refer to [Figure 77](#) and [Figure 78](#).

0: Right alignment

1: Left alignment

Bit 10 **EOCS**: End of conversion selection

This bit is set and cleared by software.

0: The EOC bit is set at the end of each sequence of regular conversions. Overrun detection is enabled only if DMA=1.

1: The EOC bit is set at the end of each regular conversion. Overrun detection is enabled.

Bit 9 **DDS**: DMA disable selection (for single ADC mode)

This bit is set and cleared by software.

0: No new DMA request is issued after the last transfer (as configured in the DMA controller)

1: DMA requests are issued as long as data are converted and DMA=1

Bit 8 **DMA**: Direct memory access mode (for single ADC mode)

This bit is set and cleared by software. Refer to the DMA controller chapter for more details.

0: DMA mode disabled

1: DMA mode enabled

Bits 7:2 Reserved, must be kept at reset value.

Bit 1 **CONT**: Continuous conversion

This bit is set and cleared by software. If it is set, conversion takes place continuously until it is cleared.

0: Single conversion mode

1: Continuous conversion mode

Bit 0 **ADON**: A/D Converter ON / OFF

This bit is set and cleared by software.

0: Disable ADC conversion and go to power down mode

1: Enable ADC

#### 15.13.4 ADC sample time register 1 (ADC\_SMPR1)

Bits 31:12 Reserved, must be kept at reset value.

Bits 11:0 **HT[11:0]**: Analog watchdog higher threshold

These bits are written by software to define the higher threshold for the analog watchdog.

**Note:** *The software can write to these registers when an ADC conversion is ongoing. The programmed value will be effective when the next conversion is complete. Writing to this register is performed with a write delay that can create uncertainty on the effective time at which the new value is programmed.*

### 15.13.8 ADC watchdog lower threshold register (ADC\_LTR)

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:20 **L[3:0]**: Regular channel sequence length

These bits are written by software to define the total number of conversions in the regular channel conversion sequence.

0000: 1 conversion

0001: 2 conversions

...

1111: 16 conversions

Bits 19:15 **SQ16[4:0]**: 16th conversion in regular sequence

These bits are written by software with the channel number (0..18) assigned as the 16th in the conversion sequence.

Bits 14:10 **SQ15[4:0]**: 15th conversion in regular sequence

Bits 9:5 **SQ14[4:0]**: 14th conversion in regular sequence

Bits 4:0 **SQ13[4:0]**: 13th conversion in regular sequence

### 15.13.10 ADC regular sequence register 2 (ADC\_SQR2)

Address offset: 0x30

Reset value: 0x0000 0000

Bits 31:30 Reserved, must be kept at reset value.

Bits 29:25 **SQ6[4:0]**: 6th conversion in regular sequence

These bits are written by software with the channel number (0..18) assigned as the 6th in the sequence to be converted.

Bits 24:20 **SQ5[4:0]**: 5th conversion in regular sequence

Bits 19:15 **SQ4[4:0]**: 4th conversion in regular sequence

Bits 14:10 **SQ3[4:0]**: 3rd conversion in regular sequence

Bits 9:5 **SQ2[4:0]**: 2nd conversion in regular sequence

Bits 4:0 **SQ1[4:0]**: 1st conversion in regular sequence

### 15.13.12 ADC injected sequence register (ADC\_JSQR)

Address offset: 0x38

Reset value: 0x0000 0000

|         |      |           |      |      |      |           |      |      |      |           |    |           |    |    |    |
|---------|------|-----------|------|------|------|-----------|------|------|------|-----------|----|-----------|----|----|----|
| 31      | 30   | 29        | 28   | 27   | 26   | 25        | 24   | 23   | 22   | 21        | 20 | 19        | 18 | 17 | 16 |
| Res.    | Res. | Res.      | Res. | Res. | Res. | Res.      | Res. | Res. | Res. | JL[1:0]   |    | JSQ4[4:1] |    |    |    |
|         |      |           |      |      |      |           |      |      |      | rw        | rw | rw        | rw | rw | rw |
| 15      | 14   | 13        | 12   | 11   | 10   | 9         | 8    | 7    | 6    | 5         | 4  | 3         | 2  | 1  | 0  |
| JSQ4[0] |      | JSQ3[4:0] |      |      |      | JSQ2[4:0] |      |      |      | JSQ1[4:0] |    |           |    |    |    |
| rw      | rw   | rw        | rw   | rw   | rw   | rw        | rw   | rw   | rw   | rw        | rw | rw        | rw | rw | rw |

Bits 31:22 Reserved, must be kept at reset value.

Bits 21:20 **JL[1:0]**: Injected sequence length

These bits are written by software to define the total number of conversions in the injected channel conversion sequence.

00: 1 conversion

01: 2 conversions

10: 3 conversions

11: 4 conversions

Bits 19:15 **JSQ4[4:0]**: 4th conversion in injected sequence (when JL[1:0]=3, see note below)

These bits are written by software with the channel number (0..18) assigned as the 4th in the sequence to be converted.

Bits 14:10 **JSQ3[4:0]**: 3rd conversion in injected sequence (when JL[1:0]=3, see note below)

Bits 9:5 **JSQ2[4:0]**: 2nd conversion in injected sequence (when JL[1:0]=3, see note below)

Bits 4:0 **JSQ1[4:0]**: 1st conversion in injected sequence (when JL[1:0]=3, see note below)

**Note:** When JL[1:0]=3 (4 injected conversions in the sequencer), the ADC converts the channels in the following order: JSQ1[4:0], JSQ2[4:0], JSQ3[4:0], and JSQ4[4:0].

When JL=2 (3 injected conversions in the sequencer), the ADC converts the channels in the following order: JSQ2[4:0], JSQ3[4:0], and JSQ4[4:0].

When JL=1 (2 injected conversions in the sequencer), the ADC converts the channels in starting from JSQ3[4:0], and then JSQ4[4:0].

When JL=0 (1 injected conversion in the sequencer), the ADC converts only JSQ4[4:0] channel.

### 15.13.13 ADC injected data register x (ADC\_JDRx) (x= 1..4)

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **DATA[15:0]**: Regular data

These bits are read-only. They contain the conversion result from the regular channels. The data are left- or right-aligned as shown in [Figure 77](#) and [Figure 78](#).

#### 15.13.15 ADC Common status register (ADC\_CSR)

Address offset: 0x00 (this offset address is relative to ADC1 base address + 0x300)

Reset value: 0x0000 0000

This register provides an image of the status bits of the different ADCs. Nevertheless it is read-only and does not allow to clear the different status bits. Instead each status bit must be cleared by writing it to 0 in the corresponding ADC\_SR register.

Bits 31:22 Reserved, must be kept at reset value.

Bit 21 **OVR3**: Overrun flag of ADC3

This bit is a copy of the OVR bit in the ADC3\_SR register.

Bit 20 **STRT3**: Regular channel Start flag of ADC3

This bit is a copy of the STRT bit in the ADC3\_SR register.

- Bit 19 **JSTRT3**: Injected channel Start flag of ADC3  
This bit is a copy of the JSTRT bit in the ADC3\_SR register.
- Bit 18 **JEOC3**: Injected channel end of conversion of ADC3  
This bit is a copy of the JEOC bit in the ADC3\_SR register.
- Bit 17 **EOC3**: End of conversion of ADC3  
This bit is a copy of the EOC bit in the ADC3\_SR register.
- Bit 16 **AWD3**: Analog watchdog flag of ADC3  
This bit is a copy of the AWD bit in the ADC3\_SR register.
- Bits 15:14 Reserved, must be kept at reset value.
- Bit 13 **OVR2**: Overrun flag of ADC2  
This bit is a copy of the OVR bit in the ADC2\_SR register.
- Bit 12 **STRT2**: Regular channel Start flag of ADC2  
This bit is a copy of the STRT bit in the ADC2\_SR register.
- Bit 11 **JSTRT2**: Injected channel Start flag of ADC2  
This bit is a copy of the JSTRT bit in the ADC2\_SR register.
- Bit 10 **JEOC2**: Injected channel end of conversion of ADC2  
This bit is a copy of the JEOC bit in the ADC2\_SR register.
- Bit 9 **EOC2**: End of conversion of ADC2  
This bit is a copy of the EOC bit in the ADC2\_SR register.
- Bit 8 **AWD2**: Analog watchdog flag of ADC2  
This bit is a copy of the AWD bit in the ADC2\_SR register.
- Bits 7:6 Reserved, must be kept at reset value.
- Bit 5 **OVR1**: Overrun flag of ADC1  
This bit is a copy of the OVR bit in the ADC1\_SR register.
- Bit 4 **STRT1**: Regular channel Start flag of ADC1  
This bit is a copy of the STRT bit in the ADC1\_SR register.
- Bit 3 **JSTRT1**: Injected channel Start flag of ADC1  
This bit is a copy of the JSTRT bit in the ADC1\_SR register.
- Bit 2 **JEOC1**: Injected channel end of conversion of ADC1  
This bit is a copy of the JEOC bit in the ADC1\_SR register.
- Bit 1 **EOC1**: End of conversion of ADC1  
This bit is a copy of the EOC bit in the ADC1\_SR register.
- Bit 0 **AWD1**: Analog watchdog flag of ADC1  
This bit is a copy of the AWD bit in the ADC1\_SR register.

#### 15.13.16 ADC common control register (ADC\_CCR)

Address offset: 0x04 (this offset address is relative to ADC1 base address + 0x300)

Reset value: 0x0000 0000

|          |      |      |      |            |      |      |      |         |       |      |            |      |      |        |    |
|----------|------|------|------|------------|------|------|------|---------|-------|------|------------|------|------|--------|----|
| 31       | 30   | 29   | 28   | 27         | 26   | 25   | 24   | 23      | 22    | 21   | 20         | 19   | 18   | 17     | 16 |

|          |      |      |      |            |      |      |      | rw      | rw    |      |            |      |      | rw     | rw |
| 15       | 14   | 13   | 12   | 11         | 10   | 9    | 8    | 7       | 6     | 5    | 4          | 3    | 2    | 1      | 0  |
| DMA[1:0] |      | DDS  | Res. | DELAY[3:0] |      |      |      | Res.    | Res.  | Res. | MULTI[4:0] |      |      |        |    |
| rw       | rw   | rw   |      | rw         | rw   | rw   | rw   |         |       |      | rw         | rw   | rw   | rw     | rw |

Bits 31:24 Reserved, must be kept at reset value.

Bit 23 **TSVREFE**: Temperature sensor and  $V_{REFINT}$  enable

This bit is set and cleared by software to enable/disable the temperature sensor and the  $V_{REFINT}$  channel.

0: Temperature sensor and  $V_{REFINT}$  channel disabled

1: Temperature sensor and  $V_{REFINT}$  channel enabled

*Note: VBATE must be disabled when TSVREFE is set. If both bits are set, only the VBAT conversion is performed.*

Bit 22 **VBATE**:  $V_{BAT}$  enable

This bit is set and cleared by software to enable/disable the  $V_{BAT}$  channel.

0:  $V_{BAT}$  channel disabled

1:  $V_{BAT}$  channel enabled

Bits 21:18 Reserved, must be kept at reset value.

Bits 17:16 **ADCPRE**: ADC prescaler

Set and cleared by software to select the frequency of the clock to the ADC. The clock is common for all the ADCs.

*Note:* 00: PCLK2 divided by 2

01: PCLK2 divided by 4

10: PCLK2 divided by 6

11: PCLK2 divided by 8

Bits 15:14 **DMA**: Direct memory access mode for multi ADC mode

This bit-field is set and cleared by software. Refer to the DMA controller section for more details.

00: DMA mode disabled

01: DMA mode 1 enabled (2 / 3 half-words one by one - 1 then 2 then 3)

10: DMA mode 2 enabled (2 / 3 half-words by pairs - 2&1 then 1&3 then 3&2)

11: DMA mode 3 enabled (2 / 3 bytes by pairs - 2&1 then 1&3 then 3&2)

Bit 13 **DDS**: DMA disable selection (for multi-ADC mode)

This bit is set and cleared by software.

0: No new DMA request is issued after the last transfer (as configured in the DMA controller). DMA bits are not cleared by hardware, however they must have been cleared and set to the wanted mode by software before new DMA requests can be generated.

1: DMA requests are issued as long as data are converted and DMA = 01, 10 or 11.

Bit 12 Reserved, must be kept at reset value.

Bits 11:8 **DELAY**: Delay between 2 sampling phases

Set and cleared by software. These bits are used in dual or triple interleaved modes.

0000:  $5 * T_{ADCCLK}$

0001:  $6 * T_{ADCCLK}$

0010:  $7 * T_{ADCCLK}$

...

1111:  $20 * T_{ADCCLK}$

Bits 7:5 Reserved, must be kept at reset value.

Bits 4:0 **MULTI[4:0]**: Multi ADC mode selection

These bits are written by software to select the operating mode.

– All the ADCs independent:

00000: Independent mode

– 00001 to 01001: Dual mode, ADC1 and ADC2 working together, ADC3 is independent

00001: Combined regular simultaneous + injected simultaneous mode

00010: Combined regular simultaneous + alternate trigger mode

00011: Reserved

00101: Injected simultaneous mode only

00110: Regular simultaneous mode only

00111: interleaved mode only

01001: Alternate trigger mode only

– 10001 to 11001: Triple mode: ADC1, 2 and 3 working together

10001: Combined regular simultaneous + injected simultaneous mode

10010: Combined regular simultaneous + alternate trigger mode

10011: Reserved

10101: Injected simultaneous mode only

10110: Regular simultaneous mode only

10111: interleaved mode only

11001: Alternate trigger mode only

All other combinations are reserved and must not be programmed

*Note: In multi mode, a change of channel configuration generates an abort that can cause a loss of synchronization. It is recommended to disable the multi ADC mode before any configuration change.*

### 15.13.17 ADC common regular data register for dual and triple modes (ADC\_CDR)

Address offset: 0x08 (this offset address is relative to ADC1 base address + 0x300)

Reset value: 0x0000 0000

|             |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|-------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31          | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| DATA2[15:0] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| r           | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  |
| 15          | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| DATA1[15:0] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| r           | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  |

Bits 31:16 **DATA2[15:0]**: 2nd data item of a pair of regular conversions

- In dual mode, these bits contain the regular data of ADC2. Refer to [Dual ADC mode](#).
- In triple mode, these bits contain alternatively the regular data of ADC2, ADC1 and ADC3. Refer to [Triple ADC mode](#).

Bits 15:0 **DATA1[15:0]**: 1st data item of a pair of regular conversions

- In dual mode, these bits contain the regular data of ADC1. Refer to [Dual ADC mode](#).
- In triple mode, these bits contain alternatively the regular data of ADC1, ADC3 and ADC2. Refer to [Triple ADC mode](#).

### 15.13.18 ADC register map

The following table summarizes the ADC registers.

**Table 99. ADC global register map**

| Offset        | Register         |
|---------------|------------------|
| 0x000 - 0x04C | ADC1             |
| 0x050 - 0x0FC | Reserved         |
| 0x100 - 0x14C | ADC2             |
| 0x118 - 0x1FC | Reserved         |
| 0x200 - 0x24C | ADC3             |
| 0x250 - 0x2FC | Reserved         |
| 0x300 - 0x308 | Common registers |

**Table 100. ADC register map and reset values for each ADC**

| Offset | Register    | 31   | 30   | 29   | 28   | 27   | 26    | 25       | 24    | 23     | 22   | 21   | 20   | 19   | 18   | 17   | 16   | 15             | 14     | 13     | 12    | 11      | 10   | 9      | 8     | 7     | 6    | 5    | 4    | 3    | 2    | 1    | 0    |

Refer to [Section 2.2.2 on page 69](#) for the register boundary addresses.

## 16 Digital-to-analog converter (DAC)

### 16.1 DAC introduction

The DAC module is a 12-bit, voltage output digital-to-analog converter. The DAC can be configured in 8- or 12-bit mode and may be used in conjunction with the DMA controller. In 12-bit mode, the data could be left- or right-aligned. The DAC has two output channels, each with its own converter. In dual DAC channel mode, conversions could be done independently or simultaneously when both channels are grouped together for synchronous update operations. An input reference pin,  $V_{REF+}$  (shared with ADC) is available for better resolution.

### 16.2 DAC main features

- Two DAC converters: one output channel each
- Left or right data alignment in 12-bit mode
- Synchronized update capability
- Noise-wave generation
- Triangular-wave generation
- Dual DAC channel for independent or simultaneous conversions
- DMA capability for each channel
- DMA underrun error detection
- External triggers for conversion
- Input voltage reference,  $V_{REF+}$

[Figure 93](#) shows the block diagram of a DAC channel and [Table 102](#) gives the pin description.

Figure 93. DAC channel block diagram

Table 102. DAC pins

| Name              | Signal type                      | Remarks                                                                                                    |
|-------------------|----------------------------------|------------------------------------------------------------------------------------------------------------|
| V <sub>REF+</sub> | Input, analog reference positive | The higher/positive reference voltage for the DAC, $1.8\text{ V} \leq V_{\text{REF+}} \leq V_{\text{DDA}}$ |
| V <sub>DDA</sub>  | Input, analog supply             | Analog power supply                                                                                        |
| V <sub>SSA</sub>  | Input, analog supply ground      | Ground for analog power supply                                                                             |
| DAC_OUTx          | Analog output signal             | DAC channelx analog output                                                                                 |

**Note:** Once the DAC channelx is enabled, the corresponding GPIO pin (PA4 or PA5) is automatically connected to the analog converter output (DAC\_OUTx). In order to avoid parasitic consumption, the PA4 or PA5 pin should first be configured to analog (AIN).

## 16.3 DAC functional description

### 16.3.1 DAC channel enable

Each DAC channel can be powered on by setting its corresponding ENx bit in the DAC\_CR register. The DAC channel is then enabled after a startup time  $t_{\text{WAKEUP}}$ .

**Note:** The *ENx* bit enables the analog DAC Channelx macrocell only. The DAC Channelx digital interface is enabled even if the *ENx* bit is reset.

### 16.3.2 DAC output buffer enable

The DAC integrates two output buffers that can be used to reduce the output impedance, and to drive external loads directly without having to add an external operational amplifier. Each DAC channel output buffer can be enabled and disabled using the corresponding *BOFFx* bit in the *DAC\_CR* register.

**Figure 94. DAC output buffer connection**

### 16.3.3 DAC data format

Depending on the selected configuration mode, the data have to be written into the specified register as described below:

- Single DAC channelx, there are three possibilities:
  - 8-bit right alignment: the software has to load data into the *DAC\_DHR8Rx* [7:0] bits (stored into the *DHRx*[11:4] bits)
  - 12-bit left alignment: the software has to load data into the *DAC\_DHR12Lx* [15:4] bits (stored into the *DHRx*[11:0] bits)
  - 12-bit right alignment: the software has to load data into the *DAC\_DHR12Rx* [11:0] bits (stored into the *DHRx*[11:0] bits)

Depending on the loaded *DAC\_DHRyyyx* register, the data written by the user is shifted and stored into the corresponding *DHRx* (data holding registerx, which are internal non-memory-mapped registers). The *DHRx* register is then loaded into the *DORx* register either automatically, by software trigger or by an external event trigger.

Figure 95. Data registers in single DAC channel mode

- Dual DAC channels, there are three possibilities:
  - 8-bit right alignment: data for DAC channel1 to be loaded into the DAC\_DHR8RD [7:0] bits (stored into the DHR1[11:4] bits) and data for DAC channel2 to be loaded into the DAC\_DHR8RD [15:8] bits (stored into the DHR2[11:4] bits)
  - 12-bit left alignment: data for DAC channel1 to be loaded into the DAC\_DHR12LD [15:4] bits (stored into the DHR1[11:0] bits) and data for DAC channel2 to be loaded into the DAC\_DHR12LD [31:20] bits (stored into the DHR2[11:0] bits)
  - 12-bit right alignment: data for DAC channel1 to be loaded into the DAC\_DHR12RD [11:0] bits (stored into the DHR1[11:0] bits) and data for DAC channel2 to be loaded into the DAC\_DHR12LD [27:16] bits (stored into the DHR2[11:0] bits)

Depending on the loaded DAC\_DHRyyyD register, the data written by the user is shifted and stored into DHR1 and DHR2 (data holding registers, which are internal non-memory-mapped registers). The DHR1 and DHR2 registers are then loaded into the DOR1 and DOR2 registers, respectively, either automatically, by software trigger or by an external event trigger.

Figure 96. Data registers in dual DAC channel mode

### 16.3.4 DAC conversion

The DAC\_DORx cannot be written directly and any data transfer to the DAC channelx must be performed by loading the DAC\_DHRx register (write to DAC\_DHR8Rx, DAC\_DHR12Lx, DAC\_DHR12Rx, DAC\_DHR8RD, DAC\_DHR12LD or DAC\_DHR12RD).

Data stored in the DAC\_DHRx register are automatically transferred to the DAC\_DORx register after one APB1 clock cycle, if no hardware trigger is selected (TENx bit in DAC\_CR register is reset). However, when a hardware trigger is selected (TENx bit in DAC\_CR register is set) and a trigger occurs, the transfer is performed three APB1 clock cycles later.

When DAC\_DORx is loaded with the DAC\_DHRx contents, the analog output voltage becomes available after a time  $t_{\text{SETTLING}}$  that depends on the power supply voltage and the analog output load.

**Figure 97. Timing diagram for conversion with trigger disabled TEN = 0**

### 16.3.5 DAC output voltage

Digital inputs are converted to output voltages on a linear conversion between 0 and  $V_{\text{REF+}}$ .

The analog output voltages on each DAC channel pin are determined by the following equation:

$$\text{DACoutput} = V_{\text{REF}} \times \frac{\text{DOR}}{4096}$$

### 16.3.6 DAC trigger selection

If the TENx control bit is set, conversion can then be triggered by an external event (timer counter, external interrupt line). The TSELx[2:0] control bits determine which out of 8 possible events will trigger conversion as shown in [Table 103](#).

**Table 103. External triggers**

| Source             | Type                                | TSEL[2:0] |
|--------------------|-------------------------------------|-----------|
| Timer 6 TRGO event | Internal signal from on-chip timers | 000       |
| Timer 8 TRGO event |                                     | 001       |
| Timer 7 TRGO event |                                     | 010       |
| Timer 5 TRGO event |                                     | 011       |
| Timer 2 TRGO event |                                     | 100       |
| Timer 4 TRGO event |                                     | 101       |
| EXTI line9         | External pin                        | 110       |
| SWTRIG             | Software control bit                | 111       |

Each time a DAC interface detects a rising edge on the selected timer TRGO output, or on the selected external interrupt line 9, the last data stored into the DAC\_DHRx register are transferred into the DAC\_DORx register. The DAC\_DORx register is updated three APB1 cycles after the trigger occurs.

If the software trigger is selected, the conversion starts once the SWTRIG bit is set. SWTRIG is reset by hardware once the DAC\_DORx register has been loaded with the DAC\_DHRx register contents.

*Note:* TSELx[2:0] bit cannot be changed when the ENx bit is set.

*When software trigger is selected, the transfer from the DAC\_DHRx register to the DAC\_DORx register takes only one APB1 clock cycle.*

### 16.3.7 DMA request

Each DAC channel has a DMA capability. Two DMA channels are used to service DAC channel DMA requests.

A DAC DMA request is generated when an external trigger (but not a software trigger) occurs while the DMAENx bit is set. The value of the DAC\_DHRx register is then transferred into the DAC\_DORx register.

In dual mode, if both DMAENx bits are set, two DMA requests are generated. If only one DMA request is needed, you should set only the corresponding DMAENx bit. In this way, the application can manage both DAC channels in dual mode by using one DMA request and a unique DMA channel.

#### DMA underrun

The DAC DMA request is not queued so that if a second external trigger arrives before the acknowledgement for the first external trigger is received (first request), then no new request is issued and the DMA channelx underrun flag DMAUDRx in the DAC\_SR register is set, reporting the error condition. DMA data transfers are then disabled and no further DMA request is treated. The DAC channelx continues to convert old data.

The software should clear the DMAUDRx flag by writing "1", clear the DMAEN bit of the used DMA stream and re-initialize both DMA and DAC channelx to restart the transfer correctly. The software should modify the DAC trigger conversion frequency or lighten the DMA workload to avoid a new DMA underrun. Finally, the DAC conversion could be resumed by enabling both DMA data transfer and conversion trigger.

For each DAC channelx, an interrupt is also generated if its corresponding DMAUDRIEx bit in the DAC\_CR register is enabled.

### 16.3.8 Noise generation

In order to generate a variable-amplitude pseudonoise, an LFSR (linear feedback shift register) is available. DAC noise generation is selected by setting WAVEx[1:0] to "01". The preloaded value in LFSR is 0xAAA. This register is updated three APB1 clock cycles after each trigger event, following a specific calculation algorithm.

Figure 98. DAC LFSR register calculation algorithm

The LFSR value, that may be masked partially or totally by means of the MAMPx[3:0] bits in the DAC\_CR register, is added up to the DAC\_DHRx contents without overflow and this value is then stored into the DAC\_DORx register.

If LFSR is 0x0000, a '1' is injected into it (antilock-up mechanism).

It is possible to reset LFSR wave generation by resetting the WAVEx[1:0] bits.

Figure 99. DAC conversion (SW trigger enabled) with LFSR wave generation

**Note:** The DAC trigger must be enabled for noise generation by setting the TENx bit in the DAC\_CR register.

### 16.3.9 Triangle-wave generation

It is possible to add a small-amplitude triangular waveform on a DC or slowly varying signal. DAC triangle-wave generation is selected by setting WAVEx[1:0] to "10". The amplitude is configured through the MAMPx[3:0] bits in the DAC\_CR register. An internal triangle counter is incremented three APB1 clock cycles after each trigger event. The value of this counter is then added to the DAC\_DHRx register without overflow and the sum is stored into the DAC\_DORx register. The triangle counter is incremented as long as it is less than the maximum amplitude defined by the MAMPx[3:0] bits. Once the configured amplitude is reached, the counter is decremented down to 0, then incremented again and so on.

It is possible to reset triangle wave generation by resetting the WAVE<sub>x</sub>[1:0] bits.

**Figure 100. DAC triangle wave generation**

**Figure 101. DAC conversion (SW trigger enabled) with triangle wave generation**

**Note:** The DAC trigger must be enabled for noise generation by setting the *TENx* bit in the *DAC\_CR* register.  
The *MAMPx[3:0]* bits must be configured before enabling the DAC, otherwise they cannot be changed.

## 16.4 Dual DAC channel conversion

To efficiently use the bus bandwidth in applications that require the two DAC channels at the same time, three dual registers are implemented: DHR8RD, DHR12RD and DHR12LD. A unique register access is then required to drive both DAC channels at the same time.

Eleven possible conversion modes are possible using the two DAC channels and these dual registers. All the conversion modes can nevertheless be obtained using separate DHR<sub>x</sub> registers if needed.

All modes are described in the paragraphs below.

### 16.4.1 Independent trigger without wave generation

To configure the DAC in this conversion mode, the following sequence is required:

- Set the two DAC channel trigger enable bits TEN1 and TEN2
- Configure different trigger sources by setting different values in the TSEL1[2:0] and TSEL2[2:0] bits
- Load the dual DAC channel data into the desired DHR register (DAC\_DHR12RD, DAC\_DHR12LD or DAC\_DHR8RD)

When a DAC channel1 trigger arrives, the DHR1 register is transferred into DAC\_DOR1 (three APB1 clock cycles later).

When a DAC channel2 trigger arrives, the DHR2 register is transferred into DAC\_DOR2 (three APB1 clock cycles later).

### 16.4.2 Independent trigger with single LFSR generation

To configure the DAC in this conversion mode, the following sequence is required:

- Set the two DAC channel trigger enable bits TEN1 and TEN2
- Configure different trigger sources by setting different values in the TSEL1[2:0] and TSEL2[2:0] bits
- Configure the two DAC channel WAVEx[1:0] bits as "01" and the same LFSR mask value in the MAMPx[3:0] bits
- Load the dual DAC channel data into the desired DHR register (DHR12RD, DHR12LD or DHR8RD)

When a DAC channel1 trigger arrives, the LFSR1 counter, with the same mask, is added to the DHR1 register and the sum is transferred into DAC\_DOR1 (three APB1 clock cycles later). Then the LFSR1 counter is updated.

When a DAC channel2 trigger arrives, the LFSR2 counter, with the same mask, is added to the DHR2 register and the sum is transferred into DAC\_DOR2 (three APB1 clock cycles later). Then the LFSR2 counter is updated.

### 16.4.3 Independent trigger with different LFSR generation

To configure the DAC in this conversion mode, the following sequence is required:

- Set the two DAC channel trigger enable bits TEN1 and TEN2
- Configure different trigger sources by setting different values in the TSEL1[2:0] and TSEL2[2:0] bits
- Configure the two DAC channel WAVEx[1:0] bits as "01" and set different LFSR masks values in the MAMP1[3:0] and MAMP2[3:0] bits
- Load the dual DAC channel data into the desired DHR register (DAC\_DHR12RD, DAC\_DHR12LD or DAC\_DHR8RD)

When a DAC channel1 trigger arrives, the LFSR1 counter, with the mask configured by MAMP1[3:0], is added to the DHR1 register and the sum is transferred into DAC\_DOR1 (three APB1 clock cycles later). Then the LFSR1 counter is updated.

When a DAC channel2 trigger arrives, the LFSR2 counter, with the mask configured by MAMP2[3:0], is added to the DHR2 register and the sum is transferred into DAC\_DOR2 (three APB1 clock cycles later). Then the LFSR2 counter is updated.

#### 16.4.4 Independent trigger with single triangle generation

To configure the DAC in this conversion mode, the following sequence is required:

- Set the two DAC channel trigger enable bits TEN1 and TEN2
- Configure different trigger sources by setting different values in the TSEL1[2:0] and TSEL2[2:0] bits
- Configure the two DAC channel WAVEx[1:0] bits as “1x” and the same maximum amplitude value in the MAMPx[3:0] bits
- Load the dual DAC channel data into the desired DHR register (DAC\_DHR12RD, DAC\_DHR12LD or DAC\_DHR8RD)

When a DAC channel1 trigger arrives, the DAC channel1 triangle counter, with the same triangle amplitude, is added to the DHR1 register and the sum is transferred into DAC\_DOR1 (three APB1 clock cycles later). The DAC channel1 triangle counter is then updated.

When a DAC channel2 trigger arrives, the DAC channel2 triangle counter, with the same triangle amplitude, is added to the DHR2 register and the sum is transferred into DAC\_DOR2 (three APB1 clock cycles later). The DAC channel2 triangle counter is then updated.

#### 16.4.5 Independent trigger with different triangle generation

To configure the DAC in this conversion mode, the following sequence is required:

- Set the two DAC channel trigger enable bits TEN1 and TEN2
- Configure different trigger sources by setting different values in the TSEL1[2:0] and TSEL2[2:0] bits
- Configure the two DAC channel WAVEx[1:0] bits as “1x” and set different maximum amplitude values in the MAMP1[3:0] and MAMP2[3:0] bits
- Load the dual DAC channel data into the desired DHR register (DAC\_DHR12RD, DAC\_DHR12LD or DAC\_DHR8RD)

When a DAC channel1 trigger arrives, the DAC channel1 triangle counter, with a triangle amplitude configured by MAMP1[3:0], is added to the DHR1 register and the sum is transferred into DAC\_DOR1 (three APB1 clock cycles later). The DAC channel1 triangle counter is then updated.

When a DAC channel2 trigger arrives, the DAC channel2 triangle counter, with a triangle amplitude configured by MAMP2[3:0], is added to the DHR2 register and the sum is transferred into DAC\_DOR2 (three APB1 clock cycles later). The DAC channel2 triangle counter is then updated.

#### 16.4.6 Simultaneous software start

To configure the DAC in this conversion mode, the following sequence is required:

- Load the dual DAC channel data to the desired DHR register (DAC\_DHR12RD, DAC\_DHR12LD or DAC\_DHR8RD)

In this configuration, one APB1 clock cycle later, the DHR1 and DHR2 registers are transferred into DAC\_DOR1 and DAC\_DOR2, respectively.

### 16.4.7 Simultaneous trigger without wave generation

To configure the DAC in this conversion mode, the following sequence is required:

- Set the two DAC channel trigger enable bits TEN1 and TEN2
- Configure the same trigger source for both DAC channels by setting the same value in the TSEL1[2:0] and TSEL2[2:0] bits
- Load the dual DAC channel data to the desired DHR register (DAC\_DHR12RD, DAC\_DHR12LD or DAC\_DHR8RD)

When a trigger arrives, the DHR1 and DHR2 registers are transferred into DAC\_DOR1 and DAC\_DOR2, respectively (after three APB1 clock cycles).

### 16.4.8 Simultaneous trigger with single LFSR generation

To configure the DAC in this conversion mode, the following sequence is required:

- Set the two DAC channel trigger enable bits TEN1 and TEN2
- Configure the same trigger source for both DAC channels by setting the same value in the TSEL1[2:0] and TSEL2[2:0] bits
- Configure the two DAC channel WAVEx[1:0] bits as “01” and the same LFSR mask value in the MAMPx[3:0] bits
- Load the dual DAC channel data to the desired DHR register (DHR12RD, DHR12LD or DHR8RD)

When a trigger arrives, the LFSR1 counter, with the same mask, is added to the DHR1 register and the sum is transferred into DAC\_DOR1 (three APB1 clock cycles later). The LFSR1 counter is then updated. At the same time, the LFSR2 counter, with the same mask, is added to the DHR2 register and the sum is transferred into DAC\_DOR2 (three APB1 clock cycles later). The LFSR2 counter is then updated.

### 16.4.9 Simultaneous trigger with different LFSR generation

To configure the DAC in this conversion mode, the following sequence is required:

- Set the two DAC channel trigger enable bits TEN1 and TEN2
- Configure the same trigger source for both DAC channels by setting the same value in the TSEL1[2:0] and TSEL2[2:0] bits
- Configure the two DAC channel WAVEx[1:0] bits as “01” and set different LFSR mask values using the MAMP1[3:0] and MAMP2[3:0] bits
- Load the dual DAC channel data into the desired DHR register (DAC\_DHR12RD, DAC\_DHR12LD or DAC\_DHR8RD)

When a trigger arrives, the LFSR1 counter, with the mask configured by MAMP1[3:0], is added to the DHR1 register and the sum is transferred into DAC\_DOR1 (three APB1 clock cycles later). The LFSR1 counter is then updated.

At the same time, the LFSR2 counter, with the mask configured by MAMP2[3:0], is added to the DHR2 register and the sum is transferred into DAC\_DOR2 (three APB1 clock cycles later). The LFSR2 counter is then updated.

### 16.4.10 Simultaneous trigger with single triangle generation

To configure the DAC in this conversion mode, the following sequence is required:

- Set the two DAC channel trigger enable bits TEN1 and TEN2
- Configure the same trigger source for both DAC channels by setting the same value in the TSEL1[2:0] and TSEL2[2:0] bits
- Configure the two DAC channel WAVEx[1:0] bits as “1x” and the same maximum amplitude value using the MAMPx[3:0] bits
- Load the dual DAC channel data into the desired DHR register (DAC\_DHR12RD, DAC\_DHR12LD or DAC\_DHR8RD)

When a trigger arrives, the DAC channel1 triangle counter, with the same triangle amplitude, is added to the DHR1 register and the sum is transferred into DAC\_DOR1 (three APB1 clock cycles later). The DAC channel1 triangle counter is then updated.

At the same time, the DAC channel2 triangle counter, with the same triangle amplitude, is added to the DHR2 register and the sum is transferred into DAC\_DOR2 (three APB1 clock cycles later). The DAC channel2 triangle counter is then updated.

### 16.4.11 Simultaneous trigger with different triangle generation

To configure the DAC in this conversion mode, the following sequence is required:

- Set the two DAC channel trigger enable bits TEN1 and TEN2
- Configure the same trigger source for both DAC channels by setting the same value in the TSEL1[2:0] and TSEL2[2:0] bits
- Configure the two DAC channel WAVEx[1:0] bits as “1x” and set different maximum amplitude values in the MAMP1[3:0] and MAMP2[3:0] bits
- Load the dual DAC channel data into the desired DHR register (DAC\_DHR12RD, DAC\_DHR12LD or DAC\_DHR8RD)

When a trigger arrives, the DAC channel1 triangle counter, with a triangle amplitude configured by MAMP1[3:0], is added to the DHR1 register and the sum is transferred into DAC\_DOR1 (three APB1 clock cycles later). Then the DAC channel1 triangle counter is updated.

At the same time, the DAC channel2 triangle counter, with a triangle amplitude configured by MAMP2[3:0], is added to the DHR2 register and the sum is transferred into DAC\_DOR2 (three APB1 clock cycles later). Then the DAC channel2 triangle counter is updated.

## 16.5 DAC registers

Refer to [Section 1 on page 62](#) for a list of abbreviations used in register descriptions.

The peripheral registers have to be accessed by words (32 bits).

### 16.5.1 DAC control register (DAC\_CR)

Address offset: 0x00

Bits 31:30 Reserved, must be kept at reset value.

Bit 29 **DMAUDRIE2**: DAC channel2 DMA underrun interrupt enable

This bit is set and cleared by software.

0: DAC channel2 DMA underrun interrupt disabled

1: DAC channel2 DMA underrun interrupt enabled

Bit 28 **DMAEN2**: DAC channel2 DMA enable

This bit is set and cleared by software.

0: DAC channel2 DMA mode disabled

1: DAC channel2 DMA mode enabled

Bits 27:24 **MAMP2[3:0]**: DAC channel2 mask/amplitude selector

These bits are written by software to select mask in wave generation mode or amplitude in triangle generation mode.

0000: Unmask bit0 of LFSR/ triangle amplitude equal to 1

0001: Unmask bits[1:0] of LFSR/ triangle amplitude equal to 3

0010: Unmask bits[2:0] of LFSR/ triangle amplitude equal to 7

0011: Unmask bits[3:0] of LFSR/ triangle amplitude equal to 15

0100: Unmask bits[4:0] of LFSR/ triangle amplitude equal to 31

0101: Unmask bits[5:0] of LFSR/ triangle amplitude equal to 63

0110: Unmask bits[6:0] of LFSR/ triangle amplitude equal to 127

0111: Unmask bits[7:0] of LFSR/ triangle amplitude equal to 255

1000: Unmask bits[8:0] of LFSR/ triangle amplitude equal to 511

1001: Unmask bits[9:0] of LFSR/ triangle amplitude equal to 1023

1010: Unmask bits[10:0] of LFSR/ triangle amplitude equal to 2047

≥ 1011: Unmask bits[11:0] of LFSR/ triangle amplitude equal to 4095

Bits 23:22 **WAVE2[1:0]**: DAC channel2 noise/triangle wave generation enable

These bits are set/reset by software.

00: wave generation disabled

01: Noise wave generation enabled

1x: Triangle wave generation enabled

*Note: Only used if bit TEN2 = 1 (DAC channel2 trigger enabled)*

Bits 21:19 **TSEL2[2:0]**: DAC channel2 trigger selection

These bits select the external event used to trigger DAC channel2

000: Timer 6 TRGO event

001: Timer 8 TRGO event

010: Timer 7 TRGO event

011: Timer 5 TRGO event

100: Timer 2 TRGO event

101: Timer 4 TRGO event

110: External line9

111: Software trigger

*Note: Only used if bit TEN2 = 1 (DAC channel2 trigger enabled).*

Bit 18 **TEN2**: DAC channel2 trigger enable

This bit is set and cleared by software to enable/disable DAC channel2 trigger

0: DAC channel2 trigger disabled and data written into the DAC\_DHRx register are transferred one APB1 clock cycle later to the DAC\_DOR2 register

1: DAC channel2 trigger enabled and data from the DAC\_DHRx register are transferred three APB1 clock cycles later to the DAC\_DOR2 register

*Note: When software trigger is selected, the transfer from the DAC\_DHRx register to the DAC\_DOR2 register takes only one APB1 clock cycle.*

Bit 17 **BOFF2**: DAC channel2 output buffer disable

This bit is set and cleared by software to enable/disable DAC channel2 output buffer.

0: DAC channel2 output buffer enabled

1: DAC channel2 output buffer disabled

Bit 16 **EN2**: DAC channel2 enable

This bit is set and cleared by software to enable/disable DAC channel2.

0: DAC channel2 disabled

1: DAC channel2 enabled

Bits 15:14 Reserved, must be kept at reset value.

Bit 13 **DMAUDRIE1**: DAC channel1 DMA Underrun Interrupt enable

This bit is set and cleared by software.

0: DAC channel1 DMA Underrun Interrupt disabled

1: DAC channel1 DMA Underrun Interrupt enabled

Bit 12 **DMAEN1**: DAC channel1 DMA enable

This bit is set and cleared by software.

0: DAC channel1 DMA mode disabled

1: DAC channel1 DMA mode enabled

Bits 11:8 **MAMP1[3:0]**: DAC channel1 mask/amplitude selector

These bits are written by software to select mask in wave generation mode or amplitude in triangle generation mode.

0000: Unmask bit0 of LFSR/ triangle amplitude equal to 1  
 0001: Unmask bits[1:0] of LFSR/ triangle amplitude equal to 3  
 0010: Unmask bits[2:0] of LFSR/ triangle amplitude equal to 7  
 0011: Unmask bits[3:0] of LFSR/ triangle amplitude equal to 15  
 0100: Unmask bits[4:0] of LFSR/ triangle amplitude equal to 31  
 0101: Unmask bits[5:0] of LFSR/ triangle amplitude equal to 63  
 0110: Unmask bits[6:0] of LFSR/ triangle amplitude equal to 127  
 0111: Unmask bits[7:0] of LFSR/ triangle amplitude equal to 255  
 1000: Unmask bits[8:0] of LFSR/ triangle amplitude equal to 511  
 1001: Unmask bits[9:0] of LFSR/ triangle amplitude equal to 1023  
 1010: Unmask bits[10:0] of LFSR/ triangle amplitude equal to 2047  
 ≥ 1011: Unmask bits[11:0] of LFSR/ triangle amplitude equal to 4095

Bits 7:6 **WAVE1[1:0]**: DAC channel1 noise/triangle wave generation enable

These bits are set and cleared by software.

00: wave generation disabled  
 01: Noise wave generation enabled  
 1x: Triangle wave generation enabled

*Note: Only used if bit TEN1 = 1 (DAC channel1 trigger enabled).*

Bits 5:3 **TSEL1[2:0]**: DAC channel1 trigger selection

These bits select the external event used to trigger DAC channel1.

000: Timer 6 TRGO event  
 001: Timer 8 TRGO event  
 010: Timer 7 TRGO event  
 011: Timer 5 TRGO event  
 100: Timer 2 TRGO event  
 101: Timer 4 TRGO event  
 110: External line9  
 111: Software trigger

*Note: Only used if bit TEN1 = 1 (DAC channel1 trigger enabled).*

Bit 2 **TEN1**: DAC channel1 trigger enable

This bit is set and cleared by software to enable/disable DAC channel1 trigger.

0: DAC channel1 trigger disabled and data written into the DAC\_DHRx register are transferred one APB1 clock cycle later to the DAC\_DOR1 register  
 1: DAC channel1 trigger enabled and data from the DAC\_DHRx register are transferred three APB1 clock cycles later to the DAC\_DOR1 register

*Note: When software trigger is selected, the transfer from the DAC\_DHRx register to the DAC\_DOR1 register takes only one APB1 clock cycle.*

Bit 1 **BOFF1**: DAC channel1 output buffer disable

This bit is set and cleared by software to enable/disable DAC channel1 output buffer.

0: DAC channel1 output buffer enabled  
 1: DAC channel1 output buffer disabled

Bit 0 **EN1**: DAC channel1 enable

This bit is set and cleared by software to enable/disable DAC channel1.

0: DAC channel1 disabled  
 1: DAC channel1 enabled

### 16.5.2 DAC software trigger register (DAC\_SWTRIGR)

Address offset: 0x04

Reset value: 0x0000 0000

|      |      |      |      |      |      |      |      |      |      |      |      |      |      |         |         |
|------|------|------|------|------|------|------|------|------|------|------|------|------|------|---------|---------|
| 31   | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21   | 20   | 19   | 18   | 17      | 16      |

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **SWTRIG2**: DAC channel2 software trigger

This bit is set and cleared by software to enable/disable the software trigger.

0: Software trigger disabled

1: Software trigger enabled

*Note: This bit is cleared by hardware (one APB1 clock cycle later) once the DAC\_DHR2 register value has been loaded into the DAC\_DOR2 register.*

Bit 0 **SWTRIG1**: DAC channel1 software trigger

This bit is set and cleared by software to enable/disable the software trigger.

0: Software trigger disabled

1: Software trigger enabled

*Note: This bit is cleared by hardware (one APB1 clock cycle later) once the DAC\_DHR1 register value has been loaded into the DAC\_DOR1 register.*

### 16.5.3 DAC channel1 12-bit right-aligned data holding register (DAC\_DHR12R1)

Address offset: 0x08

Reset value: 0x0000 0000

|      |      |      |      |                |      |      |      |      |      |      |      |      |      |      |      |

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:8 **DACC2DHR[7:0]**: DAC channel2 8-bit right-aligned data

These bits are written by software which specifies 8-bit data for DAC channel2.

Bits 7:0 **DACC1DHR[7:0]**: DAC channel1 8-bit right-aligned data

These bits are written by software which specifies 8-bit data for DAC channel1.

### 16.5.12 DAC channel1 data output register (DAC\_DOR1)

Address offset: 0x2C

Reset value: 0x0000 0000

Bits 31:30 Reserved, must be kept at reset value.

Bit 29 **DMAUDR2**: DAC channel2 DMA underrun flag

This bit is set by hardware and cleared by software (by writing it to 1).

0: No DMA underrun error condition occurred for DAC channel2

1: DMA underrun error condition occurred for DAC channel2 (the currently selected trigger is driving DAC channel2 conversion at a frequency higher than the DMA service capability rate)

Bits 28:14 Reserved, must be kept at reset value.

Bit 13 **DMAUDR1**: DAC channel1 DMA underrun flag

This bit is set by hardware and cleared by software (by writing it to 1).

0: No DMA underrun error condition occurred for DAC channel1

1: DMA underrun error condition occurred for DAC channel1 (the currently selected trigger is driving DAC channel1 conversion at a frequency higher than the DMA service capability rate)

Bits 12:0 Reserved, must be kept at reset value.

## 16.5.15 DAC register map

Table 104 summarizes the DAC registers.

Table 104. DAC register map

| Offset | Register name | 31             | 30  | 29        | 28     | 27             | 26  | 25  | 24  | 23         | 22  | 21         | 20  | 19   | 18    | 17  | 16             | 15  | 14        | 13             | 12            | 11             | 10  | 9   | 8          | 7             | 6          | 5   | 4    | 3     | 2   | 1       | 0       |     |     |     |

Refer to [Section 2.2.2 on page 69](#) for the register boundary addresses.

## 17 Digital camera interface (DCMI)

### 17.1 DCMI introduction

The digital camera is a synchronous parallel interface able to receive a high-speed data flow from an external 8-, 10-, 12- or 14-bit CMOS camera module. It supports different data formats: YCbCr4:2:2/RGB565 progressive video and compressed data (JPEG).

This interface is for use with black & white cameras, X24 and X5 cameras, and it is assumed that all preprocessing like resizing is performed in the camera module.

### 17.2 DCMI main features

- 8-, 10-, 12- or 14-bit parallel interface
- Embedded/external line and frame synchronization
- Continuous or snapshot mode
- Crop feature
- Supports the following data formats:
  - 8/10/12/14-bit progressive video: either monochrome or raw bayer
  - YCbCr 4:2:2 progressive video
  - RGB 565 progressive video
  - Compressed data: JPEG

### 17.3 DCMI clocks

The digital camera interface uses two clock domains, DCMI\_PIXCLK and HCLK. The signals generated with DCMI\_PIXCLK are sampled on the rising edge of HCLK once they are stable. An enable signal is generated in the HCLK domain, to indicate that data coming from the camera are stable and can be sampled. The maximum DCMI\_PIXCLK period must be higher than 2.5 HCLK periods.

### 17.4 DCMI functional overview

The digital camera interface is a synchronous parallel interface that can receive high-speed (up to 54 Mbytes/s) data flows. It consists of up to 14 data lines (D13-D0) and a pixel clock line (DCMI\_PIXCLK). The pixel clock has a programmable polarity, so that data can be captured on either the rising or the falling edge of the pixel clock.

The data are packed into a 32-bit data register (DCMI\_DR) and then transferred through a general-purpose DMA channel. The image buffer is managed by the DMA, not by the camera interface.

The data received from the camera can be organized in lines/frames (raw YUB/RGB/Bayer modes) or can be a sequence of JPEG images. To enable JPEG image reception, the JPEG bit (bit 3 of DCMI\_CR register) must be set.

The data flow is synchronized either by hardware using the optional DCMI\_HSYNC (horizontal synchronization) and DCMI\_VSYNC (vertical synchronization) signals or by synchronization codes embedded in the data flow.

### 17.4.1 DCMI block diagram

Figure 102 shows the DCMI block diagram.

Figure 102. DCMI block diagram

Figure 103. Top-level block diagram

### 17.4.2 DMA interface

The DMA interface is active when the CAPTURE bit in the DCMI\_CR register is set. A DMA request is generated each time the camera interface receives a complete 32-bit data block in its register.

### 17.4.3 DCMI physical interface

The interface is composed of 11/13/15/17 inputs. Only the Slave mode is supported.

The camera interface can capture 8-bit, 10-bit, 12-bit or 14-bit data depending on the EDM[1:0] bits in the DCMI\_CR register. If less than 14 bits are used, the unused input pins must be connected to ground.

[Table 105](#) shows the DCMI pins.

**Table 105. DCMI external signals**

| Signal name |               | Signal type    | Signal description                      |
|-------------|---------------|----------------|-----------------------------------------|
| 8 bits      | DCMI_D[0..7]  | Digital inputs | DCMI data                               |
| 10 bits     | DCMI_D[0..9]  |                |                                         |
| 12 bits     | DCMI_D[0..11] |                |                                         |
| 14 bits     | DCMI_D[0..13] |                |                                         |
| DCMI_PIXCLK |               | Digital input  | Pixel clock                             |
| DCMI_HSYNC  |               | Digital input  | Horizontal synchronization / Data valid |
| DCMI_VSYNC  |               | Digital input  | Vertical synchronization                |

The data are synchronous with DCMI\_PIXCLK and change on the rising/falling edge of the pixel clock depending on the polarity.

The DCMI\_HSYNC signal indicates the start/end of a line.

The DCMI\_VSYNC signal indicates the start/end of a frame

**Figure 104. DCMI signal waveforms**

1. The capture edge of DCMI\_PIXCLK is the falling edge, the active state of DCMI\_HSYNC and DCMI\_VSYNC is 1.
2. DCMI\_HSYNC and DCMI\_VSYNC can change states at the same time.

### 8-bit data

When EDM[1:0] in DCMI\_CR are programmed to “00” the interface captures 8 LSBs at its input (DCMI\_D[0:7]) and stores them as 8-bit data. The DCMI\_D[13:8] inputs are ignored. In this case, to capture a 32-bit word, the camera interface takes four pixel clock cycles.

The first captured data byte is placed in the LSB position in the 32-bit word and the 4<sup>th</sup> captured data byte is placed in the MSB position in the 32-bit word. [Table 106](#) gives an example of the positioning of captured data bytes in two 32-bit words.

**Table 106. Positioning of captured data bytes in 32-bit words (8-bit width)**

| Byte address | 31:24          | 23:16          | 15:8           | 7:0            |
|--------------|----------------|----------------|----------------|----------------|
| 0            | $D_{n+3}[7:0]$ | $D_{n+2}[7:0]$ | $D_{n+1}[7:0]$ | $D_n[7:0]$     |
| 4            | $D_{n+7}[7:0]$ | $D_{n+6}[7:0]$ | $D_{n+5}[7:0]$ | $D_{n+4}[7:0]$ |

**10-bit data**

When EDM[1:0] in DCMI\_CR are programmed to “01”, the camera interface captures 10-bit data at its input DCMI\_D[0..9] and stores them as the 10 least significant bits of a 16-bit word. The remaining most significant bits in the DCMI\_DR register (bits 11 to 15) are cleared to zero. So, in this case, a 32-bit data word is made up every two pixel clock cycles.

The first captured data are placed in the LSB position in the 32-bit word and the 2<sup>nd</sup> captured data are placed in the MSB position in the 32-bit word as shown in [Table 107](#).

**Table 107. Positioning of captured data bytes in 32-bit words (10-bit width)**

| Byte address | 31:26 | 25:16          | 15:10 | 9:0            |
|--------------|-------|----------------|-------|----------------|
| 0            | 0     | $D_{n+1}[9:0]$ | 0     | $D_n[9:0]$     |
| 4            | 0     | $D_{n+3}[9:0]$ | 0     | $D_{n+2}[9:0]$ |

**12-bit data**

When EDM[1:0] in DCMI\_CR are programmed to “10”, the camera interface captures the 12-bit data at its input DCMI\_D[0..11] and stores them as the 12 least significant bits of a 16-bit word. The remaining most significant bits are cleared to zero. So, in this case a 32-bit data word is made up every two pixel clock cycles.

The first captured data are placed in the LSB position in the 32-bit word and the 2<sup>nd</sup> captured data are placed in the MSB position in the 32-bit word as shown in [Table 108](#).

**Table 108. Positioning of captured data bytes in 32-bit words (12-bit width)**

| Byte address | 31:28 | 27:16           | 15:12 | 11:0            |
|--------------|-------|-----------------|-------|-----------------|
| 0            | 0     | $D_{n+1}[11:0]$ | 0     | $D_n[11:0]$     |
| 4            | 0     | $D_{n+3}[11:0]$ | 0     | $D_{n+2}[11:0]$ |

**14-bit data**

When EDM[1:0] in DCMI\_CR are programmed to “11”, the camera interface captures the 14-bit data at its input DCMI\_D[0..13] and stores them as the 14 least significant bits of a 16-bit word. The remaining most significant bits are cleared to zero. So, in this case a 32-bit data word is made up every two pixel clock cycles.

The first captured data are placed in the LSB position in the 32-bit word and the 2<sup>nd</sup> captured data are placed in the MSB position in the 32-bit word as shown in [Table 109](#).

Table 109. Positioning of captured data bytes in 32-bit words (14-bit width)

| Byte address | 31:30 | 29:16           | 15:14 | 13:0            |
|--------------|-------|-----------------|-------|-----------------|
| 0            | 0     | $D_{n+1}[13:0]$ | 0     | $D_n[13:0]$     |
| 4            | 0     | $D_{n+3}[13:0]$ | 0     | $D_{n+2}[13:0]$ |

#### 17.4.4 Synchronization

The digital camera interface supports embedded or hardware (DCMI\_HSYNC and DCMI\_VSYNC) synchronization. When embedded synchronization is used, it is up to the digital camera module to make sure that the 0x00 and 0xFF values are used ONLY for synchronization (not in data). Embedded synchronization codes are supported only for the 8-bit parallel data interface width (that is, in the DCMI\_CR register, the EDM[1:0] bits should be cleared to “00”).

For compressed data, the DCMI supports only the hardware synchronization mode. In this case, DCMI\_VSYNC is used as a start/end of the image, and DCMI\_HSYNC is used as a Data Valid signal. [Figure 105](#) shows the corresponding timing diagram.

Figure 105. Timing diagram

#### Hardware synchronization mode

In hardware synchronization mode, the two synchronization signals (DCMI\_HSYNC/DCMI\_VSYNC) are used.

Depending on the camera module/mode, data may be transmitted during horizontal/vertical synchronization periods. The DCMI\_HSYNC/DCMI\_VSYNC signals act like blanking signals since all the data received during DCMI\_HSYNC/DCMI\_VSYNC active periods are ignored.

In order to correctly transfer images into the DMA/RAM buffer, data transfer is synchronized with the DCMI\_VSYNC signal. When the hardware synchronization mode is selected, and

capture is enabled (CAPTURE bit set in DCMI\_CR), data transfer is synchronized with the deactivation of the DCMI\_VSYNC signal (next start of frame).

Transfer can then be continuous, with successive frames transferred by DMA to successive buffers or the same/circular buffer. To allow the DMA management of successive frames, a VSIF (Vertical synchronization interrupt flag) is activated at the end of each frame.

### Embedded data synchronization mode

In this synchronization mode, the data flow is synchronized using 32-bit codes embedded in the data flow. These codes use the 0x00/0xFF values that are *not* used in data anymore. There are 4 types of codes, all with a 0xFF0000XY format. The embedded synchronization codes are supported only in 8-bit parallel data width capture (in the DCMI\_CR register, the EDM[1:0] bits should be programmed to "00"). For other data widths, this mode generates unpredictable results and must not be used.

*Note: Camera modules can have 8 such codes (in interleaved mode). For this reason, the interleaved mode is not supported by the camera interface (otherwise, every other half-frame would be discarded).*

- Mode 2

Four embedded codes signal the following events

- Frame start (FS)
- Frame end (FE)
- Line start (LS)
- Line end (LE)

The XY values in the 0xFF0000XY format of the four codes are programmable (see [Section 17.7.7: DCMI embedded synchronization code register \(DCMI\\_ESCR\)](#)).

A 0xFF value programmed as a "frame end" means that all the unused codes are interpreted as valid frame end codes.

In this mode, once the camera interface has been enabled, the frame capture starts after the first occurrence of the frame end (FE) code followed by a frame start (FS) code.

- Mode 1

An alternative coding is the camera mode 1. This mode is ITU656 compatible.

The codes signal another set of events:

- SAV (active line) - line start
- EAV (active line) - line end
- SAV (blanking) - end of line during interframe blanking period
- EAV (blanking) - end of line during interframe blanking period

This mode can be supported by programming the following codes:

- FS ≤ 0xFF
- FE ≤ 0xFF
- LS ≤ SAV (active)
- LE ≤ EAV (active)

An embedded unmask code is also implemented for frame/line start and frame/line end codes. Using it, it is possible to compare only the selected unmasked bits with the programmed code. You can therefore select a bit to compare in the embedded code and

detect a frame/line start or frame/line end. This means that there can be different codes for the frame/line start and frame/line end with the unmasked bit position remaining the same.

### Example

FS = 0xA5

Unmask code for FS = 0x10

In this case the frame start code is embedded in the bit 4 of the frame start code.

## 17.4.5 Capture modes

This interface supports two types of capture: snapshot (single frame) and continuous grab.

### Snapshot mode (single frame)

In this mode, a single frame is captured (CM = '1' in the DCMI\_CR register). After the CAPTURE bit is set in DCMI\_CR, the interface waits for the detection of a start of frame before sampling the data. The camera interface is automatically disabled (CAPTURE bit cleared in DCMI\_CR) after receiving the first complete frame. An interrupt is generated (IT\_FRAME) if it is enabled.

In case of an overrun, the frame is lost and the CAPTURE bit is cleared.

**Figure 106. Frame capture waveforms in snapshot mode**

1. Here, the active state of DCMI\_HSYNC and DCMI\_VSYNC is 1.
2. DCMI\_HSYNC and DCMI\_VSYNC can change states at the same time.

### Continuous grab mode

In this mode (CM bit = '0' in DCMI\_CR), once the CAPTURE bit has been set in DCMI\_CR, the grabbing process starts on the next DCMI\_VSYNC or embedded frame start depending on the mode. The process continues until the CAPTURE bit is cleared in DCMI\_CR. Once the CAPTURE bit has been cleared, the grabbing process continues until the end of the current frame.

Figure 107. Frame capture waveforms in continuous grab mode

1. Here, the active state of DCMI\_HSYNC and DCMI\_VSYNC is 1.
2. DCMI\_HSYNC and DCMI\_VSYNC can change states at the same time.

In continuous grab mode, you can configure the FCRC bits in DCMI\_CR to grab all pictures, every second picture or one out of four pictures to decrease the frame capture rate.

**Note:** *In the hardware synchronization mode (ESS = '0' in DCMI\_CR), the IT\_VSYNC interrupt is generated (if enabled) even when CAPTURE = '0' in DCMI\_CR so, to reduce the frame capture rate even further, the IT\_VSYNC interrupt can be used to count the number of frames between 2 captures in conjunction with the Snapshot mode. This is not allowed by embedded data synchronization mode.*

### 17.4.6 Crop feature

With the crop feature, the camera interface can select a rectangular window from the received image. The start (upper left corner) coordinates and size (horizontal dimension in number of pixel clocks and vertical dimension in number of lines) are specified using two 32-bit registers (DCMI\_CWSTRT and DCMI\_CWSIZE). The size of the window is specified in number of pixel clocks (horizontal dimension) and in number of lines (vertical dimension).

Figure 108. Coordinates and size of the window after cropping

These registers specify the coordinates of the starting point of the capture window as a line number (in the frame, starting from 0) and a number of pixel clocks (on the line, starting from 0), and the size of the window as a line number and a number of pixel clocks. The CAPCNT value can only be a multiple of 4 (two least significant bits are forced to 0) to allow the correct transfer of data through the DMA.

If the DCMI\_VSYNC signal goes active before the number of lines is specified in the DCMI\_CWSIZE register, then the capture stops and an IT\_FRAME interrupt is generated when enabled.

**Figure 109. Data capture waveforms**

1. Here, the active state of DCMI\_HSYNC and DCMI\_VSYNC is 1.
2. DCMI\_HSYNC and DCMI\_VSYNC can change states at the same time.

#### 17.4.7 JPEG format

To allow JPEG image reception, it is necessary to set the JPEG bit in the DCMI\_CR register. JPEG images are not stored as lines and frames, so the DCMI\_VSYNC signal is used to start the capture while DCMI\_HSYNC serves as a data enable signal. The number of bytes in a line may not be a multiple of 4, you should therefore be careful when handling this case since a DMA request is generated each time a complete 32-bit word has been constructed from the captured data. When an end of frame is detected and the 32-bit word to be transferred has not been completely received, the remaining data are padded with '0s' and a DMA request is generated.

The crop feature and embedded synchronization codes cannot be used in the JPEG format.

#### 17.4.8 FIFO

##### Input mode

A four-word FIFO is implemented to manage data rate transfers on the AHB. The DCMI features a simple FIFO controller with a read pointer incremented each time the camera interface reads from the AHB, and a write pointer incremented each time the camera interface writes to the FIFO. There is no overrun protection to prevent the data from being overwritten if the AHB interface does not sustain the data transfer rate.

In case of overrun or errors in the synchronization signals, the FIFO is reset and the DCMI interface waits for a new start of frame.

## 17.5 Data format description

### 17.5.1 Data formats

Three types of data are supported:

- 8/10/12/14-bit progressive video: either monochrome or raw Bayer format
- YCbCr 4:2:2 progressive video
- RGB565 progressive video. A pixel coded in 16 bits (5 bits for blue, 5 bits for red, 6 bits for green) takes two clock cycles to be transferred.

Compressed data: JPEG

For B&W, YCbCr or RGB data, the maximum input size is  $2048 \times 2048$  pixels. No limit in JPEG compressed mode.

For monochrome, RGB & YCbCr, the frame buffer is stored in raster mode. 32-bit words are used. Only the little endian format is supported.

**Figure 110. Pixel raster scan order**

### 17.5.2 Monochrome format

Characteristics:

- Raster format
- 8 bits per pixel

[Table 110](#) shows how the data are stored.

**Table 110. Data storage in monochrome progressive video format**

| Byte address | 31:24   | 23:16   | 15:8    | 7:0     |
|--------------|---------|---------|---------|---------|
| 0            | $n + 3$ | $n + 2$ | $n + 1$ | $n$     |
| 4            | $n + 7$ | $n + 6$ | $n + 5$ | $n + 4$ |

### 17.5.3 RGB format

Characteristics:

- Raster format
- RGB
- Interleaved: one buffer: R, G & B interleaved: BRGBRGBRG, etc.
- Optimized for display output

The RGB planar format is compatible with standard OS frame buffer display formats.

Only 16 BPP (bits per pixel): RGB565 (2 pixels per 32-bit word) is supported.

The 24 BPP (palletized format) and grayscale formats are not supported. Pixels are stored in a raster scan order, that is from top to bottom for pixel rows, and from left to right within a pixel row. Pixel components are R (red), G (green) and B (blue). All components have the same spatial resolution (4:4:4 format). A frame is stored in a single part, with the components interleaved on a pixel basis.

[Table 111](#) shows how the data are stored.

**Table 111. Data storage in RGB progressive video format**

| Byte address | 31:27     | 26:21       | 20:16      | 15:11     | 10:5        | 4:0        |
|--------------|-----------|-------------|------------|-----------|-------------|------------|
| 0            | Red n + 1 | Green n + 1 | Blue n + 1 | Red n     | Green n     | Blue n     |
| 4            | Red n + 4 | Green n + 3 | Blue n + 3 | Red n + 2 | Green n + 2 | Blue n + 2 |

### 17.5.4 YCbCr format

Characteristics:

- Raster format
- YCbCr 4:2:2
- Interleaved: one Buffer: Y, Cb & Cr interleaved: CbYCrYCbYCr, etc.

Pixel components are Y (luminance or “luma”), Cb and Cr (chrominance or “chroma” blue and red). Each component is encoded in 8 bits. Luma and chroma are stored together (interleaved) as shown in [Table 112](#).

**Table 112. Data storage in YCbCr progressive video format**

| Byte address | 31:24   | 23:16    | 15:8    | 7:0      |
|--------------|---------|----------|---------|----------|
| 0            | Y n + 1 | Cr n     | Y n     | Cb n     |
| 4            | Y n + 3 | Cr n + 2 | Y n + 2 | Cb n + 2 |

### 17.5.5 YCbCr format - Y only

Characteristics:

- Raster format
- YCbCr 4:2:2
- The buffer only contains Y information - monochrome image

Pixel components are Y (luminance or “luma”), Cb and Cr (chrominance or “chroma” blue and red). In this mode, the chroma information is dropped. Only Luma component of each

pixel, encoded in 8 bits, is stored as shown in [Table 113](#).

The result is a monochrome image having the same resolution as the original YCbCr data.

**Table 113. Data storage in YCbCr progressive video format - Y extraction mode**

| Byte address | 31:24     | 23:16     | 15:8      | 7:0       |
|--------------|-----------|-----------|-----------|-----------|
| 0            | $Y_{n+3}$ | $Y_{n+2}$ | $Y_{n+1}$ | $Y_n$     |
| 4            | $Y_{n+7}$ | $Y_{n+6}$ | $Y_{n+5}$ | $Y_{n+4}$ |

### 17.5.6 Half resolution image extraction

This is a modification of the previous reception modes, being applicable to monochrome, RGB or Y extraction modes.

This mode allows to only store a half resolution image. It is selected through OELS and LSM control bits.

## 17.6 DCMI interrupts

Five interrupts are generated. All interrupts are maskable by software. The global interrupt (IT\_DCMI) is the OR of all the individual interrupts. [Table 114](#) gives the list of all interrupts.

**Table 114. DCMI interrupts**

| Interrupt name | Interrupt event                                                                     |
|----------------|-------------------------------------------------------------------------------------|
| IT_LINE        | Indicates the end of line                                                           |
| IT_FRAME       | Indicates the end of frame capture                                                  |
| IT_OVR         | indicates the overrun of data reception                                             |
| IT_VSYNC       | Indicates the synchronization frame                                                 |
| IT_ERR         | Indicates the detection of an error in the embedded synchronization frame detection |
| IT_DCMI        | Logic OR of the previous interrupts                                                 |

## 17.7 DCMI register description

All DCMI registers have to be accessed as 32-bit words, otherwise a bus error occurs.

### 17.7.1 DCMI control register (DCMI\_CR)

Address offset: 0x00

Reset value: 0x0000 0000

|      |        |      |      |          |      |           |      |       |       |        |      |      |      |          |         |
|------|--------|------|------|----------|------|-----------|------|-------|-------|--------|------|------|------|----------|---------|
| 31   | 30     | 29   | 28   | 27       | 26   | 25        | 24   | 23    | 22    | 21     | 20   | 19   | 18   | 17       | 16      |
| Res. | Res.   | Res. | Res. | Res.     | Res. | Res.      | Res. | Res.  | Res.  | Res.   | OELS | LSM  | OEBS | BSM[1:0] |         |
|      |        |      |      |          |      |           |      |       |       |        | rw   | rw   | rw   | rw       | rw      |
| 15   | 14     | 13   | 12   | 11       | 10   | 9         | 8    | 7     | 6     | 5      | 4    | 3    | 2    | 1        | 0       |
| Res. | ENABLE | Res. | Res. | EDM[1:0] |      | FCRC[1:0] |      | VSPOL | HSPOL | PCKPOL | ESS  | JPEG | CROP | CM       | CAPTURE |
|      | rw     |      |      | rw       | rw   | rw        | rw   | rw    | rw    | rw     | rw   | rw   | rw   | rw       | rw      |

Bits 31:21 Reserved, must be kept at reset value.

Bit 20 **OELS**: Odd/Even Line Select (Line Select Start)

This bit works in conjunction with LSM field (LSM = 1)

0: Interface captures first line after the frame start, second one being dropped

1: Interface captures second line from the frame start, first one being dropped

Bit 19 **LSM**: Line Select mode

0: Interface captures all received lines

1: Interface captures one line out of two.

Bit 18 **OEBS**: Odd/Even Byte Select (Byte Select Start)

This bit works in conjunction with BSM field (BSM <> 00)

0: Interface captures first data (byte or double byte) from the frame/line start, second one being dropped

1: Interface captures second data (byte or double byte) from the frame/line start, first one being dropped

Bits 17:16 **BSM[1:0]**: Byte Select mode

00: Interface captures all received data

01: Interface captures every other byte from the received data

10: Interface captures one byte out of four

11: Interface captures two bytes out of four

*Note: This mode only work for EDM[1:0]=00. For all other EDM values, this bit field must be programmed to the reset value.*

Bit 15 Reserved, must be kept at reset value.

Bit 14 **ENABLE**: DCMI enable

0: DCMI disabled

1: DCMI enabled

*Note: The DCMI configuration registers should be programmed correctly before enabling this Bit*

Bits 13:12 Reserved, must be kept at reset value.

Bits 11:10 **EDM[1:0]**: Extended data mode

00: Interface captures 8-bit data on every pixel clock

01: Interface captures 10-bit data on every pixel clock

10: Interface captures 12-bit data on every pixel clock

11: Interface captures 14-bit data on every pixel clock

Bits 9:8 **FCRC[1:0]**: Frame capture rate control

These bits define the frequency of frame capture. They are meaningful only in Continuous grab mode. They are ignored in snapshot mode.

00: All frames are captured

01: Every alternate frame captured (50% bandwidth reduction)

10: One frame in 4 frames captured (75% bandwidth reduction)

11: reserved

**Bit 7 VSPOL:** Vertical synchronization polarity

This bit indicates the level on the DCMI\_VSYNC pin when the data are not valid on the parallel interface.

0: DCMI\_VSYNC active low

1: DCMI\_VSYNC active high

**Bit 6 HSPOL:** Horizontal synchronization polarity

This bit indicates the level on the DCMI\_HSYNC pin when the data are not valid on the parallel interface.

0: DCMI\_HSYNC active low

1: DCMI\_HSYNC active high

**Bit 5 PCKPOL:** Pixel clock polarity

This bit configures the capture edge of the pixel clock

0: Falling edge active.

1: Rising edge active.

**Bit 4 ESS:** Embedded synchronization select

0: Hardware synchronization data capture (frame/line start/stop) is synchronized with the DCMI\_HSYNC/DCMI\_VSYNC signals.

1: Embedded synchronization data capture is synchronized with synchronization codes embedded in the data flow.

*Note:* Valid only for 8-bit parallel data. HSPOL/VSPOL are ignored when the ESS bit is set.

This bit is disabled in JPEG mode.

**Bit 3 JPEG:** JPEG format

0: Uncompressed video format

1: This bit is used for JPEG data transfers. The DCMI\_HSYNC signal is used as data enable. The crop and embedded synchronization features (ESS bit) cannot be used in this mode.

**Bit 2 CROP:** Crop feature

0: The full image is captured. In this case the total number of bytes in an image frame should be a multiple of 4

1: Only the data inside the window specified by the crop register will be captured. If the size of the crop window exceeds the picture size, then only the picture size is captured.

**Bit 1 CM:** Capture mode

0: Continuous grab mode - The received data are transferred into the destination memory through the DMA. The buffer location and mode (linear or circular buffer) is controlled through the system DMA.

1: Snapshot mode (single frame) - Once activated, the interface waits for the start of frame and then transfers a single frame through the DMA. At the end of the frame, the CAPTURE bit is automatically reset.

Bit 0 **CAPTURE**: Capture enable

0: Capture disabled.

1: Capture enabled.

The camera interface waits for the first start of frame, then a DMA request is generated to transfer the received data into the destination memory.

In snapshot mode, the CAPTURE bit is automatically cleared at the end of the 1st frame received.

In continuous grab mode, if the software clears this bit while a capture is ongoing, the bit will be effectively cleared after the frame end.

*Note: The DMA controller and all DCMI configuration registers should be programmed correctly before enabling this bit.*

### 17.7.2 DCMI status register (DCMI\_SR)

Address offset: 0x04

Reset value: 0x0000 0000

|      |      |      |      |      |      |      |      |      |      |      |      |      |      |       |       |
|------|------|------|------|------|------|------|------|------|------|------|------|------|------|-------|-------|
| 31   | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21   | 20   | 19   | 18   | 17    | 16    |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res.  | Res.  |
|      |      |      |      |      |      |      |      |      |      |      |      |      |      |       |       |
| 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5    | 4    | 3    | 2    | 1     | 0     |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | FNE  | VSYNC | HSYNC |
|      |      |      |      |      |      |      |      |      |      |      |      |      | r    | r     | r     |

Bits 31:3 Reserved, must be kept at reset value.

Bit 2 **FNE**: FIFO not empty

This bit gives the status of the FIFO

1: FIFO contains valid data

0: FIFO empty

Bit 1 **VSYNC**:

This bit gives the state of the DCMI\_VSYNC pin with the correct programmed polarity.

When embedded synchronization codes are used, the meaning of this bit is the following:

0: active frame

1: synchronization between frames

In case of embedded synchronization, this bit is meaningful only if the CAPTURE bit in DCMI\_CR is set.

Bit 0 **HSYNC**:

This bit gives the state of the DCMI\_HSYNC pin with the correct programmed polarity.

When embedded synchronization codes are used, the meaning of this bit is the following:

0: active line

1: synchronization between lines

In case of embedded synchronization, this bit is meaningful only if the CAPTURE bit in DCMI\_CR is set.

### 17.7.3 DCMI raw interrupt status register (DCMI\_RIS)

Address offset: 0x08

Reset value: 0x0000 0000

|      |      |      |      |      |      |      |      |      |      |      |          |           |         |         |           |
|------|------|------|------|------|------|------|------|------|------|------|----------|-----------|---------|---------|-----------|
| 31   | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21   | 20       | 19        | 18      | 17      | 16        |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res.     | Res.      | Res.    | Res.    | Res.      |
|      |      |      |      |      |      |      |      |      |      |      |          |           |         |         |           |
| 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5    | 4        | 3         | 2       | 1       | 0         |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | LINE_RIS | VSYNC_RIS | ERR_RIS | OVR_RIS | FRAME_RIS |
|      |      |      |      |      |      |      |      |      |      |      | r        | r         | r       | r       | r         |

DCMI\_RIS gives the raw interrupt status and is accessible in read only. When read, this register returns the status of the corresponding interrupt before masking with the DCMI\_IER register value.

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 **LINE\_RIS**: Line raw interrupt status

This bit gets set when the DCMI\_HSYNC signal changes from the inactive state to the active state. It goes high even if the line is not valid.

In the case of embedded synchronization, this bit is set only if the CAPTURE bit in DCMI\_CR is set.

It is cleared by writing a '1' to the LINE\_ISC bit in DCMI\_ICR.

Bit 3 **VSYNC\_RIS**: DCMI\_VSYNC raw interrupt status

This bit is set when the DCMI\_VSYNC signal changes from the inactive state to the active state.

In the case of embedded synchronization, this bit is set only if the CAPTURE bit is set in DCMI\_CR.

It is cleared by writing a '1' to the VSYNC\_ISC bit in DCMI\_ICR.

Bit 2 **ERR\_RIS**: Synchronization error raw interrupt status

0: No synchronization error detected

1: Embedded synchronization characters are not received in the correct order.

This bit is valid only in the embedded synchronization mode. It is cleared by writing a '1' to the ERR\_ISC bit in DCMI\_ICR.

*Note: This bit is available only in embedded synchronization mode.*

Bit 1 **OVR\_RIS**: Overrun raw interrupt status

0: No data buffer overrun occurred

1: A data buffer overrun occurred and the data FIFO is corrupted.

This bit is cleared by writing a '1' to the OVR\_ISC bit in DCMI\_ICR.

Bit 0 **FRAME\_RIS**: Capture complete raw interrupt status

0: No new capture

1: A frame has been captured.

This bit is set when a frame or window has been captured.

In case of a cropped window, this bit is set at the end of line of the last line in the crop. It is set even if the captured frame is empty (e.g. window cropped outside the frame).

This bit is cleared by writing a '1' to the FRAME\_ISC bit in DCMI\_ICR.

### 17.7.4 DCMI interrupt enable register (DCMI\_IER)

Address offset: 0x0C

Reset value: 0x0000 0000

|      |      |      |      |      |      |      |      |      |      |      |             |              |            |            |              |

|      |      |      |      |      |      |      |      |      |      |      |             |              |            |            |              |
| 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5    | 4           | 3            | 2          | 1          | 0            |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | LINE<br>_IE | VSYNC<br>_IE | ERR<br>_IE | OVR<br>_IE | FRAME<br>_IE |
|      |      |      |      |      |      |      |      |      |      |      | rw          | rw           | rw         | rw         | rw           |

The DCMI\_IER register is used to enable interrupts. When one of the DCMI\_IER bits is set, the corresponding interrupt is enabled. This register is accessible in both read and write.

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 **LINE\_IE**: Line interrupt enable

0: No interrupt generation when the line is received

1: An Interrupt is generated when a line has been completely received

Bit 3 **VSYNC\_IE**: DCMI\_VSYNC interrupt enable

0: No interrupt generation

1: An interrupt is generated on each DCMI\_VSYNC transition from the inactive to the active state

The active state of the DCMI\_VSYNC signal is defined by the VSPOL bit.

Bit 2 **ERR\_IE**: Synchronization error interrupt enable

0: No interrupt generation

1: An interrupt is generated if the embedded synchronization codes are not received in the correct order.

*Note: This bit is available only in embedded synchronization mode.*

Bit 1 **OVR\_IE**: Overrun interrupt enable

0: No interrupt generation

1: An interrupt is generated if the DMA was not able to transfer the last data before new data (32-bit) are received.

Bit 0 **FRAME\_IE**: Capture complete interrupt enable

0: No interrupt generation

1: An interrupt is generated at the end of each received frame/crop window (in crop mode).

### 17.7.5 DCMI masked interrupt status register (DCMI\_MIS)

This DCMI\_MIS register is a read-only register. When read, it returns the current masked status value (depending on the value in DCMI\_IER) of the corresponding interrupt. A bit in this register is set if the corresponding enable bit in DCMI\_IER is set and the corresponding bit in DCMI\_RIS is set.

Address offset: 0x10

Reset value: 0x0000 0000

|      |      |      |      |      |      |      |      |      |      |      |          |           |         |         |           |

| 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5    | 4        | 3         | 2       | 1       | 0         |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | LINE_MIS | VSYNC_MIS | ERR_MIS | OVR_MIS | FRAME_MIS |
|      |      |      |      |      |      |      |      |      |      |      | r        | r         | r       | r       | r         |

Bits 31:5 Reserved, must be kept at reset value.

**Bit 4 LINE\_MIS:** Line masked interrupt status

This bit gives the status of the masked line interrupt

0: No interrupt generation when the line is received

1: An Interrupt is generated when a line has been completely received and the LINE\_IE bit is set in DCMI\_IER.

**Bit 3 VSYNC\_MIS:** VSYNC masked interrupt status

This bit gives the status of the masked VSYNC interrupt

0: No interrupt is generated on DCMI\_VSYNC transitions

1: An interrupt is generated on each DCMI\_VSYNC transition from the inactive to the active state and the VSYNC\_IE bit is set in DCMI\_IER.

The active state of the DCMI\_VSYNC signal is defined by the VSPOL bit.

**Bit 2 ERR\_MIS:** Synchronization error masked interrupt status

This bit gives the status of the masked synchronization error interrupt

0: No interrupt is generated on a synchronization error

1: An interrupt is generated if the embedded synchronization codes are not received in the correct order and the ERR\_IE bit in DCMI\_IER is set.

*Note: This bit is available only in embedded synchronization mode.*

**Bit 1 OVR\_MIS:** Overflow masked interrupt status

This bit gives the status of the masked overflow interrupt

0: No interrupt is generated on overrun

1: An interrupt is generated if the DMA was not able to transfer the last data before new data (32-bit) are received and the OVR\_IE bit is set in DCMI\_IER.

**Bit 0 FRAME\_MIS:** Capture complete masked interrupt status

This bit gives the status of the masked capture complete interrupt

0: No interrupt is generated after a complete capture

1: An interrupt is generated at the end of each received frame/crop window (in crop mode) and the FRAME\_IE bit is set in DCMI\_IER.

### 17.7.6 DCMI interrupt clear register (DCMI\_ICR)

Address offset: 0x14

Reset value: 0x0000 0000

|      |      |      |      |      |      |      |      |      |      |      |              |               |             |             |               |
|------|------|------|------|------|------|------|------|------|------|------|--------------|---------------|-------------|-------------|---------------|
| 31   | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21   | 20           | 19            | 18          | 17          | 16            |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res.         | Res.          | Res.        | Res.        | Res.          |
|      |      |      |      |      |      |      |      |      |      |      |              |               |             |             |               |
| 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5    | 4            | 3             | 2           | 1           | 0             |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | LINE<br>_ISC | VSYNC<br>_ISC | ERR<br>_ISC | OVR<br>_ISC | FRAME<br>_ISC |
|      |      |      |      |      |      |      |      |      |      |      | w            | w             | w           | w           | w             |

The DCMI\_ICR register is write-only. Writing a '1' into a bit of this register clears the corresponding bit in the DCMI\_RIS and DCMI\_MIS registers. Writing a '0' has no effect.

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 **LINE\_ISC**: line interrupt status clear

Writing a '1' into this bit clears LINE\_RIS in the DCMI\_RIS register

Bit 3 **VSYNC\_ISC**: Vertical Synchronization interrupt status clear

Writing a '1' into this bit clears the VSYNC\_RIS bit in DCMI\_RIS

Bit 2 **ERR\_ISC**: Synchronization error interrupt status clear

Writing a '1' into this bit clears the ERR\_RIS bit in DCMI\_RIS

*Note: This bit is available only in embedded synchronization mode.*

Bit 1 **OVR\_ISC**: Overrun interrupt status clear

Writing a '1' into this bit clears the OVR\_RIS bit in DCMI\_RIS

Bit 0 **FRAME\_ISC**: Capture complete interrupt status clear

Writing a '1' into this bit clears the FRAME\_RIS bit in DCMI\_RIS

### 17.7.7 DCMI embedded synchronization code register (DCMI\_ESCR)

Address offset: 0x18

Reset value: 0x0000 0000

|          |    |    |    |    |    |    |    |          |    |    |    |    |    |    |    |
|----------|----|----|----|----|----|----|----|----------|----|----|----|----|----|----|----|
| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23       | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| FEC[7:0] |    |    |    |    |    |    |    | LEC[7:0] |    |    |    |    |    |    |    |
| rw       | rw | rw | rw | rw | rw | rw | rw | rw       | rw | rw | rw | rw | rw | rw | rw |
| 15       | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7        | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| LSC[7:0] |    |    |    |    |    |    |    | FSC[7:0] |    |    |    |    |    |    |    |
| rw       | rw | rw | rw | rw | rw | rw | rw | rw       | rw | rw | rw | rw | rw | rw | rw |

Bits 31:24 **FEC[7:0]**: Frame end delimiter code

This byte specifies the code of the frame end delimiter. The code consists of 4 bytes in the form of 0xFF, 0x00, 0x00, FEC.

If FEC is programmed to 0xFF, all the unused codes (0xFF0000XY) are interpreted as frame end delimiters.

Bits 23:16 **LEC[7:0]**: Line end delimiter code

This byte specifies the code of the line end delimiter. The code consists of 4 bytes in the form of 0xFF, 0x00, 0x00, LEC.

Bits 15:8 **LSC[7:0]**: Line start delimiter code

This byte specifies the code of the line start delimiter. The code consists of 4 bytes in the form of 0xFF, 0x00, 0x00, LSC.

Bits 7:0 **FSC[7:0]**: Frame start delimiter code

This byte specifies the code of the frame start delimiter. The code consists of 4 bytes in the form of 0xFF, 0x00, 0x00, FSC.

If FSC is programmed to 0xFF, no frame start delimiter is detected. But, the 1<sup>st</sup> occurrence of LSC after an FEC code will be interpreted as a start of frame delimiter.

### 17.7.8 DCMI embedded synchronization unmask register (DCMI\_ESUR)

Address offset: 0x1C

Reset value: 0x0000 0000

|          |    |    |    |    |    |    |    |          |    |    |    |    |    |    |    |
|----------|----|----|----|----|----|----|----|----------|----|----|----|----|----|----|----|
| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23       | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| FEU[7:0] |    |    |    |    |    |    |    | LEU[7:0] |    |    |    |    |    |    |    |
| rw       | rw | rw | rw | rw | rw | rw | rw | rw       | rw | rw | rw | rw | rw | rw | rw |
| 15       | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7        | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| LSU[7:0] |    |    |    |    |    |    |    | FSU[7:0] |    |    |    |    |    |    |    |
| rw       | rw | rw | rw | rw | rw | rw | rw | rw       | rw | rw | rw | rw | rw | rw | rw |

**Bits 31:24 FEU[7:0]:** Frame end delimiter unmask

This byte specifies the mask to be applied to the code of the frame end delimiter.

0: The corresponding bit in the FEC byte in DCMI\_ESCR is masked while comparing the frame end delimiter with the received data.

1: The corresponding bit in the FEC byte in DCMI\_ESCR is compared while comparing the frame end delimiter with the received data

**Bits 23:16 LEU[7:0]:** Line end delimiter unmask

This byte specifies the mask to be applied to the code of the line end delimiter.

0: The corresponding bit in the LEC byte in DCMI\_ESCR is masked while comparing the line end delimiter with the received data

1: The corresponding bit in the LEC byte in DCMI\_ESCR is compared while comparing the line end delimiter with the received data

**Bits 15:8 LSU[7:0]:** Line start delimiter unmask

This byte specifies the mask to be applied to the code of the line start delimiter.

0: The corresponding bit in the LSC byte in DCMI\_ESCR is masked while comparing the line start delimiter with the received data

1: The corresponding bit in the LSC byte in DCMI\_ESCR is compared while comparing the line start delimiter with the received data

**Bits 7:0 FSU[7:0]:** Frame start delimiter unmask

This byte specifies the mask to be applied to the code of the frame start delimiter.

0: The corresponding bit in the FSC byte in DCMI\_ESCR is masked while comparing the frame start delimiter with the received data

1: The corresponding bit in the FSC byte in DCMI\_ESCR is compared while comparing the frame start delimiter with the received data

### 17.7.9 DCMI crop window start (DCMI\_CWSTRT)

Address offset: 0x20

Reset value: 0x0000 0000

|      |      |               |           |     |     |     |     |     |     |     |     |     |     |     |     |
|------|------|---------------|-----------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| 31   | 30   | 29            | 28        | 27  | 26  | 25  | 24  | 23  | 22  | 21  | 20  | 19  | 18  | 17  | 16  |
| Res. | Res. | Res.          | VST[12:0] |     |     |     |     |     |     |     |     |     |     |     |     |
|      |      |               | r/w       | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w |
| 15   | 14   | 13            | 12        | 11  | 10  | 9   | 8   | 7   | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
| Res. | Res. | HOFFCNT[13:0] |           |     |     |     |     |     |     |     |     |     |     |     |     |
|      |      | r/w           | r/w       | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w |

Bits 31:29 Reserved, must be kept at reset value.

Bits 28:16 **VST[12:0]**: Vertical start line count

The image capture starts with this line number. Previous line data are ignored.

0x0000 => line 1

0x0001 => line 2

0x0002 => line 3

....

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:0 **HOFFCNT[13:0]**: Horizontal offset count

This value gives the number of pixel clocks to count before starting a capture.

### 17.7.10 DCMI crop window size (DCMI\_CWSIZE)

Address offset: 0x24

Reset value: 0x0000 0000

|      |      |              |     |     |     |     |     |     |     |     |     |     |     |     |     |
|------|------|--------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| 31   | 30   | 29           | 28  | 27  | 26  | 25  | 24  | 23  | 22  | 21  | 20  | 19  | 18  | 17  | 16  |
| Res. | Res. | VLIN[13:0]   |     |     |     |     |     |     |     |     |     |     |     |     |     |
|      |      | r/w          | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w |
| 15   | 14   | 13           | 12  | 11  | 10  | 9   | 8   | 7   | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
| Res. | Res. | CAPCNT[13:0] |     |     |     |     |     |     |     |     |     |     |     |     |     |
|      |      | r/w          | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w |

Bits 31:30 Reserved, must be kept at reset value.

Bits 29:16 **VLIN[13:0]**: Vertical line count

This value gives the number of lines to be captured from the starting point.

0x0000 => 1 line

0x0001 => 2 lines

0x0002 => 3 lines

....

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:0 **CAPCNT[13:0]**: Capture count

This value gives the number of pixel clocks to be captured from the starting point on the same line. Its value should correspond to word-aligned data for different widths of parallel interfaces.

0x0000 => 1 pixel

0x0001 => 2 pixels

0x0002 => 3 pixels

....

### 17.7.11 DCMI data register (DCMI\_DR)

Address offset: 0x28

Reset value: 0x0000 0000

|            |    |    |    |    |    |    |    |            |    |    |    |    |    |    |    |

| 15         | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7          | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| Byte1[7:0] |    |    |    |    |    |    |    | Byte0[7:0] |    |    |    |    |    |    |    |
| r          | r  | r  | r  | r  | r  | r  | r  | r          | r  | r  | r  | r  | r  | r  | r  |

Bits 31:24 **Byte3[7:0]**: Data byte 3

Bits 23:16 **Byte2[7:0]**: Data byte 2

Bits 15:8 **Byte1[7:0]**: Data byte 1

Bits 7:0 **Byte0[7:0]**: Data byte 0

The digital camera Interface packages all the received data in 32-bit format before requesting a DMA transfer. A 4-word deep FIFO is available to leave enough time for DMA transfers and avoid DMA overrun conditions.

## 17.7.12 DCMI register map

Table 115 summarizes the DCMI registers.

**Table 115. DCMI register map and reset values**

| Offset | Register name | 31    | 30   | 29          | 28        | 27   | 26   | 25   | 24   | 23    | 22   | 21   | 20   | 19   | 18   | 17   | 16   | 15           | 14            | 13   | 12   | 11   | 10   | 9    | 8    | 7     | 6     | 5     | 4      | 3        | 2         | 1       | 0       |           |
|--------|---------------|-------|------|-------------|-----------|------|------|------|------|-------|------|------|------|------|------|------|------|--------------|---------------|------|------|------|------|------|------|-------|-------|-------|--------|----------|-----------|---------|---------|-----------|

Refer to [Section 2.2.2 on page 69](#) for the register boundary addresses.

## 18 LCD-TFT display controller (LTDC)

This section applies to the whole STM32F756xx, STM32F750xx and STM32F746xx devices, unless otherwise specified.

### 18.1 Introduction

The LCD-TFT (liquid crystal display - thin film transistor) display controller provides a parallel digital RGB (red, green, blue) and signals for horizontal, vertical synchronization, pixel clock and data enable as output to interface directly to a variety of LCD and TFT panels.

### 18.2 LTDC main features

- 24-bit RGB parallel pixel output; 8 bits-per-pixel (RGB888)
- 2 display layers with dedicated FIFO (64x32-bit)
- Color look-up table (CLUT) up to 256 color (256x24-bit) per layer
- Programmable timings for different display panels
- Programmable background color
- Programmable polarity for HSYNC, VSYNC and data enable
- Up to 8 input color formats selectable per layer
  - ARGB8888
  - RGB888
  - RGB565
  - ARGB1555
  - ARGB4444
  - L8 (8-bit luminance or CLUT)
  - AL44 (4-bit alpha + 4-bit luminance)
  - AL88 (8-bit alpha + 8-bit luminance)
- Pseudo-random dithering output for low bits per channel
  - Dither width 2-bits for red, green, blue
- Flexible blending between two layers using alpha value (per pixel or constant)
- Color keying (transparency color)
- Programmable window position and size
- Supports thin film transistor (TFT) color displays
- AHB master interface with burst of 16 words
- Up to 4 programmable interrupt events

## 18.3 LTDC functional description

### 18.3.1 LTDC block diagram

The block diagram of the LTDC is shown in [Figure 111: LTDC block diagram](#).

Layer FIFO: One FIFO 64x32-bit per layer.

PFC: pixel format converter, performing the pixel format conversion from the selected input pixel format of a layer to words.

AHB interface: for data transfer from memories to the FIFO.

Blending, dithering unit and timings generator: Refer to [Section 18.4.1](#) and [Section 18.4.2](#).

### 18.3.2 LTDC pins and external signal interface

[Table 116](#) summarizes the LTDC signal interface.

**Table 116. LTDC pins and signal interface**

| LCD-TFT signals | I/O | Description                |
|-----------------|-----|----------------------------|
| LCD_CLK         | O   | Clock output               |
| LCD_HSYNC       | O   | Horizontal synchronization |
| LCD_VSYNC       | O   | Vertical synchronization   |
| LCD_DE          | O   | Not data enable            |
| LCD_R[7:0]      | O   | Data: 8-bit red data       |

Table 116. LTDC pins and signal interface (continued)

| LCD-TFT signals | I/O | Description            |
|-----------------|-----|------------------------|
| LCD_G[7:0]      | O   | Data: 8-bit green data |
| LCD_B[7:0]      | O   | Data: 8-bit blue data  |

The LTDC-TFT controller pins must be configured by the user application. The unused pins can be used for other purposes.

For LTDC outputs up to 24-bit (RGB888), if less than 8 bpp are used to output for example RGB565 or RGB666 to interface on 16- or 18-bit displays, the RGB display data lines must be connected to the MSB of the LCD-TFT controller RGB data lines. As an example, in the case of an LCD-TFT controller interfacing with a RGB565 16-bit display, the LCD display R[4:0], G[5:0] and B[4:0] data lines pins must be connected to LCD-TFT controller LCD\_R[7:3], LCD\_G[7:2] and LCD\_B[7:3].

### 18.3.3 LTDC reset and clocks

The LCD-TFT controller peripheral uses 3 clock domains:

- AHB clock domain (HCLK)  
This domain contains the LCD-TFT AHB master interface for data transfer from the memories to the Layer FIFO and the frame buffer configuration register
- APB2 clock domain (PCLK2):  
This domain contains the global configuration registers and the interrupt register.
- Pixel clock domain (LCD\_CLK)  
This domain contains the pixel data generation, the layer configuration register as well as the LCD-TFT interface signal generator. The LCD\_CLK output should be configured following the panel requirements. The LCD\_CLK is generated from a specific PLL output (refer to the reset and clock control section).

[Table 117](#) summarizes the clock domain for each register.

Table 117. Clock domain for each register

| LTDC register | Clock domain |
|---------------|--------------|
| LTDC_LxCR     | HCLK         |
| LTDC_LxCFBAR  |              |
| LTDC_LxCFBLR  |              |
| LTDC_LxCFBLNR |              |
| LTDC_SRCR     | PCLK2        |
| LTDC_IER      |              |
| LTDC_ISR      |              |
| LTDC_ICR      |              |

Table 117. Clock domain for each register (continued)

| LTDC register | Clock domain          |
|---------------|-----------------------|
| LTDC_SSCR     | Pixel clock (LCD_CLK) |
| LTDC_BPCR     |                       |
| LTDC_AWCR     |                       |
| LTDC_TWCR     |                       |
| LTDC_GCR      |                       |
| LTDC_BCCR     |                       |
| LTDC_LIPCR    |                       |
| LTDC_CPSR     |                       |
| LTDC_CDSR     |                       |
| LTDC_LxWHPCR  |                       |
| LTDC_LxWVPCR  |                       |
| LTDC_LxCCKCR  |                       |
| LTDC_LxPFCR   |                       |
| LTDC_LxCACR   |                       |
| LTDC_LxDCCR   |                       |
| LTDC_LxBFCR   |                       |
| LTDC_LxCLUTWR |                       |

Care must be taken while accessing the LTDC registers, the APB2 bus is stalled during:

- 6 PCKL2 periods + 5 LCD\_CLK periods (5 HCLK periods for register on AHB clock domain) for register write access and update;
- 7 PCKL2 periods + 5 LCD\_CLK periods (5 HCLK periods for register on AHB clock domain) for register read access.

For registers on PCKL2 clock domain, APB2 bus is stalled for 6 PCKL2 periods during the register write accesses, and for 7 PCKL2 periods during Read accesses.

The LCD controller can be reset by setting the corresponding bit in the RCC\_APB2RSTR register. It resets the three clock domains.

## 18.4 LTDC programmable parameters

The LCD-TFT controller provides flexible configurable parameters. It can be enabled or disabled through the LTDC\_GCR register.

### 18.4.1 LTDC global configuration parameters

#### Synchronous timings

[Figure 112](#) presents the configurable timing parameters generated by the synchronous timings generator block presented in the block diagram [Figure 111](#). It generates the

horizontal and vertical synchronization timings panel signals, the pixel clock and the data enable signals.

Figure 112. LCD-TFT synchronous timings

*Note:* The HBP and HFP are respectively the horizontal back porch and front porch period.  
The VBP and the VFP are respectively the vertical back porch and front porch period.

The LCD-TFT programmable synchronous timings are:

- HSYNC and VSYNC width: horizontal and vertical synchronization width, configured by programming a value of **HSYNC width - 1** and **VSYNC width - 1** in the LTDC\_SSCR register
- HBP and VBP: horizontal and vertical synchronization back porch width, configured by programming the accumulated value **HSYNC width + HBP - 1** and the accumulated value **VSYNC width + VBP - 1** in the LTDC\_BPCR register.
- Active width and active height: the active width and active height are configured by programming the accumulated value **HSYNC width + HBP + active width - 1** and the accumulated value **VSYNC width + VBP + active height - 1** in the LTDC\_AWCR register (only up to 1024x768 is supported).
- Total width: the total width is configured by programming the accumulated value **HSYNC width + HBP + active width + HFP - 1** in the LTDC\_TWCR register. The HFP is the horizontal front porch period.
- Total height: the total height is configured by programming the accumulated value **VSYNC height + VBP + active height + VFP - 1** in the LTDC\_TWCR register. The VFP is the vertical front porch period.

**Note:** *When the LTDC is enabled, the timings generated start with X/Y=0/0 position as the first horizontal synchronization pixel in the vertical synchronization area and following the back porch, active data display area and the front porch.*

When the LTDC is disabled, the timing generator block is reset to  $X = \text{total width} - 1$ ,  $Y = \text{total height} - 1$  and held the last pixel before the vertical synchronization phase and the FIFO are flushed. Therefore only blanking data is output continuously.

### Example of synchronous timings configuration

TFT-LCD timings (must be extracted from panel datasheet):

- horizontal and vertical synchronization width: 0xA pixels and 0x2 lines
- horizontal and vertical back porch: 0x14 pixels and 0x2 lines
- active width and active height: 0x140 pixels, 0xF0 lines (320x240)
- horizontal front porch: 0xA pixels
- vertical front porch: 0x4 lines

The programmed values in the LTDC timings registers are:

- LTDC\_SSCR register: to be programmed to 0x00070003. (HSW[11:0] is 0x7 and VSH[10:0] is 0x3)
- LTDC\_BPCR register: to be programmed to 0x001D0003 (AHBP[11:0] is 0x1D(0xA+0x13) and AVBP[10:0] is 0x3(0x2 + 0x1)).
- LTDC\_AWCR register: to be programmed to 0x015D00F3 (AAW[11:0] is 0x15D(0xA+0x14 +0x13F) and AAH[10:0] is 0xF3(0x2 +0x2 + 0xEF).
- LTDC\_TWCR register: to be programmed to 0x00000167 (TOTALW[11:0] is 0x167(0xA+0x14 +0x140 + 0x9).
- LTDC\_THCR register: to be programmed to 0x000000F7 (TOTALH[10:0] is 0xF7(0x2 +0x2 + 0xF0 + 3)

### Programmable polarity

The horizontal and vertical synchronization, data enable and pixel clock output signals polarity can be programmed to active high or active low through the LTDC\_GCR register.

### Background color

A constant background color (RGB888) can be programmed through the LTDC\_BCCR register. It is used for blending with the bottom layer.

### Dithering

The dithering pseudo-random technique using an LFSR is used to add a small random value (threshold) to each pixel color channel (R, G or B) value, thus rounding up the MSB in some cases when displaying a 24-bit data on 18-bit display. Thus the Dithering technique is used to round data which is different from one frame to the other.

The dithering pseudo-random technique is the same as comparing LSBs against a threshold value and adding a 1 to the MSB part only, if the LSB part is  $\geq$  the threshold. The LSBs are typically dropped once dithering was applied.

The width of the added pseudo-random value is 2 bits for each color channel: 2 bits for red, 2 bits for green and 2 bits for blue.

Once the LCD-TFT controller is enabled, the LFSR starts running with the first active pixel and it is kept running even during blanking periods and when dithering is switched off. If the LTDC is disabled, the LFSR is reset.

The dithering can be switched On and Off on the fly through the LTDC\_GCR register.

### Reload shadow registers

Some configuration registers are shadowed. The shadow registers values can be reloaded immediately to the active registers when writing to these registers or at the beginning of the vertical blanking period following the configuration in the LTDC\_SRCR register. If the immediate reload configuration is selected, the reload should be only activated when all new registers have been written.

The shadow registers should not be modified again before the reload has been done. Reading from the shadow registers returns the actual active value. The new written value can only be read after the reload has taken place.

A register reload interrupt can be generated if enabled in the LTDC\_IER register.

The shadowed registers are all the layer1 and layer2 registers except the LTDC\_LxCLUTWR register.

### Interrupt generation event

Refer to [Section 18.5: LTDC interrupts](#) for interrupt configuration.

## 18.4.2 Layer programmable parameters

Up to two layers can be enabled, disabled and configured separately. The layer display order is fixed and it is bottom up. If two layers are enabled, the layer2 is the top displayed window.

### Windowing

Every layer can be positioned and resized and it must be inside the active display area.

The window position and size are configured through the top-left and bottom-right X/Y positions and the internal timing generator that includes the synchronous, back porch size and the active data area. Refer to LTDC\_LxWHPCR and LTDC\_WVPCR registers.

The programmable layer position and size defines the first/last visible pixel of a line and the first/last visible line in the window. It allows to display either the full image frame or only a part of the image frame. Refer to [Figure 113](#).

- The first and the last visible pixel in the layer are set by configuring the WHSTPOS[11:0] and WHSPPOS[11:0] in the LTDC\_LxWHPCR register.
- The first and the last visible lines in the layer are set by configuring the WVSTPOS[10:0] and WVSPPOS[10:0] in the LTDC\_LxWVPCR register.

Figure 113. Layer window programmable parameters

### Pixel input format

The programmable pixel format is used for the data stored in the frame buffer of a layer.

Up to 8 input pixel formats can be configured for every layer through the LTDC\_LxPFCR register

The pixel data is read from the frame buffer and then transformed to the internal 8888 (ARGB) format as follows: components having a width of less than 8 bits get expanded to 8 bits by bit replication. The selected bit range is concatenated multiple times until it is longer than 8 bits. Of the resulting vector, the 8 MSB bits are chosen. Example: 5 bits of an RGB565 red channel become (bit positions): 43210432 (the 3 LSBs are filled with the 3 MSBs of the 5 bits)

[Table 118](#) describes the pixel data mapping depending on the selected format.

**Color look-up table (CLUT)**

The CLUT can be enabled at run-time for every layer through the LTDC\_LxCR register and it is only useful in case of indexed color when using the L8, AL44 and AL88 input pixel format.

First, the CLUT has to be loaded with the R, G and B values that replace the original R, G, B values of that pixel (indexed color). Each color (RGB value) has its own address which is the position within the CLUT.

The R, G and B values and their own respective address are programmed through the LTDC\_LxCLUTWR register.

- In case of L8 and AL88 input pixel format, the CLUT has to be loaded by 256 colors. The address of each color is configured in the CLUTADD bits in the LTDC\_LxCLUTWR register.
- In case of AL44 input pixel format, the CLUT has to be only loaded by 16 colors. The address of each color must be filled by replicating the 4-bit L channel to 8-bit as follows:

- L0 (indexed color 0), at address 0x00
- L1, at address 0x11
- L2, at address 0x22
- .....
- L15, at address 0xFF

### Color frame buffer address

Every layer has a start address for the color frame buffer configured through the LTDC\_LxCFBAR register.

When a layer is enabled, the data is fetched from the color frame buffer.

### Color frame buffer length

Every layer has a total line length setting for the color frame buffer in bytes and a number of lines in the frame buffer configurable in the LTDC\_LxCFBLR and LTDC\_LxCFBLNR register respectively.

The line length and the number of lines settings are used to stop the prefetching of data to the layer FIFO at the end of the frame buffer.

- If it is set to less bytes than required, a FIFO underrun interrupt is generated if it has been previously enabled.
- If it is set to more bytes than actually required, the useless data read from the FIFO is discarded. The useless data is not displayed.

### Color frame buffer pitch

Every layer has a configurable pitch for the color frame buffer, which is the distance between the start of one line and the beginning of the next line in bytes. It is configured through the LTDC\_LxCFBLR register.

### Layer blending

The blending is always active and the two layers can be blended following the blending factors configured through the LTDC\_LxBFCR register.

The blending order is fixed and it is bottom up. If two layers are enabled, first the Layer1 is blended with the Background color, then the layer2 is blended with the result of blended color of layer1 and the background. Refer to [Figure 114](#).

**Figure 114. Blending two layers with background**

### Default color

Every layer can have a default color in the format ARGB which is used outside the defined layer window or when a layer is disabled.

The default color is configured through the LTDC\_LxDCCR register.

The blending is always performed between the two layers even when a layer is disabled. To avoid displaying the default color when a layer is disabled, keep the blending factors of this layer in the LTDC\_LxBFCR register to their reset value.

### Color keying

A color key (RGB) can be configured to be representative for a transparent pixel.

If the color keying is enabled, the current pixels (after format conversion and before CLUT respectively blending) are compared to the color key. If they match for the programmed RGB value, all channels (ARGB) of that pixel are set to 0.

The color key value can be configured and used at run-time to replace the pixel RGB value.

The color keying is enabled through the LTDC\_LxCKCR register.

The color keying is configured through the LTDC\_LxCKCR register. The programmed value depends on the pixel format as it is compared to current pixel after pixel format conversion to ARGB888.

Example: if the a mid-yellow color (50% red + 50% green) is used as the transparent color key:

- In RGB565, the mid-yellow color is 0x8400. Set the LTDC\_LxCKCR to 0x848200.
- In ARGB8888, the mid-yellow color is 0x808000, set LTDC\_LxCKCR to 0x808000.
- In all CLUT-based color modes (L8, AL88, AL44), set one of the palette entry to the mid-yellow color 0x808000 and set the LTDC\_LxCKCR to 0x808000.

## 18.5 LTDC interrupts

The LTDC provides four maskable interrupts logically ORed to two interrupt vectors.

The interrupt sources can be enabled or disabled separately through the LTDC\_IER register. Setting the appropriate mask bit to 1 enables the corresponding interrupt.

The two interrupts are generated on the following events:

- Line interrupt: generated when a programmed line is reached. The line interrupt position is programmed in the LTDC\_LIPCR register
- Register reload interrupt: generated when the shadow registers reload was performed during the vertical blanking period
- FIFO underrun interrupt: generated when a pixel is requested from an empty layer FIFO
- Transfer error interrupt: generated when an AHB bus error occurs during data transfer

Those interrupts events are connected to the NVIC controller as described in [Figure 115](#).

**Figure 115. Interrupt events****Table 119. LTDC interrupt requests**

| Interrupt event | Event flag | Enable control bit |
|-----------------|------------|--------------------|
| Line            | LIF        | LIE                |
| Register reload | RRIF       | RRIEN              |
| FIFO underrun   | FUDERRIF   | FUDERRIE           |
| Transfer error  | TERRIF     | TERRIE             |

## 18.6 LTDC programming procedure

- Enable the LTDC clock in the RCC register.
- Configure the required pixel clock following the panel datasheet.
- Configure the synchronous timings: VSYNC, HSYNC, vertical and horizontal back porch, active data area and the front porch timings following the panel datasheet as

described in the [Section 18.4.1: LTDC global configuration parameters](#).

- Configure the synchronous signals and clock polarity in the LTDC\_GCR register.
- If needed, configure the background color in the LTDC\_BCCR register.
- Configure the needed interrupts in the LTDC\_IER and LTDC\_LIPCR register.
- Configure the layer1/2 parameters by:
  - programming the layer window horizontal and vertical position in the LTDC\_LxWHPCR and LTDC\_WVPCR registers. The layer window must be in the active data area.
  - programming the pixel input format in the LTDC\_LxPFCR register
  - programming the color frame buffer start address in the LTDC\_LxCFBAR register
  - programming the line length and pitch of the color frame buffer in the LTDC\_LxCFBLR register
  - programming the number of lines of the color frame buffer in the LTDC\_LxCFBLNR register
  - if needed, loading the CLUT with the RGB values and its address in the LTDC\_LxCLUTWR register
  - If needed, configuring the default color and the blending factors respectively in the LTDC\_LxDCCR and LTDC\_LxBFCR registers
- Enable layer1/2 and if needed the CLUT in the LTDC\_LxCR register.
- If needed, enable dithering and color keying respectively in the LTDC\_GCR and LTDC\_LxCKCR registers. They can be also enabled on the fly.
- Reload the shadow registers to active register through the LTDC\_SRCR register.
- Enable the LCD-TFT controller in the LTDC\_GCR register.
- All layer parameters can be modified on the fly except the CLUT. The new configuration has to be either reloaded immediately or during vertical blanking period by configuring the LTDC\_SRCR register.

**Note:** *All layer's registers are shadowed. Once a register is written, it must not be modified again before the reload has been done. Thus, a new write to the same register overrides the previous configuration if not yet reloaded.*

## 18.7 LTDC registers

### 18.7.1 LTDC synchronization size configuration register (LTDC\_SSCR)

This register defines the number of horizontal synchronization pixels minus 1 and the number of vertical synchronization lines minus 1. Refer to [Figure 112](#) and [Section 18.4: LTDC programmable parameters](#) for an example of configuration.

Address offset: 0x08

Reset value: 0x0000 0000

|      |      |      |      |           |           |     |     |     |     |     |     |     |     |     |     |

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:16 **HSW[11:0]**: horizontal synchronization width (in units of pixel clock period)

These bits define the number of Horizontal Synchronization pixel minus 1.

Bits 15:11 Reserved, must be kept at reset value.

Bits 10:0 **VSH[10:0]**: vertical synchronization height (in units of horizontal scan line)

These bits define the vertical Synchronization height minus 1. It represents the number of horizontal synchronization lines.

### 18.7.2 LTDC back porch configuration register (LTDC\_BPCR)

This register defines the accumulated number of horizontal synchronization and back porch pixels minus 1 (**HSYNC width + HBP - 1**) and the accumulated number of vertical synchronization and back porch lines minus 1 (**VSYNC height + VBP - 1**). Refer to [Figure 112](#) and [Section 18.4: LTDC programmable parameters](#) for an example of configuration.

Address offset: 0x0C

Reset value: 0x0000 0000

|      |      |      |      |            |            |     |     |     |     |     |     |     |     |     |     |

| Res. | Res. | Res. | Res. | Res.       | AVBP[10:0] |     |     |     |     |     |     |     |     |     |     |
|      |      |      |      |            | r/w        | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w |

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:16 **AHBP[11:0]**: accumulated horizontal back porch (in units of pixel clock period)

These bits define the accumulated horizontal back porch width that includes the horizontal synchronization and horizontal back porch pixels minus 1.

The horizontal back porch is the period between horizontal synchronization going inactive and the start of the active display part of the next scan line.

Bits 15:11 Reserved, must be kept at reset value.

Bits 10:0 **AVBP[10:0]**: accumulated Vertical back porch (in units of horizontal scan line)

These bits define the accumulated vertical back porch width that includes the vertical synchronization and vertical back porch lines minus 1.

The vertical back porch is the number of horizontal scan lines at a start of frame to the start of the first active scan line of the next frame.

### 18.7.3 LTDC active width configuration register (LTDC\_AWCR)

This register defines the accumulated number of horizontal synchronization, back porch and active pixels minus 1 (**HSYNC width + HBP + active width - 1**) and the accumulated number of vertical synchronization, back porch lines and active lines minus 1 (**VSYNC height + BVBP + active height - 1**). Refer to [Figure 112](#) and [Section 18.4: LTDC programmable parameters](#) for an example of configuration.

Address offset: 0x10

Reset value: 0x0000 0000

|      |      |      |      |           |           |    |    |    |    |    |    |    |    |    |    |

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:16 **AAW[11:0]**: accumulated active width (in units of pixel clock period)

These bits define the accumulated active width which includes the horizontal synchronization, horizontal back porch and active pixels minus 1.

The active width is the number of pixels in active display area of the panel scan line.

Refer to device datasheet for maximum active width supported following maximum pixel clock.

Bits 15:11 Reserved, must be kept at reset value.

Bits 10:0 **AAH[10:0]**: accumulated active height (in units of horizontal scan line)

These bits define the accumulated height which includes the vertical synchronization, vertical back porch and the active height lines minus 1. The active height is the number of active lines in the panel.

Refer to device datasheet for maximum active height supported following maximum pixel clock.

### 18.7.4 LTDC total width configuration register (LTDC\_TWCR)

This register defines the accumulated number of horizontal synchronization, back porch, active and front porch pixels minus 1 (**HSYNC width + HBP + active width + HFP - 1**) and the accumulated number of vertical synchronization, back porch lines, active and front lines minus 1 (**VSYNC height + BVBP + active height + VFP - 1**). Refer to [Figure 112](#) and [Section 18.4: LTDC programmable parameters](#) for an example of configuration.

Address offset: 0x14

Reset value: 0x0000 0000

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:16 **TOTALW[11:0]**: total width (in units of pixel clock period)

These bits defines the accumulated total width which includes the horizontal synchronization, horizontal back porch, active width and horizontal front porch pixels minus 1.

Bits 15:11 Reserved, must be kept at reset value.

Bits 10:0 **TOTALH[10:0]**: total height (in units of horizontal scan line)

These bits defines the accumulated height which includes the vertical synchronization, vertical back porch, the active height and vertical front porch height lines minus 1.

### 18.7.5 LTDC global control register (LTDC\_GCR)

This register defines the global configuration of the LCD-TFT controller.

Address offset: 0x18

Reset value: 0x0000 2220

|       |          |       |       |      |          |      |      |      |          |      |      |      |      |      |       |

- Bit 31 **HSPOL**: horizontal synchronization polarity  
This bit is set and cleared by software.  
0: horizontal synchronization polarity is active low.  
1: horizontal synchronization polarity is active high.
- Bit 30 **VSPOL**: vertical synchronization polarity  
This bit is set and cleared by software.  
0: vertical synchronization is active low.  
1: vertical synchronization is active high.
- Bit 29 **DEPOL**: not data enable polarity  
This bit is set and cleared by software.  
0: not data enable polarity is active low.  
1: not data enable polarity is active high.
- Bit 28 **PCPOL**: pixel clock polarity  
This bit is set and cleared by software.  
0: pixel clock polarity is active low.  
1: pixel clock is active high.
- Bits 27:17 Reserved, must be kept at reset value.
- Bit 16 **DEN**: dither enable  
This bit is set and cleared by software.  
0: dither disable  
1: dither enable
- Bit 15 Reserved, must be kept at reset value.
- Bits 14:12 **DRW[2:0]**: dither red width  
These bits return the Dither Red Bits.
- Bit 11 Reserved, must be kept at reset value.
- Bits 10:8 **DGW[2:0]**: dither green width  
These bits return the dither green bits.
- Bit 7 Reserved, must be kept at reset value.
- Bits 6:4 **DBW[2:0]**: dither blue width  
These bits return the dither blue bits.
- Bits 3:1 Reserved, must be kept at reset value.
- Bit 0 **LTDCEN**: LCD-TFT controller enable  
This bit is set and cleared by software.  
0: LTDC disable  
1: LTDC enable

### 18.7.6 LTDC shadow reload configuration register (LTDC\_SRCR)

This register allows to reload either immediately or during the vertical blanking period, the shadow registers values to the active registers. The shadow registers are all Layer1 and Layer2 registers except the LTDC\_L1CLUTWR and the LTDC\_L2CLUTWR.

Address offset: 0x24

Reset value: 0x0000 0000

|      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|
| 31   | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21   | 20   | 19   | 18   | 17   | 16   |

| 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0    |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | VBR  | IMR  |
|      |      |      |      |      |      |      |      |      |      |      |      |      |      | rw   | rw   |

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **VBR**: vertical blanking reload

This bit is set by software and cleared only by hardware after reload (it cannot be cleared through register write once it is set).

0: no effect

1: The shadow registers are reloaded during the vertical blanking period (at the beginning of the first line after the active display area).

Bit 0 **IMR**: immediate reload

This bit is set by software and cleared only by hardware after reload.

0: no effect

1: The shadow registers are reloaded immediately.

**Note:** *The shadow registers read back the active values. Until the reload has been done, the 'old' value is read.*

### 18.7.7 LTDC background color configuration register (LTDC\_BCCR)

This register defines the background color (RGB888).

Address offset: 0x2C

Reset value: 0x0000 0000

|              |      |      |      |      |      |      |      |             |    |    |    |    |    |    |    |
|--------------|------|------|------|------|------|------|------|-------------|----|----|----|----|----|----|----|
| 31           | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23          | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

| BCGREEN[7:0] |      |      |      |      |      |      |      | BCBLUE[7:0] |    |    |    |    |    |    |    |
| rw           | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw          | rw | rw | rw | rw | rw | rw | rw |

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:16 **BCRED[7:0]**: background color red value

These bits configure the background red value.

Bits 15:8 **BCGREEN[7:0]**: background color green value

These bits configure the background green value.

Bits 7:0 **BCBLUE[7:0]**: background color blue value

These bits configure the background blue value.

### 18.7.8 LTDC interrupt enable register (LTDC\_IER)

This register determines which status flags generate an interrupt request by setting the corresponding bit to 1.

Address offset: 0x34

Reset value: 0x0000 0000

|      |      |      |      |      |      |      |      |      |      |      |      |      |        |      |      |
|------|------|------|------|------|------|------|------|------|------|------|------|------|--------|------|------|
| 31   | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21   | 20   | 19   | 18     | 17   | 16   |

|      |      |      |      |      |      |      |      |      |      |      |      | rw   | rw     | rw   | rw   |

Bits 31:4 Reserved, must be kept at reset value.

Bit 3 **RRIE**: register reload interrupt enable

This bit is set and cleared by software.

0: register reload interrupt disable

1: register reload interrupt enable

Bit 2 **TERRIE**: transfer error interrupt enable

This bit is set and cleared by software.

0: transfer error interrupt disable

1: transfer error interrupt enable

Bit 1 **FUIE**: FIFO underrun interrupt enable

This bit is set and cleared by software.

0: FIFO underrun interrupt disable

1: FIFO underrun Interrupt enable

Bit 0 **LIE**: line interrupt enable

This bit is set and cleared by software.

0: line interrupt disable

1: line interrupt enable

### 18.7.9 LTDC interrupt status register (LTDC\_ISR)

This register returns the interrupt status flag.

Address offset: 0x38

Reset value: 0x0000 0000

|      |      |      |      |      |      |      |      |      |      |      |      |      |        |      |      |

|      |      |      |      |      |      |      |      |      |      |      |      | r    | r      | r    | r    |

Bits 31:4 Reserved, must be kept at reset value.

Bit 3 **RRIF**: register reload interrupt flag

0: no register reload interrupt generated

1: register reload interrupt generated when a vertical blanking reload occurs (and the first line after the active area is reached)

Bit 2 **TERRIF**: transfer error interrupt flag

0: no transfer error interrupt generated

1: transfer error interrupt generated when a bus error occurs

Bit 1 **FUIF**: FIFO underrun interrupt flag

0: no FIFO underrun interrupt generated.

1: FIFO underrun interrupt generated, if one of the layer FIFOs is empty and pixel data is read from the FIFO

Bit 0 **LIF**: line interrupt flag

0: no line interrupt generated

1: line interrupt generated when a programmed line is reached

### 18.7.10 LTDC Interrupt Clear Register (LTDC\_ICR)

Address offset: 0x3C

Reset value: 0x0000 0000

|      |      |      |      |      |      |      |      |      |      |      |      |       |         |       |      |
|------|------|------|------|------|------|------|------|------|------|------|------|-------|---------|-------|------|
| 31   | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21   | 20   | 19    | 18      | 17    | 16   |

|      |      |      |      |      |      |      |      |      |      |      |      | w     | w       | w     | w    |

Bits 31:4 Reserved, must be kept at reset value.

Bit 3 **CRRIF**: clears register reload interrupt flag

0: no effect

1: clears the RRIF flag in the LTDC\_ISR register

Bit 2 **CTERRIF**: clears the transfer error interrupt flag

0: no effect

1: clears the TERRIF flag in the LTDC\_ISR register.

Bit 1 **CFUIF**: clears the FIFO underrun interrupt flag

0: no effect

1: clears the FUDERRIF flag in the LTDC\_ISR register.

Bit 0 **CLIF**: clears the line interrupt flag

0: no effect

1: clears the LIF flag in the LTDC\_ISR register.

### 18.7.11 LTDC line interrupt position configuration register (LTDC\_LIPCR)

This register defines the position of the line interrupt. The line value to be programmed depends on the timings parameters. Refer to [Figure 112](#).

Address offset: 0x40

Reset value: 0x0000 0000

|      |      |      |      |      |             |      |      |      |      |      |      |      |      |      |      |
|------|------|------|------|------|-------------|------|------|------|------|------|------|------|------|------|------|
| 31   | 30   | 29   | 28   | 27   | 26          | 25   | 24   | 23   | 22   | 21   | 20   | 19   | 18   | 17   | 16   |

| 15   | 14   | 13   | 12   | 11   | 10          | 9    | 8    | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0    |
| Res. | Res. | Res. | Res. | Res. | LIPOS[10:0] |      |      |      |      |      |      |      |      |      |      |
|      |      |      |      |      | r/w         | r/w  | r/w  | r/w  | r/w  | r/w  | r/w  | r/w  | r/w  | r/w  | r/w  |

Bits 31:11 Reserved, must be kept at reset value.

Bits 10:0 **LIPOS[10:0]**: line interrupt position

These bits configure the line interrupt position.

### 18.7.12 LTDC current position status register (LTDC\_CPSR)

Address offset: 0x44

Reset value: 0x0000 0000

|             |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|-------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31          | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| CXPOS[15:0] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| r           | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  |
| 15          | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| CYPOS[15:0] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| r           | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  |

Bits 31:16 **CXPOS[15:0]**: current X position

These bits return the current X position.

Bits 15:0 **CYPOS[15:0]**: current Y position

These bits return the current Y position.

### 18.7.13 LTDC current display status register (LTDC\_CDSR)

This register returns the status of the current display phase which is controlled by the HSYNC, VSYNC, and horizontal/vertical DE signals.

Example: if the current display phase is the vertical synchronization, the VSYNCS bit is set (active high). If the current display phase is the horizontal synchronization, the HSYNCS bit is active high.

Address offset: 0x48

Reset value: 0x0000 000F

|      |      |      |      |      |      |      |      |      |      |      |      |        |        |      |      |
|------|------|------|------|------|------|------|------|------|------|------|------|--------|--------|------|------|
| 31   | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21   | 20   | 19     | 18     | 17   | 16   |

|      |      |      |      |      |      |      |      |      |      |      |      | r      | r      | r    | r    |

Bits 31:4 Reserved, must be kept at reset value.

Bit 3 **HSYNCS**: horizontal synchronization display status

0: active low

1: active high

Bit 2 **VSYNCS**: vertical synchronization display status

0: active low

1: active high

Bit 1 **HDES**: horizontal data enable display status

0: active low

1: active high

Bit 0 **VDES**: vertical data enable display status

0: active low

1: active high

**Note:** The returned status does not depend on the configured polarity in the **LTDC\_GCR** register, instead it returns the current active display phase.

### 18.7.14 LTDC layer x control register (LTDC\_LxCR)

Address offset:  $0x84 + 0x80 * (x - 1)$ , ( $x = 1$  to  $2$ )

Reset value: 0x0000 0000

|      |      |      |      |      |      |      |      |      |      |      |        |      |      |        |      |

| 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5    | 4      | 3    | 2    | 1      | 0    |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | CLUTEN | Res. | Res. | COLKEN | LEN  |
|      |      |      |      |      |      |      |      |      |      |      | rw     |      |      | rw     | rw   |

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 **CLUTEN**: color look-up table enable

This bit is set and cleared by software.

0: color look-up table disable

1: color look-up table enable

The CLUT is only meaningful for L8, AL44 and AL88 pixel format. Refer to [Color look-up table \(CLUT\)](#)

Bits 3:2 Reserved, must be kept at reset value.

Bit 1 **COLKEN**: color keying enable

This bit is set and cleared by software.

0: color keying disable

1: color keying enable

Bit 0 **LEN**: layer enable

This bit is set and cleared by software.

0: layer disable

1: layer enable

### 18.7.15 LTDC layer x window horizontal position configuration register (LTDC\_LxWHPCR)

This register defines the horizontal position (first and last pixel) of the layer 1 or 2 window.

The first visible pixel of a line is the programmed value of AHBP[11:0] bits + 1 in the LTDC\_BPCR register.

The last visible pixel of a line is the programmed value of AAW[10:0] bits in the LTDC\_AWCR register.

Address offset:  $0x88 + 0x80 * (x - 1)$ , ( $x = 1$  to  $2$ )

Reset value: 0x0000 0000

|      |      |      |      |               |    |    |    |    |    |    |    |    |    |    |    |
|------|------|------|------|---------------|----|----|----|----|----|----|----|----|----|----|----|
| 31   | 30   | 29   | 28   | 27            | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| Res. | Res. | Res. | Res. | WHSPPOS[11:0] |    |    |    |    |    |    |    |    |    |    |    |
|      |      |      |      | rw            | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |
| 15   | 14   | 13   | 12   | 11            | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| Res. | Res. | Res. | Res. | WHSTPOS[11:0] |    |    |    |    |    |    |    |    |    |    |    |
|      |      |      |      | rw            | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:16 **WHSPPOS[11:0]**: window horizontal stop position

These bits configure the last visible pixel of a line of the layer window.

WHSPPOS[11:0] must be  $\geq$  **AHBP[11:0] bits + 1** (programmed in LTDC\_BPCR register).

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:0 **WHSTPOS[11:0]**: window horizontal start position

These bits configure the first visible pixel of a line of the layer window.

WHSTPOS[11:0] must be  $\leq$  **AAW[11:0] bits** (programmed in LTDC\_AWCR register).

#### Example:

The LTDC\_BPCR register is configured to 0x000E0005 (AHBP[11:0] is 0xE) and the LTDC\_AWCR register is configured to 0x028E01E5 (AAW[11:0] is 0x28E). To configure the horizontal position of a window size of 630x460, with horizontal start offset of 5 pixels in the active data area:

1. layer window first pixel, WHSTPOS[11:0], must be programmed to 0x14 (0xE+1+0x5)
2. layer window last pixel, WHSPPOS[11:0], must be programmed to 0x28A.

### 18.7.16 LTDC layer x window vertical position configuration register (LTDC\_LxWVPCR)

This register defines the vertical position (first and last line) of the layer1 or 2 window.

The first visible line of a frame is the programmed value of AVBP[10:0] bits + 1 in the register LTDC\_BPCR register.

The last visible line of a frame is the programmed value of AAH[10:0] bits in the LTDC\_AWCR register.

Address offset:  $0x8C + 0x80 * (x - 1)$ , ( $x = 1$  to  $2$ )

Reset value: 0x0000 0000

|      |      |      |      |      |               |    |    |    |    |    |    |    |    |    |    |
|------|------|------|------|------|---------------|----|----|----|----|----|----|----|----|----|----|
| 31   | 30   | 29   | 28   | 27   | 26            | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| Res. | Res. | Res. | Res. | Res. | WVSPPOS[10:0] |    |    |    |    |    |    |    |    |    |    |
|      |      |      |      |      | rw            | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |
| 15   | 14   | 13   | 12   | 11   | 10            | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| Res. | Res. | Res. | Res. | Res. | WVSTPOS[10:0] |    |    |    |    |    |    |    |    |    |    |
|      |      |      |      |      | rw            | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 31:27 Reserved, must be kept at reset value.

Bits 26:16 **WVSPPOS[10:0]**: window vertical stop position

These bits configure the last visible line of the layer window.

WVSPPOS[10:0] must be  $\geq$  **AVBP[10:0] bits + 1** (programmed in LTDC\_BPCR register).

Bits 15:11 Reserved, must be kept at reset value.

Bits 10:0 **WVSTPOS[10:0]**: window vertical start position

These bits configure the first visible line of the layer window.

WVSTPOS[10:0] must be  $\leq$  **AAH[10:0] bits** (programmed in LTDC\_AWCR register).

#### Example:

The LTDC\_BPCR register is configured to 0x000E0005 (AVBP[10:0] is 0x5) and the LTDC\_AWCR register is configured to 0x028E01E5 (AAH[10:0] is 0x1E5).

To configure the vertical position of a window size of 630x460, with vertical start offset of 8 lines in the active data area:

1. layer window first line: WVSTPOS[10:0] must be programmed to 0xE ( $0x5 + 1 + 0x8$ ).
2. layer window last line: WVSPPOS[10:0] must be programmed to 0x1DA.

### 18.7.17 LTDC layer x color keying configuration register (LTDC\_LxCKCR)

This register defines the color key value (RGB), that is used by the color keying.

Address offset:  $0x90 + 0x80 * (x - 1)$ , ( $x = 1$  to  $2$ )

Reset value: 0x0000 0000

|              |      |      |      |      |      |      |      |             |    |    |    |    |    |    |    |
|--------------|------|------|------|------|------|------|------|-------------|----|----|----|----|----|----|----|
| 31           | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23          | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| Res.         | Res. | Res. | Res. | Res. | Res. | Res. | Res. | CKRED[7:0]  |    |    |    |    |    |    |    |
|              |      |      |      |      |      |      |      | rw          | rw | rw | rw | rw | rw | rw | rw |
| 15           | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7           | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| CKGREEN[7:0] |      |      |      |      |      |      |      | CKBLUE[7:0] |    |    |    |    |    |    |    |
| rw           | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw          | rw | rw | rw | rw | rw | rw | rw |

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:16 **CKRED[7:0]**: color key red value

Bits 15:8 **CKGREEN[7:0]**: color key green value

Bits 7:0 **CKBLUE[7:0]**: color key blue value

### 18.7.18 LTDC layer x pixel format configuration register (LTDC\_LxPFCR)

This register defines the pixel format that is used for the stored data in the frame buffer of a layer. The pixel data is read from the frame buffer and then transformed to the internal format 8888 (ARGB).

Address offset:  $0x94 + 0x80 * (x - 1)$ , ( $x = 1$  to  $2$ )

Reset value: 0x0000 0000

|      |      |      |      |      |      |      |      |      |      |      |      |      |         |      |      |
|------|------|------|------|------|------|------|------|------|------|------|------|------|---------|------|------|
| 31   | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21   | 20   | 19   | 18      | 17   | 16   |

Bits 31:3 Reserved, must be kept at reset value.

Bits 2:0 **PF[2:0]**: pixel format

These bits configure the pixel format

000: ARGB8888

001: RGB888

010: RGB565

011: ARGB1555

100: ARGB4444

101: L8 (8-bit luminance)

110: AL44 (4-bit alpha, 4-bit luminance)

111: AL88 (8-bit alpha, 8-bit luminance)

### 18.7.19 LTDC layer x constant alpha configuration register (LTDC\_LxCACR)

This register defines the constant alpha value (divided by 255 by hardware), that is used in the alpha blending. Refer to LTDC\_LxBFCR register.

Address offset:  $0x98 + 0x80 * (x - 1)$ , ( $x = 1$  to  $2$ )

Reset value: 0x0000 00FF

|      |      |      |      |      |      |      |      |             |      |      |      |      |      |      |      |

| 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7           | 6    | 5    | 4    | 3    | 2    | 1    | 0    |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | CONSTA[7:0] |      |      |      |      |      |      |      |
|      |      |      |      |      |      |      |      | rw          | rw   | rw   | rw   | rw   | rw   | rw   | rw   |

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **CONSTA[7:0]**: constant alpha

These bits configure the constant alpha used for blending. The constant alpha is divided by 255 by hardware.

Example: if the programmed constant alpha is 0xFF, the constant alpha value is  $255 / 255 = 1$ .

### 18.7.20 LTDC layer x default color configuration register (LTDC\_LxDCCR)

This register defines the default color of a layer in the format ARGB. The default color is used outside the defined layer window or when a layer is disabled. The reset value of 0x00000000 defines a transparent black color.

Address offset:  $0x9C + 0x80 * (x - 1)$ , ( $x = 1$  to  $2$ )

Reset value: 0x0000 0000

|              |    |    |    |    |    |    |    |             |    |    |    |    |    |    |    |
|--------------|----|----|----|----|----|----|----|-------------|----|----|----|----|----|----|----|
| 31           | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23          | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| DCALPHA[7:0] |    |    |    |    |    |    |    | DCRED[7:0]  |    |    |    |    |    |    |    |
| rw           | rw | rw | rw | rw | rw | rw | rw | rw          | rw | rw | rw | rw | rw | rw | rw |
| 15           | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7           | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| DCGREEN[7:0] |    |    |    |    |    |    |    | DCBLUE[7:0] |    |    |    |    |    |    |    |
| rw           | rw | rw | rw | rw | rw | rw | rw | rw          | rw | rw | rw | rw | rw | rw | rw |

Bits 31:24 **DCALPHA[7:0]**: default color alpha  
These bits configure the default alpha value.

Bits 23:16 **DCRED[7:0]**: default color red  
These bits configure the default red value.

Bits 15:8 **DCGREEN[7:0]**: default color green  
These bits configure the default green value.

Bits 7:0 **DCBLUE[7:0]**: default color blue  
These bits configure the default blue value.

### 18.7.21 LTDC layer x blending factors configuration register (LTDC\_LxBFCR)

This register defines the blending factors F1 and F2.

The general blending formula is:  $BC = BF1 \times C + BF2 \times Cs$

- BC = blended color
- BF1 = blend factor 1
- C = current layer color
- BF2 = blend factor 2
- Cs = subjacent layers blended color

Address offset:  $0xA0 + 0x80 \times (x - 1)$ , ( $x = 1$  to  $2$ )

Reset value: 0x0000 0607

|      |      |      |      |      |          |      |      |      |      |      |      |      |          |      |      |
|------|------|------|------|------|----------|------|------|------|------|------|------|------|----------|------|------|
| 31   | 30   | 29   | 28   | 27   | 26       | 25   | 24   | 23   | 22   | 21   | 20   | 19   | 18       | 17   | 16   |
| Res. | Res. | Res. | Res. | Res. | Res.     | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res.     | Res. | Res. |
|      |      |      |      |      |          |      |      |      |      |      |      |      |          |      |      |
| 15   | 14   | 13   | 12   | 11   | 10       | 9    | 8    | 7    | 6    | 5    | 4    | 3    | 2        | 1    | 0    |
| Res. | Res. | Res. | Res. | Res. | BF1[2:0] |      |      | Res. | Res. | Res. | Res. | Res. | BF2[2:0] |      |      |
|      |      |      |      |      | rw       | rw   | rw   |      |      |      |      |      | rw       | rw   | rw   |

Bits 31:11 Reserved, must be kept at reset value.

Bits 10:8 **BF1[2:0]**: blending factor 1

These bits select the blending factor F1.

000: reserved

001: reserved

010: reserved

011: reserved

100: constant alpha

101: reserved

110: pixel alpha x constant alpha

111: reserved

Bits 7:3 Reserved, must be kept at reset value.

Bits 2:0 **BF2[2:0]**: blending factor 2

These bits select the blending factor F2

000: reserved

001: reserved

010: reserved

011: reserved

100: reserved

101: 1 - constant alpha

110: reserved

111: 1 - (pixel alpha x constant alpha)

**Note:** The constant alpha value, is the programmed value in the LxCACR register divided by 255 by hardware.

**Example:** Only layer1 is enabled, BF1 configured to constant alpha. BF2 configured to 1 - constant alpha. The constant alpha programmed in the LxCACR register is 240 (0xF0). Thus, the constant alpha value is  $240/255 = 0.94$ . C: current layer color is 128.

Cs: background color is 48. Layer1 is blended with the background color.

$BC = \text{constant alpha} \times C + (1 - \text{Constant Alpha}) \times Cs = 0.94 \times 128 + (1 - 0.94) \times 48 = 123$ .

### 18.7.22 LTDC layer x color frame buffer address register (LTDC\_LxCFBAR)

This register defines the color frame buffer start address which has to point to the address where the pixel data of the top left pixel of a layer is stored in the frame buffer.

Address offset:  $0xAC + 0x80 \times (x - 1)$ , ( $x = 1$  to  $2$ )

Reset value: 0x0000 0000

|               |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|---------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31            | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| CFBADD[31:16] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rW            | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW |
| 15            | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| CFBADD[15:0]  |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rW            | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW |

Bits 31:0 **CFBADD[31:0]**: color frame buffer start address

These bits define the color frame buffer start address.

### 18.7.23 LTDC layer x color frame buffer length register (LTDC\_LxCFBLR)

This register defines the color frame buffer line length and pitch.

Address offset:  $0xB0 + 0x80 \times (x - 1)$ , ( $x = 1$  to  $2$ )

Reset value: 0x0000 0000

|      |      |      |             |    |    |    |    |    |    |    |    |    |    |    |    |
|------|------|------|-------------|----|----|----|----|----|----|----|----|----|----|----|----|
| 31   | 30   | 29   | 28          | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| Res. | Res. | Res. | CFBPP[12:0] |    |    |    |    |    |    |    |    |    |    |    |    |
|      |      |      | rW          | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW |
| 15   | 14   | 13   | 12          | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| Res. | Res. | Res. | CFBLL[12:0] |    |    |    |    |    |    |    |    |    |    |    |    |
|      |      |      | rW          | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW |

Bits 31:29 Reserved, must be kept at reset value.

Bits 28:16 **CFBPP[12:0]**: color frame buffer pitch in bytes

These bits define the pitch that is the increment from the start of one line of pixels to the start of the next line in bytes.

Bits 15:13 Reserved, must be kept at reset value.

Bits 12:0 **CFBLL[12:0]**: color frame buffer line length

These bits define the length of one line of pixels in bytes + 3.

The line length is computed as follows:

active high width \* number of bytes per pixel + 3.

Example:

- A frame buffer having the format RGB565 (2 bytes per pixel) and a width of 256 pixels (total number of bytes per line is  $256 * 2 = 512$ ), where pitch = line length requires a value of 0x02000203 to be written into this register.
- A frame buffer having the format RGB888 (3 bytes per pixel) and a width of 320 pixels (total number of bytes per line is  $320 * 3 = 960$ ), where pitch = line length requires a value of 0x03C003C3 to be written into this register.

### 18.7.24 LTDC layer x color frame buffer line number register (LTDC\_LxCFBLNR)

This register defines the number of lines in the color frame buffer.

Address offset:  $0xB4 + 0x80 * (x - 1)$ , ( $x = 1$  to 2)

Reset value: 0x0000 0000

|      |      |      |      |      |               |      |      |      |      |      |      |      |      |      |      |
|------|------|------|------|------|---------------|------|------|------|------|------|------|------|------|------|------|
| 31   | 30   | 29   | 28   | 27   | 26            | 25   | 24   | 23   | 22   | 21   | 20   | 19   | 18   | 17   | 16   |
| Res. | Res. | Res. | Res. | Res. | Res.          | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. |
|      |      |      |      |      |               |      |      |      |      |      |      |      |      |      |      |
| 15   | 14   | 13   | 12   | 11   | 10            | 9    | 8    | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0    |
| Res. | Res. | Res. | Res. | Res. | CFBLNBR[10:0] |      |      |      |      |      |      |      |      |      |      |
|      |      |      |      |      | rw            | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   |

Bits 31:11 Reserved, must be kept at reset value.

Bits 10:0 **CFBLNBR[10:0]**: frame buffer line number

These bits define the number of lines in the frame buffer that corresponds to the active high width.

**Note:** *The number of lines and line length settings define how much data is fetched per frame for every layer. If it is configured to less bytes than required, a FIFO underrun interrupt will be generated if enabled.*

*The start address and pitch settings on the other hand define the correct start of every line in memory.*

### 18.7.25 LTDC layer x CLUT write register (LTDC\_LxCLUTWR)

This register defines the CLUT address and the RGB value.

Address offset:  $0xC4 + 0x80 * (x - 1)$ , ( $x = 1$  to  $2$ )

Reset value: 0x0000 0000

|              |    |    |    |    |    |    |    |           |    |    |    |    |    |    |    |
|--------------|----|----|----|----|----|----|----|-----------|----|----|----|----|----|----|----|
| 31           | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23        | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| CLUTADD[7:0] |    |    |    |    |    |    |    | RED[7:0]  |    |    |    |    |    |    |    |
| w            | w  | w  | w  | w  | w  | w  | w  | w         | w  | w  | w  | w  | w  | w  | w  |
| 15           | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7         | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| GREEN[7:0]   |    |    |    |    |    |    |    | BLUE[7:0] |    |    |    |    |    |    |    |
| w            | w  | w  | w  | w  | w  | w  | w  | w         | w  | w  | w  | w  | w  | w  | w  |

Bits 31:24 **CLUTADD[7:0]**: CLUT address

These bits configure the CLUT address (color position within the CLUT) of each RGB value.

Bits 23:16 **RED[7:0]**: red value

These bits configure the red value.

Bits 15:8 **GREEN[7:0]**: green value

These bits configure the green value.

Bits 7:0 **BLUE[7:0]**: blue value

These bits configure the blue value.

**Note:** *The CLUT write register should only be configured during blanking period or if the layer is disabled. The CLUT can be enabled or disabled in the LTDC\_LxCR register.*

*The CLUT is only meaningful for L8, AL44 and AL88 pixel format.*

## 18.7.26 LTDC register map

The following table summarizes the LTDC registers. Refer to the register boundary addresses table for the LTDC register base address.

**Table 120. LTDC register map and reset values**

| Offset | Register name | 31          | 30    | 29    | 28    | 27           | 26   | 25   | 24   | 23         | 22   | 21   | 20   | 19   | 18   | 17   | 16           | 15   | 14       | 13   | 12   | 11          | 10   | 9            | 8    | 7    | 6    | 5        | 4    | 3    | 2       | 1      | 0    |       |  |

Refer to [Section 2.2.2](#) for the register boundary addresses.

## 19 True random number generator (RNG)

### 19.1 Introduction

The RNG is a true random number generator that continuously provides 32-bit entropy samples, based on an analog noise source. It can be used by the application as a live entropy source to build a NIST compliant Deterministic Random Bit Generator (DRBG).

The RNG true random number generator has been validated according to the German AIS-31 standard.

### 19.2 RNG main features

- The RNG delivers 32-bit true random numbers, produced by an analog entropy source post-processed with linear-feedback shift registers (LFSR).
- It is validated according to the AIS-31 pre-defined class PTG.2 evaluation methodology, which is part of the German Common Criteria (CC) scheme.
- It produces one 32-bit random samples every 42 RNG clock cycles (dedicated clock).
- It allows embedded continuous basic health tests with associated error management
  - Includes too low sampling clock detection and repetition count tests.
- It can be disabled to reduce power consumption.
- It has an AMBA AHB slave peripheral, accessible through 32-bit word single accesses only (else an AHB bus error is generated). Warning! any write not equal to 32 bits might corrupt the register content.

## 19.3 RNG functional description

### 19.3.1 RNG block diagram

Figure 116 shows the RNG block diagram.

Figure 116. RNG block diagram

MSv42096V1

### 19.3.2 RNG internal signals

Table 121 describes a list of useful-to-know internal signals available at the RNG level, not at the STM32 product level (on pads).

Table 121. RNG internal input/output signals

| Signal name | Signal type    | Description                                   |
|-------------|----------------|-----------------------------------------------|
| rng_it      | Digital output | RNG global interrupt request                  |
| rng_hclk    | Digital input  | AHB clock                                     |
| rng_clk     | Digital input  | RNG dedicated clock, asynchronous to rng_hclk |

### 19.3.3 Random number generation

The true random number generator (RNG) delivers truly random data through its AHB interface at deterministic intervals. The RNG implements the entropy source model pictured on [Figure 117](#), and provides three main functions to the application:

- Collects the bitstring output of the entropy source box
- Obtains samples of the noise source for validation purpose
- Collects error messages from continuous health tests

**Figure 117. Entropy source model**

The main components of the RNG are:

- A source of physical randomness (analog noise source)
- A digitization stage for this analog noise source
- A stage delivering post-processed noise source (raw data)
- An output buffer for the raw data. If further cryptographic conditioning is required by the application it will need to be performed by software.
- An optional output for the digitized noise source (unbuffered, on digital pads)
- Basic health tests on the digitized noise source

All those components are detailed below.

#### Noise source

The noise source is the component that contains the non-deterministic, entropy-providing activity that is ultimately responsible for the uncertainty associated with the bitstring output by the entropy source. It is composed of:

- Two analog noise sources, each based on three XORed free-running ring oscillator outputs. It is possible to disable those analog oscillators to save power, as described in

[Section 19.4: RNG low-power usage.](#)

- A sampling stage of these outputs clocked by a dedicated clock input (**rng\_clk**), delivering a 2-bit raw data output.

This noise source sampling is independent to the AHB interface clock frequency (**rng\_hclk**).

*Note:* In [Section 19.7: Entropy source validation](#) recommended RNG clock frequencies are given.

### Post processing

The sample values obtained from a true random noise source consist of 2-bit bitstrings. Because this noise source output is biased, the RNG implements a post-processing component that reduces that bias to a tolerable level.

The RNG post-processing consists of two stages, applied to each noise source bits:

- The RNG takes half of the bits from the sampled noise source, and half of the bits from inverted sampled noise source. Thus, if the source generates more '1' than '0' (or the opposite), it is filtered
- A linear feedback shift register (LFSR) performs a whitening process, producing 8-bit strings.

This component is clocked by the RNG clock.

The times required between two random number generations, and between the RNG initialization and availability of first sample are described in [Section 19.6: RNG processing time](#).

### Output buffer

The RNG\_DR data output register can store up to two 16-bit words which have been output from the post-processing component (LFSR). In order to read back 32-bit random samples it is required to wait 42 RNG clock cycles.

Whenever a random number is available through the RNG\_DR register the DRDY flag transitions from "0" to "1". This flag remains high until output buffer becomes empty after reading one word from the RNG\_DR register.

*Note:* When interrupts are enabled an interrupt is generated when this data ready flag transitions from "0" to "1". Interrupt is then cleared automatically by the RNG as explained above.

### Health checks

This component ensures that the entire entropy source (with its noise source) starts then operates as expected, obtaining assurance that failures are caught quickly and with a high probability and reliability.

The RNG implements the following health check features:

1. Behavior tests, applied to the entropy source *at run-time*
  - Repetition count test, flagging an error when:
    - a) One of the noise source has provided more than 64 consecutive bits at a constant value ("0" or "1")
    - b) One of the noise sources has delivered more than 32 consecutive occurrence of two bits patterns ("01" or "10")
2. Vendor specific continuous test
  - Real-time "too slow" sampling clock detector, flagging an error when one RNG clock cycle is smaller than AHB clock cycle divided by 16.

The CECS and SECS status bits in the RNG\_SR register indicate when an error condition is detected, as detailed in [Section 19.3.7: Error management](#).

*Note:* An interrupt can be generated when an error is detected.

### 19.3.4 RNG initialization

When a hardware reset occurs the following chain of events occurs:

1. The analog noise source is enabled, and logic starts sampling the analog output after four RNG clock cycles, filling LFSR shift register and associated 16-bit post-processing shift register.
2. The output buffer is refilled automatically according to the RNG usage.

The associated initialization time can be found in [Section 19.6: RNG processing time](#).

### 19.3.5 RNG operation

#### Normal operations

To run the RNG using interrupts the following steps are recommended:

1. Enable the interrupts by setting the IE bit in the RNG\_CR register. At the same time enable the RNG by setting the bit RNGEN=1.
2. An interrupt is now generated when a random number is ready or when an error occurs. Therefore at each interrupt, check that:
  - No error occurred. The SEIS and CEIS bits should be set to '0' in the RNG\_SR register.
  - A random number is ready. The DRDY bit must be set to '1' in the RNG\_SR register.
  - If above two conditions are true the content of the RNG\_DR register can be read.

To run the RNG in polling mode following steps are recommended:

1. Enable the random number generation by setting the RNGEN bit to “1” in the RNG\_CR register.
2. Read the RNG\_SR register and check that:
  - No error occurred (the SEIS and CEIS bits should be set to ‘0’)
  - A random number is ready (the DRDY bit should be set to ‘1’)
3. If above conditions are true read the content of the RNG\_DR register.

*Note:* When data is not ready (DRDY=“0”) RNG\_DR returns zero.

### Low-power operations

If the power consumption is a concern to the application, low-power strategies can be used, as described in [Section 19.4: RNG low-power usage on page 549](#).

### Software post-processing

If a NIST approved DRBG with 128 bits of security strength is required an approved random generator software must be built around the RNG true random number generator.

## 19.3.6 RNG clocking

The RNG runs on two different clocks: the AHB bus clock and a dedicated RNG clock.

The AHB clock is used to clock the AHB banked registers and the post-processing component. The RNG clock is used for noise source sampling. Recommended clock configurations are detailed in [Section 19.7: Entropy source validation](#).

**Caution:** When the CED bit in the RNG\_CR register is set to “0”, the RNG clock frequency **must be higher** than AHB clock frequency divided by 16, otherwise the clock checker will flag a clock error (CECS or CEIS in the RNG\_SR register) and the RNG will stop producing random numbers.

See [Section 19.3.1: RNG block diagram](#) for details (AHB and RNG clock domains).

## 19.3.7 Error management

In parallel to random number generation an health check block verifies the correct noise source behavior and the frequency of the RNG source clock as detailed in this section. Associated error state is also described.

### Clock error detection

When the clock error detection is enabled (CED = 0) and if the RNG clock frequency is too low, the RNG stops generating random numbers and sets to “1” both the **CEIS** and **CECS** bits to indicate that a clock error occurred. In this case, the application should check that the RNG clock is configured correctly (see [Section 19.3.6: RNG clocking](#)) and then it must clear the CEIS bit interrupt flag. As soon as the RNG clock operates correctly, the CECS bit will be automatically cleared.

The RNG operates only when the CECS flag is set to “0”. However note that the clock error has no impact on the previously generated random numbers, and the RNG\_DR register contents can still be used.

### Noise source error detection

When a noise source (or seed) error occurs, the RNG stops generating random numbers and sets to “1” both **SEIS** and **SECS** bits to indicate that a seed error occurred. If a value is available in the RNG\_DR register, it must not be used as it may not have enough entropy.

In order to fully recover from a seed error application must clear the SEIS bit by writing it to “0”, then clear and set the RNGEN bit to reinitialize and restart the RNG.

## 19.4 RNG low-power usage

If power consumption is a concern, the RNG can be disabled as soon as the DRDY bit is set to “1” by setting the RNGEN bit to “0” in the RNG\_CR register. The 32-bit random value stored in the RNG\_DR register will be still be available. If a new random is needed the application will need to re-enable the RNG and wait for 42+4 RNG clock cycles.

When disabling the RNG the user deactivates all the analog seed generators, whose power consumption is given in the datasheet electrical characteristics section.

## 19.5 RNG interrupts

In the RNG an interrupt can be produced on the following events:

- Data ready flag
- Seed error, see [Section 19.3.7: Error management](#)
- Clock error, see [Section 19.3.7: Error management](#)

Dedicated interrupt enable control bits are available as shown in [Table 122](#)

**Table 122. RNG interrupt requests**

| Interrupt event  | Event flag | Enable control bit |
|------------------|------------|--------------------|
| Data ready flag  | DRDY       | IE                 |
| Seed error flag  | SEIS       | IE                 |
| Clock error flag | CEIS       | IE                 |

The user can enable or disable the above interrupt sources individually by changing the mask bits or the general interrupt control bit IE in the RNG\_CR register. The status of the individual interrupt sources can be read from the RNG\_SR register.

*Note:* *Interrupts are generated only when RNG is enabled.*

## 19.6 RNG processing time

The RNG can produce one 32-bit random numbers every 42 RNG clock cycles.

After enabling or re-enabling the RNG using the RNGEN bit it takes 46 RNG clock cycles before random data are available.

## 19.7 Entropy source validation

### 19.7.1 Introduction

In order to assess the amount of entropy available from the RNG, STMicroelectronics has tested the peripheral against AIS-31 PTG.2 set of tests. The results can be provided on demand or the customer can reproduce the measurements using the AIS reference software. The customer could also test the RNG against an older NIST SP800-22 set of tests.

### 19.7.2 Validation conditions

STMicroelectronics has validated the RNG true random number generator in the following conditions:

- RNG clock rng\_clk= 48 MHz (CED bit = '0' in RNG\_CR register) and rng\_clk= 400kHz (CED bit="1" in RNG\_CR)
- AHB clock rng\_hclk= 60 MHz

### 19.7.3 Data collection

If raw data needs to be read instead of pre-processed data the developer is invited to contact STMicroelectronics to receive the correct procedure to follow.

## 19.8 RNG registers

The RNG is associated with a control register, a data register and a status register.

### 19.8.1 RNG control register (RNG\_CR)

Address offset: 0x000

Reset value: 0x0000 0000

|      |      |      |      |      |      |      |      |      |      |      |      |      |       |      |      |
|------|------|------|------|------|------|------|------|------|------|------|------|------|-------|------|------|
| 31   | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21   | 20   | 19   | 18    | 17   | 16   |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res.  | Res. | Res. |
|      |      |      |      |      |      |      |      |      |      |      |      |      |       |      |      |
| 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5    | 4    | 3    | 2     | 1    | 0    |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | CED  | Res. | IE   | RNGEN | Res. | Res. |
|      |      |      |      |      |      |      |      |      |      | rw   |      | rw   | rw    |      |      |

Bits 31:6 Reserved, must be kept at reset value

Bit 5 **CED**: Clock error detection

0: Clock error detection is enable

1: Clock error detection is disable

The clock error detection cannot be enabled nor disabled on-the-fly when the RNG is enabled, i.e. to enable or disable CED the RNG must be disabled.

Bit 4 Reserved, must be kept at reset value.

Bit 3 **IE**: Interrupt Enable

0: RNG Interrupt is disabled

1: RNG Interrupt is enabled. An interrupt is pending as soon as DRDY='1', SEIS='1' or CEIS='1' in the RNG\_SR register.

Bit 2 **RNGEN**: True random number generator enable

0: True random number generator is disabled. Analog noise sources are powered off and logic clocked by the RNG clock is gated.

1: True random number generator is enabled.

Bits 1:0 Reserved, must be kept at reset value.

## 19.8.2 RNG status register (RNG\_SR)

Address offset: 0x004

Reset value: 0x0000 0000

|      |      |      |      |      |      |      |      |      |       |       |      |      |      |      |      |
|------|------|------|------|------|------|------|------|------|-------|-------|------|------|------|------|------|
| 31   | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22    | 21    | 20   | 19   | 18   | 17   | 16   |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res.  | Res.  | Res. | Res. | Res. | Res. | Res. |
|      |      |      |      |      |      |      |      |      |       |       |      |      |      |      |      |
| 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6     | 5     | 4    | 3    | 2    | 1    | 0    |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | SEIS  | CEIS  | Res. | Res. | SECS | CECS | DRDY |
|      |      |      |      |      |      |      |      |      | rc_w0 | rc_w0 |      |      | r    | r    | r    |

Bits 31:7 Reserved, must be kept at reset value.

**Bit 6 SEIS:** Seed error interrupt status

This bit is set at the same time as SECS. It is cleared by writing it to '0'.

0: No faulty sequence detected

1: At least one faulty sequence has been detected. See **SECS** bit description for details.

An interrupt is pending if IE = '1' in the RNG\_CR register.

**Bit 5 CEIS:** Clock error interrupt status

This bit is set at the same time as CECS. It is cleared by writing it to '0'.

0: The RNG clock is correct ( $f_{\text{RNGCLK}} > f_{\text{HCLK}}/16$ )

1: The RNG has been detected too slow ( $f_{\text{RNGCLK}} < f_{\text{HCLK}}/16$ )

An interrupt is pending if IE = '1' in the RNG\_CR register.

Bits 4:3 Reserved, must be kept at reset value.

**Bit 2 SECS:** Seed error current status

0: No faulty sequence has currently been detected. If the SEIS bit is set, this means that a faulty sequence was detected and the situation has been recovered.

1: One of the noise source has provided more than 64 consecutive bits at a constant value ("0" or "1"), or more than 32 consecutive occurrence of two bits patterns ("01" or "10")

**Bit 1 CECS:** Clock error current status

0: The RNG clock is correct ( $f_{\text{RNGCLK}} > f_{\text{HCLK}}/16$ ). If the CEIS bit is set, this means that a slow clock was detected and the situation has been recovered.

1: The RNG clock is too slow ( $f_{\text{RNGCLK}} < f_{\text{HCLK}}/16$ ).

*Note: CECS bit is valid only if the CED bit in the RNG\_CR register is set to "0".*

**Bit 0 DRDY:** Data Ready

0: The RNG\_DR register is not yet valid, no random data is available.

1: The RNG\_DR register contains valid random data.

Once the RNG\_DR register has been read, this bit returns to '0' until a new random value is generated.

If IE='1' in the RNG\_CR register, an interrupt is generated when DRDY='1'.

19.8.3 RNG data register (RNG\_DR)

Address offset: 0x008

Reset value: 0x0000 0000

The RNG\_DR register is a read-only register that delivers a 32-bit random value when read. After being read this register delivers a new random value after 42 periods of RNG clock if the output FIFO is empty.

The content of this register is valid when DRDY='1', even if RNGEN='0'.

Bits 31:0 **RNDATA[31:0]**: Random data  
32-bit random data which are valid when DRDY='1'. When DRDY='0' RNDATA value is zero.

19.8.4 RNG register map

Table 123 gives the RNG register map and reset values.

Table 123. RNG register map and reset map

| Offset | Register name | 31           | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21   | 20   | 19   | 18   | 17   | 16   | 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0    |
|--------|---------------|--------------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|

| 0x008  | RNG_DR        | RNDATA[31:0] |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
|        | Reset value   | 0            | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    |

## 20 Cryptographic processor (CRYP)

This section applies to the whole STM32F756xx and STM32F750xx devices, unless otherwise specified.

### 20.1 Introduction

The cryptographic processor (CRYP) can be used both to encrypt and decrypt data using the DES, Triple-DES or AES algorithms. It is a fully compliant implementation of the following standards:

- The data encryption standard (DES) and Triple-DES (TDES) as defined by Federal Information Processing Standards Publication (FIPS PUB 46-3, Oct 1999), and the American National Standards Institute (ANSI X9.52)
- The advanced encryption standard (AES) as defined by Federal Information Processing Standards Publication (FIPS PUB 197, Nov 2001)

Multiple key sizes and chaining modes are supported:

- DES/TDES chaining modes ECB and CBC, supporting standard 56-bit keys with 8-bit parity per key
- AES chaining modes ECB, CBC, CTR, GCM, GMAC, CCM for key sizes of 128, 192 or 256 bits

The CRYP is a 32-bit AHB peripheral. It supports DMA transfers for incoming and outgoing data (two DMA channels are required). The peripheral also includes input and output FIFOs (each 8 words deep) for better performance.

The CRYP peripheral provides hardware acceleration to AES and DES cryptographic algorithms packaged in STM32 cryptographic library.

### 20.2 CRYP main features

- Compliant implementation of the following standards:
  - NIST *FIPS publication 46-3, Data Encryption Standard (DES)*
  - ANSI X9.52, *Triple Data Encryption Algorithm Modes of Operation*
  - NIST *FIPS publication 197, Advanced Encryption Standard (AES)*
- AES symmetric block cipher implementation
  - 128-bit data block processing
  - Support for 128-, 192- and 256-bit cipher key lengths
  - Encryption and decryption with multiple chaining modes: Electronic Code Book (ECB), Cipher Block Chaining (CBC), Counter mode (CTR), Galois Counter Mode (GCM), Galois Message Authentication Code mode (GMAC) and Counter with CBC-MAC (CCM).
  - 14 (respectively 18) clock cycles for processing one 128-bit block of data with a 128-bit (respectively 256-bit) key in AES-ECB mode
  - Integrated key scheduler with its key derivation stage (ECB or CBC decryption only)
- DES/TDES encryption/decryption implementation

- 64-bit data block processing
- Support for 64-, 128- and 192-bit cipher key lengths (including parity)
- Encryption and decryption with support of ECB and CBC chaining modes
- Direct implementation of simple DES algorithms (a single key K1 is used)
- 16 (respectively 64) clock cycles for processing one 64-bit block of data in DES (respectively TDES) ECB mode
- Software implementation of ciphertext stealing
- Features common to DES/TDES and AES
  - AMBA AHB slave peripheral, accessible through 32-bit word single accesses only (otherwise an AHB bus error is generated, and write accesses are ignored)
  - 256-bit register for storing the cryptographic key (8x 32-bit registers)
  - 128-bit registers for storing initialization vectors (4x 32-bit)
  - 1x32-bit INPUT buffer associated with an internal IN FIFO of eight 32-bit words, corresponding to four incoming DES blocks or two AES blocks
  - 1x32-bit OUTPUT buffer associated with an internal OUT FIFO of eight 32-bit words, corresponding to four processed DES blocks or two AES blocks
  - Automatic data flow control supporting direct memory access (DMA) using two channels (one for incoming data, one for processed data). Single and burst transfers are supported.
  - Data swapping logic to support 1-, 8-, 16- or 32-bit data
  - Possibility for software to suspend a message if the cryptographic processor needs to process another message with higher priority (suspend/resume operation)

## 20.3 CRYP functional description

### 20.3.1 CRYP block diagram

Figure 118 shows the block diagram of the cryptographic processor.

Figure 118. CRYP block diagram

### 20.3.2 CRYP internal signals

Table 124 provides a list of useful-to-know internal signals available at cryptographic processor level and not at STM32 product level (on pads).

Table 124. CRYP internal input/output signals

| Signal name  | Signal type          | Description                                                           |
|--------------|----------------------|-----------------------------------------------------------------------|
| cryp_hclk    | digital input        | AHB bus clock                                                         |
| cryp_it      | digital output       | Cryptographic processor global interrupt request                      |
| cryp_in_dma  | digital input/output | IN FIFO DMA burst request/ acknowledge                                |
| cryp_out_dma | digital input/output | OUT FIFO DMA burst request/ acknowledge (with single request for DES) |

### 20.3.3 CRYP DES/TDES cryptographic core

#### Overview

The DES/Triple-DES cryptographic core consists of three components:

- The DES Algorithm (DEA core)
- Multiple keys (one for the DES algorithm, one to three for the TDES algorithm)
- The initialization vector, which is used only in CBC mode

The DES/Triple-DES cryptographic core provides two operating modes:

- **ALGODIR=0**: Plaintext encryption using the key stored in the CRYP\_Kx registers.
- **ALGODIR=1**: Ciphertext decryption using the key stored in the CRYP\_Kx registers.

The operating mode is selected by programming the ALGODIR bit in the CRYP\_CR register.

#### Typical data processing

Typical usage of the cryptographic processor in DES modes can be found in [Section 20.3.10: CRYP DES/TDES basic chaining modes \(ECB, CBC\)](#).

*Note: The outputs of the intermediate DEA stages are never revealed outside the cryptographic boundary, with the exclusion of the IV registers in CBC mode.*

#### DES keying and chaining modes

The TDES allows three different keying options:

- *Three independent keys*  
The first option specifies that all the keys are independent, that is, K1, K2 and K3 are independent. FIPS PUB 46-3 – 1999 (and ANSI X9.52 – 1998) refers to this option as the Keying Option 1 and, to the TDES as 3-key TDES.
- *Two independent keys*  
The second option specifies that K1 and K2 are independent and K3 is equal to K1, that is, K1 and K2 are independent, K3 = K1. FIPS PUB 46-3 – 1999 (and ANSI X9.52 – 1998) refers to this second option as the Keying Option 2 and, to the TDES as 2-key TDES.
- *Three equal keys*  
The third option specifies that K1, K2 and K3 are equal, that is:  
$$K1 = K2 = K3$$
  
FIPS PUB 46-3 – 1999 (and ANSI X9.52 – 1998) refers to the third option as the Keying Option 3. This “1-key” TDES is equivalent to single DES.

The following chaining algorithms are supported by the DES hardware and can be selected through the ALGOMODE bits in the CRYP\_CR register:

- Electronic Code Book (ECB)
- Cipher Block Chaining (CBC)

These modes are described in details in [Section 20.3.10: CRYP DES/TDES basic chaining modes \(ECB, CBC\)](#).

## 20.3.4 CRYP AES cryptographic core

### Overview

The AES cryptographic core consists of the following components:

- The AES Algorithm (AEA core)
- The Multiplier over a binary Galois field (GF2mul)
- The key information
- The initialization vector (IV) or Nonce information
- Chaining algorithms logic (XOR, feedback/counter, mask)

The AES core works on 128-bit data blocks of (four words) with 128-, 192- or 256-bit key lengths. Depending on the chaining mode, the peripheral requires zero or one 128-bit initialization vector (IV).

The cryptographic peripheral features two operating modes:

- **ALGODIR=0**: Plaintext encryption using the key stored in the CRYP\_Kx registers.
- **ALGODIR=1**: Ciphertext decryption using the key stored in the CRYP\_Kx registers. When ECB and CBC chaining modes are selected, an initial key derivation process is automatically performed by the cryptographic peripheral.

The operating mode is selected by programming the ALGODIR bit in the CRYP\_CR register.

### Typical data processing

A description of cryptographic processor typical usage in AES mode can be found in [Section 20.3.11: CRYP AES basic chaining modes \(ECB, CBC\)](#).

*Note:* The outputs of the intermediate AEA stages is never revealed outside the cryptographic boundary, with the exclusion of the IV registers.

### AES chaining modes

The following chaining algorithms are supported by the cryptographic processor and can be selected through the ALGOMODE bits in the CRYP\_CR register:

- Electronic Code Book (ECB)
- Cipher Block Chaining (CBC)
- Counter Mode (CTR)
- Galois/Counter Mode (GCM)
- Galois Message Authentication Code mode (GMAC)
- Counter with CBC-MAC (CCM)

A quick introduction on these chaining modes can be found in the following subsections.

For detailed instructions, refer to [Section 20.3.11: CRYP AES basic chaining modes \(ECB, CBC\)](#) and onward.

## AES Electronic CodeBook (ECB)

Figure 119. AES-ECB mode overview

ECB is the simplest operating mode. There are no chaining operations, and no special initialization stage. The message is divided into blocks and each block is encrypted or decrypted separately.

*Note:* For decryption, a special key scheduling is required before processing the first block.

## AES Cipher block chaining (CBC)

Figure 120. AES-CBC mode overview

CBC operating mode chains the output of each block with the input of the following block. To make each message unique, an initialization vector is used during the first block processing.

*Note: For decryption, a special key scheduling is required before processing the first block.*

## AES Counter mode (CTR)

Figure 121. AES-CTR mode overview

The CTR mode uses the AES core to generate a key stream; these keys are then XORed with the plaintext to obtain the ciphertext as specified in NIST *Special Publication 800-38A, Recommendation for Block Cipher Modes of Operation*.

**Note:** Unlike ECB and CBC modes, no key scheduling is required for the CTR decryption, since in this chaining scheme the AES core is always used in encryption mode for producing the counter blocks.

### AES Galois/Counter mode (GCM)

Figure 122. AES-GCM mode overview

In Galois/Counter mode (GCM), the plaintext message is encrypted, while a message authentication code (MAC) is computed in parallel, thus generating the corresponding ciphertext and its MAC (also known as authentication tag). It is defined in NIST *Special Publication 800-38D, Recommendation for Block Cipher Modes of Operation - Galois/Counter Mode (GCM) and GMAC*.

GCM mode is based on AES in counter mode for confidentiality. It uses a multiplier over a fixed finite field for computing the message authentication code. It requires an initial value and a particular 128-bit block at the end of the message.

### AES Galois Message Authentication Code (GMAC)

Figure 123. AES-GMAC mode overview

Galois Message Authentication Code (GMAC) allows authenticating a message and generating the corresponding message authentication code (MAC). It is defined in NIST *Special Publication 800-38D, Recommendation for Block Cipher Modes of Operation - Galois/Counter Mode (GCM) and GMAC*.

GMAC is similar to Galois/Counter mode (GCM), except that it is applied on a message composed only by clear-text authenticated data (i.e. only header, no payload).

### AES Counter with CBC-MAC (CCM)

Figure 124. AES-CCM mode overview

In Counter with Cipher Block Chaining-Message Authentication Code (CCM), the plaintext message is encrypted while a message authentication code (MAC) is computed in parallel, thus generating the corresponding ciphertext and the corresponding MAC (also known as tag). It is described by NIST in *Special Publication 800-38C, Recommendation for Block Cipher Modes of Operation - The CCM Mode for Authentication and Confidentiality*.

CCM mode is based on AES in counter mode for confidentiality and it uses CBC for computing the message authentication code. It requires an initial value.

Like GCM CCM chaining mode, AES-CCM mode can be applied on a message composed only by cleartext authenticated data (i.e. only header, no payload). Note that this way of using CCM is not called CMAC (it is not similar to GCM/GMAC), and its usage is not recommended by NIST.

## 20.3.5 CRYP procedure to perform a cipher operation

### Introduction

To understand how the cryptographic peripheral operates, a typical cipher operation is described below. For the detailed peripheral usage according to the cipher mode, refer to the specific section, e.g. [Section 20.3.11: CRYP AES basic chaining modes \(ECB, CBC\)](#).

The flowcharts shown in [Figure 125](#) and [Figure 126](#) describe the way STM32 cryptographic library implements DES (respectively AES) algorithm. The cryptographic processor accelerates the execution of the following cryptographic algorithms:

- AES-128, AES-192, AES-256 bit in the following modes: ECB, CBC, CTR, CCM, GCM
- DES, TripleDES in the following modes: ECB, CBC

**Note:** For more details on the cryptographic library, refer to use manual UM1924 “STM32 crypto library” available from [www.st.com](http://www.st.com).

**Figure 125. STM32 cryptolib DES/TDES flowcharts**

Figure 126. STM32 cryptolib AES flowchart examples

### CRYP initialization

1. Initialize the cryptographic processor. The order of operations is not important except for AES-ECB and AES-CBC decryption, where the key preparation requires a specific sequence.
  - a) Disable the cryptographic processor by setting to 0 the CRYPEN bit in the CRYP\_CR register.
  - b) Configure the key size (128-, 192- or 256-bit, in the AES only) with the KEYSIZE bits in the CRYP\_CR register.
  - c) Write the symmetric key into the CRYP\_KxL/R registers (2 to 8 registers to be written depending on the algorithm).
  - d) Configure the data type (1-, 8-, 16- or 32-bit), with the DATATYPE bits in the CRYP\_CR register.
  - e) In case of decryption in AES-ECB or AES-CBC mode, prepare the key that has been written. First configure the key preparation mode by setting the ALGOMODE bits to 0b111 in the CRYP\_CR register. Then write the CRYPEN bit to 1: the BUSY

- bit is set automatically. Wait until BUSY returns to 0 (CRYPEN is automatically cleared as well): the key is prepared for decryption.
- f) Configure the algorithm and chaining with the ALGOMODE bits in the CRYP\_CR register.
  - g) Configure the direction (encryption/decryption) through the ALGODIR bit in the CRYP\_CR register.
  - h) When it is required (e.g. CBC or CTR chaining modes), write the initialization vectors into the CRYP\_IVxL/R register.
2. Flush the IN and OUT FIFOs by writing the FFLUSH bit to 1 in the CRYP\_CR register.

### Preliminary warning for all cases

If the ECB or CBC mode is selected and data are not a multiple of 64 bits (for DES) or 128 bits (for AES), the second and the last block management is more complex than the sequences below. Refer to [Section 20.3.8: CRYP stealing and data padding](#) for more details.

### Appending data using the CPU in polling mode

1. Enable the cryptographic processor by setting to 1 the CRYPEN bit in the CRYP\_CR register.
2. Write data in the IN FIFO (one block or until the FIFO is full).
3. Repeat the following sequence until the second last block of data has been processed:
  - a) Wait until the not-empty-flag OFNE is set to 1, then read the OUT FIFO (one block or until the FIFO is empty).
  - b) Wait until the not-full-flag IFNF is set to 1, then write the IN FIFO (one block or until the FIFO is full) except if it is the last block.
4. The BUSY bit is set automatically by the cryptographic processor. At the end of the processing, the BUSY bit returns to 0 and both FIFOs are empty (IN FIFO empty flag IFEM=1 and OUT FIFO not empty flag OFNE=0).
5. If the next processing block is the last block, the CPU must pad (when applicable) the data with zeroes to obtain a complete block.
6. When the operation is complete, the cryptographic processor can be disabled by clearing the CRYPEN bit in CRYP\_CR register.

### Appending data using the CPU in interrupt mode

1. Enable the interrupts by setting the INIM and OUTIM bits in the CRYP\_IMSCR register.
2. Enable the cryptographic processor by setting to 1 the CRYPEN bit in the CRYP\_CR register.
3. In the interrupt service routine that manages the input data:
  - a) If the last block is being loaded, the CPU must pad (when applicable) the data with zeroes to have a complete block. Then load the block into the IN FIFO.
  - b) If it is not the last block, load the data into the IN FIFO. You can load only one block (2 words for DES, 4 words for AES), or load data until the FIFO is full.
  - c) In all cases, after the last word of data has been written, disable the interrupt by clearing the INIM interrupt mask.
4. In the interrupt service routine that manages the input data:

- a) Read the output data from the OUT FIFO. You can read only one block (2 words for DES, 4 words for AES), or read data until the FIFO is empty.
- b) When the last word has been read, INIM and BUSY bits are set to 0 and both FIFOs are empty (IFEM=1 and OFNE=0). You can disable the interrupt by clearing the OUTIM bit, and disable the peripheral by clearing the CRYPEN bit.
- c) If you read the last block of cleartext data (i.e. decryption), optionally discard the data that is not part of message/payload.

### Appending data using the DMA

1. Prepare the last block of data by optionally padding it with zeroes to have a complete block.
2. Configure the DMA controller to transfer the input data from the memory and transfer the output data from the peripheral to the memory, as described in [Section 20.3.19: CRYP DMA interface](#). The DMA should be configured to set an interrupt on transfer completion to indicate that the processing is complete.
3. Enable the cryptographic processor by setting to 1 the CRYPEN bit in CRYP\_CR register, then enable the DMA IN and OUT requests by setting to 1 the DIEN and DOEN bits in the CRYP\_DMACR register.
4. All the transfers and processing are managed by the DMA and the cryptographic processor. The DMA interrupt indicates that the processing is complete. Both FIFOs are normally empty and BUSY flag is set 0.

**Caution:** It is important that DMA controller empties the cryptographic processor output FIFO before filling up the cryptographic processor input FIFO. To achieve this, the DMA controller should be configured so that the transfer from the cryptographic peripheral to the memory has a higher priority than the transfer from the memory to the cryptographic peripheral.

### 20.3.6 CRYP busy state

The cryptographic processor is busy and processing data (BUSY set to 1 in CRYP\_SR register) when all the conditions below are met:

- CRYPEN = 1 in CRYP\_CR register.
- There are enough data in the input FIFO (at least two words for the DES or TDES algorithm mode, four words for the AES algorithm mode).
- There is enough free-space in the output FIFO (at least two word locations for DES, four for AES).

Write operations to the CRYP\_Kx(L/R)R key registers, to the CRYP\_IVx(L/R)R initialization registers, or to bits [9:2] of the CRYP\_CR register, are ignored when cryptographic processor is busy (i.e. the registers are not modified). It is thus not possible to modify the configuration of the cryptographic processor while it is processing a data block.

It is possible to clear the CRYPEN bit while BUSY bit is set to 1. In this case the ongoing DES/TDES or AES processing first completes (i.e. the word results are written to the output FIFO) before the BUSY bit is cleared by hardware.

**Note:** *If the application needs to suspend a message to process another one with a higher priority, refer to [Section 20.3.9: CRYP suspend/resume operations](#)*

When a block is being processed in DES or TDES mode, if the output FIFO becomes full and the input FIFO contains at least one new block, then the new block is popped off the

input FIFO and the BUSY bit remains high until there is enough space to store this new block into the output FIFO.

### 20.3.7 Preparing the CRYP AES key for decryption

When performing an AES **ECB** or **CBC** decryption, the AES key has to be prepared, i.e. a complete key schedule of encryption is required before performing the decryption. In other words, the key in the last round of encryption must be used as the first round key for decryption.

This preparation is not required in any other AES modes than AES ECB or CBC decryption.

If the application software stores somehow the initial key prepared for decryption, the key scheduling operation can be performed only once for all the data to be decrypted with a given cipher key.

*Note: The latency of the key preparation operation is 14, 16 or 18 clock cycles depending on the key size (128-, 192- or 256-bit).*

The CRYP key preparation process is performed as follow:

1. Write the encryption key to K0...K3 key registers.
2. Program ALGOMODE bits to 0b111 in CRYP\_CR. Writing this value when CRYPEN is set to 1 immediately starts an AES round for key preparation. The BUSY bit in the CRYP\_SR register is set to 1.
3. When the key processing is complete, the resulting key is copied back into the K0...K3 key registers, and the BUSY bit is cleared.

*Note: As the CRYPEN bitfield is reset by hardware at the end of the key preparation, the application software must set it again for the next operation.*

### 20.3.8 CRYP stealing and data padding

When using DES or AES algorithm in **ECB** or **CBC** modes to manage messages that are not multiple of the block size (64 bits for DES, 128 bits for AES), use ciphertext stealing techniques such as those described in NIST *Special Publication 800-38A, Recommendation for Block Cipher Modes of Operation: Three Variants of Ciphertext Stealing for CBC Mode*. Since the cryptographic processor does not implement such techniques, **the last two blocks** must be handled in a special way by the application.

*Note: Ciphertext stealing techniques are not documented in this reference manual.*

Similarly, when the AES algorithm is used in other modes than ECB or CBC, incomplete input data blocks (i.e. block shorter than 128 bits) have to be padded with zeroes by the application prior to encryption (i.e. extra bits should be appended to the trailing end of the data string). After decryption, the extra bits have to be discarded. The cryptographic processor does not implement automatic data padding operation to **the last block**, so the application should follow the recommendation given in [Section 20.3.5: CRYP procedure to perform a cipher operation](#) to manage messages that are not multiple of 128 bits.

*Note: Padding data are swapped in a similar way as normal data, according to the DATATYPE field in CRYP\_CR register (see [Section 20.3.16: CRYP data registers and data swapping](#) for details).*

With this version of cryptographic processor, a special workaround is required in order to properly compute authentication tags while doing a **GCM encryption** or a **CCM decryption** with the last block of payload size **inferior to 128 bits**. This workaround is described below:

- During GCM encryption payload phase and before inserting a last plaintext block smaller than 128 bits, the application has to follow the below sequence:
  - a) Disable the peripheral by setting the CRYPEN bit to 0 in CRYP\_CR.
  - b) Load CRYP\_IV1R register content in a temporary variable. Decrement the value by 1 and reinsert the result in CRYP\_IV1R register.
  - c) Change the AES mode to CTR mode by writing the ALGOMODE bitfield to 0b0110 in the CRYP\_CR register.
  - a) Set the CRYPEN bit to 1 in CRYP\_CR to enable again the peripheral.
  - b) Pad the last block (smaller than 128 bits) with zeros to have a complete block of 128 bits, then write it into CRYP\_DIN register.
  - c) Upon encryption completion, read the 128-bit generated ciphertext from the CRYP\_DOUT register and store it as intermediate data.
  - d) Change again the AES mode to GCM mode by writing the ALGOMODE bitfield to 0b1000 in the CRYP\_CR register.
  - e) Select Final phase by writing the GCM\_CCMPH bitfield to 0b11 in the CRYP\_CR register.
  - f) In the intermediate data, set to 0 the bits corresponding to the padded bits of the last payload block then insert the resulting data to CRYP\_DIN register.
  - g) When the operation is complete, read data from CRYP\_DOUT. These data have to be discarded.
  - h) Apply the normal Final phase as described in [Section 20.3.13: CRYP AES Galois/counter mode \(GCM\)](#).
- During CCM decryption payload phase and before inserting a last ciphertext block smaller than 128 bits, the application has to follow the below sequence:
  - a) To disable the peripheral, set the CRYPEN bit to 0 in CRYP\_CR.
  - b) Load CRYP\_IV1R in a temporary variable (named here `IV1temp`).
  - c) Load CRYP\_CSGCMCCM0R, CRYP\_CSGCMCCM1R, CRYP\_CSGCMCCM2R, and CRYP\_CSGCMCCM3R registers content from LSB to MSB in 128-bit temporary variable (named here `temp1`).
  - d) Load in CRYP\_IV1R the content previously stored in `IV1temp`.
  - e) Change the AES mode to CTR mode by writing the ALGOMODE bitfield to 0b0110 in the CRYP\_CR register.
  - a) Set the CRYPEN bit to 1 in CRYP\_CR to enable again the peripheral.
  - b) Pad the last block (smaller than 128 bits) with zeros to have a complete block of 128 bits, then write it to CRYP\_DIN register.
  - c) Upon decryption completion, read the 128-bit generated data from DOUT register, and store them as intermediate data (here named `intdata_o`).
  - d) Save again CRYP\_CSGCMCCM0R, CRYP\_CSGCMCCM1R, CRYP\_CSGCMCCM2R, and CRYP\_CSGCMCCM3R registers content, from LSB to MSB, in a new 128-bit temporary variable (named here `temp2`).
  - e) Change again the AES mode to CCM mode by writing the ALGOMODE bitfield to 0b1001 in the CRYP\_CR register.

- f) Select the header phase by writing the GCM\_CCMPH bitfield to 0b01 in the CRYP\_CR register.
- g) In the intermediate data (`intdata_o` which was generated with CTR), set to 0 the bits corresponding to the padded bits of the last payload block, XOR with `temp1`, XOR with `temp2`, and insert the resulting data into CRYP\_DIN register. In other words:  

$$\text{CRYP\_DIN} = (\text{intdata\_o} \text{ AND mask}) \text{ XOR temp1 XOR temp2}.$$
- h) Wait for operation completion.
- i) Apply the normal Final phase as described in [Section 20.3.15: CRYP AES Counter with CBC-MAC \(CCM\)](#).

### 20.3.9 CRYP suspend/resume operations

A message can be suspended if another message with a higher priority has to be processed. When this highest priority message has been sent, the suspended message can be resumed in both encryption or decryption mode.

Suspend/resume operations do not break the chaining operation and the message processing can be resumed as soon as cryptographic processor is enabled again to receive the next data block.

[Figure 127](#) gives an example of suspend.resume operation: message 1 is suspended in order to send a higher priority message (message 2), which is shorter than message 1 (AES algorithm).

**Figure 127. Example of suspend mode management**

A detailed description of suspend/resume operations can be found in each AES mode section.

### 20.3.10 CRYP DES/TDES basic chaining modes (ECB, CBC)

#### Overview

FIPS PUB 46-3 – 1999 (and ANSI X9.52-1998) provides a thorough explanation of the processing involved in the four operation modes supplied by the DES computing core: TDES-ECB encryption, TDES-ECB decryption, TDES-CBC encryption and TDES-CBC decryption. This section only gives a brief explanation of each mode.

#### DES/TDES-ECB encryption

[Figure 128](#) illustrates the encryption in DES and TDES Electronic CodeBook (DES/TDES-ECB) mode. This mode is selected by writing in ALGOMODE to 0b000 and ALGODIR to 0 in CRYP\_CR.

**Figure 128. DES/TDES-ECB mode encryption**

1. K: key; C: cipher text; I: input block; O: output block; P: plain text.

A 64-bit plaintext data block (P) is used after bit/byte/half-word as the input block (I). The input block is processed through the DEA in the encrypt state using K1. The output of this process is fed back directly to the input of the DEA where the DES is performed in the decrypt state using K2. The output of this process is fed back directly to the input of the DEA where the DES is performed in the encrypt state using K3. The resultant 64-bit output block (O) is used, after bit/byte/half-word swapping, as ciphertext (C) and it is pushed into the OUT FIFO.

**Note:** For more information on data swapping, refer to [Section 20.3.16: CRYP data registers and data swapping](#).

Detailed DES/TDES encryption sequence can be found in [Section 20.3.5: CRYP procedure to perform a cipher operation](#).

## DES/TDES-ECB mode decryption

[Figure 129](#) illustrates the decryption in DES and TDES Electronic CodeBook (DES/TDES-ECB) mode. This mode is selected by writing ALGOMODE to 0b000 and ALGODIR to 1 in CRYP\_CR.

**Figure 129. DES/TDES-ECB mode decryption**

1. K: key; C: cipher text; I: input block; O: output block; P: plain text.

A 64-bit ciphertext block (C) is used, after bit/byte/half-word swapping, as the input block (I). The keying sequence is reversed compared to that used in the encryption process. The input block is processed through the DEA in the decrypt state using K3. The output of this process is fed back directly to the input of the DEA where the DES is performed in the encrypt state using K2. The new result is directly fed to the input of the DEA where the DES is performed in the decrypt state using K1. The resultant 64-bit output block (O), after bit/byte/half-word swapping, produces the plaintext (P).

**Note:** For more information on data swapping refer to [Section 20.3.16: CRYP data registers and data swapping](#).

Detailed DES/TDES encryption sequence can be found in [Section 20.3.5: CRYP procedure to perform a cipher operation](#).

## DES/TDES-CBC encryption

Figure 130 illustrates the encryption in DES and TDES Cipher Block Chaining (DES/TDES-ECB) mode. This mode is selected by writing in ALGOMODE to 0b001 and ALGODIR to 0 in CRYP\_CR.

Figure 130. DES/TDES-CBC mode encryption

K: key; C: cipher text; I: input block; O: output block; Ps: plain text before swapping (when decoding) or after swapping (when encoding); P: plain text; IV: initialization vectors.

This mode begins by dividing a plaintext message into 64-bit data blocks. In TCBC encryption, the first input block ( $I_1$ ), obtained after bit/byte/half-word swapping, is formed by exclusive-ORing the first plaintext data block ( $P_1$ ) with a 64-bit initialization vector IV ( $I_1 = IV \oplus P_1$ ). The input block is processed through the DEA in the encrypt state using K1. The output of this process is fed back directly to the input of the DEA, which performs the DES in the decrypt state using K2. The output of this process is fed directly to the input of the DEA, which performs the DES in the encrypt state using K3. The resultant 64-bit output block ( $O_1$ ) is used directly as the ciphertext ( $C_1$ ), that is,  $C_1 = O_1$ .

This first ciphertext block is then exclusive-ORed with the second plaintext data block to produce the second input block, ( $I_2 = (C_1 \oplus P_2)$ ). Note that  $I_2$  and  $P_2$  now refer to the second block. The second input block is processed through the TDEA to produce the second ciphertext block.

This encryption process continues to “chain” successive cipher and plaintext blocks together until the last plaintext block in the message is encrypted.

If the message does not consist of an integral number of data blocks, then the final partial data block should be encrypted in a manner specified for the application.

Note: For more information on data swapping refer to [Section 20.3.16: CRYP data registers and data swapping](#).

Detailed DES/TDES encryption sequence can be found in [Section 20.3.5: CRYP procedure to perform a cipher operation](#).

### DES/TDES-CBC decryption

[Figure 130](#) illustrates the decryption in DES and TDES Cipher Block Chaining (DES/TDES-ECB) mode. This mode is selected by writing ALGOMODE to 0b001 and ALGODIR to 1 in CRYP\_CR.

**Figure 131. DES/TDES-CBC mode decryption**

1. K: key; C: cipher text; I: input block; O: output block; Ps: plain text before swapping (when decoding) or after swapping (when encoding); P: plain text; IV: initialization vectors.

In this mode the first ciphertext block ( $C_1$ ) is used directly as the input block ( $I_1$ ). The keying sequence is reversed compared to that used for the encrypt process. The input block is processed through the DEA in the decrypt state using  $K_3$ . The output of this process is fed directly to the input of the DEA where the DES is processed in the encrypt state using  $K_2$ . This resulting value is directly fed to the input of the DEA where the DES is processed in the decrypt state using  $K_1$ . The resulting output block is exclusive-ORed with the IV (which must be the same as that used during encryption) to produce the first plaintext block ( $P_1 = O_1 \oplus IV$ ).

The second ciphertext block is then used as the next input block and is processed through the TDEA. The resulting output block is exclusive-ORed with the first ciphertext block to produce the second plaintext data block ( $P_2 = O_2 \oplus C_1$ ). Note that  $P_2$  and  $O_2$  refer to the second block of data.

The DES/TDES-CBC decryption process continues in this manner until the last complete ciphertext block has been decrypted.

Ciphertext representing a partial data block must be decrypted in a manner specified for the application.

*Note:* For more information on data swapping refer to [Section 20.3.16: CRYP data registers and data swapping](#).  
Detailed DES/TDES encryption sequence can be found in [Section 20.3.5: CRYP procedure to perform a cipher operation](#).

### DES/TDES suspend/resume operations in ECB/CBC modes

Before interrupting the current message, the user application must respect the following steps:

1. If DMA is used, stop the DMA transfers to the IN FIFO by clearing to 0 the DIEN bit in the CRYP\_DMACR register.
2. Wait until both the IN and the OUT FIFOs are empty (IFEM=1 and OFNE=0 in the CRYP\_SR) and the BUSY bit is cleared. Alternatively, as the input FIFO can contain up to four unprocessed DES blocks, the application could decide for real-time reason to interrupt the cryptographic processing without waiting for the IN FIFO to be empty. In this case, the alternative is:
  - a) Wait until OUT FIFO is empty (OFNE=0).
  - b) Read back the data loaded in the IN FIFO that have not been processed and save them in the memory until the IN FIFO is empty.
3. If DMA is used stop the DMA transfers from the OUT FIFO by clearing to 0 the DOEN bit in the CRYP\_DMACR register.
4. Disable the cryptographic processor by setting the CRYPEN bit to 0 in CRYP\_CR, then save the current configuration (bits [9:2] in the CRYP\_CR register). If CBC mode is selected, save the initialization vector registers, since CRYP\_IVx registers have changed from initial values during the data processing.

*Note:* Key registers do not need to be saved as the original key value is known by the application.

5. If DMA is used, save the DMA controller status (such as the pointers to IN and OUT data transfers, number of remaining bytes).

To resume message processing, the user application must respect the following sequence:

1. If DMA is used, reconfigure the DMA controller to complete the rest of the FIFO IN and FIFO OUT transfers.
2. Make sure the cryptographic processor is disabled by reading the CRYPEN bit in CRYP\_CR (it must be 0).
3. Configure again the cryptographic processor with the initial setting in CRYP\_CR, as well as the key registers using the saved configuration.
4. If the CBC mode is selected, restore CRYP\_IVx registers using the saved configuration.
5. Optionally, write the data that were saved during context saving into the IN FIFO.
6. Enable the cryptographic processor by setting the CRYPEN bit to 1.
7. If DMA is used, enable again DMA requests for the cryptographic processor, by setting to 1 the DIEN and DOEN bits in the CRYP\_DMACR register.

### 20.3.11 CRYP AES basic chaining modes (ECB, CBC)

#### Overview

FIPS PUB 197 (November 26, 2001) provides a thorough explanation of the processing involved in the four basic operation modes supplied by the AES computing core: AES-ECB encryption, AES-ECB decryption, AES-CBC encryption and AES-CBC decryption. This section only gives a brief explanation of each mode.

#### AES ECB encryption

[Figure 132](#) illustrates the AES Electronic codebook (AES-ECB) mode encryption. This mode is selected by writing ALGOMODE to 0b100 and ALGODIR to 0 in CRYP\_CR.

**Figure 132. AES-ECB mode encryption**

1. K: key; C: cipher text; I: input block; O: output block; P: plain text.
2. If Key size = 128: Key = [K3 K2].  
 If Key size = 192: Key = [K3 K2 K1].  
 If Key size = 256: Key = [K3 K2 K1 K0].

In this mode a 128-bit plaintext data block (P) is used after bit/byte/half-word swapping as the input block (I). The input block is processed through the AEA in the encrypt state using the 128, 192 or 256-bit key. The resultant 128-bit output block (O) is used after bit/byte/half-word swapping as ciphertext (C). It is then pushed into the OUT FIFO.

For more information on data swapping refer to [Section 20.3.16: CRYP data registers and data swapping](#).

## AES ECB decryption

[Figure 133](#) illustrates the AES Electronic codebook (AES-ECB) mode decryption. This mode is selected by writing in ALGOMODE to 0b100 and ALGODIR to 1 in CRYP\_CR.

**Figure 133. AES-ECB mode decryption**

1. K: key; C: cipher text; I: input block; O: output block; P: plain text.
2. If Key size = 128 => Key = [K3 K2]  
 If Key size = 192 => Key = [K3 K2 K1]  
 If Key size = 256 => Key = [K3 K2 K1 K0].

To perform an AES decryption in ECB mode, the secret key has to be prepared (it is necessary to execute the complete key schedule for encryption) by collecting the last round key, and using it as the first round key for the decryption of the ciphertext. This preparation phase is computed by the AES core. Refer to [Section 20.3.7: Preparing the CRYP AES key for decryption](#) for more details on how to prepare the key.

When the key preparation is complete, the decryption proceed as follow: a 128-bit ciphertext block (C) is used after bit/byte/half-word swapping as the input block (I). The keying sequence is reversed compared to that of the encryption process. The resultant 128-bit output block (O), after bit/byte or half-word swapping, produces the plaintext (P). The AES-CBC decryption process continues in this manner until the last complete ciphertext block has been decrypted.

For more information on data swapping refer to [Section 20.3.16: CRYP data registers and data swapping](#).

## AES CBC encryption

Figure 134 illustrates the AES Cipher block chaining (AES-CBC) mode encryption. This mode is selected by writing ALGOMODE to 0b101 and ALGODIR to 0 in CRYP\_CR.

Figure 134. AES-CBC mode encryption

1. K: key; C: cipher text; I: input block; O: output block; Ps: plain text before swapping (when decoding) or after swapping (when encoding); P: plain text; IV: Initialization vectors.
2.  $IV_x = [IV_xR \ IV_xL]$ , R=right, L=left.
3. If Key size = 128 => Key = [K3 K2].  
If Key size = 192 => Key = [K3 K2 K1].  
If Key size = 256 => Key = [K3 K2 K1 K0].

In this mode the first input block ( $I_1$ ) obtained after bit/byte/half-word swapping is formed by exclusive-ORing the first plaintext data block ( $P_1$ ) with a 128-bit initialization vector IV ( $I_1 = IV \oplus P_1$ ). The input block is processed through the AEA in the encrypt state using the 128-, 192- or 256-bit key ( $K_0 \dots K_3$ ). The resultant 128-bit output block ( $O_1$ ) is used directly as ciphertext ( $C_1$ ), that is,  $C_1 = O_1$ . This first ciphertext block is then exclusive-ORed with the second plaintext data block to produce the second input block, ( $I_2 = (C_1 \oplus P_2)$ ). Note that  $I_2$  and  $P_2$  now refer to the second block. The second input block is processed through the AEA to produce the second ciphertext block. This encryption process continues to “chain” successive cipher and plaintext blocks together until the last plaintext block in the message is encrypted.

If the message does not consist of an integral number of data blocks, then the final partial data block should be encrypted in a manner specified for the application, as explained in [Section 20.3.8: CRYP stealing and data padding](#).

For more information on data swapping, refer to [Section 20.3.16: CRYP data registers and data swapping](#).

## AES CBC decryption

Figure 135 illustrates the AES Cipher block chaining (AES-CBC) mode decryption. This mode is selected by writing ALGOMODE to 0b101 and ALGODIR to 1 in CRYP\_CR.

Figure 135. AES-CBC mode decryption

1. K: key; C: cipher text; I: input block; O: output block; Ps: plain text before swapping (when decoding) or after swapping (when encoding); P: plain text; IV: Initialization vectors.
2.  $IVx = [IVxR \ IVxL]$ , R=right, L=left.
3. If Key size = 128 => Key = [K3 K2].  
 If Key size = 192 => Key = [K3 K2 K1].  
 If Key size = 256 => Key = [K3 K2 K1 K0].

In CBC mode, like in ECB mode, the secret key must be prepared to perform an AES decryption. Refer to [Section 20.3.7: Preparing the CRYP AES key for decryption](#) for more details on how to prepare the key.

When the key preparation process is complete, the decryption proceeds as follow: the first 128-bit ciphertext block ( $C_1$ ) is used directly as the input block ( $I_1$ ). The input block is processed through the AEA in the decrypt state using the 128-, 192- or 256-bit key. The resulting output block is exclusive-ORed with the 128-bit initialization vector IV (which must be the same as that used during encryption) to produce the first plaintext block ( $P_1 = O_1 \oplus IV$ ).

The second ciphertext block is then used as the next input block and is processed through the AEA. The resulting output block is exclusive-ORed with the first ciphertext block to produce the second plaintext data block ( $P_2 = O_2 \oplus C_1$ ). Note that  $P_2$  and  $O_2$  refer to the second block of data. The AES-CBC decryption process continues in this manner until the last complete ciphertext block has been decrypted.

Ciphertext representing a partial data block must be decrypted in a manner specified for the application, as explained in [Section 20.3.8: CRYP stealing and data padding](#).

For more information on data swapping, refer to [Section 20.3.16: CRYP data registers and data swapping](#).

### AES suspend/resume operations in ECB/CBC modes

Before interrupting the current message, the user application must respect the following sequence:

1. If DMA is used, stop the DMA transfers to the IN FIFO by clearing to 0 the DIEN bit in the CRYP\_DMACR register.
2. Wait until both the IN and the OUT FIFOs are empty (IFEM=1 and OFNE=0 in the CRYP\_SR) and the BUSY bit is cleared.
3. If DMA is used, stop the DMA transfers from the OUT FIFO by clearing to 0 the DOEN bit in the CRYP\_DMACR register.
4. Disable the CRYP by setting the CRYPEN bit to 0 in CRYP\_CR, then save the current configuration (bits [9:2] in the CRYP\_CR register). If ECB mode is not selected, save the initialization vector registers, because CRYP\_IVx registers have changed from initial values during the data processing.

*Note:* Key registers do not need to be saved as the original key value is known by the application.

5. If DMA is used, save the DMA controller status (such as pointers to IN and OUT data transfers, number of remaining bytes).

To resume message processing, the user application must respect the following sequence:

1. If DMA is used, reconfigure the DMA controller to complete the rest of the FIFO IN and FIFO OUT transfers.
2. Make sure the cryptographic processor is disabled by reading the CRYPEN bit in CRYP\_CR (it must be set to 0).
3. Configure the cryptographic processor again with the initial setting in CRYP\_CR, as well as the key registers using the saved configuration.
4. For AES-ECB or AES-CBC decryption, the key must be prepared again, as described in [Section 20.3.7: Preparing the CRYP AES key for decryption](#).
5. If ECB mode is not selected, restore CRYP\_IVx registers using the saved configuration.
6. Enable the cryptographic processor by setting the CRYPEN bit to 1.
7. If DMA is used, enable again the DMA requests from the cryptographic processor, by setting DIEN and DOEN bits to 1 in the CRYP\_DMACR register.

### 20.3.12 CRYP AES counter mode (AES-CTR)

#### Overview

The AES counter mode (CTR) uses the AES block as a key stream generator. The generated keys are then XORed with the plaintext to obtain the ciphertext.

CTR chaining is defined in NIST *Special Publication 800-38A, Recommendation for Block Cipher Modes of Operation*. A typical message construction in CTR mode is given in [Figure 136](#).

**Figure 136. Message construction for the Counter mode**

The structure of this message is as below:

- A 16-byte Initial Counter Block (ICB), composed of three distinct fields:
  - A *nonce*: a 32-bit, single-use value (i.e. a new nonce should be assigned to each new communication).
  - The *initialization vector* (IV): a 64-bit value that must be unique for each execution of the mode under a given key.
  - The *counter*: a 32-bit big-endian integer that is incremented each time a block has been processed. The initial value of the counter should be set to 1.
- The plaintext (P) is both authenticated and encrypted as ciphertext C, with a known length. This length can be non-multiple of 16 bytes, in which case a plaintext padding is required.

## AES CTR processing

[Figure 137](#) (respectively [Figure 138](#)) describes the AES-CTR encryption (respectively decryption) process implemented within this peripheral. This mode is selected by writing in ALGOMODE bitfield to 0b110 in CRYP\_CR.

**Figure 137. AES-CTR mode encryption**

1. K: key; C: cipher text; I: input Block; o: output block; Ps: plain text before swapping (when decoding) or after swapping (when encoding); Cs: cipher text after swapping (when decoding) or before swapping (when encoding); P: plain text; IV: Initialization vectors.

Figure 10: AHB2 CRYPTOPATH encryption flow diagram. The diagram illustrates the data flow for encryption. It starts with an IN FIFO ciphertext P, which is then processed by a swapping block. The output of the swapping block is C, 128 bits. This is followed by an AHB2 data write (before CRYPT is enabled), which feeds into an IV0...1(L/R) block. The output of the IV block is I, 128 bits, which is then incremented by 1 (+1) and fed into a K0...3 block. The output of the K0...3 block is 128, 192, or 256 bits, which is then fed into an AEA, encrypt block. The output of the AEA, encrypt block is O, 128 bits, which is then added (+) to the output of the IV block (I, 128 bits) to produce Ps, 128 bits. This is followed by another swapping block, which produces the final output P, 128 bits, which is then fed into an OUT FIFO plaintext C. A dashed box indicates that (I + 1) is written back into IV at the same time as P is pushed in OUT FIFO.

The following sequence must be used to perform an encryption or a decryption in CTR chaining mode:

1. Make sure the cryptographic processor is disabled by clearing the CRYPEN bit in the CRYP\_CR register.
2. Configure CRYP\_CR as follows:
  - a) Program ALGOMODE bits to 0b110 to select CTR mode.
  - b) Configure the data type (1, 8, 16 or 32 bits) through the DATATYPE bits.
3. Initialize the key registers (128, 192 and 256 bits) in CRYP\_KEYRx as well as the initialization vector (IV) as described in [Table 125](#).
4. Flush the IN and OUT FIFOs by writing the FFLUSH bit to 1 in the CRYP\_CR register.
5. If it is the last block, optionally pad the data with zeros to have a complete block.
6. Append data in the cryptographic processor and read the result. The three possible scenarios are described in [Section 20.3.5: CRYP procedure to perform a cipher operation](#).
7. Repeat the previous step until the second last block is processed. For the last block, execute the two previous steps. For this last block, the driver must discard the data that is not part of the data when the last block size is less than 16 bytes.

#### Suspend/resume operations in CTR mode

Like for the CBC mode, it is possible to interrupt a message to send a higher priority message, and resume the message which was interrupted. Detailed CBC sequence can be found in [Section 20.3.11: CRYP AES basic chaining modes \(ECB, CBC\)](#).

*Note:* Like for CBC mode, IV registers must be reloaded during the resume operation.

### 20.3.13 CRYP AES Galois/counter mode (GCM)

#### Overview

The AES Galois/counter mode (GCM) allows encrypting and authenticating the plaintext, and generating the correspondent ciphertext and tag (also known as message authentication code). To ensure confidentiality, GCM algorithm is based on AES counter mode. It uses a multiplier over a fixed finite field to generate the tag.

GCM chaining is defined in NIST *Special Publication 800-38D, Recommendation for Block Cipher Modes of Operation - Galois/Counter Mode (GCM) and GMAC*. A typical message construction in GCM mode is given in [Figure 139](#).

**Figure 139. Message construction for the Galois/counter mode**

The structure of this message is defined as below:

- A 16-byte Initial Counter Block (ICB), composed of two distinct fields:
  - The *initialization vector* (IV): a 96-bit value that must be unique for each execution of the mode under a given key. Note that the GCM standard supports IV that are shorter than 96-bit, but in this case strict rules apply.
  - The *counter*: a 32-bit big-endian integer that is incremented each time a block has been processed. According to NIST specification, the counter value is 0x2 when processing the first block of payload.
- The authenticated header A (also known as Additional Authentication Data) has a known length  $Len(A)$  that can be non-multiple of 16 bytes and cannot exceed  $2^{64}-1$  bits. This part of the message is only authenticated, not encrypted.
- The plaintext message (P) is both authenticated and encrypted as ciphertext C, with a known length  $Len(P)$  that can be non-multiple of 16 bytes, and cannot exceed  $2^{32}-2$  blocks of 128-bits.

**Note:** GCM standard specifies that ciphertext C has same bit length as the plaintext P.

- When a part of the message (AAD or P) has a length which is non-multiple of 16 bytes, a special padding scheme is required.
- The last block is composed of the length of A (on 64 bits) and the length of ciphertext C (on 64 bits) as shown in [Table 126](#).

Table 126. GCM last block definition

| Endianness | Bit[0] | Bit[32]             | Bit[64] | Bit[96]              |
|------------|--------|---------------------|---------|----------------------|
| Input data | 0x0    | Header length[31:0] | 0x0     | Payload length[31:0] |

### AES GCM processing

This mode is selected by writing ALGOMODE bitfield to 0b110 in CRYP\_CR.

The mechanism for the confidentiality of the plaintext in GCM mode is a variation of the Counter mode, with a particular 32-bit incrementing function that generates the necessary sequence of counter blocks.

CRYP\_IV registers are used for processing each data block. The cryptographic processor automatically increments the 32 least significant bits of the counter block. The first counter block (CB1) written by the application is equal to the Initial Counter Block incremented by one (see [Table 127](#)).

Table 127. GCM mode IV registers initialization

| Register   | CRYP_IV1R[31:0] | CRYP_IV1L[31:0] | CRYP_IV0R[31:0] | CRYP_IV0L[31:0]                  |
|------------|-----------------|-----------------|-----------------|----------------------------------|
| Input data | ICB[127:96]     | ICB[95:64]      | ICB[63:32]      | ICB[31:0]<br>32-bit counter= 0x2 |

**Note:** *In this mode the key must NOT be prepared for decryption.*

The authentication mechanism in GCM mode is based on a hash function, called *GF2mul*, that performs multiplication by a fixed parameter, called the hash subkey (H), within a binary Galois field.

To process a GCM message, the driver must go through four phases, which are described in the following subsections.

- The Init phase: the peripheral prepares the GCM hash subkey (H) and performs the IV processing
- The Header phase: the peripheral processes the Additional Authenticated Data (AAD), with hash computation only.
- The Payload phase: the peripheral processes the plaintext (P) with hash computation, keystream encryption and data XORing. It operates in a similar way for ciphertext (C).
- The Final phase: the peripheral generates the authenticated tag (T) using the data last block.

**1. GCM init phase**

During this first step, the GCM hash subkey (H) is calculated and saved internally to be used for processing all the blocks. It is recommended to follow the sequence below:

- a) Make sure the cryptographic processor is disabled by clearing the CRYPEN bit in the CRYP\_CR register.
- b) Select the GCM chaining mode by programming ALGOMODE bits to 0b01000 in CRYP\_CR.
- c) Configure GCM\_CCMPH bits to 0b00 in CRYP\_CR to indicate that the init phase is ongoing.
- d) Initialize the key registers (128, 192 and 256 bits) in CRYP\_KEYRx as well as the initialization vector (IV) as defined in [Table 127](#).
- e) Set CRYPEN bit to 1 to start the calculation of the hash key.
- f) Wait for the CRYPEN bit to be cleared to 0 by the cryptographic processor, before moving on to the next phase.

**2. GCM header phase**

The below sequence shall be performed after the GCM init phase. It must be complete before jumping to the payload phase. The sequence is identical for encryption and decryption.

- g) Set the GCM\_CCMPH bits to 0b01 in CRYP\_CR to indicate that the header phase is ongoing.
- h) Set the CRYPEN bit to 1 to start accepting data.
- i) If it is the last block of additional authenticated data, optionally pad the data with zeros to have a complete block.
- j) Append additional authenticated data in the cryptographic processor. The three possible scenarios are described in [Section 20.3.5: CRYP procedure to perform a cipher operation](#).
- k) Repeat the previous step until the second last additional authenticated data block is processed. For the last block, execute the two previous steps. Once all the additional authenticated data have been supplied, wait until the BUSY flag is cleared before moving on to the next phase.

*Note: This phase can be skipped if there is no additional authenticated data, i.e.  $Len(A)=0$ .  
In header and payload phases, CRYPEN bit is not automatically cleared by the cryptographic processor.*

### 3. GCM payload phase (encryption or decryption)

When the payload size is not null, this sequence must be executed after the GCM header phase. During this phase, the encrypted/decrypted payload is stored in the CRYP\_DOUT register.

- l) Set the CRYPEN bit to 0.
- m) Configure GCM\_CCMPH to 0b10 in the CRYP\_CR register to indicate that the payload phase is ongoing.
- n) Select the algorithm direction (0 for encryption, 1 for decryption) through the ALGODIR bit in CRYP\_CR.
- o) Set the CRYPEN bit to 1 to start accepting data.
- p) If it is the last block of cleartext or plaintext, optionally pad the data with zeros to have a complete block. For encryption, refer to [Section 20.3.8: CRYP stealing and data padding](#) for more details.
- q) Append payload data in the cryptographic processor, and read the result. The three possible scenarios are described in [Section 20.3.5: CRYP procedure to perform a cipher operation](#).
- r) Repeat the previous step until the second last plaintext block is encrypted or until the last block of ciphertext is decrypted. For the last block of plaintext (encryption only), execute the two previous steps. For the last block, the driver must discard the bits that are not part of the cleartext or the ciphertext when the last block size is less than 16 bytes. Once all payload data have been supplied, wait until the BUSY flag is cleared.

*Note:* This phase can be skipped if there is no payload data, i.e.  $Len(C)=0$  (see GMAC mode).

### 4. GCM final phase

In this last step, the cryptographic processor generates the GCM authentication tag and stores it in CRYP\_DOUT register.

- s) Configure GCM\_CCMPH[1:0] to 0b11 in CRYP\_CR to indicate that the Final phase is ongoing. Set the ALGODIR bit to 0 in the same register.
- t) Write the input to the CRYP\_DIN register four times. The input must be composed of the length in bits of the additional authenticated data (coded on 64 bits) concatenated with the length in bits of the payload (coded of 64 bits), as show in [Table 126](#).

*Note:* In this final phase data have to be swapped according to the DATATYPE programmed in CRYP\_CR register.

- u) Wait until the OFNE flag (FIFO output not empty) is set to 1 in the CRYP\_SR register.
- v) Read the CRYP\_DOUT register 4four times: the output corresponds to the authentication tag.
- w) Disable the cryptographic processor (CRYPEN bit = 0 in CRYP\_CR)
- x) If an authenticated decryption is being performed, compare the generated tag with the expected tag passed with the message.

### Suspend/resume operations in GCM mode

Before interrupting the current message in header or payload phase, the user application must respect the following sequence:

1. If DMA is used, stop DMA transfers to the IN FIFO by clearing to 0 the DIEN bit in the CRYP\_DMACR register.
2. Wait until both the IN and the OUT FIFOs are empty (IFEM=1 and OFNE=0 in the CRYP\_SR register) and the BUSY bit is cleared.
3. If DMA is used, stop DMA transfers from the OUT FIFO by clearing to 0 the DOEN bit in the CRYP\_DMACR register.
4. Disable the cryptographic processor by setting the CRYPEN bit to 0 in CRYP\_CR, then save the current configuration (bits [9:2], bits [17:16] and bits 19 of the CRYP\_CR register). In addition, save the initialization vector registers, since CRYP\_IVx registers have changed from their initial values during data processing.

*Note:* Key registers do not need to be saved as original their key value is known by the application.

5. Save context swap registers: CRYP\_CSGCMCCM0..7 and CRYP\_CSGCM0..7
6. If DMA is used, save the DMA controller status (pointers to IN and OUT data transfers, number of remaining bytes, etc.).

To resume message processing, the user must respect the following sequence:

1. If DMA is used, reconfigure the DMA controller to complete the rest of the FIFO IN and FIFO OUT transfers.
2. Make sure the cryptographic processor is disabled by reading the CRYPEN bit in CRYP\_CR (it must be 0).
3. Configure again the cryptographic processor with the initial setting in CRYP\_CR, as well as the key registers using the saved configuration.
4. Restore context swap registers: CRYP\_CSGCMCCM0..7 and CRYP\_CSGCM0..7
5. Restore CRYP\_IVx registers using the saved configuration.
6. Enable the cryptographic processor by setting the CRYPEN bit to 1.
7. If DMA is used, enable again cryptographic processor DMA requests by setting to 1 the DIEN and DOEN bits in the CRYP\_DMACR register.

*Note:* In Header phase, DMA OUT FIFO transfer is not used.

### 20.3.14 CRYP AES Galois message authentication code (GMAC)

#### Overview

The Galois message authentication code (GMAC) allows authenticating a plaintext and generating the corresponding tag information (also known as message authentication code). It is based on GCM algorithm, as defined in NIST *Special Publication 800-38D, Recommendation for Block Cipher Modes of Operation - Galois/Counter Mode (GCM) and GMAC*.

A typical message construction in GMAC mode is given in [Figure 140](#).

**Figure 140. Message construction for the Galois Message Authentication Code mode**

#### AES GMAC processing

This mode is selected by writing ALGOMODE bitfield to 0b110 in CRYP\_CR.

GMAC algorithm corresponds to the GCM algorithm applied on a message composed only of an header. As a consequence, all steps and settings are the same as in GCM mode, except that the payload phase (3) is not used.

#### Suspend/resume operations in GMAC

GMAC is exactly the same as GCM algorithm except that only header phase (2) can be interrupted.

### 20.3.15 CRYP AES Counter with CBC-MAC (CCM)

#### Overview

The AES Counter with Cipher Block Chaining-Message Authentication Code (CCM) algorithm allows encrypting and authenticating the plaintext, and generating the correspondent ciphertext and tag (also known as message authentication code). To ensure confidentiality, CCM algorithm is based on AES counter mode. It uses Cipher Block Chaining technique to generate the message authentication code. This is commonly called CBC-MAC

**Note:** *NIST does not approve this CBC-MAC as an authentication mode outside of the context of the CCM specification.*

CCM chaining is specified in NIST *Special Publication 800-38C, Recommendation for Block Cipher Modes of Operation - The CCM Mode for Authentication and Confidentiality*. A typical message construction in CCM mode is given in [Figure 141](#)

**Figure 141. Message construction for the Counter with CBC-MAC mode**

The structure of this message is as below:

- One 16-byte first authentication block (called B0 by the standard), composed of three distinct fields:
  - Q: a bit string representation of the byte length of P (Plen)
  - A *nonce* (N): single-use value (i.e. a new nonce should be assigned to each new communication). Size of nonce  $Nlen$  + size of  $Plen$  shall be equal to 15 bytes.
  - Flags: most significant byte containing four flags for control information, as specified by the standard. It contains two 3-bit strings to encode the values  $t$  (MAC length expressed in bytes) and  $q$  (plaintext length such as  $Plen < 2^{8q}$  bytes). Note that the counter blocks range associated to  $q$  is equal to  $2^{8q-4}$ , i.e. if  $q$  maximum value is 8, the counter blocks used in cipher shall be on 60 bits.

**Note:** *The cryptographic peripheral can only manage padded plaintext/ciphertext messages of length  $Plen < 2^{36} + 1$  bytes.*

- 16-bytes blocks (B) associated to the Associated Data (A).  
This part of the message is only authenticated, not encrypted. This section has a known length, *ALen*, that can be a non-multiple of 16 bytes (see [Figure 141](#)). The standard also states that, on the MSB bits of the first message block (B1), the associated data length expressed in bytes (*a*) must be encoded as defined below:
  - If  $0 < a < 2^{16}-2^8$ , then it is encoded as  $[a]_{16}$ , i.e. two bytes.
  - If  $2^{16}-2^8 < a < 2^{32}$ , then it is encoded as  $0xff || 0xfe || [a]_{32}$ , i.e. six bytes.
  - If  $2^{32} < a < 2^{64}$ , then it is encoded as  $0xff || 0xff || [a]_{64}$ , i.e. ten bytes.
- 16-byte blocks (B) associated to the plaintext message (P), which is both authenticated and encrypted as ciphertext C, with a known length of *Plen*. This length can be a non-multiple of 16 bytes (see [Figure 141](#)) but cannot exceed  $2^{32}$  blocks of 128-bit.
- The encrypted MAC (T) of length *Tlen* appended to the ciphertext C of overall length *Clen*.
- When a part of the message (A or P) has a length which is a non-multiple of 16 bytes, a special padding scheme is required.

*Note:* CCM chaining mode can also be used with associated data only (i.e. no payload).

As an example, the C.1 section in *NIST Special Publication 800-38C* gives the following:

```

N: 10111213 141516 (Nlen= 56 bits or 0x7 bytes)
A: 00010203 04050607 (Alen= 64 bits or 0x8 bytes)
P: 20212223 (Plen= 32 bits i.e. Q= 0x4 bytes)
T: 6084341b (Tlen= 32 bits or t= 4)
B0: 4f101112 13141516 00000000 00000004
B1: 00080001 02030405 06070000 00000000
B2: 20212223 00000000 00000000 00000000
CTR0: 0710111213 141516 00000000 00000000
CTR1: 0710111213 141516 00000000 00000001

```

The usage of control blocks CTRx is explained in the following section. The generation of CTR0 from the first block (B0) must be managed by software.

## AES CCM processing

This mode is selected by writing ALGOMODE bitfield to 0b1001 in CRYP\_CR.

The data input to the generation-encryption process are a valid nonce, a valid payload string, and a valid associated data string, all properly formatted. The CBC chaining mechanism is applied to the formatted data to generate a MAC, whose length is known. Counter mode encryption, which requires a sufficiently long sequence of counter blocks as input, is applied to the payload string and separately to the MAC. The resulting data, called the ciphertext C, is the output of the generation-encryption process on plaintext P.

CRYP\_IV registers are used for processing each data block. The cryptographic processor automatically increments the CTR counter with a bit length defined by the first block (B0). The first counter written by application, CTR1, is equal to B0 with the first 5 bits zeroed and the most significant bits containing P byte length also zeroed, then incremented by one (see [Table 128](#)).

**Table 128. CCM mode IV registers initialization**

| Register   | CRYP_IV0L[31:0]                                                      | CRYP_IV0R[31:0] | CRYP_IV1L[31:0] | CRYP_IV1R[31:0]                                                                 |
|------------|----------------------------------------------------------------------|-----------------|-----------------|---------------------------------------------------------------------------------|
| Endianness | IV[0:31]                                                             | IV[32:63]       | IV[64:95]       | IV[96:127]                                                                      |
| Input data | B0[31:0], where the 5 most significant bits are set to 0 (flag bits) | B0[63:32]       | B0[95:64]       | B0[127:96], where Q length bits are set to 0, except for bit 0 that is set to 1 |

**Note:** *In this mode, the key must NOT be prepared for decryption.*

To process a CCM message, the driver must go through four phases, which are described below.

- The Init phase: the peripheral processes the first block and prepares the first counter block.
- The Header phase: the peripheral processes the Associated data (A), with hash computation only.
- The Payload phase: the peripheral processes the plaintext (P), with hash computation, counter block encryption and data XORing. It operates in a similar way for ciphertext (C).
- The Final phase: the peripheral generates the message authentication code (MAC).

### 1. CCM init phase

In this first step, the first block (B0) of the CCM message is programmed into the CRYP\_DIN register. During this phase, the CRYP\_DOUT register does not contain any output data. It is recommended to follow the sequence below:

- a) Make sure that the cryptographic processor is disabled by clearing the CRYPEN bit in the CRYP\_CR register.
- b) Select the CCM chaining mode by programming the ALGOMODE bits to 0b01001 in the CRYP\_CR register.
- c) Configure the GCM\_CCMPH bits to 0b00 in CRYP\_CR to indicate that we are in the init phase.
- d) Initialize the key registers (128, 192 and 256 bits) in CRYP\_KEYRx as well as the initialization vector (IV) with CTR1 information, as defined in [Table 128](#).
- e) Set the CRYPEN bit to 1 in CRYP\_CR to start accepting data.
- f) Write the B0 packet into CRYP\_DIN register, then wait for the CRYPEN bit to be cleared to 0 by the cryptographic processor before moving on to the next phase.

**Note:** *In this init phase data have to be swapped according to the DATATYPE programmed in CRYP\_CR register.*

### 2. CCM header phase

The below sequence shall be performed after the CCM Init phase. It must be complete before jumping to the payload phase. The sequence is identical for encryption and decryption. During this phase, the CRYP\_DOUT register does not contain any output data.

- g) Set the GCM\_CCMPH bit to 0b01 in CRYP\_CR to indicate that the header phase is ongoing.
- h) Set the CRYPEN bit to 1 to start accepting data.
- i) If it is the last block of associated data, optionally pad the data with zeros to have a complete block.
- j) Append the associated data in the cryptographic processor. The three possible scenarios are described in [Section 20.3.5: CRYP procedure to perform a cipher operation](#).
- k) Repeat the previous step until the second last associated data block is processed. For the last block, execute the two previous steps. Once all the additional authenticated data have been supplied, wait until the BUSY flag is cleared.

**Note:** *This phase can be skipped if there is no associated data (Alen=0).*

**Note:** *The first block of the associated data B1 must be formatted with the associated data length. This task must be managed by the driver.*

### 3. CCM payload phase (encryption or decryption)

When the payload size is not null, this sequence must be performed after the CCM header phase. During this phase, the encrypted/decrypted payload is stored in the CRYP\_DOUT register.

- l) Set the CRYPEN bit to 0.
- m) Configure GCM\_CCMPH bits to 0b10 in CRYP\_CR to indicate that the payload phase is ongoing.
- n) Select the algorithm direction (0 for encryption, 1 for decryption) through the ALGODIR bit in CRYP\_CR.
- o) Set the CRYPEN bit to 1 to start accepting data.
- p) If it is the last block of cleartext, optionally pad the data with zeros to have a complete block (encryption only). For decryption, refer to [Section 20.3.8: CRYP stealing and data padding](#) for more details.
- q) Append payload data in the cryptographic processor, and read the result. The three possible scenarios are described in [Section 20.3.5: CRYP procedure to perform a cipher operation](#).
- r) Repeat the previous step until the second last plaintext block is encrypted or until the last block of ciphertext is decrypted. For the last block of plaintext (encryption only), execute the two previous steps. For the last block of ciphertext (decryption only), the driver must discard the data that is not part of the cleartext when the last block size is less than 16 bytes. Once all payload data have been supplied, wait until the BUSY flag is cleared

*Note:* This phase can be skipped if there is no payload data, i.e.  $Plen=0$  or  $Clen=Tlen$

*Note:* Do not forget to remove  $LSB_{Tlen}(C)$  encrypted tag information when decrypting ciphertext  $C$ .

### 4. CCM final phase

In this last step, the cryptographic processor generates the CCM authentication tag and stores it in the CRYP\_DOUT register.

- s) Configure GCM\_CCMPH[1:0] bits to 0b11 in CRYP\_CR to indicate that the final phase is ongoing and set the ALGODIR bit to 0 in the same register.
- t) Load in CRYP\_DIN, the CTR0 information which is described in [Table 128](#) with bit[0] set to 0.

*Note:* In this final phase, data have to be swapped according to the DATATYPE programmed in CRYP\_CR register.

- u) Wait until the OFNE flag (FIFO output not empty) is set to 1 in the CRYP\_SR register.
- v) Read the CRYP\_DOUT register four times: the output corresponds to the encrypted CCM tag.
- w) Disable the cryptographic processor (CRYPEN bit set to 0 in CRYP\_CR)
- x) If an authenticated decryption is being performed, compare the generated encrypted tag with the encrypted tag padded in the ciphertext, i.e.  $LSB_{Tlen}(C) = MSB_{Tlen}(CRYP\_DOUT \text{ data})$ .

### Suspend/resume operations in CCM mode

Before interrupting the current message in payload phase, the user application must respect the following sequence:

1. If DMA is used, stop the DMA transfers to the IN FIFO by clearing to 0 the DIEN bit in the CRYP\_DMACR register.
2. Wait until both the IN and the OUT FIFOs are empty (IFEM=1 and OFNE=0 in the CRYP\_SR register) and the BUSY bit is cleared.
3. If DMA is used, stop the DMA transfers from the OUT FIFO by clearing to 0 the DOEN bit in the CRYP\_DMACR register.
4. Disable the cryptographic processor by setting the CRYPEN bit to 0 in CRYP\_CR, then save the current configuration (bits [9:2], bits [17:16] and bits 19 in the CRYP\_CR register). In addition, save the initialization vector registers, since CRYP\_IVx registers have changed from their initial values during the data processing.

*Note:* Key registers do not need to be saved as their original key value is known by the application.

5. Save context swap registers: CRYP\_CSGCMCCM0..7
6. If DMA is used, save the DMA controller status (pointers for IN and OUT data transfers, number of remaining bytes, etc.).

To resume message processing, the user application must respect the following sequence:

1. If DMA is used, reconfigure the DMA controller to complete the rest of the FIFO IN and FIFO OUT transfers.
2. Make sure the cryptographic processor is disabled by reading the CRYPEN bit in CRYP\_CR (must be 0).
3. Configure the cryptographic processor again with the initial setting in CRYP\_CR and key registers using the saved configuration.
4. Restore context swap registers: CRYP\_CSGCMCCM0..7
5. Restore CRYP\_IVx registers using the saved configuration.
6. Enable the cryptographic processor by setting the CRYPEN bit to 1.
7. If DMA is used, enable again cryptographic processor DMA requests by setting to 1 the DIEN and DOEN bits in the CRYP\_DMACR register.

*Note:* In Header phase DMA OUT FIFO transfer is not used.

## 20.3.16 CRYP data registers and data swapping

### Introduction

The CRYP\_DIN register is the 32-bit wide data input register of the peripheral. It is used to enter into the input FIFO up to four 64-bit blocks (TDES) or two 128-bit blocks (AES) of plaintext (when encrypting) or ciphertext (when decrypting), one 32-bit word at a time.

The first word written into the FIFO is the LSB of the input block. The MSB of the input block is written at the end. CRYP\_DIN data endianness can be described as below when DATATYPE="00" (no data swapping):

- In the DES/TDES modes  
Bit 1 (leftmost bit) of the data block corresponds to the MSB (bit 31) of the first word entered into the FIFO, bit 64 (rightmost bit) corresponds to the LSB (bit 0) of the second word entered into the FIFO.
- In the AES mode  
Bit 0 (leftmost bit) of the data block corresponds to the MSB (bit 31) of the first word written into the FIFO, bit 127 (rightmost bit) corresponds to the LSB (bit 0) of the 4th word written into the FIFO.

Similarly CRYP\_DOUT register is the 32-bit wide data out register of the peripheral. It is a read-only register that is used to retrieve from the output FIFO up to four 64-bit blocks (TDES) or two 128-bit blocks (AES) of plaintext (when encrypting) or ciphertext (when decrypting), one 32-bit word at a time.

Like for the input data, the LSB of the output block is the first word read from the output FIFO. The MSB of the output block is read at the end. CRYP\_DOUT data endianness can be described as below when DATATYPE="00" (no data swapping):

- In the DES/TDES modes  
Bit 1 (leftmost bit) of the data block corresponds to the MSB (bit 31) of the first word read from the FIFO, bit 64 (rightmost bit) corresponds to the LSB (bit 0) of the second word read from the FIFO.
- In the AES mode  
Bit 0 (leftmost bit) of the data block corresponds to the MSB (bit 31) of the first word read from the FIFO, bit 127 (rightmost bit) corresponds to the LSB (bit 0) of the 4th word read from the FIFO.

## DES/TDES data swapping feature

Depending on the type of data to be processed (e.g. byte swapping when data are ASCII text stream), a bit, byte, half-word or no swapping operation must be done on the data read from the input FIFO before entering the little-endian DES processing core. The same swapping must be performed on the data produced by the little-endian DES processing core before they are written to the output FIFO.

Figure 142 shows how the DES processing core 64-bit data block M1...64 is constructed from two consecutive 32-bit words popped into IN FIFO by the driver. This is done according to the DATATYPE bitfield in the CRYP\_CR register.

**Note:** The same swapping is performed between the IN FIFO and the CRYP data block, and between the CRYP data block and the OUT FIFO.

**Figure 142. 64-bit block construction according to the data type (IN FIFO)**

**Note:** The CRYP Key registers (CRYP\_Kx(L/R)) and initialization registers (CRYP\_IVx(L/R)) are not sensitive to the swap mode selected. They have a fixed little-endian configuration (refer to Section 20.3.17 and Section 20.3.18, respectively).

A typical example of data swapping is given in Table 129.

Table 129. DES/TDES data swapping feature

| DATATYPE in CRYPT_CR | Swapping performed          | Data block representation (64-bit)<br>0xABCD7720 6973FE01                                                                                                                                                                                        |

### AES data swapping feature

Depending on the type of data to be processed (e.g. byte swapping when data are ASCII text stream), a bit, byte, half-word or no swapping operation must be done on data read from the input FIFO before entering the little-endian AES processing core. The same swapping must be performed on the data produced by the little-endian AES processing core before they are written to the output FIFO.

Figure 143 shows how the AES processing core 128-bit data block P0..127 is constructed from four consecutive 32-bit words written by the driver to the CRYP\_DIN register. This is done according to the DATATYPE bitfield in the CRYP control register (CRYP\_CR).

**Note:** The same swapping is performed between the CRYP\_DIN and the CRYP data block, and between the CRYP data block and the CRYP\_DOUT.

**Figure 143. 128-bit block construction according to the data type**

**Note:** The swapping operation concerns only the CRYP\_DOUT and CRYP\_DIN registers. The CRYP\_KxL/KxR and CRYP\_IVxL/IVxR registers are not sensitive to the swap mode selected. They have a fixed little-endian configuration (refer to [Section 20.3.17](#) and [Section 20.3.18](#)).

Typical examples of data swapping are given in [Table 130](#).

**Table 130. AES data swapping feature**

| DATATYPE<br>in CRYP_CR | Swapping performed          | Data block representation (64-bit)<br>0x4E6F7720 69732074                                                                                                                                                                            |
|------------------------|-----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                        |                             | System memory data (little-endian)                                                                                                                                                                                                   |
| 0b00                   | No swapping                 | Address @: 0x4E6F7720 (LSB, written first)<br>Address @+4: 0x69732074                                                                                                                                                                |
| 0b01                   | Half-word (16-bit) swapping | Address @: 0x77204E6F (swapped LSB, written first)<br>Address @+4: 0x20746973                                                                                                                                                        |
| 0b10                   | Byte (8-bit) swapping       | Address @: 0x20776F4E (swapped LSB, written first)<br>Address @+4: 0x74207369                                                                                                                                                        |
| 0b11                   | Bit swapping                | LSB data word: 0x4E6F7720<br>0b0100 1110 0110 1111 0111 0111 0010 0000<br>MSB data word: 0x69732074<br>0b0110 1001 0111 0011 0010 0000 0111 0100<br><br>Address @: 0x4EEF672 (swapped LSB, written first)<br>Address @+4: 0x2E04CE96 |

## 20.3.17 CRYP key registers

The CRYP\_Kx registers are used to store the encryption or decryption keys.

They are organized as eight registers in a little-endian configuration, as shown in [Table 131](#).

**Table 131. Key registers CRYP\_KxR/LR endianness (TDES K1/2/3 and AES 128/192/256-bit keys)**

| K0LR[31:0] | K0RR[31:0] | K1LR[31:0] | K1RR[31:0] | K2LR[31:0] | K2RR[31:0] | K3LR[31:0] | K3RR[31:0] |
|------------|------------|------------|------------|------------|------------|------------|------------|
| -          | -          | K1[1:32]   | K1[33:64]  | K2[1:32]   | K2[33:64]  | K2[1:32]   | K2[33:64]  |
| K0LR[31:0] | K0RR[31:0] | K1LR[31:0] | K1RR[31:0] | K2LR[31:0] | K2RR[31:0] | K3LR[31:0] | K3RR[31:0] |
| -          | -          | -          | -          | k[0:31]    | k[32:63]   | k[64:95]   | k[96:127]  |
| K0LR[31:0] | K0RR[31:0] | K1LR[31:0] | K1RR[31:0] | K2LR[31:0] | K2RR[31:0] | K3LR[31:0] | K3RR[31:0] |
| -          | -          | k[0:31]    | k[32:63]   | k[64:95]   | k[96:127]  | k[128:159] | k[160:191] |
| K0LR[31:0] | K0RR[31:0] | K1LR[31:0] | K1RR[31:0] | K2LR[31:0] | K2RR[31:0] | K3LR[31:0] | K3RR[31:0] |
| k[0:31]    | k[32:63]   | k[64:95]   | k[96:127]  | k[128:159] | k[160:191] | k[192:223] | k[224:255] |

**Note:** DES/TDES keys include 8-bit parity information that are not used by the cryptographic processor. In other words, bits 8, 16, 24, 32, 40, 48, 56 and 64 of each 64-bit key value Kx[1:64] are not used.

Keys are considered as four 64-bit data items. They therefore do not have the same data format and representation in system memory as plaintext or ciphertext data.

Any write operation to the CRYP\_Kx(L/R) registers when the BUSY bit is set to 1 in the CRYP\_SR register is disregarded (i.e. register content not modified). Thus, the software must check that the BUSY equals 0 before modifying key registers.

Key registers are not affected by the data swapping feature controlled by DATATYPE value in CRYP\_CR register.

Refer to [Section 20.6: CRYP registers](#) for a detailed description of CRYP\_Kx(L/R) registers.

### 20.3.18 CRYP initialization vector registers

The CRYP\_IVxL/IVxR registers are used to store the initialization vector or the nonce, depending on the chaining mode selected. When used, these registers are updated by the core after each computation round of the TDES or AES core.

They are organized as four registers in a little-endian configuration, as shown in [Table 132](#).

**Table 132. Initialization vector registers CRYP\_IVxR endianness**

| CRYP_IV1R[31:0] | CRYP_IV1L[31:0] | CRYP_IV0R[31:0] | CRYP_IV0L[31:0] |
|-----------------|-----------------|-----------------|-----------------|
| IV[96:127]      | IV[64:95]       | IV[32:63]       | IV[0:31]        |

Initialization vector registers are considered as two 64-bit data items. They therefore do not have the same data format and representation in system memory as plaintext or ciphertext data.

Any write operation to the CRYP\_IV0...1(L/R) registers when the BUSY bit is set to 1 in the CRYP\_SR register is disregarded (i.e. register content not modified). Therefore, the software must check that the BUSY equals 0 in the CRYP\_SR register before modifying initialization vectors.

Reading the CRYP\_IV0...1(L/R) register returns the latest counter value (useful for managing suspend mode) except for CCM/GCM.

*Note:* In DES/TDES mode, only CRYP\_IV0x are used.

Initialization vector registers are not affected by the data swapping feature controlled by DATATYPE value in CRYP\_CR register.

Refer to [Section 20.6: CRYP registers](#) for a detailed description of CRYP\_IVxL/IVxR registers.

### 20.3.19 CRYP DMA interface

The cryptographic processor provides an interface to connect to the DMA (Direct Memory Access) controller. The DMA operation is controlled through the CRYP DMA control register (CRYP\_DMACR).

#### Data input using DMA

DMA can be enabled for writing data into the cryptographic peripheral by setting the DIEN bit in the CRYP\_DMACR register. When this bit is set, the cryptographic processor initiates a DMA request during the INPUT phase each time it requires a word to be written to the CRYP\_DIN register.

[Table 133](#) shows the recommended configuration to transfer data from memory to cryptographic processor through the DMA controller.

**Table 133. Cryptographic processor configuration for memory-to-peripheral DMA transfers**

| DMA channel control register field         | Programming recommendation                                                                                                                                                                                                                                                                                           |
|--------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Transfer size                              | Message length, multiple of 128-bit. This 128-bit granularity corresponds to two blocks for DES, one block for AES.<br>According to the algorithm and the mode selected, special padding/ciphertext stealing might be required. Refer to <a href="#">Section 20.3.8: CRYP stealing and data padding</a> for details. |
| Source burst size (memory)                 | CRYP_FIFO_size / 2 / transfer_width = 4                                                                                                                                                                                                                                                                              |
| Destination burst size (peripheral)        | CRYP_FIFO_size / 2 / transfer_width = 4<br>(FIFO_size = 8x32-bit, transfer_width = 32-bit)                                                                                                                                                                                                                           |
| DMA FIFO size                              | CRYP_FIFO_size / 2 = 16 bytes                                                                                                                                                                                                                                                                                        |
| Source transfer width (memory)             | 32-bit words                                                                                                                                                                                                                                                                                                         |
| Destination transfer width (peripheral)    | 32-bit words                                                                                                                                                                                                                                                                                                         |
| Source address increment (memory)          | Yes, after each 32-bit transfer.                                                                                                                                                                                                                                                                                     |
| Destination address increment (peripheral) | Fixed address of CRYP_DIN shall be used (no increment).                                                                                                                                                                                                                                                              |

#### Data output using DMA

To enable the DMA for reading data from AES peripheral, set the DOEN bit in the CRYP\_DMACR register. When this bit is set, the cryptographic processor initiates a DMA request during the OUTPUT phase each time it requires a word to be read from the CRYP\_DOUT register.

[Table 134](#) shows the recommended configuration to transfer data from cryptographic processor to memory through the DMA controller.

**Table 134. Cryptographic processor configuration for peripheral to memory DMA transfers**

| DMA channel control register field     | Programming recommendation                                                                                                                                                                            |
|----------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Transfer size                          | Message length, multiple of 128-bit. This 128-bit granularity corresponds to two blocks for DES, one block for AES.<br>Depending on the algorithm used, extra bits have to be discarded.              |
| Source burst size (peripheral)         | When <i>DES</i> is used:<br>Single transfer (burst size=1)<br>When <i>AES</i> is used:<br>$\text{CRYP\_FIFO\_size} / 2 / \text{transfer\_width} = 4$<br>(FIFO_size= 8x32-bit, transfer_width= 32-bit) |
| Destination burst size (memory)        | $\text{CRYP\_FIFO\_size} / 2 / \text{transfer\_width} = 4$                                                                                                                                            |
| DMA FIFO size                          | $\text{CRYP\_FIFO\_size} / 2 = 16$ bytes                                                                                                                                                              |
| Source transfer width (peripheral)     | 32-bit words                                                                                                                                                                                          |
| memory transfer width (memory)         | 32-bit words                                                                                                                                                                                          |
| Source address increment (peripheral)  | Fixed address of CRYP_DOUT shall be used (no increment).                                                                                                                                              |
| Destination address increment (memory) | Yes, after each 32-bit transfer.                                                                                                                                                                      |

**DMA mode**

When AES is used, the cryptographic processor manages two DMA transfer requests through `cryp_in_dma` and `cryp_out_dma` internal input/output signals, which are asserted:

- for IN FIFO: every time a block has been read from FIFO by CRYP,
- for OUT FIFO: every time a block has been written into the FIFO by the cryptographic processor.

When DES is used, the cryptographic processor manages two DMA transfer requests through `cryp_in_dma` and `cryp_out_dma` internal input/output signals, which are asserted:

- for IN FIFO: every time two blocks have been read from FIFO by the cryptographic processor
- for OUT FIFO: every time a word has been written into the FIFO by the cryptographic processor (single transfer). Note that a burst transfer is also triggered when two blocks have been written into the FIFO.

All request signals are de-asserted if the cryptographic peripheral is disabled or the DMA enable bit is cleared (DIEN bit for the IN FIFO and DOEN bit for the OUT FIFO in the CRYP\_DMACR register).

**Caution:** It is important that DMA controller empties the cryptographic peripheral output FIFO before filling up the CRYP input FIFO. To achieve it, the DMA controller should be configured so

that the transfer from the peripheral to the memory has a higher priority than the transfer from the memory to the peripheral.

For more detailed information on DMA operations, refer to [Section 20.3.5: CRYP procedure to perform a cipher operation](#).

### 20.3.20 CRYP error management

No error flags are generated by the cryptographic processor.

## 20.4 CRYP interrupts

### Overview

There are two individual maskable interrupt sources generated by the cryptographic processor to signal the following events:

- Input FIFO empty or not full
- Output FIFO full or not empty

These two sources are combined into a single interrupt signal which is the only interrupt signal from the CRYP peripheral that drives the NVIC (nested vectored interrupt controller). The interrupt logic is summarized on [Figure 144](#).

**Figure 144. CRYP interrupt mapping diagram**

You can enable or disable CRYP interrupt sources individually by changing the mask bits in the CRYPT\_IMSCR register. Setting the appropriate mask bit to 1 enables the interrupt.

The status of the individual maskable interrupt sources can be read either from the CRYPT\_RISR register, for raw interrupt status, or from the CRYPT\_MISR register for masked interrupt status. The status of the individual source of event flags can be read from the CRYPT\_SR register.

[Table 135](#) gives a summary of the available features.

Table 135. CRYP interrupt requests

| Interrupt event       | Event flag (interrupt status) | Enable control bit | Event flag (source) |
|-----------------------|-------------------------------|--------------------|---------------------|
| Output FIFO full      | OUTRIS, OUTMIS                | OUTIM and CRYPEN   | OFFU                |
| Output FIFO not empty |                               |                    | OFNE                |
| Input FIFO not full   | OUTRIS, OUTMIS                | INIM and CRYPEN    | IFNF                |
| Input FIFO empty      |                               |                    | IFEM                |

### Output FIFO service interrupt - OUTMIS

The output FIFO service interrupt is asserted when there is one or more (32-bit word) data items in the output FIFO. This interrupt is cleared by reading data from the output FIFO until there is no valid (32-bit) word left (that is when the interrupt follows the state of the output FIFO not empty flag OFNE).

The output FIFO service interrupt OUTMIS is NOT enabled with the CRYP enable bit. Consequently, disabling the CRYP will not force the OUTMIS signal low if the output FIFO is not empty.

### Input FIFO service interrupt - INMIS

The input FIFO service interrupt is asserted when there are less than four words in the input FIFO. It is cleared by performing write operations to the input FIFO until it holds four or more words.

The input FIFO service interrupt INMIS is enabled with the CRYP enable bit. Consequently, when CRYP is disabled, the INMIS signal is low even if the input FIFO is empty.

## 20.5 CRYP processing time

The time required to process a 128-bit block for each mode of operation is summarized below.

**Table 136. Processing time (in clock cycle) for ECB, CBC and CTR per 128-bit block**

| Algorithm / Key size | ECB | CBC | CTR |
|----------------------|-----|-----|-----|
| 128b                 | 14  | 14  | 14  |
| 192b                 | 16  | 16  | 16  |
| 256b                 | 18  | 18  | 18  |

**Table 137. Processing time (in clock cycle) for GCM and CCM per 128-bit block**

| Algorithm / Key size | GCM  |        |         |     |           | CCM  |        |         |     |           |
|----------------------|------|--------|---------|-----|-----------|------|--------|---------|-----|-----------|
|                      | Init | Header | Payload | Tag | Total     | Init | Header | Payload | Tag | Total     |
| 128b                 | 24   | 10     | 14      | 14  | <b>62</b> | 12   | 14     | 25      | 14  | <b>65</b> |
| 192b                 | 28   | 10     | 16      | 16  | <b>70</b> | 14   | 16     | 29      | 16  | <b>75</b> |
| 256b                 | 32   | 10     | 18      | 18  | <b>78</b> | 16   | 18     | 33      | 18  | <b>85</b> |

## 20.6 CRYP registers

The cryptographic core is associated with several control and status registers, eight key registers and four initialization vectors registers.

### 20.6.1 CRYP control register (CRYP\_CR)

Address offset: 0x00

Reset value: 0x0000 0000

|        |        |      |      |      |      |              |      |               |    |               |    |           |         |                |      |
|--------|--------|------|------|------|------|--------------|------|---------------|----|---------------|----|-----------|---------|----------------|------|
| 31     | 30     | 29   | 28   | 27   | 26   | 25           | 24   | 23            | 22 | 21            | 20 | 19        | 18      | 17             | 16   |
| Res.   | Res.   | Res. | Res. | Res. | Res. | Res.         | Res. | Res.          |    |               |    | ALGOMODE3 | Res.    | GCM_CCMPH[1:0] |      |
|        |        |      |      |      |      |              |      |               |    |               |    | rw        |         | rw             | rw   |
| 15     | 14     | 13   | 12   | 11   | 10   | 9            | 8    | 7             | 6  | 5             | 4  | 3         | 2       | 1              | 0    |
| CRYPEN | FFLUSH | Res. | Res. | Res. | Res. | KEYSIZE[1:0] |      | DATATYPE[1:0] |    | ALGOMODE[2:0] |    |           | ALGODIR | Res.           | Res. |
| rw     | w      |      |      |      |      | rw           | rw   | rw            | rw | rw            | rw | rw        | rw      |                |      |

Bits 31:20 Reserved, must be kept at reset value.

Bit 18 Reserved, must be kept at reset value.

Bits 17:16 **GCM\_CCMPH[1:0]**: GCM or CCM Phase selection

This bitfield has no effect if GCM, GMAC or CCM algorithm is not selected in ALGOMODE field.

00: Init phase

01: Header phase

10: Payload phase

11: Final phase

Bit 15 **CRYPEN**: CRYP processor Enable

0: Cryptographic processor peripheral is disabled

1: Cryptographic processor peripheral is enabled

This bit is automatically cleared by hardware when the key preparation process ends (ALGOMODE= 0b111) or after GCM/GMAC or CCM init phase.

Bit 14 **FFLUSH**: CRYP FIFO Flush

0: No FIFO flush

1: FIFO flush enabled

When CRYPEN = 0, writing this bit to 1 flushes the IN and OUT FIFOs (i.e. read and write pointers of the FIFOs are reset). Writing this bit to 0 has no effect.

When CRYPEN = 1, writing this bit to 0 or 1 has no effect.

Reading this bit always returns 0.

FFLUSH bit has to be set only when BUSY=0. If not, the FIFO is flushed, but the block being processed may be pushed into the output FIFO just after the flush operation, resulting in a non-empty FIFO condition.

Bits 13:10 Reserved, must be kept at reset value.

**Bits 9:8 KEYSIZE[1:0]:** Key Size selection (AES mode only)

This bitfield defines the bit-length of the key used for the AES cryptographic core. This bitfield is 'don't care' in the DES or TDES modes.

00: 128-bit key length

01: 192-bit key length

10: 256-bit key length

11: Reserved, do not use this value

Writing KEYSIZE bits while BUSY=1 has no effect. These bits can only be configured when BUSY=0.

**Bits 7:6 DATATYPE[1:0]:** Data Type selection

This bitfield defines the format of data written in CRYP\_DIN or read from CRYP\_DOUT registers. For more details refer to [Section 20.3.16: CRYP data registers and data swapping](#).

00: 32-bit data. No swapping for each word. First word pushed into the IN FIFO (or popped off the OUT FIFO) forms bits 1...32 of the data block, the second word forms bits 33...64 etc.

01: 16-bit data, or half-word. Each word pushed into the IN FIFO (or popped off the OUT FIFO) is considered as 2 half-words, which are swapped with each other.

10: 8-bit data, or bytes. Each word pushed into the IN FIFO (or popped off the OUT FIFO) is considered as 4 bytes, which are swapped with each other.

11: bit data, or bit-string. Each word pushed into the IN FIFO (or popped off the OUT FIFO) is considered as 32 bits (1st bit of the string at position 0), which are swapped with each other.

Writing DATATYPE bits while BUSY=1 has no effect. These bits can only be configured when BUSY=0.

**Bits 19, 5:3 ALGOMODE[3:0]:** Algorithm mode

Below definition includes the bit 19:

0000: TDES-ECB (triple-DES Electronic Codebook).

0001: TDES-CBC (triple-DES Cipher Block Chaining).

0010: DES-ECB (simple DES Electronic Codebook).

0011: DES-CBC (simple DES Cipher Block Chaining).

0100: AES-ECB (AES Electronic Codebook).

0101: AES-CBC (AES Cipher Block Chaining).

0110: AES-CTR (AES Counter Mode).

0111: AES key preparation for ECB or CBC decryption.

1000: AES-GCM (Galois Counter Mode) and AES-GMAC (Galois Message Authentication Code mode).

1001: AES-CCM (Counter with CBC-MAC).

Writing ALGOMODE bits while BUSY=1 has no effect. These bits can only be configured when BUSY=0.

**Bit 2 ALGODIR:** Algorithm Direction

0: Encrypt

1: Decrypt

Writing ALGODIR bit while BUSY=1 has no effect. It can only be configured when BUSY=0.

Bits 1:0 Reserved, must be kept at reset value.

## 20.6.2 CRYP status register (CRYP\_SR)

Address offset: 0x04

Reset value: 0x0000 0003

|      |      |      |      |      |      |      |      |      |      |      | r    | r    | r    | r    | r    |

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 **BUSY**: Busy bit

0: The CRYP core is not processing any data. The reason is:

- either that the CRYP core is disabled (CRYPEN=0 in the CRYP\_CR register) and the last processing has completed,
- or the CRYP core is waiting for enough data in the input FIFO or enough free space in the output FIFO (that is in each case at least 2 words in the DES, 4 words in the AES).

1: The CRYP core is currently processing a block of data or a key preparation is ongoing (AES ECB or CBC decryption only).

Bit 3 **OFFU**: Output FIFO full flag

0: Output FIFO is not full

1: Output FIFO is full

Bit 2 **OFNE**: Output FIFO not empty flag

0: Output FIFO is empty

1: Output FIFO is not empty

Bit 1 **IFNF**: Input FIFO not full flag

0: Input FIFO is full

1: Input FIFO is not full

Bit 0 **IFEM**: Input FIFO empty flag

0: Input FIFO is not empty

1: Input FIFO is empty

## 20.6.3 CRYP data input register (CRYP\_DIN)

Address offset: 0x08

Reset value: 0x0000 0000

The CRYP\_DIN register is the data input register. It is 32-bit wide. It is used to enter into the input FIFO up to four 64-bit blocks (TDDES) or two 128-bit blocks (AES) of plaintext (when encrypting) or ciphertext (when decrypting), one 32-bit word at a time.

To fit different data sizes, the data can be swapped after processing by configuring the DATATYPE bits in the CRYP\_CR register. Refer to [Section 20.3.16: CRYP data registers and data swapping](#) for more details.

When CRYPT\_DIN register is written to the data are pushed into the input FIFO.

- If CRYPTEN = 1, when at least two 32-bit words in the DES/TDES mode have been pushed into the input FIFO (four words in the AES mode), and when at least two words are free in the output FIFO (four words in the AES mode), the CRYP engine starts an encrypting or decrypting process.

When CRYPT\_DIN register is read:

- If CRYPTEN = 0, the FIFO is popped, and then the data present in the Input FIFO are returned, from the oldest one (first reading) to the newest one (last reading). The IFEM flag must be checked before each read operation to make sure that the FIFO is not empty.
- if CRYPTEN = 1, an undefined value is returned.

**Note:** After the CRYPT\_DIN register has been read once or several times, the FIFO must be flushed by setting the FFLUSH bit prior to processing new data.

|               |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|---------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31            | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| DATAIN[31:16] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw            | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |
| 15            | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| DATAIN[15:0]  |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw            | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 31:0 **DATAIN[31:0]**: Data Input

On read FIFO is popped (last written value is returned), and its value is returned if CRYPTEN=0. If CRYPTEN=1 DATAIN register returns an undefined value.

On write current register content is pushed inside the FIFO.

## 20.6.4 CRYP data output register (CRYPT\_DOUT)

Address offset: 0x0C

Reset value: 0x0000 0000

The CRYPT\_DOUT register is the data output register. It is read-only and 32-bit wide. It is used to retrieve from the output FIFO up to four 64-bit blocks (TDES) or two 128-bit blocks (AES) of plaintext (when encrypting) or ciphertext (when decrypting), one 32-bit word at a time.

To fit different data sizes, the data can be swapped after processing by configuring the DATATYPE bits in the CRYPT\_CR register. Refer to [Section 20.3.16: CRYP data registers and data swapping](#) for more details.

When CRYPT\_DOUT register is read, the last data entered into the output FIFO (pointed to by the read pointer) is returned.

|                |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|----------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31             | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| DATAOUT[31:16] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| r              | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  |
| 15             | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| DATAOUT[15:0]  |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| r              | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  |

Bits 31:0 **DATAOUT[31:0]**: Data Output

On read returns output FIFO content (pointed to by read pointer), else returns an undefined value.

On write, no effect.

## 20.6.5 CRYP DMA control register (CRYP\_DMCCR)

Address offset: 0x10

Reset value: 0x0000 0000

|      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|
| 31   | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21   | 20   | 19   | 18   | 17   | 16   |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. |
|      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
| 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0    |

|      |      |      |      |      |      |      |      |      |      |      |      |      |      | rw   | rw   |

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **DOEN**: DMA Output Enable

When this bit is set, DMA requests are automatically generated by the peripheral during the output data phase.

0: DMA for outgoing data transfer is disabled

1: DMA for outgoing data transfer is enabled

Bit 0 **DIEN**: DMA Input Enable

When this bit is set, DMA requests are automatically generated by the peripheral during the input data phase.

0: DMA for incoming data transfer is disabled

1: DMA for incoming data transfer is enabled

## 20.6.6 CRYP interrupt mask set/clear register (CRYP\_IMSCR)

Address offset: 0x14

Reset value: 0x0000 0000

The CRYP\_IMSCR register is the interrupt mask set or clear register. It is a read/write register. When a read operation is performed, this register gives the current value of the mask applied to the relevant interrupt. Writing 1 to the particular bit sets the mask, thus enabling the interrupt to be read. Writing 0 to this bit clears the corresponding mask. All the bits are cleared to 0 when the peripheral is reset.

|      |      |      |      |      |      |      |      |      |      |      |      |      |      |       |      |
|------|------|------|------|------|------|------|------|------|------|------|------|------|------|-------|------|
| 31   | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21   | 20   | 19   | 18   | 17    | 16   |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res.  | Res. |
|      |      |      |      |      |      |      |      |      |      |      |      |      |      |       |      |
| 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5    | 4    | 3    | 2    | 1     | 0    |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | OUTIM | INIM |
|      |      |      |      |      |      |      |      |      |      |      |      |      |      | rw    | rw   |

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **OUTIM**: Output FIFO service interrupt mask  
 0: Output FIFO service interrupt is masked  
 1: Output FIFO service interrupt is not masked

Bit 0 **INIM**: Input FIFO service interrupt mask  
 0: Input FIFO service interrupt is masked  
 1: Input FIFO service interrupt is not masked

## 20.6.7 CRYP raw interrupt status register (CRYP\_RISR)

Address offset: 0x18

Reset value: 0x0000 0001

The CRYP\_RISR register is the raw interrupt status register. It is a read-only register. When a read operation is performed, this register gives the current raw status of the corresponding interrupt, i.e. the interrupt information without taking CRYP\_IMSCR mask into account. Write operations have no effect.

|      |      |      |      |      |      |      |      |      |      |      |      |      |      |        |       |
|------|------|------|------|------|------|------|------|------|------|------|------|------|------|--------|-------|
| 31   | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21   | 20   | 19   | 18   | 17     | 16    |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res.   | Res.  |
|      |      |      |      |      |      |      |      |      |      |      |      |      |      |        |       |
| 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5    | 4    | 3    | 2    | 1      | 0     |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | OUTRIS | INRIS |
|      |      |      |      |      |      |      |      |      |      |      |      |      |      | r      | r     |

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **OUTRIS**: Output FIFO service raw interrupt status  
 This bit gives the output FIFO interrupt information without taking CRYP\_IMSCR corresponding mask into account.  
 0: Raw interrupt not pending  
 1: Raw interrupt pending

Bit 0 **INRIS**: Input FIFO service raw interrupt status  
 This bit gives the input FIFO interrupt information without taking CRYP\_IMSCR corresponding mask into account.  
 0: Raw interrupt not pending  
 1: Raw interrupt pending

## 20.6.8 CRYP masked interrupt status register (CRYP\_MISR)

Address offset: 0x1C

Reset value: 0x0000 0000

The CRYP\_MISR register is the masked interrupt status register. It is a read-only register. When a read operation is performed, this register gives the current masked status of the corresponding interrupt, i.e. the interrupt information taking CRYP\_IMSCR mask into account. Write operations have no effect.

|      |      |      |      |      |      |      |      |      |      |      |      |      |      |        |       |
|------|------|------|------|------|------|------|------|------|------|------|------|------|------|--------|-------|
| 31   | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21   | 20   | 19   | 18   | 17     | 16    |

| 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5    | 4    | 3    | 2    | 1      | 0     |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | OUTMIS | INMIS |
|      |      |      |      |      |      |      |      |      |      |      |      |      |      | r      | r     |

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **OUTMIS**: Output FIFO service masked interrupt status

This bit gives the output FIFO interrupt information without taking into account the corresponding CRYP\_IMSCR mask.

0: Interrupt not pending

1: Interrupt pending

Bit 0 **INMIS**: Input FIFO service masked interrupt status

This bit gives the input FIFO interrupt information without taking into account the corresponding CRYP\_IMSCR mask.

0: Interrupt not pending

1: Interrupt pending when CRYPEN= 1

### 20.6.9 CRYP key register 0L (CRYP\_K0LR)

Address offset: 0x20

Reset value: 0x0000 0000

CRYP key registers contain the cryptographic keys.

- In DES/TDES mode, the keys are 64-bit binary values (number from left to right, that is the leftmost bit is bit 1) and named K1, K2 and K3 (K0 is not used). Each key consists of 56 information bits and 8 parity bits.
- In AES mode, the key is considered as a single 128, 192 or 256 bits long sequence  $K_0K_1K_2...K_{127/191/255}$ . The AES key is entered into the registers as follows:
  - for AES-128:  $K_0..K_{127}$  corresponds to  $b_{127}..b_0$  ( $b_{255}..b_{128}$  are not used),
  - for AES-192:  $K_0..K_{191}$  corresponds to  $b_{191}..b_0$  ( $b_{255}..b_{192}$  are not used),
  - for AES-256:  $K_0..K_{255}$  corresponds to  $b_{255}..b_0$ .

In all cases key bit  $K_0$  is the leftmost bit in CRYP inner memory and register bit  $b_0$  is the rightmost bit in corresponding CRYP\_KxLR key register.

For more information refer to [Section 20.3.17: CRYP key registers](#).

**Note:** Write accesses to these registers are disregarded when the cryptographic processor is busy (bit *BUSY* = 1 in the CRYP\_SR register)

|      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |

| w   | w   | w   | w   | w   | w   | w   | w   | w   | w   | w   | w   | w   | w   | w   | w   |

Bits 31:0 **K[63:32]**: AES key bit x (x= 32 to 63)

In DES mode K63 corresponds to key K3 bit 1 and K32 corresponds to key K3 bit 32.

### 20.6.16 CRYP key register 3R (CRYP\_K3RR)

Address offset: 0x3C

Reset value: 0x0000 0000

Refer to [Section 20.6.9: CRYP key register 0L \(CRYP\\_K0LR\)](#) for details.

|     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| 31  | 30  | 29  | 28  | 27  | 26  | 25  | 24  | 23  | 22  | 21  | 20  | 19  | 18  | 17  | 16  |
| K31 | K30 | K29 | K28 | K27 | K26 | K25 | K24 | K23 | K22 | K21 | K20 | K19 | K18 | K17 | K16 |
| w   | w   | w   | w   | w   | w   | w   | w   | w   | w   | w   | w   | w   | w   | w   | w   |
| 15  | 14  | 13  | 12  | 11  | 10  | 9   | 8   | 7   | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
| K15 | K14 | K13 | K12 | K11 | K10 | K9  | K8  | K7  | K6  | K5  | K4  | K3  | K2  | K1  | K0  |
| w   | w   | w   | w   | w   | w   | w   | w   | w   | w   | w   | w   | w   | w   | w   | w   |

Bits 31:0 **K[31:0]**: AES key bit x (x= 0 to 31)

In DES mode K31 corresponds to key K3 bit 33 and K0 corresponds to key K3 bit 64.

## 20.6.17 CRYP initialization vector register 0L (CRYP\_IV0LR)

Address offset: 0x40

Reset value: 0x0000 0000

The CRYP\_IV0...1(L/R)R are the left-word and right-word registers for the initialization vector (64 bits for DES/TDES and 128 bits for AES). For more information refer to [Section 20.3.18: CRYP initialization vector registers](#).

IV0 is the leftmost bit whereas IV63 (DES, TDES) or IV127 (AES) are the rightmost bits of the initialization vector. IV1(L/R)R is used only in the AES. Only CRYP\_IV0(L/R) is used in DES/TDES.

**Note:** Write access to these registers are disregarded when the cryptographic processor is busy (bit *BUSY* = 1 in the *CRYP\_SR* register).

|      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|
| 31   | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21   | 20   | 19   | 18   | 17   | 16   |

## 21 Hash processor (HASH)

This section applies to the whole STM32F756xx and STM32F750xx devices, unless otherwise specified.

### 21.1 Introduction

The hash processor is a fully compliant implementation of the secure hash algorithm (SHA-1, SHA-224, SHA-256), the MD5 (message-digest algorithm 5) hash algorithm and the HMAC (keyed-hash message authentication code) algorithm suitable for a variety of applications. HMAC is suitable for applications requiring message authentication.

The hash processor computes FIPS (Federal Information Processing Standards) approved digests of length of 160, 224, 256 bits, for messages of up to  $(2^{61} - 1)$  bits. It also computes 128 bits digests for the MD5 algorithm.

### 21.2 HASH main features

- Suitable for data authentication applications, compliant with:
  - Federal Information Processing Standards Publication FIPS PUB 180-4, *Secure Hash Standard* (SHA-1 and SHA-2 family)
  - Internet Engineering Task Force (IETF) Request For Comments RFC 1321 *MD5 Message-Digest Algorithm*
  - Internet Engineering Task Force (IETF) Request For Comments RFC 2104 *HMAC: Keyed-Hashing for Message Authentication*, and Federal Information Processing Standards Publication FIPS PUB 198-1, *The Keyed-Hash Message Authentication Code (HMAC)*
- Corresponding 32-bit words of the digest from consecutive message blocks are added to each other to form the digest of the whole message
  - Automatic 32-bit words swapping to comply with the internal little-endian representation of the input bit-string
  - Word swapping supported: bits, bytes, half-words and 32-bit words
- Automatic padding to complete the input bit string to fit digest minimum block size of 512 bits ( $16 \times 32$  bits)
- Single 32-bit input register associated to an internal input FIFO of sixteen 32-bit words, corresponding to one block size
- Fast computation of SHA-1, SHA-224, SHA-256, and MD5
  - 82 (respectively 66) clock cycles for processing one 512-bit block of data using

- SHA-1 (respectively SHA-256) algorithm
- 66 clock cycles for processing one 512-bit block of data using MD5 algorithm
- AHB slave peripheral, accessible through 32-bit word accesses only (else an AHB error is generated)
- 8 × 32-bit words (H0 to H7) for output message digest
- Automatic data flow control with support of direct memory access (DMA) using one channel. Fixed burst of 4 supported.
- Interruptible message digest computation, on a per-32-bit word basis
  - Re-loadable digest registers
  - Hashing computation suspend/resume mechanism, including using DMA

## 21.3 HASH functional description

### 21.3.1 HASH block diagram

Figure 145 shows the block diagram of the hash processor.

Figure 145. HASH block diagram

### 21.3.2 HASH internal signals

Table 139 describes a list of useful to know internal signals available at HASH level, not at product level (on pads).

Table 139. HASH internal input/output signals

| Signal name | Signal type          | Description                             |
|-------------|----------------------|-----------------------------------------|
| hash_hclk2  | digital input        | AHB2 bus clock                          |
| hash_it     | digital output       | Hash processor global interrupt request |
| hash_in_dma | digital input/output | DMA burst request/ acknowledge          |

### 21.3.3 About secure hash algorithms

The hash processor is a fully compliant implementation of the secure hash algorithm defined by FIPS PUB 180-4 standard and the IETF RFC1321 publication (MD5).

With each algorithm, the HASH computes a condensed representation of a message or data file. More specifically, when a message of any length below  $2^{64}$  bits is provided on input, the SHA-1, SHA-224, SHA-256 and MD5 processing core produces respectively a 160-bit, 224 bit, 256 bit and 128-bit output string called a message digest. The message digest can then be processed with a digital signature algorithm in order to generate or verify the signature for the message.

Signing the message digest rather than the message often improves the efficiency of the process because the message digest is usually much smaller in size than the message. The verifier of a digital signature has to use the same hash algorithm as the one used by the creator of the digital signature.

The SHA-2 functions supported by the hash processor are qualified as “secure” because it is computationally infeasible to find a message that corresponds to a given message digest (SHA-1 is no more qualified as secure since February 2017), or to find two different messages that produce the same message digest. Any change to a message in transit will, with very high probability, result in a different message digest, and the signature will fail to verify.

### 21.3.4 Message data feeding

The message (or data file) to be processed by the HASH should be considered as a bit string. Per FIPS PUB 180-1 and 180-2 standards this message bit string grows from left to right, with hexadecimal words expressed in “big-endian” convention, so that within each word, the most significant bit is stored in the left-most bit position. For example message string “abc” with a bit string representation of “01100001 01100010 01100011” is represented by a 32-bit word `0x00636261`, and 8-bit words `0x61626300`.

Data are entered into the HASH one 32-bit word at a time, by writing them into the HASH\_DIN register. The current contents of the HASH\_DIN register are transferred to the 16 words input FIFO (IN FIFO) each time the register is written with new data. Hence HASH\_DIN and the input FIFO form a seventeen 32-bit words length FIFO (named the IN buffer).

In accordance to the kind of data to be processed (e.g. byte swapping when data are ASCII text stream) there must be a bit, byte, half-word or no swapping operation to be performed on data from the input FIFO before entering the little-endian hash processing core.

[Figure 146](#) shows how the hash processing core 32-bit data block M0...31 is constructed from one 32-bit words popped into IN FIFO by the driver, according to the DATATYPE bitfield in the HASH control register (HASH\_CR).

HASH\_DIN data endianness when bit swapping is disabled (DATATYPE="00") can be described as following: the least significant bit of the message has to be at MSB position in the first word entered into the hash processor, the 32nd bit of the bit string has to be at MSB position in the second word entered into the hash processor and so on.

Figure 146. Message data swapping feature

### 21.3.5 Message digest computing

The hash processor sequentially processes 512-bit blocks when computing the message digest. Thus, each time  $16 \times 32$ -bit words (= 512 bits) have been written to the hash processor by the DMA or the CPU, the HASH automatically starts computing the message digest. This operation is known as 'partial digest computation'.

As described in [Section 21.3.4: Message data feeding](#), the message to be processed is entered into the HASH 32-bit word at a time, writing to the HASH\_DIN register to fill the input FIFO. In order to perform the hash computation on this data below sequence shall be used by the application.

1. Initialize the hash processor using the HASH\_CR register:
  - Select the right algorithm using ALGO field. If needed program the correct swapping operation on the message input words using DATATYPE bitfield in HASH\_CR.
  - Set MODE=1 and select the key length using LKEY if HMAC mode has been selected.
  - Update NBLW to define the number of valid bits in last word if it is different from 32 bits. If it is the case automatic padding could be applied by the HASH.
2. Complete the initialization by setting to 1 the INIT bit in HASH\_CR. Also set the bit DMAE to 1 if data are transferred via DMA.

**Caution:** When programming step 2, it is important to set up before or at the same time the correct configuration values (ALGO, DATATYPE, HMAC mode, key length, NBLW).

3. Start filling data by writing to HASH\_DIN register, unless data are automatically transferred via DMA. Note that the processing of a block can start only once the last value of the block has entered the IN FIFO. The way the partial or final digest computation is managed depends on the way data are fed into the processor:
  - a) When data are filled by software:
    - The partial digest computation is triggered when the software writes an additional word to the HASH\_DIN register (actually the first word of the next block). Once the processor is ready again (DINIS=1 in HASH\_SR), the software can write new data to HASH\_DIN. This mechanism avoids the introduction of wait states by the HASH.
    - The final digest computation is triggered when the last block is entered and the software writes the DCAL bit to 1. If the message length is not an exact multiple of 512 bits, the NBLW field in HASH\_STR register must be written prior to writing DCAL bit (see [Section 21.3.6](#) for details).
  - b) When data are filled by DMA as a single DMA transfer (MDMAT bit="0"):
    - The partial digest computation is triggered automatically each time the FIFO is full.
    - The final digest computation is triggered automatically when the last block has been transferred to the HASH\_DIN register (DCAL bit is set to 1 by hardware). If the message length is not an exact multiple of 512 bits, the NBLW field in HASH\_STR register must be written prior to enabling the DMA (see [Section 21.3.6](#) for details).
  - c) When data are filled using multiple DMA transfers (MDMAT bit="1") :
    - The partial digest computations are triggered as for single DMA transfers. However the final digest computation is not triggered automatically when the last block has been transferred to the HASH\_DIN register (DCAL bit is not set to 1 by hardware). It allows the hash processor to receive a new DMA transfer as part of

this digest computation. To launch the final digest computation, the software must set MDMAT bit to 0 before the last DMA transfer in order to trigger the final digest computation as it is done for single DMA transfers (see description before).

4. Once computed, the digest can be read from the output registers as described in [Table 140](#).

**Table 140. Hash processor outputs**

| Algorithm | Valid output registers | Most significant bit | Digest size (in bits) |
|-----------|------------------------|----------------------|-----------------------|
| MD5       | HASH_H0 to HASH_H3     | HASH_H0[31]          | 128                   |
| SHA-1     | HASH_H0 to HASH_H4     | HASH_H0[31]          | 160                   |
| SHA-224   | HASH_H0 to HASH_H6     | HASH_H0[31]          | 224                   |
| SHA-256   | HASH_H0 to HASH_H7     | HASH_H0[31]          | 256                   |

For more information about HMAC detailed instructions, refer to [Section 21.3.7: HMAC operation](#).

## 21.3.6 Message padding

### Overview

When computing a condensed representation of a message, the process of feeding data into the hash processor (with automatic partial digest computation every 512-bit block) loops until the last bits of the original message are written to the HASH\_DIN register.

As the length (number of bits) of a message can be any integer value, the last word written to the hash processor may have a valid number of bits between 1 and 32. This number of valid bits in the last word, NBLW, has to be written to the HASH\_STR register, so that message padding is correctly performed before the final message digest computation.

### Padding processing

Detailed padding sequences with DMA is enabled or disabled are described in [Section 21.3.5: Message digest computing](#).

### Padding example

As specified by Federal Information Processing Standards PUB 180-1 and PUB 180-2, message padding consists in appending a “1” followed by  $k$  “0”s, itself followed by a 64-bit integer that is equal to the length  $L$  in bits of the message. These three padding operations generate a padded message of length  $L + 1 + k + 64$ , which by construction is a multiple of 512 bits.

For the hash processor, the “1” is added to the last word written to the HASH\_DIN register at the bit position defined by the NBLW bitfield, and the remaining upper bits are cleared (“0”s).

**Example from FIPS PUB180-2**

Let us assume that the original message is the ASCII binary-coded form of “abc”, of length  $L = 24$ :

```
byte 0    byte 1    byte 2    byte 3
01100001 01100010 01100011 UUUUUUUU
<-- 1st word written to HASH_DIN -->
```

NBLW has to be loaded with the value 24: a “1” is appended at bit location 24 in the bit string (starting counting from left to right in the above bit string), which corresponds to bit 31 in the HASH\_DIN register (little-endian convention):

```
01100001 01100010 01100011 1UUUUUUU
```

Since  $L = 24$ , the number of bits in the above bit string is 25, and 423 “0” bits are appended, making now 448 bits.

This gives in hexadecimal (byte words in big-endian format):

```
61626380 00000000 00000000 00000000
00000000 00000000 00000000 00000000
00000000 00000000 00000000 00000000
00000000 00000000
```

The message length value,  $L$ , in two-word format (that is 00000000 00000018) is appended. Hence the final padded message in hexadecimal (byte words in big-endian format):

```
61626380 00000000 00000000 00000000
00000000 00000000 00000000 00000000
00000000 00000000 00000000 00000000
00000000 00000000 00000000 00000018
```

If the hash processor is programmed to swap byte within HASH\_DIN input register (DATATYPE=10 in HASH\_CR), the above message has to be entered by following below the sequence:

1. 0xUU636261 is written to the HASH\_DIN register (where ‘U’ means don’t care).
2. 0x18 is written to the HASH\_STR register (the number of valid bits in the last word written to the HASH\_DIN register is 24, as the original message length is 24 bits).
3. 0x10 is written to the HASH\_STR register to start the message padding (described above) and then perform the digest computation.
4. The hash computing is complete with the message digest available in the HASH\_HRx registers ( $x = 0 \dots 4$ ) for the SHA-1 algorithm. For this FIPS example, the expected value is as follows:

```
HASH_H0 = 0xA9993E36
HASH_H1 = 0x4706816A
HASH_H2 = 0xBA3E2571
HASH_H3 = 0x7850C26C
HASH_H4 = 0x9CD0D89D
```

### 21.3.7 HMAC operation

#### Overview

As specified by Internet Engineering Task Force *RFC2104, HMAC: keyed-hashing for message authentication*, the HMAC algorithm is used for message authentication by irreversibly binding the message being processed to a key chosen by the user. The algorithm consists of two nested hash operations:

$$\text{HMAC}(\text{message}) = \text{Hash}((\text{key} \mid \text{pad}) \text{ XOR } [0x5C]_n \mid \text{Hash}((\text{key} \mid \text{pad}) \text{ XOR } [0x36]_n \mid \text{message}))$$

where:

- $[X]_n$  represents a repetition of  $X$   $n$  times, where  $n$  equal to the size of the underlying hash function data block that is 512 bits for SHA-1, SHA224, SHA-256, MD5 hash algorithms (i.e.  $n=64$ ).
- $\text{pad}$  is a sequence of zeroes needed to extend the key to the length  $n$  defined above. If the key length is greater than  $n$ , the application shall first hash the key using  $\text{Hash}()$  function and then use the resultant byte string as the actual key to HMAC.
- $\mid$  represents the concatenation operator.

#### HMAC processing

Four different steps are required to compute the HMAC:

1. The block is initialized by writing the INIT bit to 1 with the MODE bit at 1 and the ALGO bits set to the value corresponding to the desired algorithm. The LKEY bit must also be set to 1 if the key being used is longer than 64 bytes. In this case, as required by HMAC specifications, the hash processor will use the hash of the key instead of the real key.
2. The key to be used for the inner hash function must be provided to the hash processor: The key loading operation follows the same mechanism as the message bit string loading, i.e. write key data into HASH\_DIN and complete the transfer by writing to HASH\_STR register.

*Note:* Endianness details can be found in [Section 21.3.4: Message data feeding](#).

3. Once the last key word has been entered and computation has started, the hash processor elaborates the inner key material. Once this operation has completed, it is ready to accept the message bit string as described in [Section 21.3.4: Message data feeding](#).
4. After the final hash round, the hash processor returns “ready” to indicate that it is ready to receive the key to be used for the outer hash function (normally, this key is the same as the one used for the inner hash function). When the last word of the key is entered and computation starts, the HMAC result can be found in the HASH\_H0...HASH\_H7 registers.

*Note:* The computation latency of the HMAC primitive depends on the lengths of the keys and message, as described in [Section 21.5: HASH processing time](#).

#### HMAC example

Below is an example of HMAC SHA-1 algorithm (ALGO="00" and MODE="1" in HASH\_CR) as specified by NIST.

Let us assume that the original message is the ASCII binary-coded form of “Sample message for keylen=blocklen”, of length  $L = 34$  bytes. If the HASH is programmed in

no swapping mode (DATATYPE=00 in HASH\_CR), the following data must be loaded sequentially into HASH\_DIN register:

1. **Inner hash key** input (length=64, i.e. no padding), specified by NIST. As key length=64, LKEY bit is set to 0 in HASH\_CR register

```
00010203 04050607 08090A0B 0C0D0E0F 10111213 14151617
18191A1B 1C1D1E1F 20212223 24252627 28292A2B 2C2D2E2F
30313233 34353637 38393A3B 3C3D3E3F
```

2. **Message** input (length=34, i.e. padding required). HASH\_STR must be set to 0x20 to start message padding and inner hash computation (see 'U' as don't care)

```
53616D70 6C65206D 65737361 67652066 6F72206B 65796C65
6E3D626C 6F636B6C 656EUUUU
```

3. **Outer hash key** input (length=64, i.e. no padding). A key identical to the inner hash key is entered here.

4. **Final outer hash computing** is then performed by the HASH. The HMAC SHA-1 digest result is available in the HASH\_HRx registers (x = 0...4), as shown below:

```
HASH_H0 = 0x5FD596EE
HASH_H1 = 0x78D5553C
HASH_H2 = 0x8FF4E72D
HASH_H3 = 0x266DFD19
HASH_H4 = 0x2366DA29
```

### 21.3.8 Context swapping

#### Overview

It is possible to interrupt a hash/HMAC operation to perform another processing with a higher priority. The interrupted process completes later when the higher-priority task has been processed, as shown in [Figure 147](#).

**Figure 147. HASH save/restore mechanism**

To do so, the context of the interrupted task must be saved from the HASH registers to memory, and then be restored from memory to the HASH registers.

The procedures where the data flow is controlled by software or by DMA are described below.

### Data loaded by software

When the DMA is not used to load the message into the hash processor, the context can be saved only when no block processing is ongoing. This means that the user application must wait until DINIS = 1 (last block processed and input FIFO empty) or NBW ≠ 0 (FIFO not full and no processing ongoing). The detailed procedure is described below.

- **Current context saving**

Before interrupting the current message digest calculation, the application must store the contents of the following registers into memory:

- HASH\_IMR
- HASH\_STR
- HASH\_CR
- HASH\_CSR0 to HASH\_CSR53

- **Current context restoring**

To resume processing the interrupted message, the application must respect the following steps:

- a) Write the following registers with the values saved in memory: HASH\_IMR, HASH\_STR and HASH\_CR.
- b) Initialize the hash processor by setting the INIT bit in the HASH\_CR register.
- c) Write the HASH\_CSR0 to HASH\_CSR53 registers with the values saved in memory.
- d) Restart the processing from the point where it has been interrupted.

### Data loaded by DMA

When the DMA is used to load the message into the hash processor, it is not possible to predict if a DMA transfer is ongoing. The user application must thus stop DMA transfers, then wait until the hash processor is ready before interrupting the current message digest calculation. The detailed procedure is described below.

- **Current context saving**

Before interrupting the current message digest calculation using DMA, the application must respect the following steps:

- a) Clear the DMAE bit to disable the DMA interface.
- b) Wait until the current DMA transfer is complete (wait for DMAS = 0 in the HASH\_SR register). Note that the block may or may not have been totally transferred to the HASH.
- c) Disable the corresponding channel in the DMA controller.
- d) Wait until the hash processor is ready (no block is being processed), that is wait for DINIS = 1

- **Current context restoring**

To resume processing the interrupted message using DMA, the application must respect the following steps:

- a) Reconfigure the DMA controller so that it proceeds with the transfer of the message up to the end if it is not interrupted again.
- b) Restart the processing from the point where it was interrupted by setting the DMAE bit.

**Note:** *If the context swapping does not involve HMAC operations, the HASH\_CSR38 to HASH\_CSR53 registers do not need to be saved and restored.*

*If the context swapping occurs between two blocks (the last block was completely processed and the next block has not yet been pushed into the IN FIFO, NBW = 000 in the HASH\_CR register), the HASH\_CSR22 to HASH\_CSR37 registers do not need to be saved and restored.*

### 21.3.9 HASH DMA interface

The hash processor provides an interface to connect to the DMA controller. This DMA can be used to write data to the HASH by setting the DMAE bit in the HASH\_CR register. When this bit is set, the HASH asserts the burst request signal to the DMA controller when there is enough free words in the FIFO to support a burst of four words.

Once four 32-bit words have been received, the HASH automatically restarts this process, checks the FIFO size, and asserts a new request if the FIFO status allow a burst reception. For more information refer to [Section 21.3.5: Message digest computing](#).

Before starting the DMA transfer, the software must program the number of valid bits in the last word that will be copied into HASH\_DIN register. This is done by writing in HASH\_STR register the following value:

$$NBLW = \text{Len}(\text{Message}) \% 32$$

where “x%32” gives the remainder of x divided by 32.

DMAS bit in HASH\_SR register provides information on the DMA interface activity. This bit is set with DMAE and cleared when DMAE is cleared to 0 and no DMA transfer is ongoing.

**Note:** *No interrupt is associated to DMAS bit.*

### 21.3.10 HASH error management

No error flags are generated by the HASH hardware.

## 21.4 HASH interrupts

Two individual maskable interrupt sources are generated by the hash processor to signal following events:

- Digest calculation completion (DCIS)
- Data input buffer ready (DINIS)

Both interrupt sources are connected to the same global interrupt request signal, as shown on [Figure 148](#).

**Figure 148. HASH interrupt mapping diagram**

The above interrupt sources can be enabled or disabled individually by changing the mask bits in the HASH\_IMR register. Setting the appropriate mask bit to 1 enables the interrupt.

The status of the individual interrupt events can be read from the HASH\_SR register.

[Table 141](#) gives a summary of the available features.

**Table 141. HASH interrupt requests**

| Interrupt event                                 | Event flag | Enable control bit |
|-------------------------------------------------|------------|--------------------|
| Digest computation completed flag               | DCIS       | DCIE               |
| Data input buffer ready to get a new block flag | DINIS      | DINIE              |

## 21.5 HASH processing time

[Table 142](#) summarizes the time required to process a 512-bit intermediate block for each mode of operation.

**Table 142. Processing time (in clock cycle)**

| Mode of operation | FIFO load <sup>(1)</sup> | Computation phase | Total     |
|-------------------|--------------------------|-------------------|-----------|
| MD5               | 16                       | 50                | <b>66</b> |
| SHA-1             | 16                       | 66                | <b>82</b> |
| SHA-224           | 16                       | 50                | <b>66</b> |
| SHA-256           |                          |                   |           |

1. The time required to load the 16 words of the block into the processor must be added to this value.

The time required to process the last block of a message (or of a key in HMAC) can be longer. This time depends on the length of the last block and the size of the key (in HMAC mode).

Compared to the processing of an intermediate block, it can be increased by the factor below:

- **1 to 2.5** for a hash message
- **~2.5** for an HMAC input-key
- **1 to 2.5** for an HMAC message
- **~2.5** for an HMAC output key in case of a short key
- **3.5 to 5** for an HMAC output key in case of a long key

## 21.6 HASH registers

The HASH core is associated with several control and status registers and five message digest registers. All these registers are accessible through 32-bit word accesses only, else an AHB2 error is generated.

### 21.6.1 HASH control register (HASH\_CR)

Address offset: 0x00

Reset value: 0x0000 0000

| 31   | 30   | 29    | 28    | 27       | 26   | 25   | 24   | 23      | 22   | 21            | 20   | 19   | 18      | 17   | 16   |
|------|------|-------|-------|----------|------|------|------|---------|------|---------------|------|------|---------|------|------|
| Res. | Res. | Res.  | Res.  | Res.     | Res. | Res. | Res. | Res.    | Res. | Res.          | Res. | Res. | ALGO[1] | Res. | LKEY |
|      |      |       |       |          |      |      |      |         |      |               |      |      | rw      |      | rw   |

| Res. | Res. | MDMAT | DINNE | NBW[3:0] |      |      |      | ALGO[0] | MODE | DATATYPE[1:0] |      | DMAE | INIT    | Res. | Res. |
|      |      | rw    | r     | r        | r    | r    | r    | rw      | rw   | rw            | rw   | rw   | w       |      |      |

Bits 31:19 Reserved, must be kept at reset value.

Bit 17 Reserved, must be kept at reset value.

Bit 16 **LKEY**: Long key selection

This bit selects between short key ( $\leq 64$  bytes) or long key ( $> 64$  bytes) in HMAC mode.

0: Short key ( $\leq 64$  bytes)

1: Long key ( $> 64$  bytes)

*Note: This selection is only taken into account when the INIT bit is set and MODE= 1. Changing this bit during a computation has no effect.*

Bit 15 Reserved, must be kept at reset value.

Bit 14 Reserved, must be kept at reset value.

Bit 13 **MDMAT**: Multiple DMA Transfers

This bit is set when hashing large files when multiple DMA transfers are needed.

0: DCAL is automatically set at the end of a DMA transfer.

1: DCAL is not automatically set at the end of a DMA transfer.

Bit 12 **DINNE**: DIN not empty

This bit is set when the HASH\_DIN register holds valid data (that is after being written at least once). It is cleared when either the INIT bit (initialization) or the DCAL bit (completion of the previous message processing) is written to 1.

0: No data are present in the data input buffer

1: The input buffer contains at least one word of data

Bits 11:8 **NBW[3:0]**: Number of words already pushed

This bitfield reflects the number of words in the message that have already been pushed into the IN FIFO. NBW increments (+1) when a write access is performed to the HASH\_DIN register while DINNE = 1.

It goes to zero when the INIT bit is written to 1 or when a digest calculation starts (DCAL written to 1 or DMA end of transfer).

**If the DMA is not used**

0000 and DINNE=0: no word has been pushed into the DIN buffer, i.e. both HASH\_DIN register and IN FIFO are empty.

0000 and DINNE=1: one word has been pushed into the DIN buffer, i.e. HASH\_DIN register contains one word and IN FIFO is empty.

0001: two words have been pushed into the DIN buffer, i.e. HASH\_DIN register and the IN FIFO contain one word each.

...

1111: 16 words have been pushed into the DIN buffer.

**If the DMA is used**

NBW is the exact number of words that have been pushed into the IN FIFO by the DMA.

Bits 18, 7 **ALGO[1:0]**: Algorithm selection

These bits select the SHA-1, SHA-224, SHA-256 or the MD5 algorithm:

00: SHA-1 algorithm selected

01: MD5 algorithm selected

10: SHA-224 algorithm selected

11: SHA-256 algorithm selected

*Note: This selection is only taken into account when the INIT bit is set. Changing this bit during a computation has no effect.*

Bit 6 **MODE**: Mode selection

This bit selects the HASH or HMAC mode for the selected algorithm:

0: Hash mode selected

1: HMAC mode selected. LKEY must be set if the key being used is longer than 64 bytes.

*Note: This selection is only taken into account when the INIT bit is set. Changing this bit during a computation has no effect.*

Bits 5:4 **DATATYPE[1:0]**: Data type selection

These bits define the format of the data entered into the HASH\_DIN register:

00: 32-bit data. The data written to HASH\_DIN are directly used by the hash processing, without reordering.

01: 16-bit data or half-word. The data written to HASH\_DIN are considered as two half-words, and are swapped before being used by the hash processing.

10: 8-bit data or bytes. The data written to HASH\_DIN are considered as four bytes, and are swapped before being used by the hash processing.

11: bit data or bit-string. The data written to HASH\_DIN are considered as 32 bits (1st bit of the string at position 0), and are swapped before being used by the hash processing (first bit of the string at position 31).

Bit 3 **DMAE**: DMA enable

0: DMA transfers disabled

1: DMA transfers enabled. A DMA request is sent as soon as the hash core is ready to receive data.

After this bit is set it is cleared by hardware while the last data of the message is written to the hash processor.

Setting this bit to 0 while a DMA transfer is on-going is not aborting this current transfer. Instead, the DMA interface of the HASH remains internally enabled until the transfer is complete or INIT is written to 1.

Setting INIT bit to 1 does not clear DMAE bit.

Bit 2 **INIT**: Initialize message digest calculation

Writing this bit to 1 resets the hash processor core, so that the HASH is ready to compute the message digest of a new message.

Writing this bit to 0 has no effect. Reading this bit always return 0.

Bits 1:0 Reserved, must be kept at reset value.

## 21.6.2 HASH data input register (HASH\_DIN)

Address offset: 0x04

Reset value: 0x0000 0000

HASH\_DIN is the data input register. It is 32-bit wide. This register is used to enter the message by blocks of 512 bits. When the HASH\_DIN register is programmed, the value presented on the AHB databus is 'pushed' into the hash core and the register takes the new value presented on the AHB databus. To get a correct message format, the DATATYPE bits must have been previously configured in the HASH\_CR register.

When a block of 16 words has been written to the HASH\_DIN register, an intermediate digest calculation is launched:

- by writing new data into the HASH\_DIN register (the first word of the next block) if the DMA is not used (intermediate digest calculation),
- automatically if the DMA is used.

When the last block has been written to the HASH\_DIN register, the final digest calculation (including padding) is launched:

- by writing the DCAL bit to 1 in the HASH\_STR register (final digest calculation),
- automatically if the DMA is used and MDMAT bit is set to 0.

When a digest calculation (intermediate or final) is ongoing and a new write access to the HASH\_DIN register is performed, wait-states are inserted on the AHB2 bus until the hash calculation completes.

When the HASH\_DIN register is read, the last word written to this location is accessed (zero after reset).

|               |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|---------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31            | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| DATAIN[31:16] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw            | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |
| 15            | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| DATAIN[15:0]  |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw            | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 31:0 **DATAIN[31:0]**: Data input

Reading this register returns the current register content.

Writing this register pushes the current register content into the IN FIFO, and the register takes the new value presented on the AHB databus.

### 21.6.3 HASH start register (HASH\_STR)

Address offset: 0x08

Reset value: 0x0000 0000

The HASH\_STR register has two functions:

- It is used to define the number of valid bits in the last word of the message entered in the hash processor (that is the number of valid least significant bits in the last data written to the HASH\_DIN register)
- It is used to start the processing of the last block in the message by writing the DCAL bit to 1

|      |      |      |      |      |      |      |      |      |      |      |           |      |      |      |      |
|------|------|------|------|------|------|------|------|------|------|------|-----------|------|------|------|------|
| 31   | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21   | 20        | 19   | 18   | 17   | 16   |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res.      | Res. | Res. | Res. | Res. |
|      |      |      |      |      |      |      |      |      |      |      |           |      |      |      |      |
| 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5    | 4         | 3    | 2    | 1    | 0    |
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | DCAL | Res. | Res. | Res. | NBLW[4:0] |      |      |      |      |
|      |      |      |      |      |      |      | w    |      |      |      | rw        | rw   | rw   | rw   | rw   |

Bits 31:9 Reserved, must be kept at reset value.

Bit 8 **DCAL**: Digest calculation

Writing this bit to 1 starts the message padding, using the previously written value of NBLW, and starts the calculation of the final message digest with all data words written to the IN FIFO since the INIT bit was last written to 1.

Reading this bit returns 0.

Bits 7:5 Reserved, must be kept at reset value.

Bits 4:0 **NBLW[4:0]**: Number of valid bits in the last word

When the last word of the message bit string is written in HASH\_DIN register, the hash processor takes only the valid bits specified as below, after internal data swapping:

0x00: All 32 bits of the last data written are valid message bits i.e. M[31:0]

0x01: Only one bit of the last data written (after swapping) is valid i.e. M[0]

0x02: Only two bits of the last data written (after swapping) are valid i.e. M[1:0]

0x03: Only three bits of the last data written (after swapping) are valid i.e. M[2:0]

...

0x1F: Only 31 bits of the last data written (after swapping) are valid i.e. M[30:0]

The above mechanism is valid only if DCAL=0. If NBLW bits are written while DCAL is set to 1, the NBLW bitfield remains unchanged. In other words it is not possible to configure NBLW and set DCAL at the same time.

Reading NBLW bits returns the last value written to NBLW.

## 21.6.4 HASH digest registers (HASH\_HR0..7)

These registers contain the message digest result named as follows:

- HASH\_HR0, HASH\_HR1, HASH\_HR2, HASH\_HR3 and HASH\_HR4 registers return the SHA-1 digest result  
HASH\_HR5 to HASH\_HR7 registers are not used, and they are read as zero.
- HASH\_HR0, HASH\_HR1, HASH\_HR2 and HASH\_HR3 registers return A, B, C and D (respectively), as defined by MD5.  
HASH\_HR4 to HASH\_HR7 registers are not used, and they are read as zero.
- HASH\_HR0 to HASH\_HR6 registers return the SHA-224 digest result.  
HASH\_HR7 register is not used, and it is read as zero.
- HASH\_HR0 to HASH\_HR7 registers return the SHA-256 digest result.

In all cases, the digest most significant bit is stored in HASH\_HR0[31] and it is not used.

If a read access to one of these registers is performed while the hash core is calculating an intermediate digest or a final message digest (that is when the DCAL bit has been written to 1), then the read operation is stalled until the hash calculation completes.

*Note:* *HASH\_HR0, HASH\_HR1, HASH\_HR2, HASH\_HR3 and HASH\_HR4 mapping are duplicated in two memory regions.*

| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | BUSY | DMAS | DCIS  | DINIS |
|      |      |      |      |      |      |      |      |      |      |      |      | r    | r    | rc_w0 | rc_w0 |

Bits 31:4 Reserved, must be kept at reset value.

Bit 3 **BUSY**: Busy bit

- 0: No block is currently being processed
- 1: The hash core is processing a block of data

Bit 2 **DMAS**: DMA Status

This bit provides information on the DMA interface activity. It is set with DMAE and cleared when DMAE=0 and no DMA transfer is ongoing. No interrupt is associated with this bit.

- 0: DMA interface is disabled (DMAE=0) and no transfer is ongoing
- 1: DMA interface is enabled (DMAE=1) or a transfer is ongoing

Bit 1 **DCIS**: Digest calculation completion interrupt status

This bit is set by hardware when a digest becomes ready (the whole message has been processed). It is cleared by writing it to 0 or by writing the INIT bit to 1 in the HASH\_CR register.

- 0: No digest available in the HASH\_HRx registers
- 1: Digest calculation complete, a digest is available in the HASH\_HRx registers. An interrupt is generated if the DCIE bit is set in the HASH\_IMR register.

Bit 0 **DINIS**: Data input interrupt status

This bit is set by hardware when the input buffer is ready to get a new block (16 locations are free). It is cleared by writing it to 0 or by writing the HASH\_DIN register.

- 0: Less than 16 locations are free in the input buffer
- 1: A new block can be entered into the input buffer. An interrupt is generated if the DINIE bit is set in the HASH\_IMR register.

## 21.6.7 HASH context swap registers (HASH\_CSRx)

These registers contain the complete internal register states of the hash processor. They are useful when a context swap has to be done because a high-priority task needs to use the hash processor while it is already used by another task.

When such an event occurs, the HASH\_CSRx registers have to be read and the read values have to be saved in the system memory space. Then the hash processor can be used by the preemptive task, and when the hash computation is complete, the saved context can be read from memory and written back into the HASH\_CSRx registers.

### HASH\_CSR0

Address offset: 0x0F8

Reset value: 0x0000 0002

Refer to [Section 2.2.2 on page 69](#) for the register boundary addresses.

## 22 Advanced-control timers (TIM1/TIM8)

### 22.1 TIM1/TIM8 introduction

The advanced-control timers (TIM1/TIM8) consist of a 16-bit auto-reload counter driven by a programmable prescaler.

It may be used for a variety of purposes, including measuring the pulse lengths of input signals (input capture) or generating output waveforms (output compare, PWM, complementary PWM with dead-time insertion).

Pulse lengths and waveform periods can be modulated from a few microseconds to several milliseconds using the timer prescaler and the RCC clock controller prescalers.

The advanced-control (TIM1/TIM8) and general-purpose (TIMy) timers are completely independent, and do not share any resources. They can be synchronized together as described in [Section 22.3.25: Timer synchronization](#).

### 22.2 TIM1/TIM8 main features

TIM1/TIM8 timer features include:

- 16-bit up, down, up/down auto-reload counter.
- 16-bit programmable prescaler allowing dividing (also “on the fly”) the counter clock frequency either by any factor between 1 and 65536.
- Up to 6 independent channels for:
  - Input Capture (but channels 5 and 6)
  - Output Compare
  - PWM generation (Edge and Center-aligned Mode)
  - One-pulse mode output
- Complementary outputs with programmable dead-time
- Synchronization circuit to control the timer with external signals and to interconnect several timers together.
- Repetition counter to update the timer registers only after a given number of cycles of the counter.
- 2 break inputs to put the timer’s output signals in a safe user selectable configuration.
- Interrupt/DMA generation on the following events:
  - Update: counter overflow/underflow, counter initialization (by software or internal/external trigger)
  - Trigger event (counter start, stop, initialization or count by internal/external trigger)
  - Input capture
  - Output compare
- Supports incremental (quadrature) encoder and Hall-sensor circuitry for positioning purposes
- Trigger input for external clock or cycle-by-cycle current management

## 22.3 TIM1/TIM8 functional description

### 22.3.1 Time-base unit

The main block of the programmable advanced-control timer is a 16-bit counter with its related auto-reload register. The counter can count up, down or both up and down. The counter clock can be divided by a prescaler.

The counter, the auto-reload register and the prescaler register can be written or read by software. This is true even when the counter is running.

The time-base unit includes:

- Counter register (TIMx\_CNT)
- Prescaler register (TIMx\_PSC)
- Auto-reload register (TIMx\_ARR)
- Repetition counter register (TIMx\_RCR)

The auto-reload register is preloaded. Writing to or reading from the auto-reload register accesses the preload register. The content of the preload register are transferred into the shadow register permanently or at each update event (UEV), depending on the auto-reload preload enable bit (ARPE) in TIMx\_CR1 register. The update event is sent when the counter reaches the overflow (or underflow when downcounting) and if the UDIS bit equals 0 in the TIMx\_CR1 register. It can also be generated by software. The generation of the update event is described in detailed for each configuration.

The counter is clocked by the prescaler output CK\_CNT, which is enabled only when the counter enable bit (CEN) in TIMx\_CR1 register is set (refer also to the slave mode controller description to get more details on counter enabling).

Note that the counter starts counting 1 clock cycle after setting the CEN bit in the TIMx\_CR1 register.

#### Prescaler description

The prescaler can divide the counter clock frequency by any factor between 1 and 65536. It is based on a 16-bit counter controlled through a 16-bit register (in the TIMx\_PSC register). It can be changed on the fly as this control register is buffered. The new prescaler ratio is taken into account at the next update event.

*Figure 150* and *Figure 151* give some examples of the counter behavior when the prescaler ratio is changed on the fly:

Figure 150. Counter timing diagram with prescaler division change from 1 to 2

Figure 151. Counter timing diagram with prescaler division change from 1 to 4

## 22.3.2 Counter modes

### Upcounting mode

In upcounting mode, the counter counts from 0 to the auto-reload value (content of the TIMx\_ARR register), then restarts from 0 and generates a counter overflow event.

If the repetition counter is used, the update event (UEV) is generated after upcounting is repeated for the number of times programmed in the repetition counter register (TIMx\_RCR) + 1. Else the update event is generated at each counter overflow.

Setting the UG bit in the TIMx\_EGR register (by software or by using the slave mode controller) also generates an update event.

The UEV event can be disabled by software by setting the UDIS bit in the TIMx\_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until the UDIS bit has been written to 0. However, the counter restarts from 0, as well as the counter of the prescaler (but the prescale rate does not change). In addition, if the URS bit (update request selection) in TIMx\_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt or DMA request is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMx\_SR register) is set (depending on the URS bit):

- The repetition counter is reloaded with the content of TIMx\_RCR register,
- The auto-reload shadow register is updated with the preload value (TIMx\_ARR),
- The buffer of the prescaler is reloaded with the preload value (content of the TIMx\_PSC register).

The following figures show some examples of the counter behavior for different clock frequencies when TIMx\_ARR=0x36.

Figure 156. Counter timing diagram, update event when ARPE=0 (TIMx\_ARR not preloaded)

Figure 157. Counter timing diagram, update event when ARPE=1 (TIMx\_ARR preloaded)

### Downcounting mode

In downcounting mode, the counter counts from the auto-reload value (content of the TIMx\_ARR register) down to 0, then restarts from the auto-reload value and generates a counter underflow event.

If the repetition counter is used, the update event (UEV) is generated after downcounting is repeated for the number of times programmed in the repetition counter register (TIMx\_RCR) + 1. Else the update event is generated at each counter underflow.

Setting the UG bit in the TIMx\_EGR register (by software or by using the slave mode controller) also generates an update event.

The UEV update event can be disabled by software by setting the UDIS bit in TIMx\_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until UDIS bit has been written to 0. However, the counter restarts from the current auto-reload value, whereas the counter of the prescaler restarts from 0 (but the prescale rate doesn't change).

In addition, if the URS bit (update request selection) in TIMx\_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt or DMA request is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMx\_SR register) is set (depending on the URS bit):

- The repetition counter is reloaded with the content of TIMx\_RCR register.
- The buffer of the prescaler is reloaded with the preload value (content of the TIMx\_PSC register).
- The auto-reload active register is updated with the preload value (content of the TIMx\_ARR register). Note that the auto-reload is updated before the counter is reloaded, so that the next period is the expected one.

The following figures show some examples of the counter behavior for different clock frequencies when TIMx\_ARR=0x36.

Figure 158. Counter timing diagram, internal clock divided by 1

Figure 159. Counter timing diagram, internal clock divided by 2

Figure 160. Counter timing diagram, internal clock divided by 4

Figure 161. Counter timing diagram, internal clock divided by N

**Figure 162. Counter timing diagram, update event when repetition counter is not used**

### Center-aligned mode (up/down counting)

In center-aligned mode, the counter counts from 0 to the auto-reload value (content of the TIMx\_ARR register) – 1, generates a counter overflow event, then counts from the auto-reload value down to 1 and generates a counter underflow event. Then it restarts counting from 0.

Center-aligned mode is active when the CMS bits in TIMx\_CR1 register are not equal to '00'. The Output compare interrupt flag of channels configured in output is set when: the counter counts down (Center aligned mode 1, CMS = "01"), the counter counts up (Center aligned mode 2, CMS = "10") the counter counts up and down (Center aligned mode 3, CMS = "11").

In this mode, the DIR direction bit in the TIMx\_CR1 register cannot be written. It is updated by hardware and gives the current direction of the counter.

The update event can be generated at each counter overflow and at each counter underflow or by setting the UG bit in the TIMx\_EGR register (by software or by using the slave mode controller) also generates an update event. In this case, the counter restarts counting from 0, as well as the counter of the prescaler.

The UEV update event can be disabled by software by setting the UDIS bit in the TIMx\_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until UDIS bit has been written to 0. However, the counter continues counting up and down, based on the current auto-reload value.

In addition, if the URS bit (update request selection) in TIMx\_CR1 register is set, setting the UG bit generates an UEV update event but without setting the UIF flag (thus no interrupt or

DMA request is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMx\_SR register) is set (depending on the URS bit):

- The repetition counter is reloaded with the content of TIMx\_RCR register
- The buffer of the prescaler is reloaded with the preload value (content of the TIMx\_PSC register)
- The auto-reload active register is updated with the preload value (content of the TIMx\_ARR register). Note that if the update source is a counter overflow, the auto-reload is updated before the counter is reloaded, so that the next period is the expected one (the counter is loaded with the new value).

The following figures show some examples of the counter behavior for different clock frequencies.

**Figure 163. Counter timing diagram, internal clock divided by 1, TIMx\_ARR = 0x6**

1. Here, center-aligned mode 1 is used (for more details refer to [Section 22.4: TIM1/TIM8 registers](#)).

Figure 166. Counter timing diagram, internal clock divided by N

Figure 167. Counter timing diagram, update event with ARPE=1 (counter underflow)

**Figure 168. Counter timing diagram, Update event with ARPE=1 (counter overflow)**

### 22.3.3 Repetition counter

[Section 22.3.1: Time-base unit](#) describes how the update event (UEV) is generated with respect to the counter overflows/underflows. It is actually generated only when the repetition counter has reached zero. This can be useful when generating PWM signals.

This means that data are transferred from the preload registers to the shadow registers (TIMx\_ARR auto-reload register, TIMx\_PSC prescaler register, but also TIMx\_CCRx capture/compare registers in compare mode) every N+1 counter overflows or underflows, where N is the value in the TIMx\_RCR repetition counter register.

The repetition counter is decremented:

- At each counter overflow in upcounting mode,
  - At each counter underflow in downcounting mode,
  - At each counter overflow and at each counter underflow in center-aligned mode.
- Although this limits the maximum number of repetition to 32768 PWM cycles, it makes it possible to update the duty cycle twice per PWM period. When refreshing compare registers only once per PWM period in center-aligned mode, maximum resolution is  $2xT_{ck}$ , due to the symmetry of the pattern.

The repetition counter is an auto-reload type; the repetition rate is maintained as defined by the TIMx\_RCR register value (refer to [Figure 169](#)). When the update event is generated by software (by setting the UG bit in TIMx\_EGR register) or by hardware through the slave mode controller, it occurs immediately whatever the value of the repetition counter is and the repetition counter is reloaded with the content of the TIMx\_RCR register.

In Center aligned mode, for odd values of RCR, the update event occurs either on the overflow or on the underflow depending on when the RCR register was written and when the counter was launched: if the RCR was written before launching the counter, the UEV occurs on the overflow. If the RCR was written after launching the counter, the UEV occurs on the underflow.

For example, for RCR = 3, the UEV is generated each 4th overflow or underflow event depending on when the RCR was written.

**Figure 169. Update rate examples depending on mode and TIMx\_RCR register settings**

### 22.3.4 External trigger input

The timer features an external trigger input ETR. It can be used as:

- external clock (external clock mode 2, see [Section 22.3.5](#))
- trigger for the slave mode (see [Section 22.3.25](#))
- PWM reset input for cycle-by-cycle current regulation (see [Section 22.3.7](#))

[Figure 170](#) below describes the ETR input conditioning. The input polarity is defined with the ETP bit in TIMxSMCR register. The trigger can be prescaled with the divider programmed by the ETPS[1:0] bitfield and digitally filtered with the ETF[3:0] bitfield.

**Figure 170. External trigger input block**

### 22.3.5 Clock selection

The counter clock can be provided by the following clock sources:

- Internal clock (CK\_INT)
- External clock mode1: external input pin
- External clock mode2: external trigger input ETR
- Encoder mode

#### Internal clock source (CK\_INT)

If the slave mode controller is disabled (SMS=000), then the CEN, DIR (in the TIMx\_CR1 register) and UG bits (in the TIMx\_EGR register) are actual control bits and can be changed only by software (except UG which remains cleared automatically). As soon as the CEN bit is written to 1, the prescaler is clocked by the internal clock CK\_INT.

*Figure 171* shows the behavior of the control circuit and the upcounter in normal mode, without prescaler.

**Figure 171. Control circuit in normal mode, internal clock divided by 1**

#### External clock source mode 1

This mode is selected when SMS=111 in the TIMx\_SMCR register. The counter can count at each rising or falling edge on a selected input.

Figure 172. TI2 external clock connection example

For example, to configure the upcounter to count in response to a rising edge on the TI2 input, use the following procedure:

1. Configure channel 2 to detect rising edges on the TI2 input by writing CC2S = '01' in the TIMx\_CCMR1 register.
2. Configure the input filter duration by writing the IC2F[3:0] bits in the TIMx\_CCMR1 register (if no filter is needed, keep IC2F=0000).
3. Select rising edge polarity by writing CC2P=0 and CC2NP=0 in the TIMx\_CCER register.
4. Configure the timer in external clock mode 1 by writing SMS=111 in the TIMx\_SMCR register.
5. Select TI2 as the trigger input source by writing TS=110 in the TIMx\_SMCR register.
6. Enable the counter by writing CEN=1 in the TIMx\_CR1 register.

**Note:** The capture prescaler is not used for triggering, so the user does not need to configure it.

When a rising edge occurs on TI2, the counter counts once and the TIF flag is set.

The delay between the rising edge on TI2 and the actual clock of the counter is due to the resynchronization circuit on TI2 input.

Figure 173. Control circuit in external clock mode 1

External clock source mode 2

This mode is selected by writing ECE=1 in the TIMx\_SMCR register.

The counter can count at each rising or falling edge on the external trigger input ETR.

The [Figure 174](#) gives an overview of the external trigger input block.

Figure 174. External trigger input block

For example, to configure the upcounter to count each 2 rising edges on ETR, use the following procedure:

1. As no filter is needed in this example, write  $ETF[3:0]=0000$  in the TIMx\_SMCR register.
2. Set the prescaler by writing  $ETPS[1:0]=01$  in the TIMx\_SMCR register
3. Select rising edge detection on the ETR pin by writing  $ETP=0$  in the TIMx\_SMCR register
4. Enable external clock mode 2 by writing  $ECE=1$  in the TIMx\_SMCR register.
5. Enable the counter by writing  $CEN=1$  in the TIMx\_CR1 register.

The counter counts once each 2 ETR rising edges.

The delay between the rising edge on ETR and the actual clock of the counter is due to the resynchronization circuit on the ETRP signal.

**Figure 175. Control circuit in external clock mode 2**

### 22.3.6 Capture/compare channels

Each Capture/Compare channel is built around a capture/compare register (including a shadow register), an input stage for capture (with digital filter, multiplexing, and prescaler, except for channels 5 and 6) and an output stage (with comparator and output control).

[Figure 176](#) to [Figure 179](#) give an overview of one Capture/Compare channel.

The input stage samples the corresponding TIx input to generate a filtered signal TIxF. Then, an edge detector with polarity selection generates a signal (TIxFPx) which can be used as trigger input by the slave mode controller or as the capture command. It is prescaled before the capture register (ICxPS).

**Figure 176. Capture/compare channel (example: channel 1 input stage)**

MS33115V1

The output stage generates an intermediate waveform which is then used for reference: OCxRef (active high). The polarity acts at the end of the chain.

**Figure 177. Capture/compare channel 1 main circuit**

**Figure 178. Output stage of capture/compare channel (channel 1, idem ch. 2 and 3)**

1. OCxREF, where x is the rank of the complementary channel

**Figure 179. Output stage of capture/compare channel (channel 4)****Figure 180. Output stage of capture/compare channel (channel 5, idem ch. 6)**

1. Not available externally.

The capture/compare block is made of one preload register and one shadow register. Write and read always access the preload register.

In capture mode, captures are actually done in the shadow register, which is copied into the preload register.

In compare mode, the content of the preload register is copied into the shadow register which is compared to the counter.

### 22.3.7 Input capture mode

In Input capture mode, the Capture/Compare Registers (TIMx\_CCRx) are used to latch the value of the counter after a transition detected by the corresponding ICx signal. When a capture occurs, the corresponding CCXIF flag (TIMx\_SR register) is set and an interrupt or

a DMA request can be sent if they are enabled. If a capture occurs while the CCxIF flag was already high, then the over-capture flag CCxOF (TIMx\_SR register) is set. CCxIF can be cleared by software by writing it to '0' or by reading the captured data stored in the TIMx\_CCRx register. CCxOF is cleared when you write it to '0'.

The following example shows how to capture the counter value in TIMx\_CCR1 when TI1 input rises. To do this, use the following procedure:

1. Select the active input: TIMx\_CCR1 must be linked to the TI1 input, so write the CC1S bits to 01 in the TIMx\_CCMR1 register. As soon as CC1S becomes different from 00, the channel is configured in input and the TIMx\_CCR1 register becomes read-only.
2. Program the input filter duration you need with respect to the signal you connect to the timer (when the input is one of the TIx (ICxF bits in the TIMx\_CCMRx register). Let's imagine that, when toggling, the input signal is not stable during at most 5 internal clock cycles. We must program a filter duration longer than these 5 clock cycles. We can validate a transition on TI1 when 8 consecutive samples with the new level have been detected (sampled at  $f_{DTS}$  frequency). Then write IC1F bits to 0011 in the TIMx\_CCMR1 register.
3. Select the edge of the active transition on the TI1 channel by writing CC1P and CC1NP bits to 0 in the TIMx\_CCER register (rising edge in this case).
4. Program the input prescaler. In our example, we wish the capture to be performed at each valid transition, so the prescaler is disabled (write IC1PS bits to '00' in the TIMx\_CCMR1 register).
5. Enable capture from the counter into the capture register by setting the CC1E bit in the TIMx\_CCER register.
6. If needed, enable the related interrupt request by setting the CC1IE bit in the TIMx\_DIER register, and/or the DMA request by setting the CC1DE bit in the TIMx\_DIER register.

When an input capture occurs:

- The TIMx\_CCR1 register gets the value of the counter on the active transition.
- CC1IF flag is set (interrupt flag). CC1OF is also set if at least two consecutive captures occurred whereas the flag was not cleared.
- An interrupt is generated depending on the CC1IE bit.
- A DMA request is generated depending on the CC1DE bit.

In order to handle the overcapture, it is recommended to read the data before the overcapture flag. This is to avoid missing an overcapture which could happen after reading the flag and before reading the data.

*Note: IC interrupt and/or DMA requests can be generated by software by setting the corresponding CCxG bit in the TIMx\_EGR register.*

### 22.3.8 PWM input mode

This mode is a particular case of input capture mode. The procedure is the same except:

- Two ICx signals are mapped on the same TIx input.
- These 2 ICx signals are active on edges with opposite polarity.
- One of the two TIxFP signals is selected as trigger input and the slave mode controller is configured in reset mode.

For example, the user can measure the period (in TIMx\_CCR1 register) and the duty cycle (in TIMx\_CCR2 register) of the PWM applied on TI1 using the following procedure (depending on CK\_INT frequency and prescaler value):

1. Select the active input for TIMx\_CCR1: write the CC1S bits to 01 in the TIMx\_CCMR1 register (TI1 selected).
2. Select the active polarity for TI1FP1 (used both for capture in TIMx\_CCR1 and counter clear): write the CC1P and CC1NP bits to '0' (active on rising edge).
3. Select the active input for TIMx\_CCR2: write the CC2S bits to 10 in the TIMx\_CCMR1 register (TI1 selected).
4. Select the active polarity for TI1FP2 (used for capture in TIMx\_CCR2): write the CC2P and CC2NP bits to CC2P/CC2NP='10' (active on falling edge).
5. Select the valid trigger input: write the TS bits to 101 in the TIMx\_SMCR register (TI1FP1 selected).
6. Configure the slave mode controller in reset mode: write the SMS bits to 0100 in the TIMx\_SMCR register.
7. Enable the captures: write the CC1E and CC2E bits to '1' in the TIMx\_CCER register.

**Figure 181. PWM input mode timing**

### 22.3.9 Forced output mode

In output mode (CCxS bits = 00 in the TIMx\_CCMRx register), each output compare signal (OCxREF and then OCx/OCxN) can be forced to active or inactive level directly by software, independently of any comparison between the output compare register and the counter.

To force an output compare signal (OCxREF/OCx) to its active level, user just needs to write 0101 in the OCxM bits in the corresponding TIMx\_CCMRx register. Thus OCxREF is forced high (OCxREF is always active high) and OCx get opposite value to CCxP polarity bit.

For example: CCxP=0 (OCx active high) => OCx is forced to high level.

The OCxREF signal can be forced low by writing the OCxM bits to 0100 in the TIMx\_CCMRx register.

Anyway, the comparison between the TIMx\_CCRx shadow register and the counter is still performed and allows the flag to be set. Interrupt and DMA requests can be sent accordingly. This is described in the output compare mode section below.

### 22.3.10 Output compare mode

This function is used to control an output waveform or indicate when a period of time has elapsed. Channels 1 to 4 can be output, while Channel 5 and 6 are only available inside the microcontroller (for instance, for compound waveform generation or for ADC triggering).

When a match is found between the capture/compare register and the counter, the output compare function:

- Assigns the corresponding output pin to a programmable value defined by the output compare mode (OCxM bits in the TIMx\_CCMRx register) and the output polarity (CCxP bit in the TIMx\_CCER register). The output pin can keep its level (OCxM=0000), be set active (OCxM=0001), be set inactive (OCxM=0010) or can toggle (OCxM=0011) on match.
- Sets a flag in the interrupt status register (CCxIF bit in the TIMx\_SR register).
- Generates an interrupt if the corresponding interrupt mask is set (CCXIE bit in the TIMx\_DIER register).
- Sends a DMA request if the corresponding enable bit is set (CCxDE bit in the TIMx\_DIER register, CCDS bit in the TIMx\_CR2 register for the DMA request selection).

The TIMx\_CCRx registers can be programmed with or without preload registers using the OCxPE bit in the TIMx\_CCMRx register.

In output compare mode, the update event UEV has no effect on OCxREF and OCx output. The timing resolution is one count of the counter. Output compare mode can also be used to output a single pulse (in One Pulse mode).

#### Procedure

1. Select the counter clock (internal, external, prescaler).
2. Write the desired data in the TIMx\_ARR and TIMx\_CCRx registers.
3. Set the CCXIE bit if an interrupt request is to be generated.
4. Select the output mode. For example:
  - Write OCxM = 0011 to toggle OCx output pin when CNT matches CCRx
  - Write OCxPE = 0 to disable preload register
  - Write CCxP = 0 to select active high polarity
  - Write CCxE = 1 to enable the output
5. Enable the counter by setting the CEN bit in the TIMx\_CR1 register.

The TIMx\_CCRx register can be updated at any time by software to control the output waveform, provided that the preload register is not enabled (OCxPE=0', else TIMx\_CCRx shadow register is updated only at the next update event UEV). An example is given in [Figure 182](#).

**Figure 182. Output compare mode, toggle on OC1**

### 22.3.11 PWM mode

Pulse Width Modulation mode allows you to generate a signal with a frequency determined by the value of the TIMx\_ARR register and a duty cycle determined by the value of the TIMx\_CCRx register.

The PWM mode can be selected independently on each channel (one PWM per OCx output) by writing '0110' (PWM mode 1) or '0111' (PWM mode 2) in the OCxM bits in the TIMx\_CCMRx register. You must enable the corresponding preload register by setting the OCxPE bit in the TIMx\_CCMRx register, and eventually the auto-reload preload register (in upcounting or center-aligned modes) by setting the ARPE bit in the TIMx\_CR1 register.

As the preload registers are transferred to the shadow registers only when an update event occurs, before starting the counter, you have to initialize all the registers by setting the UG bit in the TIMx\_EGR register.

OCx polarity is software programmable using the CCxP bit in the TIMx\_CCER register. It can be programmed as active high or active low. OCx output is enabled by a combination of the CCxE, CCxNE, MOE, OSSI and OSSR bits (TIMx\_CCER and TIMx\_BDTR registers). Refer to the TIMx\_CCER register description for more details.

In PWM mode (1 or 2), TIMx\_CNT and TIMx\_CCRx are always compared to determine whether  $TIMx\_CCRx \leq TIMx\_CNT$  or  $TIMx\_CNT \leq TIMx\_CCRx$  (depending on the direction of the counter).

The timer is able to generate PWM in edge-aligned mode or center-aligned mode depending on the CMS bits in the TIMx\_CR1 register.

### PWM edge-aligned mode

- Upcounting configuration

Upcounting is active when the DIR bit in the TIMx\_CR1 register is low. Refer to the [Upcounting mode on page 652](#).

In the following example, we consider PWM mode 1. The reference PWM signal OCxREF is high as long as TIMx\_CNT < TIMx\_CCRx else it becomes low. If the compare value in TIMx\_CCRx is greater than the auto-reload value (in TIMx\_ARR) then OCxREF is held at '1'. If the compare value is 0 then OCxRef is held at '0'.

[Figure 183](#) shows some edge-aligned PWM waveforms in an example where TIMx\_ARR=8.

**Figure 183. Edge-aligned PWM waveforms (ARR=8)**

- Downcounting configuration

Downcounting is active when DIR bit in TIMx\_CR1 register is high. Refer to the [Downcounting mode on page 656](#)

In PWM mode 1, the reference signal OCxRef is low as long as TIMx\_CNT > TIMx\_CCRx else it becomes high. If the compare value in TIMx\_CCRx is greater than the auto-reload value in TIMx\_ARR, then OCxREF is held at '1'. 0% PWM is not possible in this mode.

### PWM center-aligned mode

Center-aligned mode is active when the CMS bits in TIMx\_CR1 register are different from '00' (all the remaining configurations having the same effect on the OCxRef/OCx signals). The compare flag is set when the counter counts up, when it counts down or both when it counts up and down depending on the CMS bits configuration. The direction bit (DIR) in the TIMx\_CR1 register is updated by hardware and must not be changed by software. Refer to

the [Center-aligned mode \(up/down counting\) on page 659](#).

[Figure 184](#) shows some center-aligned PWM waveforms in an example where:

- TIMx\_ARR=8,
- PWM mode is the PWM mode 1,
- The flag is set when the counter counts down corresponding to the center-aligned mode 1 selected for CMS=01 in TIMx\_CR1 register.

**Figure 184. Center-aligned PWM waveforms (ARR=8)**

Hints on using center-aligned mode

- When starting in center-aligned mode, the current up-down configuration is used. It means that the counter counts up or down depending on the value written in the DIR bit

in the TIMx\_CR1 register. Moreover, the DIR and CMS bits must not be changed at the same time by the software.

- Writing to the counter while running in center-aligned mode is not recommended as it can lead to unexpected results. In particular:
  - The direction is not updated if you write a value in the counter that is greater than the auto-reload value (TIMx\_CNT > TIMx\_ARR). For example, if the counter was counting up, it continues to count up.
  - The direction is updated if you write 0 or write the TIMx\_ARR value in the counter but no Update Event UEV is generated.
- The safest way to use center-aligned mode is to generate an update by software (setting the UG bit in the TIMx\_EGR register) just before starting the counter and not to write the counter while it is running.

### 22.3.12 Asymmetric PWM mode

Asymmetric mode allows two center-aligned PWM signals to be generated with a programmable phase shift. While the frequency is determined by the value of the TIMx\_ARR register, the duty cycle and the phase-shift are determined by a pair of TIMx\_CCRx register. One register controls the PWM during up-counting, the second during down counting, so that PWM is adjusted every half PWM cycle:

- OC1REFC (or OC2REFC) is controlled by TIMx\_CCR1 and TIMx\_CCR2
- OC3REFC (or OC4REFC) is controlled by TIMx\_CCR3 and TIMx\_CCR4

Asymmetric PWM mode can be selected independently on two channel (one OCx output per pair of CCR registers) by writing '1110' (Asymmetric PWM mode 1) or '1111' (Asymmetric PWM mode 2) in the OCxM bits in the TIMx\_CCMRx register.

*Note: The OCxM[3:0] bit field is split into two parts for compatibility reasons, the most significant bit is not contiguous with the 3 least significant ones.*

When a given channel is used as asymmetric PWM channel, its complementary channel can also be used. For instance, if an OC1REFC signal is generated on channel 1 (Asymmetric PWM mode 1), it is possible to output either the OC2REF signal on channel 2, or an OC2REFC signal resulting from asymmetric PWM mode 1.

[Figure 185](#) represents an example of signals that can be generated using Asymmetric PWM mode (channels 1 to 4 are configured in Asymmetric PWM mode 1). Together with the deadtime generator, this allows a full-bridge phase-shifted DC to DC converter to be controlled.

**Figure 185. Generation of 2 phase-shifted PWM signals with 50% duty cycle**

### 22.3.13 Combined PWM mode

Combined PWM mode allows two edge or center-aligned PWM signals to be generated with programmable delay and phase shift between respective pulses. While the frequency is determined by the value of the TIMx\_ARR register, the duty cycle and delay are determined by the two TIMx\_CCRx registers. The resulting signals, OCxREFC, are made of an OR or AND logical combination of two reference PWMs:

- OC1REFC (or OC2REFC) is controlled by TIMx\_CCR1 and TIMx\_CCR2
- OC3REFC (or OC4REFC) is controlled by TIMx\_CCR3 and TIMx\_CCR4

Combined PWM mode can be selected independently on two channels (one OCx output per pair of CCR registers) by writing '1100' (Combined PWM mode 1) or '1101' (Combined PWM mode 2) in the OCxM bits in the TIMx\_CCMRx register.

When a given channel is used as combined PWM channel, its complementary channel must be configured in the opposite PWM mode (for instance, one in Combined PWM mode 1 and the other in Combined PWM mode 2).

**Note:** The OCxM[3:0] bit field is split into two parts for compatibility reasons, the most significant bit is not contiguous with the 3 least significant ones.

Figure 186 represents an example of signals that can be generated using Asymmetric PWM mode, obtained with the following configuration:

- Channel 1 is configured in Combined PWM mode 2,
- Channel 2 is configured in PWM mode 1,
- Channel 3 is configured in Combined PWM mode 2,
- Channel 4 is configured in PWM mode 1.

Figure 186. Combined PWM mode on channel 1 and 3

### 22.3.14 Combined 3-phase PWM mode

Combined 3-phase PWM mode allows one to three center-aligned PWM signals to be generated with a single programmable signal ANDed in the middle of the pulses. The OC5REF signal is used to define the resulting combined signal. The 3-bits GC5C[3:1] in the TIMx\_CCR5 allow selection on which reference signal the OC5REF is combined. The resulting signals, OCxREFC, are made of an AND logical combination of two reference PWMs:

- If GC5C1 is set, OC1REFC is controlled by TIMx\_CCR1 and TIMx\_CCR5
- If GC5C2 is set, OC2REFC is controlled by TIMx\_CCR2 and TIMx\_CCR5
- If GC5C3 is set, OC3REFC is controlled by TIMx\_CCR3 and TIMx\_CCR5

Combined 3-phase PWM mode can be selected independently on channels 1 to 3 by setting at least one of the 3-bits GC5C[3:1].

**Figure 187. 3-phase combined PWM signals with multiple trigger pulses per period**

The TRGO2 waveform shows how the ADC can be synchronized on given 3-phase PWM signals. Refer to [Section 22.3.26: ADC synchronization](#) for more details.

### 22.3.15 Complementary outputs and dead-time insertion

The advanced-control timers (TIM1/TIM8) can output two complementary signals and manage the switching-off and the switching-on instants of the outputs.

This time is generally known as dead-time and you have to adjust it depending on the devices you have connected to the outputs and their characteristics (intrinsic delays of level-shifters, delays due to power switches...)

You can select the polarity of the outputs (main output OCx or complementary OCxN) independently for each output. This is done by writing to the CCxP and CCxNP bits in the TIMx\_CCER register.

The complementary signals OCx and OCxN are activated by a combination of several control bits: the CCxE and CCxNE bits in the TIMx\_CCER register and the MOE, OISx, OISxN, OSSI and OSSR bits in the TIMx\_BDTR and TIMx\_CR2 registers. Refer to [Table 147: Output control bits for complementary OCx and OCxN channels with break feature on page 727](#) for more details. In particular, the dead-time is activated when switching to the idle state (MOE falling down to 0).

Dead-time insertion is enabled by setting both CCxE and CCxNE bits, and the MOE bit if the break circuit is present. There is one 10-bit dead-time generator for each channel. From a reference waveform OCxREF, it generates 2 outputs OCx and OCxN. If OCx and OCxN are active high:

- The OCx output signal is the same as the reference signal except for the rising edge, which is delayed relative to the reference rising edge.
- The OCxN output signal is the opposite of the reference signal except for the rising edge, which is delayed relative to the reference falling edge.

If the delay is greater than the width of the active output (OCx or OCxN) then the corresponding pulse is not generated.

The following figures show the relationships between the output signals of the dead-time generator and the reference signal OCxREF. (we suppose CCxP=0, CCxNP=0, MOE=1, CCxE=1 and CCxNE=1 in these examples)

**Figure 188. Complementary output with dead-time insertion**

**Figure 189. Dead-time waveforms with delay greater than the negative pulse**

**Figure 190. Dead-time waveforms with delay greater than the positive pulse**

The dead-time delay is the same for each of the channels and is programmable with the DTG bits in the TIMx\_BDTR register. Refer to [Section 22.4.18: TIMx break and dead-time register \(TIMx\\_BDTR\)\(x = 1, 8\)](#) for delay calculation.

### Re-directing OCxREF to OCx or OCxN

In output mode (forced, output compare or PWM), OCxREF can be re-directed to the OCx output or to OCxN output by configuring the CCxE and CCxNE bits in the TIMx\_CCER register.

This allows you to send a specific waveform (such as PWM or static active level) on one output while the complementary remains at its inactive level. Other alternative possibilities are to have both outputs at inactive level or both outputs active and complementary with dead-time.

**Note:** When only OCxN is enabled (CCxE=0, CCxNE=1), it is not complemented and becomes active as soon as OCxREF is high. For example, if CCxNP=0 then OCxN=OCxRef. On the other hand, when both OCx and OCxN are enabled (CCxE=CCxNE=1) OCx becomes active when OCxREF is high whereas OCxN is complemented and becomes active when OCxREF is low.

## 22.3.16 Using the break function

The purpose of the break function is to protect power switches driven by PWM signals generated with the TIM1 and TIM8 timers. The two break inputs are usually connected to fault outputs of power stages and 3-phase inverters. When activated, the break circuitry shuts down the PWM outputs and forces them to a predefined safe state. A number of internal MCU events can also be selected to trigger an output shut-down.

The break features two channels. A break channel which gathers both system-level fault (clock failure,...) and application fault (from input pins), and can force the outputs to a predefined level (either active or inactive) after a deadtime duration. A break2 channel which only includes application faults and is able to force the outputs to an inactive state.

The output enable signal and output levels during break are depending on several control bits:

- the MOE bit in TIMx\_BDTR register allows to enable /disable the outputs by software and is reset in case of break or break2 event.
- the OSSI bit in the TIMx\_BDTR register defines whether the timer controls the output in inactive state or releases the control to the GPIO controller (typically to have it in Hi-Z mode)
- the OISx and OISxN bits in the TIMx\_CR2 register which are setting the output shut-down level, either active or inactive. The OCx and OCxN outputs cannot be set both to active level at a given time, whatever the OISx and OISxN values. Refer to [Table 147: Output control bits for complementary OCx and OCxN channels with break feature on page 727](#) for more details.

When exiting from reset, the break circuit is disabled and the MOE bit is low. You can enable the break functions by setting the BKE and BKE2 bits in the TIMx\_BDTR register. The break input polarities can be selected by configuring the BKP and BKP2 bits in the same register. BKEx and BKPx can be modified at the same time. When the BKEx and BKPx bits are written, a delay of 1 APB clock cycle is applied before the writing is effective. Consequently, it is necessary to wait 1 APB clock period to correctly read back the bit after the write operation.

Because MOE falling edge can be asynchronous, a resynchronization circuit has been inserted between the actual signal (acting on the outputs) and the synchronous control bit (accessed in the TIMx\_BDTR register). It results in some delays between the asynchronous and the synchronous signals. In particular, if you write MOE to 1 whereas it was low, you must insert a delay (dummy instruction) before reading it correctly. This is because you write the asynchronous signal and read the synchronous signal.

The break (BRK) event can be generated by two sources of events ORed together:

- An external source connected to one of the BKIN pin (as per selection done in the AFIO controller)
- An internal source: clock failure event generated by the CSS detector

The break2 (BRK2) can be generated by an external source connected to one of the BKIN2 pin (as per selection done in the AFIO controller).

Break events can also be generated by software using BG and B2G bits in the TIMx\_EGR register. The software break generation using BG and BG2 is active whatever the BKE and BKE2 enable bits values.

Figure 191. Break and Break2 circuitry overview

**Note:** *An asynchronous (clockless) operation is only guaranteed when the programmable filter is disabled. If it is enabled, a fail safe clock mode (for example by using the internal PLL and/or the CSS) must be used to guarantee that break events are handled.*

When one of the breaks occurs (selected level on one of the break inputs):

- The MOE bit is cleared asynchronously, putting the outputs in inactive state, idle state or even releasing the control to the GPIO controller (selected by the OSS1 bit). This feature is enabled even if the MCU oscillator is off.
- Each output channel is driven with the level programmed in the OISx bit in the TIMx\_CR2 register as soon as MOE=0. If OSS1=0, the timer releases the output control (taken over by the GPIO controller), otherwise the enable output remains high.
- When complementary outputs are used:
  - The outputs are first put in inactive state (depending on the polarity). This is done asynchronously so that it works even if no clock is provided to the timer.
  - If the timer clock is still present, then the dead-time generator is reactivated in order to drive the outputs with the level programmed in the OISx and OISxN bits after a dead-time. Even in this case, OCx and OCxN cannot be driven to their

- active level together. Note that because of the resynchronization on MOE, the dead-time duration is slightly longer than usual (around 2 ck\_tim clock cycles).
- If OSSR=0, the timer releases the output control (taken over by the GPIO controller which forces a Hi-Z state), otherwise the enable outputs remain or become high as soon as one of the CCxE or CCxNE bits is high.
  - The break status flag (SBIF, BIF and B2IF bits in the TIMx\_SR register) is set. An interrupt is generated if the BIE bit in the TIMx\_DIER register is set. A DMA request can be sent if the BDE bit in the TIMx\_DIER register is set.
  - If the AOE bit in the TIMx\_BDTR register is set, the MOE bit is automatically set again at the next update event (UEV). As an example, this can be used to perform a regulation. Otherwise, MOE remains low until the application sets it to '1' again. In this case, it can be used for security and you can connect the break input to an alarm from power drivers, thermal sensors or any security components.

**Note:** *The break inputs are active on level. Thus, the MOE cannot be set while the break input is active (neither automatically nor by software). In the meantime, the status flag BIF and B2IF cannot be cleared.*

In addition to the break input and the output management, a write protection has been implemented inside the break circuit to safeguard the application. It allows to freeze the configuration of several parameters (dead-time duration, OCx/OCxN polarities and state when disabled, OCxM configurations, break enable and polarity). The application can choose from 3 levels of protection selected by the LOCK bits in the TIMx\_BDTR register. Refer to [Section 22.4.18: TIMx break and dead-time register \(TIMx\\_BDTR\)\(x = 1, 8\)](#). The LOCK bits can be written only once after an MCU reset.

[Figure 192](#) shows an example of behavior of the outputs in response to a break.

**Figure 192. Various output behavior in response to a break event on BRK (OSS1 = 1)**

The two break inputs have different behaviors on timer outputs:

- The BRK input can either disable (inactive state) or force the PWM outputs to a predefined safe state.
- BRK2 can only disable (inactive state) the PWM outputs.

The BRK has a higher priority than BRK2 input, as described in [Table 144](#).

**Note:** *BRK2 must only be used with OSSR = OSSl = 1.*

**Table 144. Behavior of timer outputs versus BRK/BRK2 inputs**

| BRK      | BRK2   | Timer outputs state                                                                                                                                                                 | Typical use case                   |                                    |
|----------|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------|------------------------------------|
|          |        |                                                                                                                                                                                     | OCxN output<br>(low side switches) | OCx output<br>(high side switches) |
| Active   | X      | <ul style="list-style-type: none"> <li>– Inactive then forced output state (after a deadtime)</li> <li>– Outputs disabled if OSSl = 0 (control taken over by GPIO logic)</li> </ul> | ON after deadtime insertion        | OFF                                |
| Inactive | Active | Inactive                                                                                                                                                                            | OFF                                | OFF                                |

[Figure 193](#) gives an example of OCx and OCxN output behavior in case of active signals on BRK and BRK2 inputs. In this case, both outputs have active high polarities (CCxP = CCxNP = 0 in TIMx\_CCER register).

**Figure 193. PWM output state following BRK and BRK2 pins assertion (OSSl=1)**

**Figure 194. PWM output state following BRK assertion (OSSI=0)**

### 22.3.17 Clearing the OCxREF signal on an external event

The OCxREF signal for a given channel can be driven low by applying a high level to the ETRF input (OCxCE enable bit of the corresponding TIMx\_CCMRx register set to '1'). The OCxREF signal remains low until the next update event, UEV, occurs.

When ETRF is chosen, ETR must be configured as follows:

1. The External Trigger Prescaler should be kept off: bits ETPS[1:0] of the TIMx\_SMCR register set to '00'.
2. The external clock mode 2 must be disabled: bit ECE of the TIMx\_SMCR register set to '0'.
3. The External Trigger Polarity (ETP) and the External Trigger Filter (ETF) can be configured according to the user needs.

[Figure 195](#) shows the behavior of the OCxREF signal when the ETRF Input becomes High, for both values of the enable bit OCxCE. In this example, the timer TIMx is programmed in PWM mode.

Figure 195. Clearing TIMx OCxREF

Note:

*In case of a PWM with a 100% duty cycle (if  $CCR_x > ARR$ ), then OCxREF is enabled again at the next counter overflow.*

### 22.3.18 6-step PWM generation

When complementary outputs are used on a channel, preload bits are available on the OCxM, CCxE and CCxNE bits. The preload bits are transferred to the shadow bits at the COM commutation event. Thus you can program in advance the configuration for the next step and change the configuration of all the channels at the same time. COM can be generated by software by setting the COM bit in the TIMx\_EGR register or by hardware (on TRGI rising edge).

A flag is set when the COM event occurs (COMIF bit in the TIMx\_SR register), which can generate an interrupt (if the COMIE bit is set in the TIMx\_DIER register) or a DMA request (if the COMDE bit is set in the TIMx\_DIER register).

The [Figure 196](#) describes the behavior of the OCx and OCxN outputs when a COM event occurs, in 3 different examples of programmed configurations.

**Figure 196. 6-step generation, COM example (OSSR=1)**

### 22.3.19 One-pulse mode

One-pulse mode (OPM) is a particular case of the previous modes. It allows the counter to be started in response to a stimulus and to generate a pulse with a programmable length after a programmable delay.

Starting the counter can be controlled through the slave mode controller. Generating the waveform can be done in output compare mode or PWM mode. You select One-pulse mode by setting the OPM bit in the TIMx\_CR1 register. This makes the counter stop automatically at the next update event UEV.

A pulse can be correctly generated only if the compare value is different from the counter initial value. Before starting (when the timer is waiting for the trigger), the configuration must be:

- In upcounting:  $CNT < CCRx \leq ARR$  (in particular,  $0 < CCRx$ )
- In downcounting:  $CNT > CCRx$

**Figure 197. Example of one pulse mode.**

For example you may want to generate a positive pulse on OC1 with a length of  $t_{PULSE}$  and after a delay of  $t_{DELAY}$  as soon as a positive edge is detected on the TI2 input pin.

Let's use TI2FP2 as trigger 1:

1. Map TI2FP2 to TI2 by writing CC2S='01' in the TIMx\_CCMR1 register.
2. TI2FP2 must detect a rising edge, write CC2P='0' and CC2NP='0' in the TIMx\_CCER register.
3. Configure TI2FP2 as trigger for the slave mode controller (TRGI) by writing TS=110 in the TIMx\_SMCR register.
4. TI2FP2 is used to start the counter by writing SMS to '110' in the TIMx\_SMCR register (trigger mode).

The OPM waveform is defined by writing the compare registers (taking into account the clock frequency and the counter prescaler).

- The  $t_{\text{DELAY}}$  is defined by the value written in the TIMx\_CCR1 register.
- The  $t_{\text{PULSE}}$  is defined by the difference between the auto-reload value and the compare value (TIMx\_ARR - TIMx\_CCR1).
- Let's say you want to build a waveform with a transition from '0' to '1' when a compare match occurs and a transition from '1' to '0' when the counter reaches the auto-reload value. To do this you enable PWM mode 2 by writing OC1M=111 in the TIMx\_CCMR1 register. You can optionally enable the preload registers by writing OC1PE='1' in the TIMx\_CCMR1 register and ARPE in the TIMx\_CR1 register. In this case you have to write the compare value in the TIMx\_CCR1 register, the auto-reload value in the TIMx\_ARR register, generate an update by setting the UG bit and wait for external trigger event on TI2. CC1P is written to '0' in this example.

In our example, the DIR and CMS bits in the TIMx\_CR1 register should be low.

You only want 1 pulse (Single mode), so you write '1' in the OPM bit in the TIMx\_CR1 register to stop the counter at the next update event (when the counter rolls over from the auto-reload value back to 0). When OPM bit in the TIMx\_CR1 register is set to '0', so the Repetitive Mode is selected.

Particular case: OCx fast enable:

In One-pulse mode, the edge detection on Tlx input set the CEN bit which enables the counter. Then the comparison between the counter and the compare value makes the output toggle. But several clock cycles are needed for these operations and it limits the minimum delay  $t_{\text{DELAY min}}$  we can get.

If you want to output a waveform with the minimum delay, you can set the OCxFE bit in the TIMx\_CCMRx register. Then OCxRef (and OCx) are forced in response to the stimulus, without taking in account the comparison. Its new level is the same as if a compare match had occurred. OCxFE acts only if the channel is configured in PWM1 or PWM2 mode.

### 22.3.20 Retriggerable one pulse mode (OPM)

This mode allows the counter to be started in response to a stimulus and to generate a pulse with a programmable length, but with the following differences with Non-retriggerable one pulse mode described in [Section 22.3.19](#):

- The pulse starts as soon as the trigger occurs (no programmable delay)
- The pulse is extended if a new trigger occurs before the previous one is completed

The timer must be in Slave mode, with the bits SMS[3:0] = '1000' (Combined Reset + trigger mode) in the TIMx\_SMCR register, and the OCxM[3:0] bits set to '1000' or '1001' for Retriggerable OPM mode 1 or 2.

If the timer is configured in Up-counting mode, the corresponding CCRx must be set to 0 (the ARR register sets the pulse length). If the timer is configured in Down-counting mode, CCRx must be above or equal to ARR.

*Note:* The OCxM[3:0] and SMS[3:0] bit fields are split into two parts for compatibility reasons, the most significant bit are not contiguous with the 3 least significant ones.

*This mode must not be used with center-aligned PWM modes. It is mandatory to have CMS[1:0] = 00 in TIMx\_CR1.*

Figure 198. Retriggerable one pulse mode

MS33106V1

### 22.3.21 Encoder interface mode

To select Encoder Interface mode write SMS='001' in the TIMx\_SMCR register if the counter is counting on TI2 edges only, SMS='010' if it is counting on TI1 edges only and SMS='011' if it is counting on both TI1 and TI2 edges.

Select the TI1 and TI2 polarity by programming the CC1P and CC2P bits in the TIMx\_CCER register. When needed, you can program the input filter as well. CC1NP and CC2NP must be kept low.

The two inputs TI1 and TI2 are used to interface to an quadrature encoder. Refer to [Table 145](#). The counter is clocked by each valid transition on TI1FP1 or TI2FP2 (TI1 and TI2 after input filter and polarity selection, TI1FP1=TI1 if not filtered and not inverted, TI2FP2=TI2 if not filtered and not inverted) assuming that it is enabled (CEN bit in TIMx\_CR1 register written to '1'). The sequence of transitions of the two inputs is evaluated and generates count pulses as well as the direction signal. Depending on the sequence the counter counts up or down, the DIR bit in the TIMx\_CR1 register is modified by hardware accordingly. The DIR bit is calculated at each transition on any input (TI1 or TI2), whatever the counter is counting on TI1 only, TI2 only or both TI1 and TI2.

Encoder interface mode acts simply as an external clock with direction selection. This means that the counter just counts continuously between 0 and the auto-reload value in the TIMx\_ARR register (0 to ARR or ARR down to 0 depending on the direction). So you must configure TIMx\_ARR before starting. In the same way, the capture, compare, repetition counter, trigger output features continue to work as normal. Encoder mode and External clock mode 2 are not compatible and must not be selected together.

**Note:** *The prescaler must be set to zero when encoder mode is enabled*

In this mode, the counter is modified automatically following the speed and the direction of the quadrature encoder and its content, therefore, always represents the encoder's position. The count direction correspond to the rotation direction of the connected sensor. The table summarizes the possible combinations, assuming TI1 and TI2 don't switch at the same time.

Table 145. Counting direction versus encoder signals

| Active edge             | Level on opposite signal (TI1FP1 for TI2, TI2FP2 for TI1) | TI1FP1 signal |          | TI2FP2 signal |          |
|-------------------------|-----------------------------------------------------------|---------------|----------|---------------|----------|
|                         |                                                           | Rising        | Falling  | Rising        | Falling  |
| Counting on TI1 only    | High                                                      | Down          | Up       | No Count      | No Count |
|                         | Low                                                       | Up            | Down     | No Count      | No Count |
| Counting on TI2 only    | High                                                      | No Count      | No Count | Up            | Down     |
|                         | Low                                                       | No Count      | No Count | Down          | Up       |
| Counting on TI1 and TI2 | High                                                      | Down          | Up       | Up            | Down     |
|                         | Low                                                       | Up            | Down     | Down          | Up       |

A quadrature encoder can be connected directly to the MCU without external interface logic. However, comparators are normally be used to convert the encoder's differential outputs to digital signals. This greatly increases noise immunity. The third encoder output which indicate the mechanical zero position, may be connected to an external interrupt input and trigger a counter reset.

The [Figure 199](#) gives an example of counter operation, showing count signal generation and direction control. It also shows how input jitter is compensated where both edges are selected. This might occur if the sensor is positioned near to one of the switching points. For this example we assume that the configuration is the following:

- CC1S='01' (TIMx\_CCMR1 register, TI1FP1 mapped on TI1).
- CC2S='01' (TIMx\_CCMR2 register, TI1FP2 mapped on TI2).
- CC1P='0' and CC1NP='0' (TIMx\_CCER register, TI1FP1 non-inverted, TI1FP1=TI1).
- CC2P='0' and CC2NP='0' (TIMx\_CCER register, TI1FP2 non-inverted, TI1FP2= TI2).
- SMS='011' (TIMx\_SMCR register, both inputs are active on both rising and falling edges).
- CEN='1' (TIMx\_CR1 register, Counter enabled).

Figure 199. Example of counter operation in encoder interface mode.

Figure 200 gives an example of counter behavior when TI1FP1 polarity is inverted (same configuration as above except CC1P='1').

**Figure 200. Example of encoder interface mode with TI1FP1 polarity inverted.**

The timer, when configured in Encoder Interface mode provides information on the sensor's current position. You can obtain dynamic information (speed, acceleration, deceleration) by measuring the period between two encoder events using a second timer configured in capture mode. The output of the encoder which indicates the mechanical zero can be used for this purpose. Depending on the time between two events, the counter can also be read at regular times. You can do this by latching the counter value into a third input capture register if available (then the capture signal must be periodic and can be generated by another timer). when available, it is also possible to read its value through a DMA request.

The IUFREMAP bit in the TIMx\_CR1 register forces a continuous copy of the update interrupt flag (UIF) into the timer counter register's bit 31 (TIMxCNT[31]). This allows both the counter value and a potential roll-over condition signaled by the UIFCPY flag to be read in an atomic way. It eases the calculation of angular speed by avoiding race conditions caused, for instance, by a processing shared between a background task (counter reading) and an interrupt (update interrupt).

There is no latency between the UIF and UIFCPY flag assertions.

In 32-bit timer implementations, when the IUFREMAP bit is set, bit 31 of the counter is overwritten by the UIFCPY flag upon read access (the counter's most significant bit is only accessible in write mode).

### 22.3.22 UIF bit remapping

The IUFREMAP bit in the TIMx\_CR1 register forces a continuous copy of the Update Interrupt Flag UIF into the timer counter register's bit 31 (TIMxCNT[31]). This allows both the counter value and a potential roll-over condition signaled by the UIFCPY flag to be read in an atomic way. In particular cases, it can ease the calculations by avoiding race conditions, caused for instance by a processing shared between a background task (counter reading) and an interrupt (Update Interrupt).

There is no latency between the UIF and UIFCPY flags assertion.

### 22.3.23 Timer input XOR function

The TI1S bit in the TIMx\_CR2 register, allows the input filter of channel 1 to be connected to the output of an XOR gate, combining the three input pins TIMx\_CH1, TIMx\_CH2 and TIMx\_CH3.

The XOR output can be used with all the timer input functions such as trigger or input capture. It is convenient to measure the interval between edges on two input signals, as per [Figure 201](#) below.

**Figure 201. Measuring time interval between edges on 3 signals**

### 22.3.24 Interfacing with Hall sensors

This is done using the advanced-control timers (TIM1 or TIM8) to generate PWM signals to drive the motor and another timer TIMx (TIM2, TIM3, TIM4) referred to as “interfacing timer” in [Figure 202](#). The “interfacing timer” captures the 3 timer input pins (CC1, CC2, CC3) connected through a XOR to the TI1 input channel (selected by setting the TI1S bit in the TIMx\_CR2 register).

The slave mode controller is configured in reset mode; the slave input is TI1F\_ED. Thus, each time one of the 3 inputs toggles, the counter restarts counting from 0. This creates a time base triggered by any change on the Hall inputs.

On the “interfacing timer”, capture/compare channel 1 is configured in capture mode, capture signal is TRC (See [Figure 176: Capture/compare channel \(example: channel 1 input stage\) on page 670](#)). The captured value, which corresponds to the time elapsed between 2 changes on the inputs, gives information about motor speed.

The “interfacing timer” can be used in output mode to generate a pulse which changes the configuration of the channels of the advanced-control timer (TIM1 or TIM8) (by triggering a COM event). The TIM1 timer is used to generate PWM signals to drive the motor. To do this, the interfacing timer channel must be programmed so that a positive pulse is generated after a programmed delay (in output compare or PWM mode). This pulse is sent to the advanced-control timer (TIM1 or TIM8) through the TRGO output.

Example: you want to change the PWM configuration of your advanced-control timer TIM1 after a programmed delay each time a change occurs on the Hall inputs connected to one of the TIMx timers.

- Configure 3 timer inputs ORed to the TI1 input channel by writing the TI1S bit in the TIMx\_CR2 register to '1',
- Program the time base: write the TIMx\_ARR to the max value (the counter must be cleared by the TI1 change. Set the prescaler to get a maximum counter period longer than the time between 2 changes on the sensors,
- Program the channel 1 in capture mode (TRC selected): write the CC1S bits in the TIMx\_CCMR1 register to '01'. You can also program the digital filter if needed,
- Program the channel 2 in PWM 2 mode with the desired delay: write the OC2M bits to '111' and the CC2S bits to '00' in the TIMx\_CCMR1 register,
- Select OC2REF as trigger output on TRGO: write the MMS bits in the TIMx\_CR2 register to '101',

In the advanced-control timer TIM1, the right ITR input must be selected as trigger input, the timer is programmed to generate PWM signals, the capture/compare control signals are preloaded (CCPC=1 in the TIMx\_CR2 register) and the COM event is controlled by the trigger input (CCUS=1 in the TIMx\_CR2 register). The PWM control bits (CCxE, OCxM) are written after a COM event for the next step (this can be done in an interrupt subroutine generated by the rising edge of OC2REF).

The [Figure 202](#) describes this example.

Figure 202. Example of Hall sensor interface

### 22.3.25 Timer synchronization

The TIMx timers are linked together internally for timer synchronization or chaining. They can be synchronized in several modes: Reset mode, Gated mode, and Trigger mode.

#### Slave mode: Reset mode

The counter and its prescaler can be reinitialized in response to an event on a trigger input. Moreover, if the URS bit from the TIMx\_CR1 register is low, an update event UEV is generated. Then all the preloaded registers (TIMx\_ARR, TIMx\_CCRx) are updated.

In the following example, the upcounter is cleared in response to a rising edge on TI1 input:

- Configure the channel 1 to detect rising edges on TI1. Configure the input filter duration (in this example, we don't need any filter, so we keep IC1F=0000). The capture prescaler is not used for triggering, so you don't need to configure it. The CC1S bits select the input capture source only, CC1S = 01 in the TIMx\_CCMR1 register. Write CC1P=0 and CC1NP='0' in TIMx\_CCER register to validate the polarity (and detect rising edges only).
- Configure the timer in reset mode by writing SMS=100 in TIMx\_SMCR register. Select TI1 as the input source by writing TS=101 in TIMx\_SMCR register.
- Start the counter by writing CEN=1 in the TIMx\_CR1 register.

The counter starts counting on the internal clock, then behaves normally until TI1 rising edge. When TI1 rises, the counter is cleared and restarts from 0. In the meantime, the trigger flag is set (TIF bit in the TIMx\_SR register) and an interrupt request, or a DMA request can be sent if enabled (depending on the TIE and TDE bits in TIMx\_DIER register).

The following figure shows this behavior when the auto-reload register TIMx\_ARR=0x36. The delay between the rising edge on TI1 and the actual reset of the counter is due to the resynchronization circuit on TI1 input.

**Figure 203. Control circuit in reset mode**

### Slave mode: Gated mode

The counter can be enabled depending on the level of a selected input.

In the following example, the upcounter counts only when TI1 input is low:

- Configure the channel 1 to detect low levels on TI1. Configure the input filter duration (in this example, we don't need any filter, so we keep IC1F=0000). The capture prescaler is not used for triggering, so you don't need to configure it. The CC1S bits select the input capture source only, CC1S=01 in TIMx\_CCMR1 register. Write CC1P=1 and CC1NP='0' in TIMx\_CCER register to validate the polarity (and detect low level only).
- Configure the timer in gated mode by writing SMS=101 in TIMx\_SMCR register. Select TI1 as the input source by writing TS=101 in TIMx\_SMCR register.
- Enable the counter by writing CEN=1 in the TIMx\_CR1 register (in gated mode, the counter doesn't start if CEN=0, whatever is the trigger input level).

The counter starts counting on the internal clock as long as TI1 is low and stops as soon as TI1 becomes high. The TIF flag in the TIMx\_SR register is set both when the counter starts or stops.

The delay between the rising edge on TI1 and the actual stop of the counter is due to the resynchronization circuit on TI1 input.

**Figure 204. Control circuit in Gated mode**

### Slave mode: Trigger mode

The counter can start in response to an event on a selected input.

In the following example, the upcounter starts in response to a rising edge on TI2 input:

- Configure the channel 2 to detect rising edges on TI2. Configure the input filter duration (in this example, we don't need any filter, so we keep IC2F=0000). The capture prescaler is not used for triggering, so you don't need to configure it. The CC2S bits are configured to select the input capture source only, CC2S=01 in TIMx\_CCMR1 register.

Write CC2P=1 and CC2NP=0 in TIMx\_CCER register to validate the polarity (and detect low level only).

- Configure the timer in trigger mode by writing SMS=110 in TIMx\_SMCR register. Select TI2 as the input source by writing TS=110 in TIMx\_SMCR register.

When a rising edge occurs on TI2, the counter starts counting on the internal clock and the TIF flag is set.

The delay between the rising edge on TI2 and the actual start of the counter is due to the resynchronization circuit on TI2 input.

**Figure 205. Control circuit in trigger mode**

MS31403V1

### Slave mode: Combined reset + trigger mode

In this case, a rising edge of the selected trigger input (TRGI) reinitializes the counter, generates an update of the registers, and starts the counter.

This mode is used for one-pulse mode.

### Slave mode: external clock mode 2 + trigger mode

The external clock mode 2 can be used in addition to another slave mode (except external clock mode 1 and encoder mode). In this case, the ETR signal is used as external clock input, and another input can be selected as trigger input (in reset mode, gated mode or trigger mode). It is recommended not to select ETR as TRGI through the TS bits of TIMx\_SMCR register.

In the following example, the upcounter is incremented at each rising edge of the ETR signal as soon as a rising edge of TI1 occurs:

1. Configure the external trigger input circuit by programming the TIMx\_SMCR register as follows:
  - ETF = 0000: no filter
  - ETPS=00: prescaler disabled
  - ETP=0: detection of rising edges on ETR and ECE=1 to enable the external clock mode 2.
2. Configure the channel 1 as follows, to detect rising edges on TI:
  - IC1F=0000: no filter.
  - The capture prescaler is not used for triggering and does not need to be configured.
  - CC1S=01 in TIMx\_CCMR1 register to select only the input capture source
  - CC1P=0 and CC1NP='0' in TIMx\_CCER register to validate the polarity (and detect rising edge only).
3. Configure the timer in trigger mode by writing SMS=110 in TIMx\_SMCR register. Select TI1 as the input source by writing TS=101 in TIMx\_SMCR register.

A rising edge on TI1 enables the counter and sets the TIF flag. The counter then counts on ETR rising edges.

The delay between the rising edge of the ETR signal and the actual reset of the counter is due to the resynchronization circuit on ETRP input.

**Figure 206. Control circuit in external clock mode 2 + trigger mode**

**Note:** The clock of the slave peripherals (timer, ADC, ...) receiving the TRGO or the TRGO2 signals must be enabled prior to receive events from the master timer, and the clock frequency (prescaler) must not be changed on-the-fly while triggers are received from the master timer.

### 22.3.26 ADC synchronization

The timer can generate an ADC triggering event with various internal signals, such as reset, enable or compare events. It is also possible to generate a pulse issued by internal edge detectors, such as:

- Rising and falling edges of OC4ref
- Rising edge on OC5ref or falling edge on OC6ref

The triggers are issued on the TRGO2 internal line which is redirected to the ADC. There is a total of 16 possible events, which can be selected using the MMS2[3:0] bits in the TIMx\_CR2 register.

An example of an application for 3-phase motor drives is given in [Figure 187 on page 682](#).

*Note: The clock of the slave peripherals (timer, ADC, ...) receiving the TRGO or the TRGO2 signals must be enabled prior to receive events from the master timer, and the clock frequency (prescaler) must not be changed on-the-fly while triggers are received from the master timer.*

*Note: The clock of the ADC must be enabled prior to receive events from the master timer, and must not be changed on-the-fly while triggers are received from the timer.*

### 22.3.27 DMA burst mode

The TIMx timers have the capability to generate multiple DMA requests upon a single event. The main purpose is to be able to re-program part of the timer multiple times without software overhead, but it can also be used to read several registers in a row, at regular intervals.

The DMA controller destination is unique and must point to the virtual register TIMx\_DMAR. On a given timer event, the timer launches a sequence of DMA requests (burst). Each write into the TIMx\_DMAR register is actually redirected to one of the timer registers.

The DBL[4:0] bits in the TIMx\_DCR register set the DMA burst length. The timer recognizes a burst transfer when a read or a write access is done to the TIMx\_DMAR address, i.e. the number of transfers (either in half-words or in bytes).

The DBA[4:0] bits in the TIMx\_DCR registers define the DMA base address for DMA transfers (when read/write access are done through the TIMx\_DMAR address). DBA is defined as an offset starting from the address of the TIMx\_CR1 register:

Example:

00000: TIMx\_CR1

00001: TIMx\_CR2

00010: TIMx\_SMCR

As an example, the timer DMA burst feature is used to update the contents of the CCRx registers (x = 2, 3, 4) upon an update event, with the DMA transferring half words into the CCRx registers.

This is done in the following steps:

1. Configure the corresponding DMA channel as follows:
  - DMA channel peripheral address is the DMAR register address
  - DMA channel memory address is the address of the buffer in the RAM containing the data to be transferred by DMA into CCRx registers.
  - Number of data to transfer = 3 (See note below).
  - Circular mode disabled.
2. Configure the DCR register by configuring the DBA and DBL bit fields as follows:  
DBL = 3 transfers, DBA = 0xE.
3. Enable the TIMx update DMA request (set the UDE bit in the DIER register).
4. Enable TIMx
5. Enable the DMA channel

This example is for the case where every CCRx register to be updated once. If every CCRx register is to be updated twice for example, the number of data to transfer should be 6. Let's take the example of a buffer in the RAM containing data1, data2, data3, data4, data5 and data6. The data is transferred to the CCRx registers as follows: on the first update DMA request, data1 is transferred to CCR2, data2 is transferred to CCR3, data3 is transferred to CCR4 and on the second update DMA request, data4 is transferred to CCR2, data5 is transferred to CCR3 and data6 is transferred to CCR4.

*Note:* A null value can be written to the reserved registers.

### 22.3.28 Debug mode

When the microcontroller enters debug mode (Cortex<sup>®</sup>-M7 core halted), the TIMx counter either continues to work normally or stops, depending on DBG\_TIMx\_STOP configuration bit in DBG module.

For safety purposes, when the counter is stopped (DBG\_TIMx\_STOP = 1), the outputs are disabled (as if the MOE bit was reset). The outputs can either be forced to an inactive state (OSSR bit = 1), or have their control taken over by the GPIO controller (OSSR bit = 0), typically to force a Hi-Z.

For more details, refer to [Section 40.16.2: Debug support for timers, watchdog, bxCAN and I2C](#).

For safety purposes, when the counter is stopped (DBG\_TIMx\_STOP = 1), the outputs are disabled (as if the MOE bit was reset). The outputs can either be forced to an inactive state (OSSR bit = 1), or have their control taken over by the GPIO controller (OSSR bit = 0) to force them to Hi-Z.

## 22.4 TIM1/TIM8 registers

Refer to for a list of abbreviations used in register descriptions.

### 22.4.1 TIMx control register 1 (TIMx\_CR1)(x = 1, 8)

Address offset: 0x00

Reset value: 0x0000

| 15   | 14   | 13   | 12   | 11           | 10   | 9        | 8   | 7    | 6        | 5   | 4   | 3   | 2   | 1    | 0   |
|------|------|------|------|--------------|------|----------|-----|------|----------|-----|-----|-----|-----|------|-----|
| Res. | Res. | Res. | Res. | UIFRE<br>MAP | Res. | CKD[1:0] |     | ARPE | CMS[1:0] |     | DIR | OPM | URS | UDIS | CEN |
|      |      |      |      | r/w          |      | r/w      | r/w | r/w  | r/w      | r/w | r/w | r/w | r/w | r/w  | r/w |

Bits 15:12 Reserved, must be kept at reset value.

Bit 11 **UIFREMAP**: UIF status bit remapping

0: No remapping. UIF status bit is not copied to TIMx\_CNT register bit 31.

1: Remapping enabled. UIF status bit is copied to TIMx\_CNT register bit 31.

Bit 10 Reserved, must be kept at reset value.

Bits 9:8 **CKD[1:0]**: Clock division

This bit-field indicates the division ratio between the timer clock (CK\_INT) frequency and the dead-time and sampling clock ( $t_{DTS}$ ) used by the dead-time generators and the digital filters (ETR, TIx),

00:  $t_{DTS}=t_{CK\_INT}$

01:  $t_{DTS}=2*t_{CK\_INT}$

10:  $t_{DTS}=4*t_{CK\_INT}$

11: Reserved, do not program this value

Bit 7 **ARPE**: Auto-reload preload enable

0: TIMx\_ARR register is not buffered

1: TIMx\_ARR register is buffered

Bits 6:5 **CMS[1:0]**: Center-aligned mode selection

00: Edge-aligned mode. The counter counts up or down depending on the direction bit (DIR).

01: Center-aligned mode 1. The counter counts up and down alternatively. Output compare interrupt flags of channels configured in output (CCxS=00 in TIMx\_CCMRx register) are set only when the counter is counting down.

10: Center-aligned mode 2. The counter counts up and down alternatively. Output compare interrupt flags of channels configured in output (CCxS=00 in TIMx\_CCMRx register) are set only when the counter is counting up.

11: Center-aligned mode 3. The counter counts up and down alternatively. Output compare interrupt flags of channels configured in output (CCxS=00 in TIMx\_CCMRx register) are set both when the counter is counting up or down.

*Note: It is not allowed to switch from edge-aligned mode to center-aligned mode as long as the counter is enabled (CEN=1)*

Bit 4 **DIR**: Direction

0: Counter used as upcounter

1: Counter used as downcounter

*Note: This bit is read only when the timer is configured in Center-aligned mode or Encoder mode.*

Bit 3 **OPM**: One pulse mode

0: Counter is not stopped at update event

1: Counter stops counting at the next update event (clearing the bit CEN)

Bit 2 **URS**: Update request source

This bit is set and cleared by software to select the UEV event sources.

0: Any of the following events generate an update interrupt or DMA request if enabled.

These events can be:

- Counter overflow/underflow
- Setting the UG bit
- Update generation through the slave mode controller

1: Only counter overflow/underflow generates an update interrupt or DMA request if enabled.

Bit 1 **UDIS**: Update disable

This bit is set and cleared by software to enable/disable UEV event generation.

0: UEV enabled. The Update (UEV) event is generated by one of the following events:

- Counter overflow/underflow
- Setting the UG bit
- Update generation through the slave mode controller

Buffered registers are then loaded with their preload values.

1: UEV disabled. The Update event is not generated, shadow registers keep their value (ARR, PSC, CCRx). However the counter and the prescaler are reinitialized if the UG bit is set or if a hardware reset is received from the slave mode controller.

Bit 0 **CEN**: Counter enable

0: Counter disabled

1: Counter enabled

*Note: External clock, gated mode and encoder mode can work only if the CEN bit has been previously set by software. However trigger mode can set the CEN bit automatically by hardware.*

## 22.4.2 TIMx control register 2 (TIMx\_CR2)(x = 1, 8)

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:20 **MMS2[3:0]**: Master mode selection 2

These bits allow the information to be sent to ADC for synchronization (TRGO2) to be selected. The combination is as follows:

0000: **Reset** - the UG bit from the TIMx\_EGR register is used as trigger output (TRGO2). If the reset is generated by the trigger input (slave mode controller configured in reset mode), the signal on TRGO2 is delayed compared to the actual reset.

0001: **Enable** - the Counter Enable signal CNT\_EN is used as trigger output (TRGO2). It is useful to start several timers at the same time or to control a window in which a slave timer is enabled. The Counter Enable signal is generated by a logic OR between the CEN control bit and the trigger input when configured in Gated mode. When the Counter Enable signal is controlled by the trigger input, there is a delay on TRGO2, except if the Master/Slave mode is selected (see the MSM bit description in TIMx\_SMCR register).

0010: **Update** - the update event is selected as trigger output (TRGO2). For instance, a master timer can then be used as a prescaler for a slave timer.

0011: **Compare pulse** - the trigger output sends a positive pulse when the CC1IF flag is to be set (even if it was already high), as soon as a capture or compare match occurs (TRGO2).

0100: **Compare** - OC1REF signal is used as trigger output (TRGO2)

0101: **Compare** - OC2REF signal is used as trigger output (TRGO2)

0110: **Compare** - OC3REF signal is used as trigger output (TRGO2)

0111: **Compare** - OC4REF signal is used as trigger output (TRGO2)

1000: **Compare** - OC5REF signal is used as trigger output (TRGO2)

1001: **Compare** - OC6REF signal is used as trigger output (TRGO2)

1010: **Compare Pulse** - OC4REF rising or falling edges generate pulses on TRGO2

1011: **Compare Pulse** - OC6REF rising or falling edges generate pulses on TRGO2

1100: **Compare Pulse** - OC4REF or OC6REF rising edges generate pulses on TRGO2

1101: **Compare Pulse** - OC4REF rising or OC6REF falling edges generate pulses on TRGO2

1110: **Compare Pulse** - OC5REF or OC6REF rising edges generate pulses on TRGO2

1111: **Compare Pulse** - OC5REF rising or OC6REF falling edges generate pulses on TRGO2

*Note: The clock of the slave timer or ADC must be enabled prior to receive events from the master timer, and must not be changed on-the-fly while triggers are received from the master timer.*

Bit 19 Reserved, must be kept at reset value.

Bit 18 **OIS6**: Output Idle state 6 (OC6 output)

Refer to OIS1 bit

Bit 17 Reserved, must be kept at reset value.

Bit 16 **OIS5**: Output Idle state 5 (OC5 output)

Refer to OIS1 bit

Bit 15 Reserved, must be kept at reset value.

Bit 14 **OIS4**: Output Idle state 4 (OC4 output)

Refer to OIS1 bit

Bit 13 **OIS3N**: Output Idle state 3 (OC3N output)

Refer to OIS1N bit

Bit 12 **OIS3**: Output Idle state 3 (OC3 output)

Refer to OIS1 bit

- Bit 11 **OIS2N**: Output Idle state 2 (OC2N output)  
Refer to OIS1N bit
- Bit 10 **OIS2**: Output Idle state 2 (OC2 output)  
Refer to OIS1 bit
- Bit 9 **OIS1N**: Output Idle state 1 (OC1N output)  
0: OC1N=0 after a dead-time when MOE=0  
1: OC1N=1 after a dead-time when MOE=0  
*Note: This bit can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIMx\_BDTR register).*
- Bit 8 **OIS1**: Output Idle state 1 (OC1 output)  
0: OC1=0 (after a dead-time if OC1N is implemented) when MOE=0  
1: OC1=1 (after a dead-time if OC1N is implemented) when MOE=0  
*Note: This bit can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIMx\_BDTR register).*
- Bit 7 **TI1S**: TI1 selection  
0: The TIMx\_CH1 pin is connected to TI1 input  
1: The TIMx\_CH1, CH2 and CH3 pins are connected to the TI1 input (XOR combination)
- Bits 6:4 **MMS[2:0]**: Master mode selection  
These bits allow to select the information to be sent in master mode to slave timers for synchronization (TRGO). The combination is as follows:  
000: **Reset** - the UG bit from the TIMx\_EGR register is used as trigger output (TRGO). If the reset is generated by the trigger input (slave mode controller configured in reset mode) then the signal on TRGO is delayed compared to the actual reset.  
001: **Enable** - the Counter Enable signal CNT\_EN is used as trigger output (TRGO). It is useful to start several timers at the same time or to control a window in which a slave timer is enable. The Counter Enable signal is generated by a logic OR between CEN control bit and the trigger input when configured in gated mode. When the Counter Enable signal is controlled by the trigger input, there is a delay on TRGO, except if the master/slave mode is selected (see the MSM bit description in TIMx\_SMCR register).  
010: **Update** - The update event is selected as trigger output (TRGO). For instance a master timer can then be used as a prescaler for a slave timer.  
011: **Compare Pulse** - The trigger output send a positive pulse when the CC1IF flag is to be set (even if it was already high), as soon as a capture or a compare match occurred. (TRGO).  
100: **Compare** - OC1REF signal is used as trigger output (TRGO)  
101: **Compare** - OC2REF signal is used as trigger output (TRGO)  
110: **Compare** - OC3REF signal is used as trigger output (TRGO)  
111: **Compare** - OC4REF signal is used as trigger output (TRGO)  
*Note: The clock of the slave timer or ADC must be enabled prior to receive events from the master timer, and must not be changed on-the-fly while triggers are received from the master timer.*
- Bit 3 **CCDS**: Capture/compare DMA selection  
0: CCx DMA request sent when CCx event occurs  
1: CCx DMA requests sent when update event occurs

Bit 2 **CCUS**: Capture/compare control update selection

0: When capture/compare control bits are preloaded (CCPC=1), they are updated by setting the COMG bit only

1: When capture/compare control bits are preloaded (CCPC=1), they are updated by setting the COMG bit or when an rising edge occurs on TRGI

*Note: This bit acts only on channels that have a complementary output.*

Bit 1 Reserved, must be kept at reset value.

Bit 0 **CCPC**: Capture/compare preloaded control

0: CCxE, CCxNE and OCxM bits are not preloaded

1: CCxE, CCxNE and OCxM bits are preloaded, after having been written, they are updated only when a commutation event (COM) occurs (COMG bit set or rising edge detected on TRGI, depending on the CCUS bit).

*Note: This bit acts only on channels that have a complementary output.*

| rw   | rw   | rw        | rw   | rw       | rw   | rw   | rw   | rw   | rw      | rw   | rw   |      | rw       | rw   | rw     |

Bits 31:17 Reserved, must be kept at reset value.

Bit 15 **ETP**: External trigger polarity

This bit selects whether ETR or  $\overline{\text{ETR}}$  is used for trigger operations

0: ETR is non-inverted, active at high level or rising edge.

1: ETR is inverted, active at low level or falling edge.

Bit 14 **ECE**: External clock enable

This bit enables External clock mode 2.

0: External clock mode 2 disabled

1: External clock mode 2 enabled. The counter is clocked by any active edge on the ETRF signal.

*Note: 1: Setting the ECE bit has the same effect as selecting external clock mode 1 with TRGI connected to ETRF (SMS=111 and TS=111).*

*2: It is possible to simultaneously use external clock mode 2 with the following slave modes: reset mode, gated mode and trigger mode. Nevertheless, TRGI must not be connected to ETRF in this case (TS bits must not be 111).*

*3: If external clock mode 1 and external clock mode 2 are enabled at the same time, the external clock input is ETRF.*

Bits 13:12 **ETPS[1:0]**: External trigger prescaler

External trigger signal ETRP frequency must be at most 1/4 of TIMxCLK frequency. A prescaler can be enabled to reduce ETRP frequency. It is useful when inputting fast external clocks.

- 00: Prescaler OFF
- 01: ETRP frequency divided by 2
- 10: ETRP frequency divided by 4
- 11: ETRP frequency divided by 8

Bits 11:8 **ETF[3:0]**: External trigger filter

This bit-field then defines the frequency used to sample ETRP signal and the length of the digital filter applied to ETRP. The digital filter is made of an event counter in which N consecutive events are needed to validate a transition on the output:

- 0000: No filter, sampling is done at  $f_{DTS}$
- 0001:  $f_{SAMPLING}=f_{CK\_INT}$ , N=2
- 0010:  $f_{SAMPLING}=f_{CK\_INT}$ , N=4
- 0011:  $f_{SAMPLING}=f_{CK\_INT}$ , N=8
- 0100:  $f_{SAMPLING}=f_{DTS}/2$ , N=6
- 0101:  $f_{SAMPLING}=f_{DTS}/2$ , N=8
- 0110:  $f_{SAMPLING}=f_{DTS}/4$ , N=6
- 0111:  $f_{SAMPLING}=f_{DTS}/4$ , N=8
- 1000:  $f_{SAMPLING}=f_{DTS}/8$ , N=6
- 1001:  $f_{SAMPLING}=f_{DTS}/8$ , N=8
- 1010:  $f_{SAMPLING}=f_{DTS}/16$ , N=5
- 1011:  $f_{SAMPLING}=f_{DTS}/16$ , N=6
- 1100:  $f_{SAMPLING}=f_{DTS}/16$ , N=8
- 1101:  $f_{SAMPLING}=f_{DTS}/32$ , N=5
- 1110:  $f_{SAMPLING}=f_{DTS}/32$ , N=6
- 1111:  $f_{SAMPLING}=f_{DTS}/32$ , N=8

Bit 7 **MSM**: Master/slave mode

- 0: No action
- 1: The effect of an event on the trigger input (TRGI) is delayed to allow a perfect synchronization between the current timer and its slaves (through TRGO). It is useful if we want to synchronize several timers on a single external event.

Bits 6:4 **TS[2:0]**: Trigger selection

This bit-field selects the trigger input to be used to synchronize the counter.

- 000: Internal Trigger 0 (ITR0)
- 001: Internal Trigger 1 (ITR1)
- 010: Internal Trigger 2 (ITR2)
- 011: Internal Trigger 3 (ITR3)
- 100: TI1 Edge Detector (TI1F\_ED)
- 101: Filtered Timer Input 1 (TI1FP1)
- 110: Filtered Timer Input 2 (TI2FP2)
- 111: External Trigger input (ETRF)

See [Table 146: TIMx internal trigger connection on page 713](#) for more details on ITRx meaning for each Timer.

*Note:* These bits must be changed only when they are not used (e.g. when SMS=000) to avoid wrong edge detections at the transition.

*Note:* The other bit is at position 16 in the same register

Bit 3 Reserved, must be kept at reset value.

Bits 16, 2, 1, 0 **SMS[3:0]**: Slave mode selection

When external signals are selected the active edge of the trigger signal (TRGI) is linked to the polarity selected on the external input (see Input Control register and Control Register description).

0000: Slave mode disabled - if CEN = '1' then the prescaler is clocked directly by the internal clock.

0001: Encoder mode 1 - Counter counts up/down on TI1FP1 edge depending on TI2FP2 level.

0010: Encoder mode 2 - Counter counts up/down on TI2FP2 edge depending on TI1FP1 level.

0011: Encoder mode 3 - Counter counts up/down on both TI1FP1 and TI2FP2 edges depending on the level of the other input.

0100: Reset Mode - Rising edge of the selected trigger input (TRGI) reinitializes the counter and generates an update of the registers.

0101: Gated Mode - The counter clock is enabled when the trigger input (TRGI) is high. The counter stops (but is not reset) as soon as the trigger becomes low. Both start and stop of the counter are controlled.

0110: Trigger Mode - The counter starts at a rising edge of the trigger TRGI (but it is not reset). Only the start of the counter is controlled.

0111: External Clock Mode 1 - Rising edges of the selected trigger (TRGI) clock the counter.

1000: Combined reset + trigger mode - Rising edge of the selected trigger input (TRGI) reinitializes the counter, generates an update of the registers and starts the counter.

Codes above 1000: Reserved.

*Note: The gated mode must not be used if TI1F\_ED is selected as the trigger input (TS=100). Indeed, TI1F\_ED outputs 1 pulse for each transition on TI1F, whereas the gated mode checks the level of the trigger signal.*

*Note: The clock of the slave peripherals (timer, ADC, ...) receiving the TRGO or the TRGO2 signals must be enabled prior to receive events from the master timer, and the clock frequency (prescaler) must not be changed on-the-fly while triggers are received from the master timer.*

**Table 146. TIMx internal trigger connection**

| Slave TIM | ITR0 (TS = 000) | ITR1 (TS = 001) | ITR2 (TS = 010) | ITR3 (TS = 011) |
|-----------|-----------------|-----------------|-----------------|-----------------|
| TIM1      | TIM5            | TIM2            | TIM3            | TIM4            |

Bits 31:18 Reserved, must be kept at reset value.

Bit 17 **CC6IF**: Compare 6 interrupt flag

Refer to CC1IF description (Note: Channel 6 can only be configured as output)

Bit 16 **CC5IF**: Compare 5 interrupt flag

Refer to CC1IF description (Note: Channel 5 can only be configured as output)

Bits 15: Reserved, must be kept at reset value.

Bit 12 **CC4OF**: Capture/Compare 4 overcapture flag

Refer to CC1OF description

Bit 11 **CC3OF**: Capture/Compare 3 overcapture flag

Refer to CC1OF description

Bit 10 **CC2OF**: Capture/Compare 2 overcapture flag

Refer to CC1OF description

Bit 9 **CC1OF**: Capture/Compare 1 overcapture flag

This flag is set by hardware only when the corresponding channel is configured in input capture mode. It is cleared by software by writing it to '0'.

0: No overcapture has been detected.

1: The counter value has been captured in TIMx\_CCR1 register while CC1IF flag was already set

Bit 8 **B2IF**: Break 2 interrupt flag

This flag is set by hardware as soon as the break 2 input goes active. It can be cleared by software if the break 2 input is not active.

0: No break event occurred.

1: An active level has been detected on the break 2 input. An interrupt is generated if BIE=1 in the TIMx\_DIER register.

Bit 7 **BIF**: Break interrupt flag

This flag is set by hardware as soon as the break input goes active. It can be cleared by software if the break input is not active.

0: No break event occurred.

1: An active level has been detected on the break input. An interrupt is generated if BIE=1 in the TIMx\_DIER register.

Bit 6 **TIF**: Trigger interrupt flag

This flag is set by hardware on trigger event (active edge detected on TRGI input when the slave mode controller is enabled in all modes but gated mode. It is set when the counter starts or stops when gated mode is selected. It is cleared by software.

0: No trigger event occurred.

1: Trigger interrupt pending.

Bit 5 **COMIF**: COM interrupt flag

This flag is set by hardware on COM event (when Capture/compare Control bits - CCxE, CCxNE, OCxM - have been updated). It is cleared by software.

0: No COM event occurred.

1: COM interrupt pending.

Bit 4 **CC4IF**: Capture/Compare 4 interrupt flag

Refer to CC1IF description

Bit 3 **CC3IF**: Capture/Compare 3 interrupt flag

Refer to CC1IF description

Bit 2 **CC2IF**: Capture/Compare 2 interrupt flag

Refer to CC1IF description

Bit 1 **CC1IF**: Capture/Compare 1 interrupt flag

**If channel CC1 is configured as output:** This flag is set by hardware when the counter matches the compare value, with some exception in center-aligned mode (refer to the CMS bits in the TIMx\_CR1 register description). It is cleared by software.

0: No match.

1: The content of the counter TIMx\_CNT matches the content of the TIMx\_CCR1 register. When the contents of TIMx\_CCR1 are greater than the contents of TIMx\_ARR, the CC1IF bit goes high on the counter overflow (in upcounting and up/down-counting modes) or underflow (in downcounting mode)

**If channel CC1 is configured as input:** This bit is set by hardware on a capture. It is cleared by software or by reading the TIMx\_CCR1 register.

0: No input capture occurred

1: The counter value has been captured in TIMx\_CCR1 register (An edge has been detected on IC1 which matches the selected polarity)

Bit 0 **UIF**: Update interrupt flag

This bit is set by hardware on an update event. It is cleared by software.

0: No update occurred.

1: Update interrupt pending. This bit is set by hardware when the registers are updated:

- At overflow or underflow regarding the repetition counter value (update if repetition counter = 0) and if the UDIS=0 in the TIMx\_CR1 register.
- When CNT is reinitialized by software using the UG bit in TIMx\_EGR register, if URS=0 and UDIS=0 in the TIMx\_CR1 register.
- When CNT is reinitialized by a trigger event (refer to [Section 22.4.3: TIMx slave mode control register \(TIMx\\_SMCR\)\(x = 1, 8\)](#)), if URS=0 and UDIS=0 in the TIMx\_CR1 register.

## 22.4.6 TIMx event generation register (TIMx\_EGR)(x = 1, 8)

Address offset: 0x14

Reset value: 0x0000

| 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8   | 7  | 6  | 5    | 4    | 3    | 2    | 1    | 0  |
|------|------|------|------|------|------|------|-----|----|----|------|------|------|------|------|----|
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | B2G | BG | TG | COMG | CC4G | CC3G | CC2G | CC1G | UG |
|      |      |      |      |      |      |      | w   | w  | w  | w    | w    | w    | w    | w    | w  |

Bits 15:9 Reserved, must be kept at reset value.

**Bit 8 B2G:** Break 2 generation

This bit is set by software in order to generate an event, it is automatically cleared by hardware.

0: No action

1: A break 2 event is generated. MOE bit is cleared and B2IF flag is set. Related interrupt can occur if enabled.

**Bit 7 BG:** Break generation

This bit is set by software in order to generate an event, it is automatically cleared by hardware.

0: No action

1: A break event is generated. MOE bit is cleared and BIF flag is set. Related interrupt or DMA transfer can occur if enabled.

**Bit 6 TG:** Trigger generation

This bit is set by software in order to generate an event, it is automatically cleared by hardware.

0: No action

1: The TIF flag is set in TIMx\_SR register. Related interrupt or DMA transfer can occur if enabled.

**Bit 5 COMG:** Capture/Compare control update generation

This bit can be set by software, it is automatically cleared by hardware

0: No action

1: When CCPC bit is set, it allows to update CCxE, CCxNE and OCxM bits

*Note: This bit acts only on channels having a complementary output.*

**Bit 4 CC4G:** Capture/Compare 4 generation

Refer to CC1G description

**Bit 3 CC3G:** Capture/Compare 3 generation

Refer to CC1G description

**Bit 2 CC2G:** Capture/Compare 2 generation

Refer to CC1G description

Bit 1 **CC1G**: Capture/Compare 1 generation

This bit is set by software in order to generate an event, it is automatically cleared by hardware.

0: No action

1: A capture/compare event is generated on channel 1:

**If channel CC1 is configured as output:**

CC1IF flag is set, Corresponding interrupt or DMA request is sent if enabled.

**If channel CC1 is configured as input:**

The current value of the counter is captured in TIMx\_CCR1 register. The CC1IF flag is set, the corresponding interrupt or DMA request is sent if enabled. The CC1OF flag is set if the CC1IF flag was already high.

Bit 0 **UG**: Update generation

This bit can be set by software, it is automatically cleared by hardware.

0: No action

1: Reinitialize the counter and generates an update of the registers. Note that the prescaler counter is cleared too (anyway the prescaler ratio is not affected). The counter is cleared if the center-aligned mode is selected or if DIR=0 (upcounting), else it takes the auto-reload value (TIMx\_ARR) if DIR=1 (downcounting).

## 22.4.7 TIMx capture/compare mode register 1 (TIMx\_CCMR1)(x = 1, 8)

Address offset: 0x18

Reset value: 0x0000 0000

The channels can be used in input (capture mode) or in output (compare mode). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function in input and in output mode. For a given bit, OCxx describes its function when the channel is configured in output, ICxx describes its function when the channel is configured in input. So you must take care that the same bit can have a different meaning for the input stage and for the output stage.

### Output compare mode

Bits 31:25 Reserved, must be kept at reset value.

Bit 24 **OC2M[3]**: Output Compare 2 mode - bit 3

Refer to OC2M description on bits 14:12.

Bits 23:17 Reserved, must be kept at reset value.

Bits 16 **OC1M[3]**: Output Compare 1 mode - bit 3

Refer to OC1M description on bits 6:4

Bit 15 **OC2CE**: Output Compare 2 clear enable

Bits 14:12 **OC2M[2:0]**: Output Compare 2 mode

Bit 11 **OC2PE**: Output Compare 2 preload enable

Bit 10 **OC2FE**: Output Compare 2 fast enable

Bits 9:8 **CC2S[1:0]**: Capture/Compare 2 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

00: CC2 channel is configured as output

01: CC2 channel is configured as input, IC2 is mapped on TI2

10: CC2 channel is configured as input, IC2 is mapped on TI1

11: CC2 channel is configured as input, IC2 is mapped on TRC. This mode is working only if an internal trigger input is selected through the TS bit (TIMx\_SMCR register)

*Note: CC2S bits are writable only when the channel is OFF (CC2E = '0' in TIMx\_CCER).*

Bit 7 **OC1CE**: Output Compare 1 clear enable

0: OC1Ref is not affected by the ETRF input

1: OC1Ref is cleared as soon as a High level is detected on ETRF input

Bits 6:4 **OC1M**: Output Compare 1 mode

These bits define the behavior of the output reference signal OC1REF from which OC1 and OC1N are derived. OC1REF is active high whereas OC1 and OC1N active level depends on CC1P and CC1NP bits.

0000: Frozen - The comparison between the output compare register TIMx\_CCR1 and the counter TIMx\_CNT has no effect on the outputs.(this mode is used to generate a timing base).

0001: Set channel 1 to active level on match. OC1REF signal is forced high when the counter TIMx\_CNT matches the capture/compare register 1 (TIMx\_CCR1).

0010: Set channel 1 to inactive level on match. OC1REF signal is forced low when the counter TIMx\_CNT matches the capture/compare register 1 (TIMx\_CCR1).

0011: Toggle - OC1REF toggles when TIMx\_CNT=TIMx\_CCR1.

0100: Force inactive level - OC1REF is forced low.

0101: Force active level - OC1REF is forced high.

0110: PWM mode 1 - In upcounting, channel 1 is active as long as TIMx\_CNT<TIMx\_CCR1 else inactive. In downcounting, channel 1 is inactive (OC1REF='0') as long as TIMx\_CNT>TIMx\_CCR1 else active (OC1REF='1').

0111: PWM mode 2 - In upcounting, channel 1 is inactive as long as TIMx\_CNT<TIMx\_CCR1 else active. In downcounting, channel 1 is active as long as TIMx\_CNT>TIMx\_CCR1 else inactive.

1000: Retriggerable OPM mode 1 - In up-counting mode, the channel is active until a trigger event is detected (on TRGI signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes active again at the next update. In down-counting mode, the channel is inactive until a trigger event is detected (on TRGI signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes inactive again at the next update.

1001: Retriggerable OPM mode 2 - In up-counting mode, the channel is inactive until a trigger event is detected (on TRGI signal). Then, a comparison is performed as in PWM mode 2 and the channels becomes inactive again at the next update. In down-counting mode, the channel is active until a trigger event is detected (on TRGI signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes active again at the next update.

1010: Reserved,

1011: Reserved,

1100: Combined PWM mode 1 - OC1REF has the same behavior as in PWM mode 1. OC1REFC is the logical OR between OC1REF and OC2REF.

1101: Combined PWM mode 2 - OC1REF has the same behavior as in PWM mode 2. OC1REFC is the logical AND between OC1REF and OC2REF.

1110: Asymmetric PWM mode 1 - OC1REF has the same behavior as in PWM mode 1. OC1REFC outputs OC1REF when the counter is counting up, OC2REF when it is counting down.

1111: Asymmetric PWM mode 2 - OC1REF has the same behavior as in PWM mode 2. OC1REFC outputs OC1REF when the counter is counting up, OC2REF when it is counting down.

*Note: These bits can not be modified as long as LOCK level 3 has been programmed (LOCK bits in TIMx\_BDTR register) and CC1S='00' (the channel is configured in output).*

*Note: In PWM mode, the OCREF level changes only when the result of the comparison changes or when the output compare mode switches from "frozen" mode to "PWM" mode.*

*Note: On channels having a complementary output, this bit field is preloaded. If the CCPC bit is set in the TIMx\_CR2 register then the OC1M active bits take the new value from the preloaded bits only when a COM event is generated.*

Bit 3 **OC1PE**: Output Compare 1 preload enable

0: Preload register on TIMx\_CCR1 disabled. TIMx\_CCR1 can be written at anytime, the new value is taken in account immediately.

1: Preload register on TIMx\_CCR1 enabled. Read/Write operations access the preload register. TIMx\_CCR1 preload value is loaded in the active register at each update event.

*Note: 1: These bits can not be modified as long as LOCK level 3 has been programmed (LOCK bits in TIMx\_BDTR register) and CC1S='00' (the channel is configured in output).*

*2: The PWM mode can be used without validating the preload register only in one pulse mode (OPM bit set in TIMx\_CR1 register). Else the behavior is not guaranteed.*

Bit 2 **OC1FE**: Output Compare 1 fast enable

This bit is used to accelerate the effect of an event on the trigger in input on the CC output.

0: CC1 behaves normally depending on counter and CCR1 values even when the trigger is ON. The minimum delay to activate CC1 output when an edge occurs on the trigger input is 5 clock cycles.

1: An active edge on the trigger input acts like a compare match on CC1 output. Then, OC is set to the compare level independently from the result of the comparison. Delay to sample the trigger input and to activate CC1 output is reduced to 3 clock cycles. OC1FE acts only if the channel is configured in PWM1 or PWM2 mode.

Bits 1:0 **CC1S**: Capture/Compare 1 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

00: CC1 channel is configured as output

01: CC1 channel is configured as input, IC1 is mapped on TI1

10: CC1 channel is configured as input, IC1 is mapped on TI2

11: CC1 channel is configured as input, IC1 is mapped on TRC. This mode is working only if an internal trigger input is selected through TS bit (TIMx\_SMCR register)

*Note: CC1S bits are writable only when the channel is OFF (CC1E = '0' in TIMx\_CCER).*

## Input capture mode

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:12 **IC2F**: Input capture 2 filter

Bits 11:10 **IC2PSC[1:0]**: Input capture 2 prescaler

Bits 9:8 **CC2S**: Capture/Compare 2 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

00: CC2 channel is configured as output

01: CC2 channel is configured as input, IC2 is mapped on TI2

10: CC2 channel is configured as input, IC2 is mapped on TI1

11: CC2 channel is configured as input, IC2 is mapped on TRC. This mode is working only if an internal trigger input is selected through TS bit (TIMx\_SMCR register)

*Note: CC2S bits are writable only when the channel is OFF (CC2E = '0' in TIMx\_CCER).*

Bits 7:4 **IC1F[3:0]**: Input capture 1 filter

This bit-field defines the frequency used to sample TI1 input and the length of the digital filter applied to TI1. The digital filter is made of an event counter in which N consecutive events are needed to validate a transition on the output:

0000: No filter, sampling is done at  $f_{DTS}$

0001:  $f_{SAMPLING}=f_{CK\_INT}$ , N=2

0010:  $f_{SAMPLING}=f_{CK\_INT}$ , N=4

0011:  $f_{SAMPLING}=f_{CK\_INT}$ , N=8

0100:  $f_{SAMPLING}=f_{DTS}/2$ , N=6

0101:  $f_{SAMPLING}=f_{DTS}/2$ , N=8

0110:  $f_{SAMPLING}=f_{DTS}/4$ , N=6

0111:  $f_{SAMPLING}=f_{DTS}/4$ , N=8

1000:  $f_{SAMPLING}=f_{DTS}/8$ , N=6

1001:  $f_{SAMPLING}=f_{DTS}/8$ , N=8

1010:  $f_{SAMPLING}=f_{DTS}/16$ , N=5

1011:  $f_{SAMPLING}=f_{DTS}/16$ , N=6

1100:  $f_{SAMPLING}=f_{DTS}/16$ , N=8

1101:  $f_{SAMPLING}=f_{DTS}/32$ , N=5

1110:  $f_{SAMPLING}=f_{DTS}/32$ , N=6

1111:  $f_{SAMPLING}=f_{DTS}/32$ , N=8

Bits 3:2 **IC1PSC**: Input capture 1 prescaler

This bit-field defines the ratio of the prescaler acting on CC1 input (IC1). The prescaler is reset as soon as CC1E='0' (TIMx\_CCER register).

00: no prescaler, capture is done each time an edge is detected on the capture input

01: capture is done once every 2 events

10: capture is done once every 4 events

11: capture is done once every 8 events

Bits 1:0 **CC1S**: Capture/Compare 1 Selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

00: CC1 channel is configured as output

01: CC1 channel is configured as input, IC1 is mapped on TI1

10: CC1 channel is configured as input, IC1 is mapped on TI2

11: CC1 channel is configured as input, IC1 is mapped on TRC. This mode is working only if an internal trigger input is selected through TS bit (TIMx\_SMCR register)

*Note:* CC1S bits are writable only when the channel is OFF (CC1E = '0' in TIMx\_CCER).

## 22.4.8 TIMx capture/compare mode register 2 (TIMx\_CCMR2)(x = 1, 8)

Address offset: 0x1C

Reset value: 0x0000 0000

Refer to the above CCMR1 register description.

## Output compare mode

Bits 31:25 Reserved, must be kept at reset value.

Bit 24 **OC4M[3]**: Output Compare 4 mode - bit 3

Bits 23:17 Reserved, must be kept at reset value.

Bit 16 **OC3M[3]**: Output Compare 3 mode - bit 3

Bit 15 **OC4CE**: Output compare 4 clear enable

Bits 14:12 **OC4M**: Output compare 4 mode

Bit 11 **OC4PE**: Output compare 4 preload enable

Bit 10 **OC4FE**: Output compare 4 fast enable

Bits 9:8 **CC4S**: Capture/Compare 4 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

00: CC4 channel is configured as output

01: CC4 channel is configured as input, IC4 is mapped on TI4

10: CC4 channel is configured as input, IC4 is mapped on TI3

11: CC4 channel is configured as input, IC4 is mapped on TRC. This mode is working only if an internal trigger input is selected through TS bit (TIMx\_SMCR register)

*Note: CC4S bits are writable only when the channel is OFF (CC4E = '0' in TIMx\_CCER).*

Bit 7 **OC3CE**: Output compare 3 clear enable

Bits 6:4 **OC3M**: Output compare 3 mode

Bit 3 **OC3PE**: Output compare 3 preload enable

Bit 2 **OC3FE**: Output compare 3 fast enable

Bits 1:0 **CC3S**: Capture/Compare 3 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

00: CC3 channel is configured as output

01: CC3 channel is configured as input, IC3 is mapped on TI3

10: CC3 channel is configured as input, IC3 is mapped on TI4

11: CC3 channel is configured as input, IC3 is mapped on TRC. This mode is working only if an internal trigger input is selected through TS bit (TIMx\_SMCR register)

*Note: CC3S bits are writable only when the channel is OFF (CC3E = '0' in TIMx\_CCER).*

## Input capture mode

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:12 **IC4F**: Input capture 4 filter

Bits 11:10 **IC4PSC**: Input capture 4 prescaler

Bits 9:8 **CC4S**: Capture/Compare 4 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

00: CC4 channel is configured as output

01: CC4 channel is configured as input, IC4 is mapped on TI4

10: CC4 channel is configured as input, IC4 is mapped on TI3

11: CC4 channel is configured as input, IC4 is mapped on TRC. This mode is working only if an internal trigger input is selected through TS bit (TIMx\_SMCR register)

*Note: CC4S bits are writable only when the channel is OFF (CC4E = '0' in TIMx\_CCER).*

Bits 7:4 **IC3F**: Input capture 3 filter

Bits 3:2 **IC3PSC**: Input capture 3 prescaler

Bits 1:0 **CC3S**: Capture/compare 3 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

00: CC3 channel is configured as output

01: CC3 channel is configured as input, IC3 is mapped on TI3

10: CC3 channel is configured as input, IC3 is mapped on TI4

11: CC3 channel is configured as input, IC3 is mapped on TRC. This mode is working only if an internal trigger input is selected through TS bit (TIMx\_SMCR register)

*Note: CC3S bits are writable only when the channel is OFF (CC3E = '0' in TIMx\_CCER).*

## 22.4.9 TIMx capture/compare enable register (TIMx\_CCER)(x = 1, 8)

Bits 31:22 Reserved, must be kept at reset value.

Bit 21 **CC6P**: Capture/Compare 6 output polarity

Refer to CC1P description

Bit 20 **CC6E**: Capture/Compare 6 output enable

Refer to CC1E description

Bits 19:18 Reserved, must be kept at reset value.

Bit 17 **CC5P**: Capture/Compare 5 output polarity

Refer to CC1P description

Bit 16 **CC5E**: Capture/Compare 5 output enable

Refer to CC1E description

Bit 15 **CC4NP**: Capture/Compare 4 complementary output polarity

Refer to CC1NP description

Bit 14 Reserved, must be kept at reset value.

Bit 13 **CC4P**: Capture/Compare 4 output polarity

Refer to CC1P description

Bit 12 **CC4E**: Capture/Compare 4 output enable

Refer to CC1E description

Bit 11 **CC3NP**: Capture/Compare 3 complementary output polarity

Refer to CC1NP description

Bit 10 **CC3NE**: Capture/Compare 3 complementary output enable

Refer to CC1NE description

Bit 9 **CC3P**: Capture/Compare 3 output polarity  
Refer to CC1P description

Bit 8 **CC3E**: Capture/Compare 3 output enable  
Refer to CC1E description

Bit 7 **CC2NP**: Capture/Compare 2 complementary output polarity  
Refer to CC1NP description

Bit 6 **CC2NE**: Capture/Compare 2 complementary output enable  
Refer to CC1NE description

Bit 5 **CC2P**: Capture/Compare 2 output polarity  
Refer to CC1P description

Bit 4 **CC2E**: Capture/Compare 2 output enable  
Refer to CC1E description

Bit 3 **CC1NP**: Capture/Compare 1 complementary output polarity  
**CC1 channel configured as output:**

0: OC1N active high.

1: OC1N active low.

**CC1 channel configured as input:**

This bit is used in conjunction with CC1P to define the polarity of TI1FP1 and TI2FP1. Refer to CC1P description.

*Note: This bit is not writable as soon as LOCK level 2 or 3 has been programmed (LOCK bits in TIMx\_BDTR register) and CC1S="00" (channel configured as output).*

*On channels having a complementary output, this bit is preloaded. If the CCPC bit is set in the TIMx\_CR2 register then the CC1NP active bit takes the new value from the preloaded bit only when a Commutation event is generated.*

Bit 2 **CC1NE**: Capture/Compare 1 complementary output enable

0: Off - OC1N is not active. OC1N level is then function of MOE, OSS1, OSSR, OIS1, OIS1N and CC1E bits.

1: On - OC1N signal is output on the corresponding output pin depending on MOE, OSS1, OSSR, OIS1, OIS1N and CC1E bits.

*On channels having a complementary output, this bit is preloaded. If the CCPC bit is set in the TIMx\_CR2 register then the CC1NE active bit takes the new value from the preloaded bit only when a Commutation event is generated.*

Bit 1 **CC1P**: Capture/Compare 1 output polarity

**CC1 channel configured as output:**

0: OC1 active high

1: OC1 active low

**CC1 channel configured as input:** CC1NP/CC1P bits select the active polarity of TI1FP1 and TI2FP1 for trigger or capture operations.

00: non-inverted/rising edge. The circuit is sensitive to TIxFP1 rising edge (capture or trigger operations in reset, external clock or trigger mode), TIxFP1 is not inverted (trigger operation in gated mode or encoder mode).

01: inverted/falling edge. The circuit is sensitive to TIxFP1 falling edge (capture or trigger operations in reset, external clock or trigger mode), TIxFP1 is inverted (trigger operation in gated mode or encoder mode).

10: reserved, do not use this configuration.

11: non-inverted/both edges/ The circuit is sensitive to both TIxFP1 rising and falling edges (capture or trigger operations in reset, external clock or trigger mode), TIxFP1 is not inverted (trigger operation in gated mode). This configuration must not be used in encoder mode.

*Note: This bit is not writable as soon as LOCK level 2 or 3 has been programmed (LOCK bits in TIMx\_BDTR register).*

*On channels having a complementary output, this bit is preloaded. If the CCPC bit is set in the TIMx\_CR2 register then the CC1P active bit takes the new value from the preloaded bit only when a Commutation event is generated.*

Bit 0 **CC1E**: Capture/Compare 1 output enable

**CC1 channel configured as output:**

0: Off - OC1 is not active. OC1 level is then function of MOE, OSS1, OSSR, OIS1, OIS1N and CC1NE bits.

1: On - OC1 signal is output on the corresponding output pin depending on MOE, OSS1, OSSR, OIS1, OIS1N and CC1NE bits.

**CC1 channel configured as input:** This bit determines if a capture of the counter value can actually be done into the input capture/compare register 1 (TIMx\_CCR1) or not.

0: Capture disabled.

1: Capture enabled.

*On channels having a complementary output, this bit is preloaded. If the CCPC bit is set in the TIMx\_CR2 register then the CC1E active bit takes the new value from the preloaded bit only when a Commutation event is generated.*

Table 147. Output control bits for complementary OCx and OCxN channels with break feature

| Control bits |          |          |          |                                                                                                                                                                                                                                                                                                                                                  | Output states <sup>(1)</sup>                                                                                                        |                                                              |

Bit 31 **UIFCPY**: UIF copy

This bit is a read-only copy of the UIF bit of the TIMx\_ISR register. If the UIFREMAP bit in the TIMxCR1 is reset, bit 31 is reserved and read at 0.

Bits 30:16 Reserved, must be kept at reset value.

Bits 15:0 **CNT[15:0]**: Counter value**22.4.11 TIMx prescaler (TIMx\_PSC)(x = 1, 8)**

Address offset: 0x28

Reset value: 0x0000

|           |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

| rw        | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 15:0 **PSC[15:0]**: Prescaler value

The counter clock frequency (CK\_CNT) is equal to  $f_{CK\_PSC} / (PSC[15:0] + 1)$ .

PSC contains the value to be loaded in the active prescaler register at each update event (including when the counter is cleared through UG bit of TIMx\_EGR register or through trigger controller when configured in “reset mode”).

**22.4.12 TIMx auto-reload register (TIMx\_ARR)(x = 1, 8)**

Address offset: 0x2C

Reset value: 0xFFFF

|           |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

|-----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 15        | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| REP[15:0] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw        | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 15:0 **REP[15:0]**: Repetition counter value

These bits allow the user to set-up the update rate of the compare registers (i.e. periodic transfers from preload to active registers) when preload registers are enable, as well as the update interrupt generation rate, if this interrupt is enable.

Each time the REP\_CNT related downcounter reaches zero, an update event is generated and it restarts counting from REP value. As REP\_CNT is reloaded with REP value only at the repetition update event U\_RC, any write to the TIMx\_RCR register is not taken in account until the next repetition update event.

It means in PWM mode (REP+1) corresponds to:  
the number of PWM periods in edge-aligned mode  
the number of half PWM period in center-aligned mode.

### 22.4.14 TIMx capture/compare register 1 (TIMx\_CCR1)(x = 1, 8)

Address offset: 0x34

Reset value: 0x0000

|            |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 15         | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| CCR1[15:0] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw         | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 15:0 **CCR1[15:0]**: Capture/Compare 1 value

**If channel CC1 is configured as output:** CCR1 is the value to be loaded in the actual capture/compare 1 register (preload value).

It is loaded permanently if the preload feature is not selected in the TIMx\_CCMR1 register (bit OC1PE). Else the preload value is copied in the active capture/compare 1 register when an update event occurs.

The active capture/compare register contains the value to be compared to the counter TIMx\_CNT and signaled on OC1 output.

**If channel CC1 is configured as input:** CR1 is the counter value transferred by the last input capture 1 event (IC1). The TIMx\_CCR1 register is read-only and cannot be programmed.

**22.4.15 TIMx capture/compare register 2 (TIMx\_CCR2)(x = 1, 8)**

Address offset: 0x38

Reset value: 0x0000

|            |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 15         | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| CCR2[15:0] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw         | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 15:0 **CCR2[15:0]**: Capture/Compare 2 value

**If channel CC2 is configured as output:** CCR2 is the value to be loaded in the actual capture/compare 2 register (preload value).

It is loaded permanently if the preload feature is not selected in the TIMx\_CCMR1 register (bit OC2PE). Else the preload value is copied in the active capture/compare 2 register when an update event occurs.

The active capture/compare register contains the value to be compared to the counter TIMx\_CNT and signaled on OC2 output.

**If channel CC2 is configured as input:** CCR2 is the counter value transferred by the last input capture 2 event (IC2). The TIMx\_CCR2 register is read-only and cannot be programmed.

**22.4.16 TIMx capture/compare register 3 (TIMx\_CCR3)(x = 1, 8)**

Address offset: 0x3C

Reset value: 0x0000

|            |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 15         | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| CCR3[15:0] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw         | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 15:0 **CCR3[15:0]**: Capture/Compare value

**If channel CC3 is configured as output:** CCR3 is the value to be loaded in the actual capture/compare 3 register (preload value).

It is loaded permanently if the preload feature is not selected in the TIMx\_CCMR2 register (bit OC3PE). Else the preload value is copied in the active capture/compare 3 register when an update event occurs.

The active capture/compare register contains the value to be compared to the counter TIMx\_CNT and signalled on OC3 output.

**If channel CC3 is configured as input:** CCR3 is the counter value transferred by the last input capture 3 event (IC3). The TIMx\_CCR3 register is read-only and cannot be programmed.

## 22.4.17 TIMx capture/compare register 4 (TIMx\_CCR4)(x = 1, 8)

Address offset: 0x40

Reset value: 0x0000

|            |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 15         | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| CCR4[15:0] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw         | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 15:0 **CCR4[15:0]**: Capture/Compare value

**If channel CC4 is configured as output:** CCR4 is the value to be loaded in the actual capture/compare 4 register (preload value).

It is loaded permanently if the preload feature is not selected in the TIMx\_CCMR2 register (bit OC4PE). Else the preload value is copied in the active capture/compare 4 register when an update event occurs.

The active capture/compare register contains the value to be compared to the counter TIMx\_CNT and signalled on OC4 output.

**If channel CC4 is configured as input:** CCR4 is the counter value transferred by the last input capture 4 event (IC4). The TIMx\_CCR4 register is read-only and cannot be programmed.

## 22.4.18 TIMx break and dead-time register (TIMx\_BDTR)(x = 1, 8)

Address offset: 0x44

Reset value: 0x0000 0000

|      |      |      |      |      |      |           |      |           |    |    |    |          |    |    |    |
|------|------|------|------|------|------|-----------|------|-----------|----|----|----|----------|----|----|----|
| 31   | 30   | 29   | 28   | 27   | 26   | 25        | 24   | 23        | 22 | 21 | 20 | 19       | 18 | 17 | 16 |
| Res. | Res. | Res. | Res. | Res. | Res. | BK2P      | BK2E | BK2F[3:0] |    |    |    | BKF[3:0] |    |    |    |
|      |      |      |      |      |      | rw        | rw   | rw        | rw | rw | rw | rw       | rw | rw | rw |
| 15   | 14   | 13   | 12   | 11   | 10   | 9         | 8    | 7         | 6  | 5  | 4  | 3        | 2  | 1  | 0  |
| MOE  | AOE  | BKP  | BKE  | OSSR | OSSI | LOCK[1:0] |      | DTG[7:0]  |    |    |    |          |    |    |    |
| rw   | rw   | rw   | rw   | rw   | rw   | rw        | rw   | rw        | rw | rw | rw | rw       | rw | rw | rw |

**Note:** As the bits BK2P, BK2E, BK2F[3:0], BKF[3:0], AOE, BKP, BKE, OSSI, OSSR and DTG[7:0] can be write-locked depending on the LOCK configuration, it can be necessary to configure all of them during the first write access to the TIMx\_BDTR register.

Bits 31:26 Reserved, must be kept at reset value.

Bit 25 **BK2P**: Break 2 polarity

0: Break input BRK2 is active low

1: Break input BRK2 is active high

**Note:** This bit cannot be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx\_BDTR register).

**Note:** Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.

Bit 24 **BK2E**: Break 2 enable

This bit enables the complete break 2 protection (including all sources connected to bk\_acth and BKIN sources, as per [Figure 191: Break and Break2 circuitry overview](#)).

0: Break2 function disabled

1: Break2 function enabled

*Note: The BRKIN2 must only be used with OSSR = OSS1 = 1.*

*Note: This bit cannot be modified when LOCK level 1 has been programmed (LOCK bits in TIMx\_BDTR register).*

*Note: Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.*

Bits 23:20 **BK2F[3:0]**: Break 2 filter

This bit-field defines the frequency used to sample BRK2 input and the length of the digital filter applied to BRK2. The digital filter is made of an event counter in which N consecutive events are needed to validate a transition on the output:

0000: No filter, BRK2 acts asynchronously

0001:  $f_{\text{SAMPLING}} = f_{\text{CK\_INT}}$ , N=2

0010:  $f_{\text{SAMPLING}} = f_{\text{CK\_INT}}$ , N=4

0011:  $f_{\text{SAMPLING}} = f_{\text{CK\_INT}}$ , N=8

0100:  $f_{\text{SAMPLING}} = f_{\text{DTS}}/2$ , N=6

0101:  $f_{\text{SAMPLING}} = f_{\text{DTS}}/2$ , N=8

0110:  $f_{\text{SAMPLING}} = f_{\text{DTS}}/4$ , N=6

0111:  $f_{\text{SAMPLING}} = f_{\text{DTS}}/4$ , N=8

1000:  $f_{\text{SAMPLING}} = f_{\text{DTS}}/8$ , N=6

1001:  $f_{\text{SAMPLING}} = f_{\text{DTS}}/8$ , N=8

1010:  $f_{\text{SAMPLING}} = f_{\text{DTS}}/16$ , N=5

1011:  $f_{\text{SAMPLING}} = f_{\text{DTS}}/16$ , N=6

1100:  $f_{\text{SAMPLING}} = f_{\text{DTS}}/16$ , N=8

1101:  $f_{\text{SAMPLING}} = f_{\text{DTS}}/32$ , N=5

1110:  $f_{\text{SAMPLING}} = f_{\text{DTS}}/32$ , N=6

1111:  $f_{\text{SAMPLING}} = f_{\text{DTS}}/32$ , N=8

*Note: This bit cannot be modified when LOCK level 1 has been programmed (LOCK bits in TIMx\_BDTR register).*

Bits 19:16 **BKF[3:0]**: Break filter

This bit-field defines the frequency used to sample BRK input and the length of the digital filter applied to BRK. The digital filter is made of an event counter in which N consecutive events are needed to validate a transition on the output:

0000: No filter, BRK acts asynchronously

0001:  $f_{\text{SAMPLING}} = f_{\text{CK\_INT}}$ , N=2

0010:  $f_{\text{SAMPLING}} = f_{\text{CK\_INT}}$ , N=4

0011:  $f_{\text{SAMPLING}} = f_{\text{CK\_INT}}$ , N=8

0100:  $f_{\text{SAMPLING}} = f_{\text{DTS}}/2$ , N=6

0101:  $f_{\text{SAMPLING}} = f_{\text{DTS}}/2$ , N=8

0110:  $f_{\text{SAMPLING}} = f_{\text{DTS}}/4$ , N=6

0111:  $f_{\text{SAMPLING}} = f_{\text{DTS}}/4$ , N=8

1000:  $f_{\text{SAMPLING}} = f_{\text{DTS}}/8$ , N=6

1001:  $f_{\text{SAMPLING}} = f_{\text{DTS}}/8$ , N=8

1010:  $f_{\text{SAMPLING}} = f_{\text{DTS}}/16$ , N=5

1011:  $f_{\text{SAMPLING}} = f_{\text{DTS}}/16$ , N=6

1100:  $f_{\text{SAMPLING}} = f_{\text{DTS}}/16$ , N=8

1101:  $f_{\text{SAMPLING}} = f_{\text{DTS}}/32$ , N=5

1110:  $f_{\text{SAMPLING}} = f_{\text{DTS}}/32$ , N=6

1111:  $f_{\text{SAMPLING}} = f_{\text{DTS}}/32$ , N=8

*Note: This bit cannot be modified when LOCK level 1 has been programmed (LOCK bits in TIMx\_BDTR register).*

Bit 15 **MOE**: Main output enable

This bit is cleared asynchronously by hardware as soon as one of the break inputs is active (BRK or BRK2). It is set by software or automatically depending on the AOE bit. It is acting only on the channels which are configured in output.

0: In response to a break 2 event. OC and OCN outputs are disabled

In response to a break event or if MOE is written to 0: OC and OCN outputs are disabled or forced to idle state depending on the OSSR bit.

1: OC and OCN outputs are enabled if their respective enable bits are set (CCxE, CCxNE in TIMx\_CCER register).

See OC/OCN enable description for more details ([Section 22.4.9: TIMx capture/compare enable register \(TIMx\\_CCER\)\(x = 1, 8\)](#)).

Bit 14 **AOE**: Automatic output enable

0: MOE can be set only by software

1: MOE can be set by software or automatically at the next update event (if none of the break inputs BRK and BRK2 is active)

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx\_BDTR register).*

Bit 13 **BKP**: Break polarity

0: Break input BRK is active low

1: Break input BRK is active high

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx\_BDTR register).*

*Note: Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.*

Bit 12 **BKE**: Break enable

This bit enables the complete break protection (including all sources connected to bk\_ach and BKIN sources, as per [Figure 191: Break and Break2 circuitry overview](#)).

0: Break function disabled

1: Break function enabled

*Note: This bit cannot be modified when LOCK level 1 has been programmed (LOCK bits in TIMx\_BDTR register).*

*Note: Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.*

Bit 11 **OSSR**: Off-state selection for Run mode

This bit is used when MOE=1 on channels having a complementary output which are configured as outputs. OSSR is not implemented if no complementary output is implemented in the timer.

See OC/OCN enable description for more details ([Section 22.4.9: TIMx capture/compare enable register \(TIMx\\_CCER\)\(x = 1, 8\)](#)).

0: When inactive, OC/OCN outputs are disabled (the timer releases the output control which is taken over by the GPIO logic, which forces a Hi-Z state).

1: When inactive, OC/OCN outputs are enabled with their inactive level as soon as CCxE=1 or CCxNE=1 (the output is still controlled by the timer).

*Note: This bit can not be modified as soon as the LOCK level 2 has been programmed (LOCK bits in TIMx\_BDTR register).*

Bit 10 **OSSI**: Off-state selection for Idle mode

This bit is used when MOE=0 due to a break event or by a software write, on channels configured as outputs.

See OC/OCN enable description for more details ([Section 22.4.9: TIMx capture/compare enable register \(TIMx\\_CCER\)\(x = 1, 8\)](#)).

0: When inactive, OC/OCN outputs are disabled (the timer releases the output control which is taken over by the GPIO logic and which imposes a Hi-Z state).

1: When inactive, OC/OCN outputs are first forced with their inactive level then forced to their idle level after the deadtime. The timer maintains its control over the output.

*Note: This bit can not be modified as soon as the LOCK level 2 has been programmed (LOCK bits in TIMx\_BDTR register).*

Bits 9:8 **LOCK[1:0]**: Lock configuration

These bits offer a write protection against software errors.

00: LOCK OFF - No bit is write protected.

01: LOCK Level 1 = DTG bits in TIMx\_BDTR register, OISx and OISxN bits in TIMx\_CR2 register and BKE/BKP/AOE bits in TIMx\_BDTR register can no longer be written.

10: LOCK Level 2 = LOCK Level 1 + CC Polarity bits (CCxP/CCxNP bits in TIMx\_CCER register, as long as the related channel is configured in output through the CCxS bits) as well as OSSR and OSSI bits can no longer be written.

11: LOCK Level 3 = LOCK Level 2 + CC Control bits (OCxM and OCxPE bits in TIMx\_CCMRx registers, as long as the related channel is configured in output through the CCxS bits) can no longer be written.

*Note: The LOCK bits can be written only once after the reset. Once the TIMx\_BDTR register has been written, their content is frozen until the next reset.*

Bits 7:0 **DTG[7:0]**: Dead-time generator setup

This bit-field defines the duration of the dead-time inserted between the complementary outputs. DT correspond to this duration.

DTG[7:5]=0xx => DT=DTG[7:0]x  $t_{dtg}$  with  $t_{dtg}=t_{DTS}$ .

DTG[7:5]=10x => DT=(64+DTG[5:0])x  $t_{dtg}$  with  $T_{dtg}=2xt_{DTS}$ .

DTG[7:5]=110 => DT=(32+DTG[4:0])x  $t_{dtg}$  with  $T_{dtg}=8xt_{DTS}$ .

DTG[7:5]=111 => DT=(32+DTG[4:0])x  $t_{dtg}$  with  $T_{dtg}=16xt_{DTS}$ .

Example if  $T_{DTS}=125ns$  (8MHz), dead-time possible values are:

0 to 15875 ns by 125 ns steps,

16 us to 31750 ns by 250 ns steps,

32 us to 63us by 1 us steps,

64 us to 126 us by 2 us steps

*Note: This bit-field can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIMx\_BDTR register).*

**22.4.19 TIMx DMA control register (TIMx\_DCR)(x = 1, 8)**

Address offset: 0x48

Reset value: 0x0000

| 15   | 14   | 13   | 12       | 11 | 10 | 9  | 8  | 7    | 6    | 5    | 4        | 3  | 2  | 1  | 0  |
|------|------|------|----------|----|----|----|----|------|------|------|----------|----|----|----|----|
| Res. | Res. | Res. | DBL[4:0] |    |    |    |    | Res. | Res. | Res. | DBA[4:0] |    |    |    |    |
|      |      |      | rw       | rw | rw | rw | rw |      |      |      | rw       | rw | rw | rw | rw |

Bits 15:13 Reserved, must be kept at reset value.

Bits 12:8 **DBL[4:0]**: DMA burst length

This 5-bit vector defines the length of DMA transfers (the timer recognizes a burst transfer when a read or a write access is done to the TIMx\_DMAR address), i.e. the number of transfers. Transfers can be in half-words or in bytes (see example below).

00000: 1 transfer

00001: 2 transfers

00010: 3 transfers

...

10001: 18 transfers

**Example:** Let us consider the following transfer: DBL = 7 bytes & DBA = TIM2\_CR1.

- If DBL = 7 bytes and DBA = TIM2\_CR1 represents the address of the byte to be transferred, the address of the transfer should be given by the following equation:

(TIMx\_CR1 address) + DBA + (DMA index), where DMA index = DBL

In this example, 7 bytes are added to (TIMx\_CR1 address) + DBA, which gives us the address from/to which the data will be copied. In this case, the transfer is done to 7 registers starting from the following address: (TIMx\_CR1 address) + DBA

According to the configuration of the DMA Data Size, several cases may occur:

- If you configure the DMA Data Size in half-words, 16-bit data will be transferred to each of the 7 registers.
- If you configure the DMA Data Size in bytes, the data will also be transferred to 7 registers: the first register will contain the first MSB byte, the second register, the first LSB byte and so on. So with the transfer Timer, you also have to specify the size of data transferred by DMA.

Bits 7:5 Reserved, must be kept at reset value.

Bits 4:0 **DBA[4:0]**: DMA base address

This 5-bits vector defines the base-address for DMA transfers (when read/write access are done through the TIMx\_DMAR address). DBA is defined as an offset starting from the address of the TIMx\_CR1 register.

Example:

00000: TIMx\_CR1,

00001: TIMx\_CR2,

00010: TIMx\_SMCR,

...

## 22.4.20 TIMx DMA address for full transfer (TIMx\_DMAR)(x = 1, 8)

Address offset: 0x4C

Reset value: 0x0000 0000

|             |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|-------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31          | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| DMAB[31:16] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw          | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |
| 15          | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| DMAB[15:0]  |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw          | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 31:0 **DMAB[31:0]**: DMA register for burst accesses

A read or write operation to the DMAR register accesses the register located at the address (TIMx\_CR1 address) + (DBA + DMA index) x 4

where TIMx\_CR1 address is the address of the control register 1, DBA is the DMA base address configured in TIMx\_DCR register, DMA index is automatically controlled by the DMA transfer, and ranges from 0 to DBL (DBL configured in TIMx\_DCR).

## 22.4.21 TIMx capture/compare mode register 3 (TIMx\_CCMR3)(x = 1, 8)

Address offset: 0x54

Reset value: 0x0000 0000

Refer to the above CCMR1 register description. Channels 5 and 6 can only be configured in output.

### Output compare mode

Bits 31:25 Reserved, must be kept at reset value.

Bits 23:17 Reserved, must be kept at reset value.

Bit 15 **OC6CE**: Output compare 6 clear enable

Bits 24, 14, 13, 12 **OC6M[3:0]**: Output compare 6 mode

Bit 11 **OC6PE**: Output compare 6 preload enable

Bit 10 **OC6FE**: Output compare 6 fast enable

Bits 9:8 Reserved, must be kept at reset value.

Bit 7 **OC5CE**: Output compare 5 clear enable

Bits 16, 6, 5, 4 **OC5M[3:0]**: Output compare 5 mode

Bit 3 **OC5PE**: Output compare 5 preload enable

Bit 2 **OC5FE**: Output compare 5 fast enable

Bits 1:0 Reserved, must be kept at reset value.

## 22.4.22 TIMx capture/compare register 5 (TIMx\_CCR5)(x = 1, 8)

Address offset: 0x58

Reset value: 0x0000 0000

|            |       |       |      |      |      |      |      |      |      |      |      |      |      |      |      |

Bit 31 **GC5C3**: Group Channel 5 and Channel 3

Distortion on Channel 3 output:

0: No effect of OC5REF on OC3REFC

1: OC3REFC is the logical AND of OC3REFC and OC5REF

This bit can either have immediate effect or be preloaded and taken into account after an update event (if preload feature is selected in TIMxCCMR2).

*Note: it is also possible to apply this distortion on combined PWM signals.*

Bit 30 **GC5C2**: Group Channel 5 and Channel 2

Distortion on Channel 2 output:

0: No effect of OC5REF on OC2REFC

1: OC2REFC is the logical AND of OC2REFC and OC5REF

This bit can either have immediate effect or be preloaded and taken into account after an update event (if preload feature is selected in TIMxCCMR1).

*Note: it is also possible to apply this distortion on combined PWM signals.*

Bit 29 **GC5C1**: Group Channel 5 and Channel 1

Distortion on Channel 1 output:

0: No effect of OC5REF on OC1REFC5

1: OC1REFC is the logical AND of OC1REFC and OC5REF

This bit can either have immediate effect or be preloaded and taken into account after an update event (if preload feature is selected in TIMxCCMR1).

*Note: it is also possible to apply this distortion on combined PWM signals.*

Bits 28:16 Reserved, must be kept at reset value.

Bits 15:0 **CCR5[15:0]**: Capture/Compare 5 value

CCR5 is the value to be loaded in the actual capture/compare 5 register (preload value).

It is loaded permanently if the preload feature is not selected in the TIMx\_CCMR3 register (bit OC5PE). Else the preload value is copied in the active capture/compare 5 register when an update event occurs.

The active capture/compare register contains the value to be compared to the counter TIMx\_CNT and signaled on OC5 output.

22.4.23 TIMx capture/compare register 6 (TIMx\_CCR6)(x = 1, 8)

Address offset: 0x5C

Reset value: 0x0000

|            |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 15         | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| CCR6[15:0] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

Bits 15:0 **CCR6[15:0]**: Capture/Compare 6 value

CCR6 is the value to be loaded in the actual capture/compare 6 register (preload value). It is loaded permanently if the preload feature is not selected in the TIMx\_CCMR3 register (bit OC6PE). Else the preload value is copied in the active capture/compare 6 register when an update event occurs.

The active capture/compare register contains the value to be compared to the counter TIMx\_CNT and signaled on OC6 output.

## 22.4.24 TIM1 register map

TIM1 registers are mapped as 16-bit addressable registers as described in the table below:

**Table 148. TIM1 register map and reset values**

| Offset | Register name                     | 31     | 30        | 29 | 28 | 27 | 26 | 25 | 24      | 23        | 22   | 21   | 20 | 19 | 18   | 17    | 16      | 15        | 14         | 13          | 12            | 11          | 10        | 9           | 8     | 7             | 6       | 5           | 4     | 3           | 2     | 1     | 0    |      |     |

Refer to [Section 2.2.2: Memory map and register boundary addresses](#) for the register boundary addresses.

## 22.4.25 TIM8 register map

TIM8 registers are mapped as 16-bit addressable registers as described in the table below:

**Table 149. TIM8 register map and reset values**

| Offset | Register name                     | 31     | 30   | 29   | 28   | 27   | 26   | 25   | 24      | 23        | 22   | 21   | 20   | 19   | 18   | 17   | 16      | 15        | 14         | 13          | 12            | 11          | 10        | 9           | 8             | 7           | 6     | 5         | 4        | 3           | 2     | 1     | 0    |  |
|--------|-----------------------------------|--------|------|------|------|------|------|------|---------|-----------|------|------|------|------|------|------|---------|-----------|------------|-------------|---------------|-------------|-----------|-------------|---------------|-------------|-------|-----------|----------|-------------|-------|-------|------|--|

## 23 General-purpose timers (TIM2/TIM3/TIM4/TIM5)

### 23.1 TIM2/TIM3/TIM4/TIM5 introduction

The general-purpose timers consist of a 16-bit or 32-bit auto-reload counter driven by a programmable prescaler.

They may be used for a variety of purposes, including measuring the pulse lengths of input signals (*input capture*) or generating output waveforms (*output compare and PWM*).

Pulse lengths and waveform periods can be modulated from a few microseconds to several milliseconds using the timer prescaler and the RCC clock controller prescalers.

The timers are completely independent, and do not share any resources. They can be synchronized together as described in [Section 23.3.19: Timer synchronization](#).

### 23.2 TIM2/TIM3/TIM4/TIM5 main features

General-purpose TIMx timer features include:

- 16-bit (TIM3, TIM4) or 32-bit (TIM2 and TIM5) up, down, up/down auto-reload counter.
- 16-bit programmable prescaler used to divide (also “on the fly”) the counter clock frequency by any factor between 1 and 65535.
- Up to 4 independent channels for:
  - Input capture
  - Output compare
  - PWM generation (Edge- and Center-aligned modes)
  - One-pulse mode output
- Synchronization circuit to control the timer with external signals and to interconnect several timers.
- Interrupt/DMA generation on the following events:
  - Update: counter overflow/underflow, counter initialization (by software or internal/external trigger)
  - Trigger event (counter start, stop, initialization or count by internal/external trigger)
  - Input capture
  - Output compare
- Supports incremental (quadrature) encoder and hall-sensor circuitry for positioning purposes
- Trigger input for external clock or cycle-by-cycle current management

## 23.3 TIM2/TIM3/TIM4/TIM5 functional description

### 23.3.1 Time-base unit

The main block of the programmable timer is a 16-bit/32-bit counter with its related auto-reload register. The counter can count up, down or both up and down but also down or both up and down. The counter clock can be divided by a prescaler.

The counter, the auto-reload register and the prescaler register can be written or read by software. This is true even when the counter is running.

The time-base unit includes:

- Counter Register (TIMx\_CNT)
- Prescaler Register (TIMx\_PSC):
- Auto-Reload Register (TIMx\_ARR)

The auto-reload register is preloaded. Writing to or reading from the auto-reload register accesses the preload register. The content of the preload register are transferred into the shadow register permanently or at each update event (UEV), depending on the auto-reload preload enable bit (ARPE) in TIMx\_CR1 register. The update event is sent when the counter reaches the overflow (or underflow when downcounting) and if the UDIS bit equals 0 in the TIMx\_CR1 register. It can also be generated by software. The generation of the update event is described in detail for each configuration.

The counter is clocked by the prescaler output CK\_CNT, which is enabled only when the counter enable bit (CEN) in TIMx\_CR1 register is set (refer also to the slave mode controller description to get more details on counter enabling).

Note that the actual counter enable signal CNT\_EN is set 1 clock cycle after CEN.

#### Prescaler description

The prescaler can divide the counter clock frequency by any factor between 1 and 65536. It is based on a 16-bit counter controlled through a 16-bit/32-bit register (in the TIMx\_PSC register). It can be changed on the fly as this control register is buffered. The new prescaler ratio is taken into account at the next update event.

[Figure 208](#) and [Figure 209](#) give some examples of the counter behavior when the prescaler ratio is changed on the fly:

Figure 208. Counter timing diagram with prescaler division change from 1 to 2

Figure 209. Counter timing diagram with prescaler division change from 1 to 4

### 23.3.2 Counter modes

#### Upcounting mode

In upcounting mode, the counter counts from 0 to the auto-reload value (content of the TIMx\_ARR register), then restarts from 0 and generates a counter overflow event.

An Update event can be generated at each counter overflow or by setting the UG bit in the TIMx\_EGR register (by software or by using the slave mode controller).

The UEV event can be disabled by software by setting the UDIS bit in TIMx\_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until the UDIS bit has been written to 0. However, the counter restarts from 0, as well as the counter of the prescaler (but the prescale rate does not change). In addition, if the URS bit (update request selection) in TIMx\_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt or DMA request is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMx\_SR register) is set (depending on the URS bit):

- The buffer of the prescaler is reloaded with the preload value (content of the TIMx\_PSC register)
- The auto-reload shadow register is updated with the preload value (TIMx\_ARR)

The following figures show some examples of the counter behavior for different clock frequencies when TIMx\_ARR=0x36.

**Figure 210. Counter timing diagram, internal clock divided by 1**

Figure 212. Counter timing diagram, internal clock divided by 4

Figure 213. Counter timing diagram, internal clock divided by N

Figure 214. Counter timing diagram, Update event when ARPE=0 (TIMx\_ARR not preloaded)

**Figure 215. Counter timing diagram, Update event when ARPE=1 (TIMx\_ARR preloaded)**

### Downcounting mode

In downcounting mode, the counter counts from the auto-reload value (content of the TIMx\_ARR register) down to 0, then restarts from the auto-reload value and generates a counter underflow event.

An Update event can be generated at each counter underflow or by setting the UG bit in the TIMx\_EGR register (by software or by using the slave mode controller)

The UEV update event can be disabled by software by setting the UDIS bit in TIMx\_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until UDIS bit has been written to 0. However, the counter restarts from the current auto-reload value, whereas the counter of the prescaler restarts from 0 (but the prescale rate doesn't change).

In addition, if the URS bit (update request selection) in TIMx\_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt or DMA request is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMx\_SR register) is set (depending on the URS bit):

- The buffer of the prescaler is reloaded with the preload value (content of the TIMx\_PSC register).
- The auto-reload active register is updated with the preload value (content of the TIMx\_ARR register). Note that the auto-reload is updated before the counter is reloaded, so that the next period is the expected one.

The following figures show some examples of the counter behavior for different clock frequencies when TIMx\_ARR=0x36.

Figure 216. Counter timing diagram, internal clock divided by 1

Figure 217. Counter timing diagram, internal clock divided by 2

Figure 218. Counter timing diagram, internal clock divided by 4

Figure 219. Counter timing diagram, internal clock divided by N

**Figure 220. Counter timing diagram, Update event when repetition counter is not used****Center-aligned mode (up/down counting)**

In center-aligned mode, the counter counts from 0 to the auto-reload value (content of the TIMx\_ARR register) – 1, generates a counter overflow event, then counts from the auto-reload value down to 1 and generates a counter underflow event. Then it restarts counting from 0.

Center-aligned mode is active when the CMS bits in TIMx\_CR1 register are not equal to '00'. The Output compare interrupt flag of channels configured in output is set when: the counter counts down (Center aligned mode 1, CMS = "01"), the counter counts up (Center aligned mode 2, CMS = "10") the counter counts up and down (Center aligned mode 3, CMS = "11").

In this mode, the direction bit (DIR from TIMx\_CR1 register) cannot be written. It is updated by hardware and gives the current direction of the counter.

The update event can be generated at each counter overflow and at each counter underflow or by setting the UG bit in the TIMx\_EGR register (by software or by using the slave mode controller) also generates an update event. In this case, the counter restarts counting from 0, as well as the counter of the prescaler.

The UEV update event can be disabled by software by setting the UDIS bit in TIMx\_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until the UDIS bit has been written to 0. However, the counter continues counting up and down, based on the current auto-reload value.

In addition, if the URS bit (update request selection) in TIMx\_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt or

DMA request is sent). This is to avoid generating both update and capture interrupt when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMx\_SR register) is set (depending on the URS bit):

- The buffer of the prescaler is reloaded with the preload value (content of the TIMx\_PSC register).
- The auto-reload active register is updated with the preload value (content of the TIMx\_ARR register). Note that if the update source is a counter overflow, the auto-reload is updated before the counter is reloaded, so that the next period is the expected one (the counter is loaded with the new value).

The following figures show some examples of the counter behavior for different clock frequencies.

**Figure 221. Counter timing diagram, internal clock divided by 1, TIMx\_ARR=0x6**

1. Here, center-aligned mode 1 is used (for more details refer to [Section 23.4.1: TIMx control register 1 \(TIMx\\_CR1\)\(x = 2 to 5\) on page 788](#)).

**Figure 226. Counter timing diagram, Update event with ARPE=1 (counter overflow)**

### 23.3.3 Clock selection

The counter clock can be provided by the following clock sources:

- Internal clock (CK\_INT)
- External clock mode1: external input pin (TIx)
- External clock mode2: external trigger input (ETR)
- Internal trigger inputs (ITRx): using one timer as prescaler for another timer, for example, you can configure Timer 13 to act as a prescaler for Timer 2. Refer to : [Using one timer as prescaler for another timer on page 783](#) for more details.

#### Internal clock source (CK\_INT)

If the slave mode controller is disabled (SMS=000 in the TIMx\_SMCR register), then the CEN, DIR (in the TIMx\_CR1 register) and UG bits (in the TIMx\_EGR register) are actual control bits and can be changed only by software (except UG which remains cleared automatically). As soon as the CEN bit is written to 1, the prescaler is clocked by the internal clock CK\_INT.

[Figure 227](#) shows the behavior of the control circuit and the upcounter in normal mode, without prescaler.

Figure 227. Control circuit in normal mode, internal clock divided by 1

External clock source mode 1

This mode is selected when SMS=111 in the TIMx\_SMCR register. The counter can count at each rising or falling edge on a selected input.

Figure 228. TI2 external clock connection example

For example, to configure the upcounter to count in response to a rising edge on the TI2 input, use the following procedure:

For example, to configure the upcounter to count in response to a rising edge on the TI2 input, use the following procedure:

1. Configure channel 2 to detect rising edges on the TI2 input by writing CC2S= '01 in the TIMx\_CCMR1 register.
2. Configure the input filter duration by writing the IC2F[3:0] bits in the TIMx\_CCMR1 register (if no filter is needed, keep IC2F=0000).

*Note:* The capture prescaler is not used for triggering, so you don't need to configure it.

3. Select rising edge polarity by writing CC2P=0 and CC2NP=0 and CC2NP=0 in the TIMx\_CCER register.
4. Configure the timer in external clock mode 1 by writing SMS=111 in the TIMx\_SMCR register.
5. Select TI2 as the input source by writing TS=110 in the TIMx\_SMCR register.
6. Enable the counter by writing CEN=1 in the TIMx\_CR1 register.

When a rising edge occurs on TI2, the counter counts once and the TIF flag is set.

The delay between the rising edge on TI2 and the actual clock of the counter is due to the resynchronization circuit on TI2 input.

**Figure 229. Control circuit in external clock mode 1**

### External clock source mode 2

This mode is selected by writing ECE=1 in the TIMx\_SMCR register.

The counter can count at each rising or falling edge on the external trigger input ETR.

[Figure 230](#) gives an overview of the external trigger input block.

Figure 230. External trigger input block

MS33116V1

For example, to configure the upcounter to count each 2 rising edges on ETR, use the following procedure:

1. As no filter is needed in this example, write ETF[3:0]=0000 in the TIMx\_SMCR register.
2. Set the prescaler by writing ETPS[1:0]=01 in the TIMx\_SMCR register
3. Select rising edge detection on the ETR pin by writing ETP=0 in the TIMx\_SMCR register
4. Enable external clock mode 2 by writing ECE=1 in the TIMx\_SMCR register.
5. Enable the counter by writing CEN=1 in the TIMx\_CR1 register.

The counter counts once each 2 ETR rising edges.

The delay between the rising edge on ETR and the actual clock of the counter is due to the resynchronization circuit on the ETRP signal.

Figure 231. Control circuit in external clock mode 2

### 23.3.4 Capture/Compare channels

Each Capture/Compare channel is built around a capture/compare register (including a shadow register), a input stage for capture (with digital filter, multiplexing and prescaler) and an output stage (with comparator and output control).

The following figure gives an overview of one Capture/Compare channel.

The input stage samples the corresponding  $TIx$  input to generate a filtered signal  $TIxF$ . Then, an edge detector with polarity selection generates a signal ( $TIxFPx$ ) which can be used as trigger input by the slave mode controller or as the capture command. It is prescaled before the capture register ( $ICxPS$ ).

**Figure 232. Capture/Compare channel (example: channel 1 input stage)**

The output stage generates an intermediate waveform which is then used for reference: OCxRef (active high). The polarity acts at the end of the chain.

**Figure 233. Capture/Compare channel 1 main circuit**

Figure 234. Output stage of Capture/Compare channel (channel 1)

The capture/compare block is made of one preload register and one shadow register. Write and read always access the preload register.

In capture mode, captures are actually done in the shadow register, which is copied into the preload register.

In compare mode, the content of the preload register is copied into the shadow register which is compared to the counter.

### 23.3.5 Input capture mode

In Input capture mode, the Capture/Compare Registers (TIMx\_CCRx) are used to latch the value of the counter after a transition detected by the corresponding ICx signal. When a capture occurs, the corresponding CCXIF flag (TIMx\_SR register) is set and an interrupt or a DMA request can be sent if they are enabled. If a capture occurs while the CCxIF flag was already high, then the over-capture flag CCxOF (TIMx\_SR register) is set. CCxIF can be cleared by software by writing it to 0 or by reading the captured data stored in the TIMx\_CCRx register. CCxOF is cleared when you write it to 0.

The following example shows how to capture the counter value in TIMx\_CCR1 when TI1 input rises. To do this, use the following procedure:

1. Select the active input: TIMx\_CCR1 must be linked to the TI1 input, so write the CC1S bits to 01 in the TIMx\_CCMR1 register. As soon as CC1S becomes different from 00, the channel is configured in input and the TIMx\_CCR1 register becomes read-only.
2. Program the input filter duration you need with respect to the signal you connect to the timer (when the input is one of the TIx (ICxF bits in the TIMx\_CCMRx register). Let's imagine that, when toggling, the input signal is not stable during at most 5 internal clock cycles. We must program a filter duration longer than these 5 clock cycles. We can validate a transition on TI1 when 8 consecutive samples with the new level have been

detected (sampled at  $f_{DTS}$  frequency). Then write IC1F bits to 0011 in the TIMx\_CCMR1 register.

3. Select the edge of the active transition on the TI1 channel by writing the CC1P and CC1NP and CC1NP bits to 000 in the TIMx\_CCER register (rising edge in this case).
4. Program the input prescaler. In our example, we wish the capture to be performed at each valid transition, so the prescaler is disabled (write IC1PS bits to 00 in the TIMx\_CCMR1 register).
5. Enable capture from the counter into the capture register by setting the CC1E bit in the TIMx\_CCER register.
6. If needed, enable the related interrupt request by setting the CC1IE bit in the TIMx\_DIER register, and/or the DMA request by setting the CC1DE bit in the TIMx\_DIER register.

When an input capture occurs:

- The TIMx\_CCR1 register gets the value of the counter on the active transition.
- CC1IF flag is set (interrupt flag). CC1OF is also set if at least two consecutive captures occurred whereas the flag was not cleared.
- An interrupt is generated depending on the CC1IE bit.
- A DMA request is generated depending on the CC1DE bit.

In order to handle the overcapture, it is recommended to read the data before the overcapture flag. This is to avoid missing an overcapture which could happen after reading the flag and before reading the data.

*Note:* IC interrupt and/or DMA requests can be generated by software by setting the corresponding CCxG bit in the TIMx\_EGR register.

### 23.3.6 PWM input mode

This mode is a particular case of input capture mode. The procedure is the same except:

- Two ICx signals are mapped on the same TIx input.
- These 2 ICx signals are active on edges with opposite polarity.
- One of the two TIxFP signals is selected as trigger input and the slave mode controller is configured in reset mode.

For example, you can measure the period (in TIMx\_CCR1 register) and the duty cycle (in TIMx\_CCR2 register) of the PWM applied on TI1 using the following procedure (depending on CK\_INT frequency and prescaler value):

1. Select the active input for TIMx\_CCR1: write the CC1S bits to 01 in the TIMx\_CCMR1 register (TI1 selected).
2. Select the active polarity for TI1FP1 (used both for capture in TIMx\_CCR1 and counter clear): write the CC1P to '0' and the CC1NP bit to '0' (active on rising edge).
3. Select the active input for TIMx\_CCR2: write the CC2S bits to 10 in the TIMx\_CCMR1 register (TI1 selected).
4. Select the active polarity for TI1FP2 (used for capture in TIMx\_CCR2): write the CC2P bit to '1' and the CC2NP bit to '0' (active on falling edge).
5. Select the valid trigger input: write the TS bits to 101 in the TIMx\_SMCR register (TI1FP1 selected).
6. Configure the slave mode controller in reset mode: write the SMS bits to 100 in the TIMx\_SMCR register.
7. Enable the captures: write the CC1E and CC2E bits to '1' in the TIMx\_CCER register.

**Figure 235. PWM input mode timing**

1. The PWM input mode can be used only with the TIMx\_CH1/TIMx\_CH2 signals due to the fact that only TI1FP1 and TI2FP2 are connected to the slave mode controller.

### 23.3.7 Forced output mode

In output mode (CCxS bits = 00 in the TIMx\_CCMRx register), each output compare signal (OCxREF and then OCx) can be forced to active or inactive level directly by software, independently of any comparison between the output compare register and the counter.

To force an output compare signal (ocxref/OCx) to its active level, you just need to write 101 in the OCxM bits in the corresponding TIMx\_CCMRx register. Thus ocxref is forced high (OCxREF is always active high) and OCx get opposite value to CCxP polarity bit.

e.g.: CCxP=0 (OCx active high) => OCx is forced to high level.

ocxref signal can be forced low by writing the OCxM bits to 100 in the TIMx\_CCMRx register.

Anyway, the comparison between the TIMx\_CCRx shadow register and the counter is still performed and allows the flag to be set. Interrupt and DMA requests can be sent accordingly. This is described in the Output Compare Mode section.

### 23.3.8 Output compare mode

This function is used to control an output waveform or indicating when a period of time has elapsed.

When a match is found between the capture/compare register and the counter, the output compare function:

- Assigns the corresponding output pin to a programmable value defined by the output compare mode (OCxM bits in the TIMx\_CCMRx register) and the output polarity (CCxP bit in the TIMx\_CCER register). The output pin can keep its level (OCxM=000), be set active (OCxM=001), be set inactive (OCxM=010) or can toggle (OCxM=011) on match.
- Sets a flag in the interrupt status register (CCxIF bit in the TIMx\_SR register).
- Generates an interrupt if the corresponding interrupt mask is set (CCxIE bit in the TIMx\_DIER register).
- Sends a DMA request if the corresponding enable bit is set (CCxDE bit in the TIMx\_DIER register, CCDS bit in the TIMx\_CR2 register for the DMA request selection).

The TIMx\_CCRx registers can be programmed with or without preload registers using the OCxPE bit in the TIMx\_CCMRx register.

In output compare mode, the update event UEV has no effect on ocxref and OCx output. The timing resolution is one count of the counter. Output compare mode can also be used to output a single pulse (in One-pulse mode).

#### Procedure

1. Select the counter clock (internal, external, prescaler).
2. Write the desired data in the TIMx\_ARR and TIMx\_CCRx registers.
3. Set the CCxIE and/or CCxDE bits if an interrupt and/or a DMA request is to be generated.
4. Select the output mode. For example, you must write OCxM=011, OCxPE=0, CCxP=0 and CCxE=1 to toggle OCx output pin when CNT matches CCRx, CCRx preload is not used, OCx is enabled and active high.
5. Enable the counter by setting the CEN bit in the TIMx\_CR1 register.

The TIMx\_CCRx register can be updated at any time by software to control the output waveform, provided that the preload register is not enabled (OCxPE=0, else TIMx\_CCRx shadow register is updated only at the next update event UEV). An example is given in [Figure 236](#).

Figure 236. Output compare mode, toggle on OC1

### 23.3.9 PWM mode

Pulse width modulation mode allows you to generate a signal with a frequency determined by the value of the TIMx\_ARR register and a duty cycle determined by the value of the TIMx\_CCRx register.

The PWM mode can be selected independently on each channel (one PWM per OCx output) by writing 110 (PWM mode 1) or '111 (PWM mode 2) in the OCxM bits in the TIMx\_CCMRx register. You must enable the corresponding preload register by setting the OCxPE bit in the TIMx\_CCMRx register, and eventually the auto-reload preload register (in upcounting or center-aligned modes) by setting the ARPE bit in the TIMx\_CR1 register.

As the preload registers are transferred to the shadow registers only when an update event occurs, before starting the counter, you have to initialize all the registers by setting the UG bit in the TIMx\_EGR register.

OCx polarity is software programmable using the CCxP bit in the TIMx\_CCER register. It can be programmed as active high or active low. OCx output is enabled by the CCxE bit in the TIMx\_CCER register. Refer to the TIMx\_CCERx register description for more details.

In PWM mode (1 or 2), TIMx\_CNT and TIMx\_CCRx are always compared to determine whether  $TIMx\_CCRx \leq TIMx\_CNT$  or  $TIMx\_CNT \leq TIMx\_CCRx$  (depending on the direction of the counter). However, to comply with the OCREF\_CLR functionality (OCREF can be cleared by an external event through the ETR signal until the next PWM period), the OCREF signal is asserted only:

- When the result of the comparison or
- When the output compare mode (OCxM bits in TIMx\_CCMRx register) switches from the "frozen" configuration (no comparison, OCxM='000) to one of the PWM modes (OCxM='110 or '111).

This forces the PWM by software while the timer is running.

The timer is able to generate PWM in edge-aligned mode or center-aligned mode depending on the CMS bits in the TIMx\_CR1 register.

### PWM edge-aligned mode

#### Upcounting configuration

Upcounting is active when the DIR bit in the TIMx\_CR1 register is low. Refer to [Upcounting mode on page 747](#).

In the following example, we consider PWM mode 1. The reference PWM signal OCxREF is high as long as TIMx\_CNT < TIMx\_CCRx else it becomes low. If the compare value in TIMx\_CCRx is greater than the auto-reload value (in TIMx\_ARR) then OCxREF is held at '1'. If the compare value is 0 then OCxREF is held at '0'. [Figure 237](#) shows some edge-aligned PWM waveforms in an example where TIMx\_ARR=8.

**Figure 237. Edge-aligned PWM waveforms (ARR=8)**

#### Downcounting configuration

Downcounting is active when DIR bit in TIMx\_CR1 register is high. Refer to [Downcounting mode on page 750](#).

In PWM mode 1, the reference signal ocxref is low as long as TIMx\_CNT > TIMx\_CCRx else it becomes high. If the compare value in TIMx\_CCRx is greater than the auto-reload value in TIMx\_ARR, then ocxref is held at 100%. PWM is not possible in this mode.

### PWM center-aligned mode

Center-aligned mode is active when the CMS bits in TIMx\_CR1 register are different from '00' (all the remaining configurations having the same effect on the ocxref/OCx signals). The

compare flag is set when the counter counts up, when it counts down or both when it counts up and down depending on the CMS bits configuration. The direction bit (DIR) in the TIMx\_CR1 register is updated by hardware and must not be changed by software. Refer to [Center-aligned mode \(up/down counting\) on page 753](#).

Figure 238 shows some center-aligned PWM waveforms in an example where:

- TIMx\_ARR=8,
- PWM mode is the PWM mode 1,
- The flag is set when the counter counts down corresponding to the center-aligned mode 1 selected for CMS=01 in TIMx\_CR1 register.

**Figure 238. Center-aligned PWM waveforms (ARR=8)**

Hints on using center-aligned mode:

- When starting in center-aligned mode, the current up-down configuration is used. It means that the counter counts up or down depending on the value written in the DIR bit

in the TIMx\_CR1 register. Moreover, the DIR and CMS bits must not be changed at the same time by the software.

- Writing to the counter while running in center-aligned mode is not recommended as it can lead to unexpected results. In particular:
  - The direction is not updated if you write a value in the counter that is greater than the auto-reload value (TIMx\_CNT > TIMx\_ARR). For example, if the counter was counting up, it continues to count up.
  - The direction is updated if you write 0 or write the TIMx\_ARR value in the counter but no Update Event UEV is generated.
- The safest way to use center-aligned mode is to generate an update by software (setting the UG bit in the TIMx\_EGR register) just before starting the counter and not to write the counter while it is running.

### 23.3.10 Asymmetric PWM mode

Asymmetric mode allows two center-aligned PWM signals to be generated with a programmable phase shift. While the frequency is determined by the value of the TIMx\_ARR register, the duty cycle and the phase-shift are determined by a pair of TIMx\_CCRx registers. One register controls the PWM during up-counting, the second during down-counting, so that PWM is adjusted every half PWM cycle:

- OC1REFC (or OC2REFC) is controlled by TIMx\_CCR1 and TIMx\_CCR2
- OC3REFC (or OC4REFC) is controlled by TIMx\_CCR3 and TIMx\_CCR4

Asymmetric PWM mode can be selected independently on two channels (one OCx output per pair of CCR registers) by writing '1110' (Asymmetric PWM mode 1) or '1111' (Asymmetric PWM mode 2) in the OCxM bits in the TIMx\_CCMRx register.

*Note:* The OCxM[3:0] bit field is split into two parts for compatibility reasons, the most significant bit is not contiguous with the 3 least significant ones.

When a given channel is used as asymmetric PWM channel, its secondary channel can also be used. For instance, if an OC1REFC signal is generated on channel 1 (Asymmetric PWM mode 1), it is possible to output either the OC2REF signal on channel 2, or an OC2REFC signal resulting from asymmetric PWM mode 2.

Figure 239 shows an example of signals that can be generated using Asymmetric PWM mode (channels 1 to 4 are configured in Asymmetric PWM mode 1).

**Figure 239. Generation of 2 phase-shifted PWM signals with 50% duty cycle**

### 23.3.11 Combined PWM mode

Combined PWM mode allows two edge or center-aligned PWM signals to be generated with programmable delay and phase shift between respective pulses. While the frequency is determined by the value of the TIMx\_ARR register, the duty cycle and delay are determined by the two TIMx\_CCRx registers. The resulting signals, OCxREFC, are made of an OR or AND logical combination of two reference PWMs:

- OC1REFC (or OC2REFC) is controlled by TIMx\_CCR1 and TIMx\_CCR2
- OC3REFC (or OC4REFC) is controlled by TIMx\_CCR3 and TIMx\_CCR4

Combined PWM mode can be selected independently on two channels (one OCx output per pair of CCR registers) by writing '1100' (Combined PWM mode 1) or '1101' (Combined PWM mode 2) in the OCxM bits in the TIMx\_CCMRx register.

When a given channel is used as combined PWM channel, its secondary channel must be configured in the opposite PWM mode (for instance, one in Combined PWM mode 1 and the other in Combined PWM mode 2).

*Note: The OCxM[3:0] bit field is split into two parts for compatibility reasons, the most significant bit is not contiguous with the 3 least significant ones.*

[Figure 240](#) shows an example of signals that can be generated using Asymmetric PWM mode, obtained with the following configuration:

- Channel 1 is configured in Combined PWM mode 2,
- Channel 2 is configured in PWM mode 1,
- Channel 3 is configured in Combined PWM mode 2,
- Channel 4 is configured in PWM mode 1

Figure 240. Combined PWM mode on channels 1 and 3

### 23.3.12 Clearing the OCxREF signal on an external event

The OCxREF signal of a given channel can be cleared when a high level is applied on the ocref\_clr\_int input (OCxCE enable bit in the corresponding TIMx\_CCMRx register set to 1). OCxREF remains low until the next update event (UEV) occurs. This function can only be used in Output compare and PWM modes. It does not work in Forced mode.

OCREF\_CLR\_INPUT can be selected between the OCREF\_CLR input and ETRF (ETR after the filter) by configuring the OCCS bit in the TIMx\_SMCR register.

The OCxREF signal for a given channel can be reset by applying a high level on the ETRF input (OCxCE enable bit set to 1 in the corresponding TIMx\_CCMRx register). OCxREF remains low until the next update event (UEV) occurs.

This function can be used only in the output compare and PWM modes. It does not work in forced mode.

For example, the OCxREF signal can be connected to the output of a comparator to be used for current handling. In this case, ETR must be configured as follows:

1. The external trigger prescaler should be kept off: bits ETPS[1:0] in the TIMx\_SMCR register are cleared to 00.
2. The external clock mode 2 must be disabled: bit ECE in the TIM1\_SMCR register is cleared to 0.
3. The external trigger polarity (ETP) and the external trigger filter (ETF) can be configured according to the application's needs.

Figure 241 shows the behavior of the OCxREF signal when the ETRF input becomes high, for both values of the OCxCE enable bit. In this example, the timer TIMx is programmed in PWM mode.

Figure 241. Clearing TIMx OCxREF

Note:

In case of a PWM with a 100% duty cycle (if  $CCR_x > ARR$ ), OCxREF is enabled again at the next counter overflow.

### 23.3.13 One-pulse mode

One-pulse mode (OPM) is a particular case of the previous modes. It allows the counter to be started in response to a stimulus and to generate a pulse with a programmable length after a programmable delay.

Starting the counter can be controlled through the slave mode controller. Generating the waveform can be done in output compare mode or PWM mode. You select One-pulse mode by setting the OPM bit in the TIMx\_CR1 register. This makes the counter stop automatically at the next update event UEV.

A pulse can be correctly generated only if the compare value is different from the counter initial value. Before starting (when the timer is waiting for the trigger), the configuration must be:

- $CNT < CCRx \leq ARR$  (in particular,  $0 < CCRx$ ),

**Figure 242. Example of one-pulse mode.**

For example you may want to generate a positive pulse on OC1 with a length of  $t_{PULSE}$  and after a delay of  $t_{DELAY}$  as soon as a positive edge is detected on the TI2 input pin.

Let's use TI2FP2 as trigger 1:

1. Map TI2FP2 on TI2 by writing CC2S=01 in the TIMx\_CCMR1 register.
2. TI2FP2 must detect a rising edge, write CC2P=0 and CC2NP='0' in the TIMx\_CCER register.
3. Configure TI2FP2 as trigger for the slave mode controller (TRGI) by writing TS=110 in the TIMx\_SMCR register.
4. TI2FP2 is used to start the counter by writing SMS to '110 in the TIMx\_SMCR register (trigger mode).

The OPM waveform is defined by writing the compare registers (taking into account the clock frequency and the counter prescaler).

- The  $t_{\text{DELAY}}$  is defined by the value written in the TIMx\_CCR1 register.
- The  $t_{\text{PULSE}}$  is defined by the difference between the auto-reload value and the compare value (TIMx\_ARR - TIMx\_CCR1).
- Let's say you want to build a waveform with a transition from '0' to '1' when a compare match occurs and a transition from '1' to '0' when the counter reaches the auto-reload value. To do this you enable PWM mode 2 by writing OC1M=111 in the TIMx\_CCMR1 register. You can optionally enable the preload registers by writing OC1PE=1 in the TIMx\_CCMR1 register and ARPE in the TIMx\_CR1 register. In this case you have to write the compare value in the TIMx\_CCR1 register, the auto-reload value in the TIMx\_ARR register, generate an update by setting the UG bit and wait for external trigger event on TI2. CC1P is written to '0' in this example.

In our example, the DIR and CMS bits in the TIMx\_CR1 register should be low.

You only want 1 pulse (Single mode), so you write '1' in the OPM bit in the TIMx\_CR1 register to stop the counter at the next update event (when the counter rolls over from the auto-reload value back to 0). When OPM bit in the TIMx\_CR1 register is set to '0', so the Repetitive Mode is selected.

#### Particular case: OCx fast enable:

In One-pulse mode, the edge detection on TIx input set the CEN bit which enables the counter. Then the comparison between the counter and the compare value makes the output toggle. But several clock cycles are needed for these operations and it limits the minimum delay  $t_{\text{DELAY}}$  min we can get.

If you want to output a waveform with the minimum delay, you can set the OCxFE bit in the TIMx\_CCMRx register. Then OCxRef (and OCx) is forced in response to the stimulus, without taking in account the comparison. Its new level is the same as if a compare match had occurred. OCxFE acts only if the channel is configured in PWM1 or PWM2 mode.

### 23.3.14 Retriggerable one pulse mode (OPM)

This mode allows the counter to be started in response to a stimulus and to generate a pulse with a programmable length, but with the following differences with Non-retriggerable one pulse mode described in [Section 23.3.13](#):

- The pulse starts as soon as the trigger occurs (no programmable delay)
- The pulse is extended if a new trigger occurs before the previous one is completed

The timer must be in Slave mode, with the bits SMS[3:0] = '1000' (Combined Reset + trigger mode) in the TIMx\_SMCR register, and the OCxM[3:0] bits set to '1000' or '1001' for Retriggerable OPM mode 1 or 2.

If the timer is configured in Up-counting mode, the corresponding CCRx must be set to 0 (the ARR register sets the pulse length). If the timer is configured in Down-counting mode CCRx must be above or equal to ARR.

*Note:* In retriggerable one pulse mode, the CCxIF flag is not significant.

*The OCxM[3:0] and SMS[3:0] bit fields are split into two parts for compatibility reasons, the most significant bit is not contiguous with the 3 least significant ones.*

*This mode must not be used with center-aligned PWM modes. It is mandatory to have CMS[1:0] = 00 in TIMx\_CR1.*

Figure 243 Retriggerable one pulse mode

### 23.3.15 Encoder interface mode

To select Encoder Interface mode write SMS='001 in the TIMx\_SMCR register if the counter is counting on TI2 edges only, SMS=010 if it is counting on TI1 edges only and SMS=011 if it is counting on both TI1 and TI2 edges.

Select the TI1 and TI2 polarity by programming the CC1P and CC2P bits in the TIMx\_CCER register. CC1NP and CC2NP must be kept cleared. When needed, you can program the input filter as well. CC1NP and CC2NP must be kept low.

The two inputs TI1 and TI2 are used to interface to an incremental encoder. Refer to [Table 150](#). The counter is clocked by each valid transition on TI1FP1 or TI2FP2 (TI1 and TI2 after input filter and polarity selection, TI1FP1=TI1 if not filtered and not inverted, TI2FP2=TI2 if not filtered and not inverted) assuming that it is enabled (CEN bit in TIMx\_CR1 register written to '1'). The sequence of transitions of the two inputs is evaluated and generates count pulses as well as the direction signal. Depending on the sequence the counter counts up or down, the DIR bit in the TIMx\_CR1 register is modified by hardware accordingly. The DIR bit is calculated at each transition on any input (TI1 or TI2), whatever the counter is counting on TI1 only, TI2 only or both TI1 and TI2.

Encoder interface mode acts simply as an external clock with direction selection. This means that the counter just counts continuously between 0 and the auto-reload value in the TIMx\_ARR register (0 to ARR or ARR down to 0 depending on the direction). So you must configure TIMx\_ARR before starting. In the same way, the capture, compare, prescaler, trigger output features continue to work as normal.

In this mode, the counter is modified automatically following the speed and the direction of the-quadrature encoder and its content, therefore, always represents the encoder's position. The count direction correspond to the rotation direction of the connected sensor. The table summarizes the possible combinations, assuming TI1 and TI2 don't switch at the same time.

**Table 150. Counting direction versus encoder signals**

| Active edge             | Level on opposite signal (TI1FP1 for TI2, TI2FP2 for TI1) | TI1FP1 signal |          | TI2FP2 signal |          |
|-------------------------|-----------------------------------------------------------|---------------|----------|---------------|----------|
|                         |                                                           | Rising        | Falling  | Rising        | Falling  |
| Counting on TI1 only    | High                                                      | Down          | Up       | No Count      | No Count |
|                         | Low                                                       | Up            | Down     | No Count      | No Count |
| Counting on TI2 only    | High                                                      | No Count      | No Count | Up            | Down     |
|                         | Low                                                       | No Count      | No Count | Down          | Up       |
| Counting on TI1 and TI2 | High                                                      | Down          | Up       | Up            | Down     |
|                         | Low                                                       | Up            | Down     | Down          | Up       |

An external incremental encoder can be connected directly to the MCU without external interface logic. However, comparators are normally be used to convert the encoder's differential outputs to digital signals. This greatly increases noise immunity. The third encoder output which indicate the mechanical zero position, may be connected to an external interrupt input and trigger a counter reset.

[Figure 244](#) gives an example of counter operation, showing count signal generation and direction control. It also shows how input jitter is compensated where both edges are selected. This might occur if the sensor is positioned near to one of the switching points. For this example we assume that the configuration is the following:

- CC1S= 01 (TIMx\_CCMR1 register, TI1FP1 mapped on TI1)
- CC2S= 01 (TIMx\_CCMR2 register, TI2FP2 mapped on TI2)
- CC1P and CC1NP = '0' (TIMx\_CCER register, TI1FP1 noninverted, TI1FP1=TI1)
- CC2P and CC2NP = '0' (TIMx\_CCER register, TI2FP2 noninverted, TI2FP2=TI2)
- SMS= 011 (TIMx\_SMCR register, both inputs are active on both rising and falling edges)
- CEN= 1 (TIMx\_CR1 register, Counter is enabled)

**Figure 244. Example of counter operation in encoder interface mode**

[Figure 245](#) gives an example of counter behavior when TI1FP1 polarity is inverted (same configuration as above except CC1P=1).

**Figure 245. Example of encoder interface mode with TI1FP1 polarity inverted**

The timer, when configured in Encoder Interface mode provides information on the sensor's current position. You can obtain dynamic information (speed, acceleration, deceleration) by measuring the period between two encoder events using a second timer configured in capture mode. The output of the encoder which indicates the mechanical zero can be used for this purpose. Depending on the time between two events, the counter can also be read at regular times. You can do this by latching the counter value into a third input capture register if available (then the capture signal must be periodic and can be generated by another timer). when available, it is also possible to read its value through a DMA request generated by a Real-Time clock.

### 23.3.16 UIF bit remapping

The IUFREMAP bit in the TIMx\_CR1 register forces a continuous copy of the update interrupt flag (UIF) into bit 31 of the timer counter register's bit 31 (TIMxCNT[31]). This allows to atomically read both the counter value and a potential roll-over condition signaled by the UIFCPY flag. It eases the calculation of angular speed by avoiding race conditions caused, for instance, by a processing shared between a background task (counter reading) and an interrupt (update interrupt).

There is no latency between the UIF and UIFCPY flag assertions.

In 32-bit timer implementations, when the IUFREMAP bit is set, bit 31 of the counter is overwritten by the UIFCPY flag upon read access (the counter's most significant bit is only accessible in write mode).

### 23.3.17 Timer input XOR function

The TI1S bit in the TIM1xx\_CR2 register, allows the input filter of channel 1 to be connected to the output of a XOR gate, combining the three input pins TIMx\_CH1 to TIMx\_CH3.

The XOR output can be used with all the timer input functions such as trigger or input capture.

An example of this feature used to interface Hall sensors is given in [Section 22.3.24: Interfacing with Hall sensors on page 698](#).

### 23.3.18 Timers and external trigger synchronization

The TIMx Timers can be synchronized with an external trigger in several modes: Reset mode, Gated mode and Trigger mode.

#### Slave mode: Reset mode

The counter and its prescaler can be reinitialized in response to an event on a trigger input. Moreover, if the URS bit from the TIMx\_CR1 register is low, an update event UEV is generated. Then all the preloaded registers (TIMx\_ARR, TIMx\_CCRx) are updated.

In the following example, the upcounter is cleared in response to a rising edge on TI1 input:

1. Configure the channel 1 to detect rising edges on TI1. Configure the input filter duration (in this example, we don't need any filter, so we keep IC1F=0000). The capture prescaler is not used for triggering, so you don't need to configure it. The CC1S bits select the input capture source only, CC1S = 01 in the TIMx\_CCMR1 register. Write CC1P=0 and CC1NP=0 in TIMx\_CCER register to validate the polarity (and detect rising edges only).
2. Configure the timer in reset mode by writing SMS=100 in TIMx\_SMCR register. Select TI1 as the input source by writing TS=101 in TIMx\_SMCR register.
3. Start the counter by writing CEN=1 in the TIMx\_CR1 register.

The counter starts counting on the internal clock, then behaves normally until TI1 rising edge. When TI1 rises, the counter is cleared and restarts from 0. In the meantime, the trigger flag is set (TIF bit in the TIMx\_SR register) and an interrupt request, or a DMA request can be sent if enabled (depending on the TIE and TDE bits in TIMx\_DIER register).

The following figure shows this behavior when the auto-reload register TIMx\_ARR=0x36. The delay between the rising edge on TI1 and the actual reset of the counter is due to the resynchronization circuit on TI1 input.

**Figure 246. Control circuit in reset mode**

#### Slave mode: Gated mode

The counter can be enabled depending on the level of a selected input.

In the following example, the upcounter counts only when TI1 input is low:

1. Configure the channel 1 to detect low levels on TI1. Configure the input filter duration (in this example, we don't need any filter, so we keep IC1F=0000). The capture prescaler is not used for triggering, so you don't need to configure it. The CC1S bits select the input capture source only, CC1S=01 in TIMx\_CCMR1 register. Write CC1P=1 and CC1NP=0 in TIMx\_CCER register to validate the polarity (and detect low level only).
2. Configure the timer in gated mode by writing SMS=101 in TIMx\_SMCR register. Select TI1 as the input source by writing TS=101 in TIMx\_SMCR register.
3. Enable the counter by writing CEN=1 in the TIMx\_CR1 register (in gated mode, the counter doesn't start if CEN=0, whatever is the trigger input level).

The counter starts counting on the internal clock as long as TI1 is low and stops as soon as TI1 becomes high. The TIF flag in the TIMx\_SR register is set both when the counter starts or stops.

The delay between the rising edge on TI1 and the actual stop of the counter is due to the resynchronization circuit on TI1 input.

**Figure 247. Control circuit in gated mode**

1. The configuration "CCxP=CCxNP=1" (detection of both rising and falling edges) does not have any effect in gated mode because gated mode acts on a level and not on an edge.

**Note:** *The configuration "CCxP=CCxNP=1" (detection of both rising and falling edges) does not have any effect in gated mode because gated mode acts on a level and not on an edge.*

### Slave mode: Trigger mode

The counter can start in response to an event on a selected input.

In the following example, the upcounter starts in response to a rising edge on TI2 input:

1. Configure the channel 2 to detect rising edges on TI2. Configure the input filter duration (in this example, we don't need any filter, so we keep IC2F=0000). The capture prescaler is not used for triggering, so you don't need to configure it. CC2S bits are selecting the input capture source only, CC2S=01 in TIMx\_CCMR1 register. Write

CC2P=1 and CC2NP=0 in TIMx\_CCER register to validate the polarity (and detect low level only).

2. Configure the timer in trigger mode by writing SMS=110 in TIMx\_SMCR register. Select TI2 as the input source by writing TS=110 in TIMx\_SMCR register.

When a rising edge occurs on TI2, the counter starts counting on the internal clock and the TIF flag is set.

The delay between the rising edge on TI2 and the actual start of the counter is due to the resynchronization circuit on TI2 input.

**Figure 248. Control circuit in trigger mode**

### Slave mode: External Clock mode 2 + trigger mode

The external clock mode 2 can be used in addition to another slave mode (except external clock mode 1 and encoder mode). In this case, the ETR signal is used as external clock input, and another input can be selected as trigger input when operating in reset mode, gated mode or trigger mode. It is recommended not to select ETR as TRGI through the TS bits of TIMx\_SMCR register.

In the following example, the upcounter is incremented at each rising edge of the ETR signal as soon as a rising edge of TI1 occurs:

1. Configure the external trigger input circuit by programming the TIMx\_SMCR register as follows:
  - ETF = 0000: no filter
  - ETPS=00: prescaler disabled
  - ETP=0: detection of rising edges on ETR and ECE=1 to enable the external clock mode 2.
2. Configure the channel 1 as follows, to detect rising edges on TI1:
  - IC1F=0000: no filter.
  - The capture prescaler is not used for triggering and does not need to be configured.
  - CC1S=01 in TIMx\_CCMR1 register to select only the input capture source
  - CC1P=0 and CC1NP=0 in TIMx\_CCER register to validate the polarity (and detect rising edge only).
3. Configure the timer in trigger mode by writing SMS=110 in TIMx\_SMCR register. Select TI1 as the input source by writing TS=101 in TIMx\_SMCR register.

A rising edge on TI1 enables the counter and sets the TIF flag. The counter then counts on ETR rising edges.

The delay between the rising edge of the ETR signal and the actual reset of the counter is due to the resynchronization circuit on ETRP input.

**Figure 249. Control circuit in external clock mode 2 + trigger mode**

### 23.3.19 Timer synchronization

The TIMx timers are linked together internally for timer synchronization or chaining. When one Timer is configured in Master Mode, it can reset, start, stop or clock the counter of another Timer configured in Slave Mode.

*Figure 250: Master/Slave timer example* presents an overview of the trigger selection and the master mode selection blocks.

**Figure 250. Master/Slave timer example**

### Using one timer as prescaler for another timer

For example, you can configure TIM3 to act as a prescaler for TIM. Refer to [Figure 250](#). To do this:

1. Configure TIM3 in master mode so that it outputs a periodic trigger signal on each update event UEV. If you write MMS=010 in the TIM3\_CR2 register, a rising edge is output on TRGO each time an update event is generated.
2. To connect the TRGO output of TIM3 to TIM, TIM must be configured in slave mode using ITR2 as internal trigger. You select this through the TS bits in the TIM\_SMCR register (writing TS=010).
3. Then you put the slave mode controller in external clock mode 1 (write SMS=111 in the TIM\_SMCR register). This causes TIM to be clocked by the rising edge of the periodic TIM3 trigger signal (which correspond to the TIM3 counter overflow).
4. Finally both timers must be enabled by setting their respective CEN bits (TIMx\_CR1 register).

**Note:** If OCx is selected on TIM3 as the trigger output (MMS=1xx), its rising edge is used to clock the counter of TIM.

### Using one timer to enable another timer

In this example, we control the enable of TIM with the output compare 1 of Timer 3. Refer to [Figure 250](#) for connections. TIM counts on the divided internal clock only when OC1REF of TIM3 is high. Both counter clock frequencies are divided by 3 by the prescaler compared to CK\_INT ( $f_{CK\_CNT} = f_{CK\_INT}/3$ ).

1. Configure TIM3 master mode to send its Output Compare 1 Reference (OC1REF) signal as trigger output (MMS=100 in the TIM3\_CR2 register).
2. Configure the TIM3 OC1REF waveform (TIM3\_CCMR1 register).
3. Configure TIM to get the input trigger from TIM3 (TS=010 in the TIM\_SMCR register).
4. Configure TIM in gated mode (SMS=101 in TIM\_SMCR register).
5. Enable TIM by writing '1 in the CEN bit (TIM\_CR1 register).
6. Start TIM3 by writing '1 in the CEN bit (TIM3\_CR1 register).

**Note:** The counter clock is not synchronized with counter 1, this mode only affects the TIM counter enable signal.

**Figure 251. Gating TIM with OC1REF of TIM3**

In the example in [Figure 251](#), the TIM counter and prescaler are not initialized before being started. So they start counting from their current value. It is possible to start from a given

value by resetting both timers before starting TIM3. You can then write any value you want in the timer counters. The timers can easily be reset by software using the UG bit in the TIMx\_EGR registers.

In the next example (refer to [Figure 252](#)), we synchronize TIM3 and TIM. TIM3 is the master and starts from 0. TIM is the slave and starts from 0xE7. The prescaler ratio is the same for both timers. TIM stops when TIM3 is disabled by writing '0 to the CEN bit in the TIM3\_CR1 register:

1. Configure TIM3 master mode to send its Output Compare 1 Reference (OC1REF) signal as trigger output (MMS=100 in the TIM3\_CR2 register).
2. Configure the TIM3 OC1REF waveform (TIM3\_CCMR1 register).
3. Configure TIM to get the input trigger from TIM3 (TS=010 in the TIM\_SMCR register).
4. Configure TIM in gated mode (SMS=101 in TIM\_SMCR register).
5. Reset TIM3 by writing '1 in UG bit (TIM3\_EGR register).
6. Reset TIM by writing '1 in UG bit (TIM\_EGR register).
7. Initialize TIM to 0xE7 by writing '0xE7' in the TIM counter (TIM\_CNT).
8. Enable TIM by writing '1 in the CEN bit (TIM\_CR1 register).
9. Start TIM3 by writing '1 in the CEN bit (TIM3\_CR1 register).
10. Stop TIM3 by writing '0 in the CEN bit (TIM3\_CR1 register).

**Figure 252. Gating TIM with Enable of TIM3**

### Using one timer to start another timer

In this example, we set the enable of Timer with the update event of Timer 3. Refer to [Figure 250](#) for connections. Timer starts counting from its current value (which can be non-zero) on the divided internal clock as soon as the update event is generated by Timer 1. When Timer receives the trigger signal its CEN bit is automatically set and the counter counts until we write '0 to the CEN bit in the TIM\_CR1 register. Both counter clock frequencies are divided by 3 by the prescaler compared to CK\_INT ( $f_{CK\_CNT} = f_{CK\_INT}/3$ ).

1. Configure TIM3 master mode to send its Update Event (UEV) as trigger output (MMS=010 in the TIM3\_CR2 register).
2. Configure the TIM3 period (TIM3\_ARR registers).
3. Configure TIM to get the input trigger from TIM3 (TS=010 in the TIM\_SMCR register).
4. Configure TIM in trigger mode (SMS=110 in TIM\_SMCR register).
5. Start TIM3 by writing '1' in the CEN bit (TIM3\_CR1 register).

**Figure 253. Triggering TIM with update of TIM3**

As in the previous example, you can initialize both counters before starting counting. [Figure 254](#) shows the behavior with the same configuration as in [Figure 253](#) but in trigger mode instead of gated mode (SMS=110 in the TIM\_SMCR register).

**Figure 254. Triggering TIM with Enable of TIM3**

### Starting 2 timers synchronously in response to an external trigger

In this example, we set the enable of TIM3 when its TI1 input rises, and the enable of TIM2 with the enable of TIM3. Refer to [Figure 250](#) for connections. To ensure the counters are aligned, TIM3 must be configured in Master/Slave mode (slave with respect to TI1, master with respect to TIM2):

1. Configure TIM3 master mode to send its Enable as trigger output (MMS=001 in the TIM3\_CR2 register).
2. Configure TIM3 slave mode to get the input trigger from TI1 (TS=100 in the TIM3\_SMCR register).
3. Configure TIM3 in trigger mode (SMS=110 in the TIM3\_SMCR register).
4. Configure the TIM3 in Master/Slave mode by writing MSM=1 (TIM3\_SMCR register).
5. Configure TIM2 to get the input trigger from TIM3 (TS=000 in the TIM2\_SMCR register).
6. Configure TIM2 in trigger mode (SMS=110 in the TIM2\_SMCR register).

When a rising edge occurs on TI1 (TIM3), both counters starts counting synchronously on the internal clock and both TIF flags are set.

**Note:** In this example both timers are initialized before starting (by setting their respective UG bits). Both counters starts from 0, but you can easily insert an offset between them by writing any of the counter registers (TIMx\_CNT). You can see that the master/slave mode insert a delay between CNT\_EN and CK\_PSC on TIM3.

### Figure 255. Triggering TIM3 and TIM2 with TIM3 TI1 input

*Note: The clock of the slave peripherals (timer, ADC, ...) receiving the TRGO or the TRGO2 signals must be enabled prior to receive events from the master timer, and the clock frequency (prescaler) must not be changed on-the-fly while triggers are received from the master timer.*

### 23.3.20 DMA burst mode

The TIMx timers have the capability to generate multiple DMA requests upon a single event. The main purpose is to be able to re-program part of the timer multiple times without software overhead, but it can also be used to read several registers in a row, at regular intervals.

The DMA controller destination is unique and must point to the virtual register TIMx\_DMAR. On a given timer event, the timer launches a sequence of DMA requests (burst). Each write into the TIMx\_DMAR register is actually redirected to one of the timer registers.

The DBL[4:0] bits in the TIMx\_DCR register set the DMA burst length. The timer recognizes a burst transfer when a read or a write access is done to the TIMx\_DMAR address), i.e. the number of transfers (either in half-words or in bytes).

The DBA[4:0] bits in the TIMx\_DCR registers define the DMA base address for DMA transfers (when read/write access are done through the TIMx\_DMAR address). DBA is defined as an offset starting from the address of the TIMx\_CR1 register:

Example:

00000: TIMx\_CR1

00001: TIMx\_CR2

00010: TIMx\_SMCR

As an example, the timer DMA burst feature is used to update the contents of the CCRx registers (x = 2, 3, 4) upon an update event, with the DMA transferring half words into the CCRx registers.

This is done in the following steps:

1. Configure the corresponding DMA channel as follows:
  - DMA channel peripheral address is the DMAR register address
  - DMA channel memory address is the address of the buffer in the RAM containing the data to be transferred by DMA into CCRx registers.
  - Number of data to transfer = 3 (See note below).
  - Circular mode disabled.
2. Configure the DCR register by configuring the DBA and DBL bit fields as follows:  
DBL = 3 transfers, DBA = 0xE.
3. Enable the TIMx update DMA request (set the UDE bit in the DIER register).
4. Enable TIMx
5. Enable the DMA channel

This example is for the case where every CCRx register has to be updated once. If every CCRx register is to be updated twice for example, the number of data to transfer should be 6. Let's take the example of a buffer in the RAM containing data1, data2, data3, data4, data5 and data6. The data is transferred to the CCRx registers as follows: on the first update DMA request, data1 is transferred to CCR2, data2 is transferred to CCR3, data3 is transferred to CCR4 and on the second update DMA request, data4 is transferred to CCR2, data5 is transferred to CCR3 and data6 is transferred to CCR4.

*Note: A null value can be written to the reserved registers.*

### 23.3.21 Debug mode

When the microcontroller enters debug mode (Cortex<sup>®</sup>-M7 core - halted), the TIMx counter either continues to work normally or stops, depending on DBG\_TIMx\_STOP configuration bit in DBGMCU module. For more details, refer to [Section 40.16.2: Debug support for timers, watchdog, bxCAN and I2C](#).

## 23.4 TIM2/TIM3/TIM4/TIM5 registers

Refer to [Section 1.2](#) for a list of abbreviations used in register descriptions.

The peripheral registers can be accessed by half-words (16-bit) or words (32-bit).

### 23.4.1 TIMx control register 1 (TIMx\_CR1)(x = 2 to 5)

Address offset: 0x00

Reset value: 0x0000

| 15   | 14   | 13   | 12   | 11           | 10   | 9        | 8  | 7    | 6   | 5  | 4   | 3   | 2   | 1    | 0   |
|------|------|------|------|--------------|------|----------|----|------|-----|----|-----|-----|-----|------|-----|
| Res. | Res. | Res. | Res. | UIFRE<br>MAP | Res. | CKD[1:0] |    | ARPE | CMS |    | DIR | OPM | URS | UDIS | CEN |
|      |      |      |      | rW           |      | rW       | rW | rW   | rW  | rW | rW  | rW  | rW  | rW   | rW  |

Bits 15:12 Reserved, must be kept at reset value.

Bit 11 **UIFREMAP**: UIF status bit remapping

0: No remapping. UIF status bit is not copied to TIMx\_CNT register bit 31.

1: Remapping enabled. UIF status bit is copied to TIMx\_CNT register bit 31.

Bit 10 Reserved, must be kept at reset value.

Bits 9:8 **CKD[1:0]**: Clock division

This bit-field indicates the division ratio between the timer clock (CK\_INT) frequency and sampling clock used by the digital filters (ETR, Tlx),

00:  $t_{DTS} = t_{CK\_INT}$

01:  $t_{DTS} = 2 \times t_{CK\_INT}$

10:  $t_{DTS} = 4 \times t_{CK\_INT}$

11: Reserved

Bit 7 **ARPE**: Auto-reload preload enable

0: TIMx\_ARR register is not buffered

1: TIMx\_ARR register is buffered

Bits 6:5 **CMS**: Center-aligned mode selection

00: Edge-aligned mode. The counter counts up or down depending on the direction bit (DIR).

01: Center-aligned mode 1. The counter counts up and down alternatively. Output compare interrupt flags of channels configured in output (CCxS=00 in TIMx\_CCMRx register) are set only when the counter is counting down.

10: Center-aligned mode 2. The counter counts up and down alternatively. Output compare interrupt flags of channels configured in output (CCxS=00 in TIMx\_CCMRx register) are set only when the counter is counting up.

11: Center-aligned mode 3. The counter counts up and down alternatively. Output compare interrupt flags of channels configured in output (CCxS=00 in TIMx\_CCMRx register) are set both when the counter is counting up or down.

*Note: It is not allowed to switch from edge-aligned mode to center-aligned mode as long as the counter is enabled (CEN=1)*

Bit 4 **DIR**: Direction

0: Counter used as upcounter

1: Counter used as downcounter

*Note: This bit is read only when the timer is configured in Center-aligned mode or Encoder mode.*

Bit 3 **OPM**: One-pulse mode

0: Counter is not stopped at update event

1: Counter stops counting at the next update event (clearing the bit CEN)

Bit 2 **URS**: Update request source

This bit is set and cleared by software to select the UEV event sources.

0: Any of the following events generate an update interrupt or DMA request if enabled.

These events can be:

- Counter overflow/underflow
- Setting the UG bit
- Update generation through the slave mode controller

1: Only counter overflow/underflow generates an update interrupt or DMA request if enabled.

Bit 1 **UDIS**: Update disable

This bit is set and cleared by software to enable/disable UEV event generation.

0: UEV enabled. The Update (UEV) event is generated by one of the following events:

- Counter overflow/underflow
- Setting the UG bit
- Update generation through the slave mode controller

Buffered registers are then loaded with their preload values.

1: UEV disabled. The Update event is not generated, shadow registers keep their value (ARR, PSC, CCRx). However the counter and the prescaler are reinitialized if the UG bit is set or if a hardware reset is received from the slave mode controller.

Bit 0 **CEN**: Counter enable

0: Counter disabled

1: Counter enabled

*Note: External clock, gated mode and encoder mode can work only if the CEN bit has been previously set by software. However trigger mode can set the CEN bit automatically by hardware.*

CEN is cleared automatically in one-pulse mode, when an update event occurs.

## 23.4.2 TIMx control register 2 (TIMx\_CR2)(x = 2 to 5)

Address offset: 0x04

Reset value: 0x0000

| 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6        | 5  | 4  | 3    | 2    | 1    | 0    |
|------|------|------|------|------|------|------|------|------|----------|----|----|------|------|------|------|
| Res. | Res. | Res. | Res. | Res. | Res. | Res. | Res. | TI1S | MMS[2:0] |    |    | CCDS | Res. | Res. | Res. |
|      |      |      |      |      |      |      |      | rw   | rw       | rw | rw | rw   |      |      |      |

Bits 15:8 Reserved, must be kept at reset value.

Bit 7 **TI1S**: TI1 selection

0: The TIMx\_CH1 pin is connected to TI1 input

1: The TIMx\_CH1, CH2 and CH3 pins are connected to the TI1 input (XOR combination)

See also [Section 22.3.24: Interfacing with Hall sensors on page 698](#)

Bits 6:4 **MMS[2:0]**: Master mode selection

These bits allow to select the information to be sent in master mode to slave timers for synchronization (TRGO). The combination is as follows:

000: **Reset** - the UG bit from the TIMx\_EGR register is used as trigger output (TRGO). If the reset is generated by the trigger input (slave mode controller configured in reset mode) then the signal on TRGO is delayed compared to the actual reset.

001: **Enable** - the Counter enable signal, CNT\_EN, is used as trigger output (TRGO). It is useful to start several timers at the same time or to control a window in which a slave timer is enabled. The Counter Enable signal is generated by a logic OR between CEN control bit and the trigger input when configured in gated mode.

When the Counter Enable signal is controlled by the trigger input, there is a delay on TRGO, except if the master/slave mode is selected (see the MSM bit description in TIMx\_SMCR register).

010: **Update** - The update event is selected as trigger output (TRGO). For instance a master timer can then be used as a prescaler for a slave timer.

011: **Compare Pulse** - The trigger output send a positive pulse when the CC1IF flag is to be set (even if it was already high), as soon as a capture or a compare match occurred. (TRGO)

100: **Compare** - OC1REF signal is used as trigger output (TRGO)

101: **Compare** - OC2REF signal is used as trigger output (TRGO)

110: **Compare** - OC3REF signal is used as trigger output (TRGO)

111: **Compare** - OC4REF signal is used as trigger output (TRGO)

*Note: The clock of the slave timer or ADC must be enabled prior to receive events from the master timer, and must not be changed on-the-fly while triggers are received from the master timer.*

Bit 3 **CCDS**: Capture/compare DMA selection

0: CCx DMA request sent when CCx event occurs

1: CCx DMA requests sent when update event occurs

Bits 2:0 Reserved, must be kept at reset value.

### 23.4.3 TIMx slave mode control register (TIMx\_SMCR)(x = 2 to 5)

Address offset: 0x08

Reset value: 0x0000 0000

|      |      |           |      |          |      |      |      |      |         |      |      |      |          |      |        |
|------|------|-----------|------|----------|------|------|------|------|---------|------|------|------|----------|------|--------|
| 31   | 30   | 29        | 28   | 27       | 26   | 25   | 24   | 23   | 22      | 21   | 20   | 19   | 18       | 17   | 16     |
| Res. | Res. | Res.      | Res. | Res.     | Res. | Res. | Res. | Res. | Res.    | Res. | Res. | Res. | Res.     | Res. | SMS[3] |
|      |      |           |      |          |      |      |      |      |         |      |      |      |          |      | rw     |
| 15   | 14   | 13        | 12   | 11       | 10   | 9    | 8    | 7    | 6       | 5    | 4    | 3    | 2        | 1    | 0      |
| ETP  | ECE  | ETPS[1:0] |      | ETF[3:0] |      |      |      | MSM  | TS[2:0] |      |      | OCCS | SMS[2:0] |      |        |
| rw   | rw   | rw        | rw   | rw       | rw   | rw   | rw   | rw   | rw      | rw   | rw   | rw   | rw       | rw   | rw     |

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **SMS[3]**: Slave mode selection - bit 3

Refer to SMS description - bits 2:0.

Bit 15 **ETP**: External trigger polarity

This bit selects whether ETR or  $\overline{\text{ETR}}$  is used for trigger operations

0: ETR is non-inverted, active at high level or rising edge

1: ETR is inverted, active at low level or falling edge

Bit 14 **ECE**: External clock enable

This bit enables External clock mode 2.

0: External clock mode 2 disabled

1: External clock mode 2 enabled. The counter is clocked by any active edge on the ETRF signal.

**1:** Setting the ECE bit has the same effect as selecting external clock mode 1 with TRGI connected to ETRF (SMS=111 and TS=111).

**2:** It is possible to simultaneously use external clock mode 2 with the following slave modes: reset mode, gated mode and trigger mode. Nevertheless, TRGI must not be connected to ETRF in this case (TS bits must not be 111).

**3:** If external clock mode 1 and external clock mode 2 are enabled at the same time, the external clock input is ETRF.

Bits 13:12 **ETPS[1:0]**: External trigger prescaler

External trigger signal ETRP frequency must be at most 1/4 of CK\_INT frequency. A prescaler can be enabled to reduce ETRP frequency. It is useful when inputting fast external clocks.

00: Prescaler OFF

01: ETRP frequency divided by 2

10: ETRP frequency divided by 4

11: ETRP frequency divided by 8

Bits 11:8 **ETF[3:0]**: External trigger filter

This bit-field then defines the frequency used to sample ETRP signal and the length of the digital filter applied to ETRP. The digital filter is made of an event counter in which N consecutive events are needed to validate a transition on the output:

0000: No filter, sampling is done at  $f_{DTS}$

0001:  $f_{SAMPLING}=f_{CK\_INT}$ , N=2

0010:  $f_{SAMPLING}=f_{CK\_INT}$ , N=4

0011:  $f_{SAMPLING}=f_{CK\_INT}$ , N=8

0100:  $f_{SAMPLING}=f_{DTS}/2$ , N=6

0101:  $f_{SAMPLING}=f_{DTS}/2$ , N=8

0110:  $f_{SAMPLING}=f_{DTS}/4$ , N=6

0111:  $f_{SAMPLING}=f_{DTS}/4$ , N=8

1000:  $f_{SAMPLING}=f_{DTS}/8$ , N=6

1001:  $f_{SAMPLING}=f_{DTS}/8$ , N=8

1010:  $f_{SAMPLING}=f_{DTS}/16$ , N=5

1011:  $f_{SAMPLING}=f_{DTS}/16$ , N=6

1100:  $f_{SAMPLING}=f_{DTS}/16$ , N=8

1101:  $f_{SAMPLING}=f_{DTS}/32$ , N=5

1110:  $f_{SAMPLING}=f_{DTS}/32$ , N=6

1111:  $f_{SAMPLING}=f_{DTS}/32$ , N=8

Bit 7 **MSM**: Master/Slave mode

0: No action

1: The effect of an event on the trigger input (TRGI) is delayed to allow a perfect synchronization between the current timer and its slaves (through TRGO). It is useful if we want to synchronize several timers on a single external event.

Bits 6:4 **TS**: Trigger selection

This bit-field selects the trigger input to be used to synchronize the counter.

000: Internal Trigger 0 (ITR0).

001: Internal Trigger 1 (ITR1).

010: Internal Trigger 2 (ITR2).

011: Internal Trigger 3 (ITR3).

100: TI1 Edge Detector (TI1F\_ED)

101: Filtered Timer Input 1 (TI1FP1)

110: Filtered Timer Input 2 (TI2FP2)

111: External Trigger input (ETRF)

See [Table 151: TIMx internal trigger connection on page 794](#) for more details on ITRx meaning for each Timer.

*Note: These bits must be changed only when they are not used (e.g. when SMS=000) to avoid wrong edge detections at the transition.*

Bit 3 **OCCS**: OCREF clear selection

This bit is used to select the OCREF clear source

0: OCREF\_CLR\_INT is connected to the OCREF\_CLR input

1: OCREF\_CLR\_INT is connected to ETRF

Bits 16, 2, 1, 0 **SMS[3:0]**: Slave mode selection

When external signals are selected the active edge of the trigger signal (TRGI) is linked to the polarity selected on the external input (see Input Control register and Control Register description).

0000: Slave mode disabled - if CEN = '1 then the prescaler is clocked directly by the internal clock.

0001: Encoder mode 1 - Counter counts up/down on TI1FP1 edge depending on TI2FP2 level.

0010: Encoder mode 2 - Counter counts up/down on TI2FP2 edge depending on TI1FP1 level.

0011: Encoder mode 3 - Counter counts up/down on both TI1FP1 and TI2FP2 edges depending on the level of the other input.

0100: Reset Mode - Rising edge of the selected trigger input (TRGI) reinitializes the counter and generates an update of the registers.

0101: Gated Mode - The counter clock is enabled when the trigger input (TRGI) is high. The counter stops (but is not reset) as soon as the trigger becomes low. Both start and stop of the counter are controlled.

0110: Trigger Mode - The counter starts at a rising edge of the trigger TRGI (but it is not reset). Only the start of the counter is controlled.

0111: External Clock Mode 1 - Rising edges of the selected trigger (TRGI) clock the counter.

1000: Combined reset + trigger mode - Rising edge of the selected trigger input (TRGI) reinitializes the counter, generates an update of the registers and starts the counter.

*Note: The gated mode must not be used if TI1F\_ED is selected as the trigger input (TS=100). Indeed, TI1F\_ED outputs 1 pulse for each transition on TI1F, whereas the gated mode checks the level of the trigger signal.*

*Note: The clock of the slave peripherals (timer, ADC, ...) receiving the TRGO or the TRGO2 signals must be enabled prior to receive events from the master timer, and the clock frequency (prescaler) must not be changed on-the-fly while triggers are received from the master timer.*

Table 151. TIMx internal trigger connection

| Slave TIM | ITR0 (TS = 000) | ITR1 (TS = 001)                                   | ITR2 (TS = 010) | ITR3 (TS = 011) |
|-----------|-----------------|---------------------------------------------------|-----------------|-----------------|
| TIM2      | TIM1            | TIM8/ETH_PTP/OTG_FS_SOF/OTG_HS_SOF <sup>(1)</sup> | TIM3            | TIM4            |
| TIM3      | TIM1            | TIM2                                              | TIM5            | TIM4            |
| TIM4      | TIM1            | TIM2                                              | TIM3            | TIM8            |
| TIM5      | TIM2            | TIM3                                              | TIM4            | TIM8            |

1. Depends on the bit ITR1\_RMP in TIM2\_OR1 register.

### 23.4.4 TIMx DMA/Interrupt enable register (TIMx\_DIER)(x = 2 to 5)

Address offset: 0x0C

Reset value: 0x0000

Bits 15:13 Reserved, must be kept at reset value.

Bit 12 **CC4OF**: Capture/Compare 4 overcapture flag  
 refer to CC1OF description

Bit 11 **CC3OF**: Capture/Compare 3 overcapture flag  
 refer to CC1OF description

Bit 10 **CC2OF**: Capture/compare 2 overcapture flag  
 refer to CC1OF description

Bit 9 **CC1OF**: Capture/Compare 1 overcapture flag  
 This flag is set by hardware only when the corresponding channel is configured in input capture mode. It is cleared by software by writing it to '0'.  
 0: No overcapture has been detected.  
 1: The counter value has been captured in TIMx\_CCR1 register while CC1IF flag was already set

Bits 8:7 Reserved, must be kept at reset value.

Bit 6 **TIF**: Trigger interrupt flag  
 This flag is set by hardware on trigger event (active edge detected on TRGI input when the slave mode controller is enabled in all modes but gated mode. It is set when the counter starts or stops when gated mode is selected. It is cleared by software.  
 0: No trigger event occurred.  
 1: Trigger interrupt pending.

Bit 5 Reserved, must be kept at reset value.

Bit 4 **CC4IF**: Capture/Compare 4 interrupt flag

Refer to CC1IF description

Bit 3 **CC3IF**: Capture/Compare 3 interrupt flag

Refer to CC1IF description

Bit 2 **CC2IF**: Capture/Compare 2 interrupt flag

Refer to CC1IF description

Bit 1 **CC1IF**: Capture/compare 1 interrupt flag

**If channel CC1 is configured as output:** This flag is set by hardware when the counter matches the compare value, with some exception in center-aligned mode (refer to the CMS bits in the TIMx\_CR1 register description) and in retriggeable one pulse mode. It is cleared by software.

0: No match.

1: The content of the counter TIMx\_CNT has matched the content of the TIMx\_CCR1 register.

**If channel CC1 is configured as input:** This bit is set by hardware on a capture. It is cleared by software or by reading the TIMx\_CCR1 register.

0: No input capture occurred.

1: The counter value has been captured in TIMx\_CCR1 register (An edge has been detected on IC1 which matches the selected polarity).

Bit 0 **UIF**: Update interrupt flag

This bit is set by hardware on an update event. It is cleared by software.

0: No update occurred

1: Update interrupt pending. This bit is set by hardware when the registers are updated:

At overflow or underflow (for TIM2 to TIM4) and if UDIS=0 in the TIMx\_CR1 register.

When CNT is reinitialized by software using the UG bit in TIMx\_EGR register, if URS=0 and UDIS=0 in the TIMx\_CR1 register.

When CNT is reinitialized by a trigger event (refer to the synchro control register description), if URS=0 and UDIS=0 in the TIMx\_CR1 register.

### 23.4.6 TIMx event generation register (TIMx\_EGR)(x = 2 to 5)

Address offset: 0x14

Reset value: 0x0000

| 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6  | 5    | 4    | 3    | 2    | 1    | 0  |

|      |      |      |      |      |      |      |      |      | w  |      | w    | w    | w    | w    | w  |

Bits 15:7 Reserved, must be kept at reset value.

Bit 6 **TG**: Trigger generation

This bit is set by software in order to generate an event, it is automatically cleared by hardware.

0: No action

1: The TIF flag is set in TIMx\_SR register. Related interrupt or DMA transfer can occur if enabled.

Bit 5 Reserved, must be kept at reset value.

Bit 4 **CC4G**: Capture/compare 4 generation

Refer to CC1G description

Bit 3 **CC3G**: Capture/compare 3 generation

Refer to CC1G description

Bit 2 **CC2G**: Capture/compare 2 generation

Refer to CC1G description

Bit 1 **CC1G**: Capture/compare 1 generation

This bit is set by software in order to generate an event, it is automatically cleared by hardware.

0: No action

1: A capture/compare event is generated on channel 1:

**If channel CC1 is configured as output:**

CC1IF flag is set, Corresponding interrupt or DMA request is sent if enabled.

**If channel CC1 is configured as input:**

The current value of the counter is captured in TIMx\_CCR1 register. The CC1IF flag is set, the corresponding interrupt or DMA request is sent if enabled. The CC1OF flag is set if the CC1IF flag was already high.

Bit 0 **UG**: Update generation

This bit can be set by software, it is automatically cleared by hardware.

0: No action

1: Re-initialize the counter and generates an update of the registers. Note that the prescaler counter is cleared too (anyway the prescaler ratio is not affected). The counter is cleared if the center-aligned mode is selected or if DIR=0 (upcounting), else it takes the auto-reload value (TIMx\_ARR) if DIR=1 (downcounting).

### 23.4.7 TIMx capture/compare mode register 1 (TIMx\_CCMR1)(x = 2 to 5)

Address offset: 0x18

Reset value: 0x0000

The channels can be used in input (capture mode) or in output (compare mode). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function in input and in output mode. For a given bit, OCxx describes its function when the channel is configured in output, ICxx describes its function when the channel is configured in input. So you must take care that the same bit can have a different meaning for the input stage and for the output stage.

#### Output compare mode

Bits 31:25 Reserved, always read as 0.

Bit 24 **OC2M[3]**: Output Compare 2 mode - bit 3

Bits 23:17 Reserved, always read as 0.

- Bit 16 **OC1M[3]**: Output Compare 1 mode - bit 3
- Bit 15 **OC2CE**: Output compare 2 clear enable
- Bits 14:12 **OC2M[2:0]**: Output compare 2 mode  
refer to OC1M description on bits 6:4
- Bit 11 **OC2PE**: Output compare 2 preload enable
- Bit 10 **OC2FE**: Output compare 2 fast enable
- Bits 9:8 **CC2S[1:0]**: Capture/Compare 2 selection  
This bit-field defines the direction of the channel (input/output) as well as the used input.  
00: CC2 channel is configured as output  
01: CC2 channel is configured as input, IC2 is mapped on TI2  
10: CC2 channel is configured as input, IC2 is mapped on TI1  
11: CC2 channel is configured as input, IC2 is mapped on TRC. This mode is working only if  
an internal trigger input is selected through the TS bit (TIMx\_SMCR register)  
*Note: CC2S bits are writable only when the channel is OFF (CC2E = 0 in TIMx\_CCER).*
- Bit 7 **OC1CE**: Output compare 1 clear enable  
0: OC1Ref is not affected by the ETRF input  
1: OC1Ref is cleared as soon as a High level is detected on ETRF input

Bits 6:4 **OC1M**: Output compare 1 mode

These bits define the behavior of the output reference signal OC1REF from which OC1 and OC1N are derived. OC1REF is active high whereas OC1 and OC1N active level depends on CC1P and CC1NP bits.

0000: Frozen - The comparison between the output compare register TIMx\_CCR1 and the counter TIMx\_CNT has no effect on the outputs.(this mode is used to generate a timing base).

0001: Set channel 1 to active level on match. OC1REF signal is forced high when the counter TIMx\_CNT matches the capture/compare register 1 (TIMx\_CCR1).

0010: Set channel 1 to inactive level on match. OC1REF signal is forced low when the counter TIMx\_CNT matches the capture/compare register 1 (TIMx\_CCR1).

0011: Toggle - OC1REF toggles when TIMx\_CNT=TIMx\_CCR1.

0100: Force inactive level - OC1REF is forced low.

0101: Force active level - OC1REF is forced high.

0110: PWM mode 1 - In upcounting, channel 1 is active as long as TIMx\_CNT<TIMx\_CCR1 else inactive. In downcounting, channel 1 is inactive (OC1REF=0) as long as TIMx\_CNT>TIMx\_CCR1 else active (OC1REF=1).

0111: PWM mode 2 - In upcounting, channel 1 is inactive as long as TIMx\_CNT<TIMx\_CCR1 else active. In downcounting, channel 1 is active as long as TIMx\_CNT>TIMx\_CCR1 else inactive.

1000: Retriggerable OPM mode 1 - In up-counting mode, the channel is active until a trigger event is detected (on TRGI signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes inactive again at the next update. In down-counting mode, the channel is inactive until a trigger event is detected (on TRGI signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes inactive again at the next update.

1001: Retriggerable OPM mode 2 - In up-counting mode, the channel is inactive until a trigger event is detected (on TRGI signal). Then, a comparison is performed as in PWM mode 2 and the channels becomes inactive again at the next update. In down-counting mode, the channel is active until a trigger event is detected (on TRGI signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes active again at the next update.

1010: Reserved,

1011: Reserved,

1100: Combined PWM mode 1 - OC1REF has the same behavior as in PWM mode 1. OC1REFC is the logical OR between OC1REF and OC2REF.

1101: Combined PWM mode 2 - OC1REF has the same behavior as in PWM mode 2. OC1REFC is the logical AND between OC1REF and OC2REF.

1110: Asymmetric PWM mode 1 - OC1REF has the same behavior as in PWM mode 1. OC1REFC outputs OC1REF when the counter is counting up, OC2REF when it is counting down.

1111: Asymmetric PWM mode 2 - OC1REF has the same behavior as in PWM mode 2. OC1REFC outputs OC1REF when the counter is counting up, OC2REF when it is counting down.

*Note: 1: These bits can not be modified as long as LOCK level 3 has been programmed (LOCK bits in TIMx\_BDTR register) and CC1S=00 (the channel is configured in output).*

*2: In PWM mode, the OCREF level changes only when the result of the comparison changes or when the output compare mode switches from "frozen" mode to "PWM" mode.*

Bit 3 **OC1PE**: Output compare 1 preload enable

0: Preload register on TIMx\_CCR1 disabled. TIMx\_CCR1 can be written at anytime, the new value is taken in account immediately.

1: Preload register on TIMx\_CCR1 enabled. Read/Write operations access the preload register. TIMx\_CCR1 preload value is loaded in the active register at each update event.

*Note: 1: These bits can not be modified as long as LOCK level 3 has been programmed (LOCK bits in TIMx\_BDTR register) and CC1S=00 (the channel is configured in output).*

*2: The PWM mode can be used without validating the preload register only in one-pulse mode (OPM bit set in TIMx\_CR1 register). Else the behavior is not guaranteed.*

Bit 2 **OC1FE**: Output compare 1 fast enable

This bit is used to accelerate the effect of an event on the trigger in input on the CC output.

0: CC1 behaves normally depending on counter and CCR1 values even when the trigger is ON. The minimum delay to activate CC1 output when an edge occurs on the trigger input is 5 clock cycles.

1: An active edge on the trigger input acts like a compare match on CC1 output. Then, OC is set to the compare level independently from the result of the comparison. Delay to sample the trigger input and to activate CC1 output is reduced to 3 clock cycles. OCFE acts only if the channel is configured in PWM1 or PWM2 mode.

Bits 1:0 **CC1S**: Capture/Compare 1 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

00: CC1 channel is configured as output.

01: CC1 channel is configured as input, IC1 is mapped on TI1.

10: CC1 channel is configured as input, IC1 is mapped on TI2.

11: CC1 channel is configured as input, IC1 is mapped on TRC. This mode is working only if an internal trigger input is selected through TS bit (TIMx\_SMCR register)

*Note: CC1S bits are writable only when the channel is OFF (CC1E = 0 in TIMx\_CCER).*

## Input capture mode

Bits 31:16 Reserved, always read as 0.
