

**THE DATASHEET OF  
MAX155AEPI+**

**Absolute Maximum Ratings**

V <sub>DD</sub> to AGND	-0.3V, +6V
V <sub>DD</sub> to DGND	-0.3V, +6V
AGND to DGND	-0.3V, (V <sub>DD</sub> + 0.3V)
V <sub>SS</sub> to AGND	+0.3V, -6V
V <sub>SS</sub> to DGND	+0.3V, -6V
CS, WR, RD, CLK, MODE to DGND	-0.3V, (V <sub>DD</sub> + 0.3V)
BUSY, D0–D7 to DGND	-0.3V, (V <sub>DD</sub> + 0.3V)
REFOUT to AGND	-0.3V, (V <sub>DD</sub> + 0.3V)
REFIN to AGND	-0.3V, (V <sub>DD</sub> + 0.3V)
AIN to AGND	(V <sub>SS</sub> - 0.3V), (V <sub>DD</sub> + 0.3V)
Output Current (REFOUT)	30mA

Continuous Power Dissipation (T<sub>A</sub> = +70°C)

24-Pin PDIP (derate 8.7mW/°C above +70°C)	696mW
28-Pin PDIP (derate 9.09mW/°C above +70°C)	727mW
28-Pin Wide SO (derate 12.5mW/°C above +70°C)	1000mW

Operating Temperature Ranges:

MAX155/MAX156_C_	0°C to +70°C
MAX155/MAX156_E_	-40°C to +85°C

Storage Temperature Range: -65°C to +150°C

Lead Temperature (soldering, 10s): +300°C

Soldering Temperature (reflow): +260°C

Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

**Electrical Characteristics**

(V<sub>DD</sub> = +5V, V<sub>REFIN</sub> = +2.5V. External Reference, V<sub>AGND</sub> = V<sub>DGND</sub> = 0V, V<sub>SS</sub> = 0V or -5V, f<sub>CLK</sub> = 5MHz external, Unipolar range single-ended mode, T<sub>A</sub> = T<sub>MIN</sub> to T<sub>MAX</sub>, unless otherwise noted.)

### Pin Configuration

## Pin Description

PIN			NAME	FUNCTION
MAX155	MAX156			
PDIP/SO	PDIP	SO		
1	23	26	AIN3	Sampling Analog Input, Channel 3
2	24	28	AIN2	Sampling Analog Input, Channel 2
3	1	2	AIN1	Sampling Analog Input, Channel 1
4	2	4	AIN0	Sampling Analog Input, Channel 0
5	3	5	MODE	Mode configures multiplexer and converter. See Table 4.
6	4	6	V <sub>SS</sub>	Negative Supply. Power V <sub>SS</sub> with -5V for extended input range.
7	5	7	CS	$\overline{\text{CHIP SELECT}}$ Input must be low for the ADC to recognize $\overline{\text{RD}}$ , or $\overline{\text{WR}}$
8	6	8	RD	$\overline{\text{READ}}$ Input reads data sequentially from RAM
9	7	9	WR	$\overline{\text{WRITE}}$ Input's rising edge initiates conversion and updates channel configuration register. Falling edge samples inputs.
10	8	10	BUSY	$\overline{\text{BUSY}}$ Output low when conversion is in progress
11	9	11	CLK	External Clock Input
12	10	12	D7/ALL	Three-State Data Output Bit 7 (MSB)/Sequential or Specific Conversion
13	11	13	D6/DIFF	Three-State Data Output Bit 6/Single-Ended/Differential Select
14	12	14	DGND	Digital Ground
15	13	15	D5/BIP	Three-State Data Output Bit 5/Unipolar/Bipolar Conversion
16	14	16	D4/INH	Three-State Data Output Bit 4/Inhibit Conversion Input
17	15	17	D3/PD	Three-State Data Output Bit 3/Power-Down Input
18	16	18	D2/A2	Three-State Data Output Bit 2/RAM Address Bit A2 (MAX155 Only)
19	17	19	D1/A1	Three-State Data Output Bit 1/RAM Address Bit A1
20	18	20	D0/A0	Three-State Data Output Bit 0/RAM Address Bit A0
21	19	21	REFOUT	Reference Output, +2.5V
22	20	22	REFIN	Reference Input, +2.5 Normally
23	21	23	AGND	Analog Ground
24	22	24	V <sub>DD</sub>	Power-Supply Voltage, +5V Normally
25–28	—	—	AIN7–4	Sampling Analog Input, Channels 7–4
—	—	1, 3, 25, 27	N.C.	No Connection. No internal connection—pin unconnected.

## Detailed Description

### ADC Operation

The MAX155/MAX156 contain a 3.6 $\mu$ s successive approximation ADC and 8/4 track-and-hold (T/H) inputs. When a conversion is started, all AIN inputs are simultaneously sampled. All channels sample whether or not they are selected for the conversion. Either a single-channel or multichannel conversion may be requested and channel configurations may be mixed, ADC results are then stored in an internal RAM.

In hard-wired mode (see the *Multiplexer and A/D Configurations* section) multichannel conversions are initiated with one write operation. In input/output (I/O) mode, multichannel configurations are set up prior to the conversion by loading channel selections into the con-

figuration register. This register also selects single-ended/differential, unipolar/bipolar (Figure 9), power-down, and other functions. Each channel selection requires a separate write operation (i.e. 8 writes for 8 channels), but only after power-up. Once the desired channel arrangement is loaded, each subsequent write converts all selected channels without reconfiguring the multiplexer (mux). I/O mode requires more write operations, but provides more flexibility than hard-wired mode.

To access conversion results, successive  $\overline{RD}$  pulses automatically sense through RAM, beginning with channel 0. Each  $\overline{RD}$  pulse increments the RAM address counter, which resets to 0 when  $\overline{WR}$  goes low in multi channel conversions. An arbitrary RAM location may also be read by writing a 1 to INH while loading the RAM address (A0–A2), and then performing a read operation.

**Table 1. Multiplexer Configurations**

PIN	NAME	FUNCTION
D0/A0 D1/A1 D2/A2	1 or 0	A0–A2 select a multiple channel for the configurations described below, or select a RAM address for reading with a subsequent $\overline{RD}$ .
D3/PD	0	Normal ADC operation
	1	Power-down reduces the power-supply current. Configuration data may be loaded and is maintained during power-down.
D4/INH	0	A conversion starts when $\overline{WR}$ goes high
	1	Inhibits the conversion when $\overline{WR}$ goes high. Allows mux configuration to be loaded and RAM locations to be accessed without starting a conversion.
D5/BIP**	0	Unipolar conversion (Figure 9a) for the channel specified by A0–A2. Input range = 0V to $V_{REF}$ .
	1	Bipolar conversion (Figure 9b) for the channel specified by A0–A2. Input range = $\pm V_{REF}$ .
D6/DIFF**	0	Single-ended configuration for the channel specified by A0–A2 as described in Table 2
	1	Differential configuration for the channel specified by A0–A2 as described in Table 2
D7/ $\overline{ALL}$	0	All previously configured channels are converted. Data is read with consecutive $\overline{RD}$ pulses, beginning with the lowest configured channel.
	1	Only the channel specified by A2–A0 is converted. A single $\overline{RD}$ pulse reads the result of that conversion.

\*Configuration inputs are shared with data outputs D0–D7. The functions of D0–D7 are not described in this table.

\*\*DIFF and BIP are not implemented on the current conversion, but go into effect on the following conversion.

**Multiplexer and A/D Configuration**

A conversion is started with a  $\overline{WR}$  pulse. All channels sample on  $\overline{WR}$ 's falling edge. Mux configuration data is loaded on  $\overline{WR}$ 's rising edge. In I/O mode (MODE = Open Circuit), selections for channel number, single or multi-channel conversion, unipolar or bipolar input, and single-ended or differential input are made with A0-A2,  $\overline{ALL}$ , BIP, and DIFF (Table 1). These input pins are also shared with the RAM data outputs D0–D7. An alternate, simpler interface is provided by the hard-wired mode, which selects some general mux configurations without requiring ADC programming. Hard-wired connections of MODE and  $V_{SS}$

select from 4 mux configurations as listed in Table 4 (see the *Hard-Wired Mode* section).

On the rising edge of  $\overline{WR}$ , the mux configuration register is updated; falling edge initiates sampling of all inputs. A channel selection can be implemented on the current conversion, but changes from unipolar to bipolar (with BIP) or from singleended to differential operation (with DIFF) do not go into effect until the following  $\overline{WR}$ . This can be overcome by writing to the configuration register while inhibiting the conversion (INH = 1), or by changing DIFF and BIP one conversion early, i.e. on the previous write.

**Table 2. Single-Ended Channel Selection (MODE = Open Circuit)**

MUX ADDRESS				SINGLE-ENDED CHANNEL SELECTION								
A0	A1	A2	DIFF	0	1	2	3	4	5	6	7	AGND
0	0	0	0	+								-
1	0	0	0		+							-
0	1	0	0			+						-
1	1	0	0				+					-
0	0	1	0					+				-
1	0	1	0						+			-
0	1	1	0							+		-
1	1	1	0								+	-

**Note:** Shaded areas represent MAX156 operation.

**Table 3. Differential Channel Selection (MODE = Open Circuit)**

MUX ADDRESS				DIFFERENTIAL CHANNEL SELECTION							
A0	A1	A2	DIFF	0	1	2	3	4	5	6	7
0	0	0	1	+	-						
0	1	0	1			+	-				
0	0	1	1					+	-		
0	1	1	1							+	-
1	0	0	1	-	+						
1	1	0	1			-	+				
1	0	1	1					-	+		
1	1	1	1							-	+

**Note:** Shaded areas represent MAX156 operation.

## Interface Timing

### Input/Output Mode, Multichannel Conversion Timing

I/O mode is selected when the MODE input is open circuit. In I/O mode, the mux configuration register determines the conversion type. The register is updated on the rising edge of  $\overline{WR}$ .

Table 1 lists all conversion options. For example, at D6/DIFF, a logic 0 or 1 selects a single-ended or differential conversion. Data is loaded into addressed locations in the configuration register with a series of  $\overline{WR}$  pulses. If INH is high while writing, no conversion takes place. A conversion is started by writing INH = 0 to the configuration register. When a change is made to the contents of the configuration register, a “dummy” conversion may be necessary. This is due to a built-in latency of one full conversion for unipolar/bipolar and single-ended/differential selections.

It is not necessary to update the configuration register before every conversion. A particular mux configuration must be loaded only once after power-up (but the configuration may require several writes to be loaded). A mux configuration is retained for successive conversions and during power-down (PD = 1) so that reconfiguring is unnecessary when the ADC returns to normal operation (PD = 0). Configuration and RAM data is lost only when power is removed from the ADC at  $V_{DD}$ .

When updating the configuration register, INH should be high for all except the last  $\overline{WR}$  so the conversion is not started until the mux is set. On  $\overline{WR}$ 's falling edge, all input channels sample simultaneously.  $\overline{BUSY}$  goes low at the beginning of the conversion, and channels are converted sequentially starting with the lowest selected channel. When  $\overline{BUSY}$  goes high, conversion results are stored in RAM. At conversion end, a microprocessor ( $\mu P$ ) can access the RAM contents with consecutive  $\overline{RD}$  pulses. The first accessed data is the lowest channel's result.

Subsequent  $\overline{RD}$  pulses access conversion results for the remaining channels.

The configuration data determines which RAM locations are sequentially read by consecutive  $\overline{RD}$  pulses, so new data should be placed in the configuration register only after a full  $\overline{RD}$  operation. It is not necessary to update the configuration register for every conversion. A new conversion is initiated with a  $\overline{WR}$  pulse (when INH = 0), regardless of the number of channels that have been read.

Figure 4a shows the MAX155 timing for an 8-channel unipolar configuration. 8 channels are configured and 8 consecutive  $\overline{RD}$  pulses access data. Figure 4b illustrates 4-channel differential conversion timing involving 4 sampled channels and 4  $\overline{RD}$  pulses. In cases where conflicting differential configurations are loaded, the last channel selected with DIFF = 1 will be the positive input of the differential channel.

### Input/Output Mode, Single-Channel Conversion Timing

Figure 5a shows timing for a single-channel ( $\overline{ALL} = 1$ ), single-ended conversion; Figure 5b shows a differential conversion. With MODE floating, the configuration register is updated on the rising edge of  $\overline{WR}$ .  $\overline{BUSY}$  goes low at the beginning of the conversion and returns high when the channel designated by the configuration register has been converted. All channels are sampled on the falling edge of  $\overline{WR}$  even if only a single channel has been requested. At conversion end, the  $\mu P$  can read the result for the selected channel with a single  $\overline{RD}$  pulse. Subsequent  $\overline{RD}$  pulses will access old conversion results remaining in other RAM locations. The next conversion is initiated with a  $\overline{WR}$  pulse, regardless of the number of channels that have been read.

INH and A0–A2, in the configuration register, access locations in RAM. INH = 1 allows the RAM address pointer to be updated without starting a conversion. A  $\overline{READ}$  pulse then reads the contents of the addressed location.

Figure 4a. Input/Output Mode Timing—Eight Single-Ended Conversions

Figure 4b. Input/Output Mode Timing—Four Differential Conversions

Figure 5a. Input/Output Mode Timing—Single-Channel, Single-Ended Conversion

Figure 5b. Input/Output Mode Timing—Single-Channel, Differential Conversion

Figure 6. Input/Output Mode Timing—Reading Arbitrary RAM Locations

**Hard-Wired Mode**

For simpler applications, the MODE and V<sub>SS</sub> pins can be hard-wired to specify the type of conversion as outlined in Table 4. In this mode, the configuration register is not used, so input data on DO-D7 is ignored. For example, with MODE tied low, an 8-channel, single-ended conversion begins with  $\overline{WR}$ . With MODE tied high, a 4-channel, differential conversion is initiated with  $\overline{WR}$ . Again, the configuration register is not affected by the data present on 00-07. These conversions are otherwise identical to those shown in Figure 4.

**Analog Considerations**

**Internal Reference**

The internal 2.5V reference (REFOUT) must be bypassed to AGND (Figure 8a) with a 4.7µF electrolytic and a 0.1µF ceramic capacitor to ensure stability.

**Table 4. Hard-Wired Mode—Multiplexer Selections**

MODE	V <sub>SS</sub>	CONVERSION TYPE
OPEN CIRCUIT	X	Multiplexer configuration register determines conversion type. Not hard-wired.
0	AGND	8-Channel, Single-Ended, Unipolar Conversion
1	AGND	4-Channel, Differential, Unipolar Conversion
0	-5V	8-Channel, Single-Ended, Bipolar Conversion
1	-5V	4-Channel, Differential, Bipolar Conversion

Figure 7a. Hard-Wired Mode Timing—Eight Single-Ended Conversions

Figure 7b. Hard-Wired Mode Timing—Eight Single-Ended Conversions

Figure 8a. Internal Reference

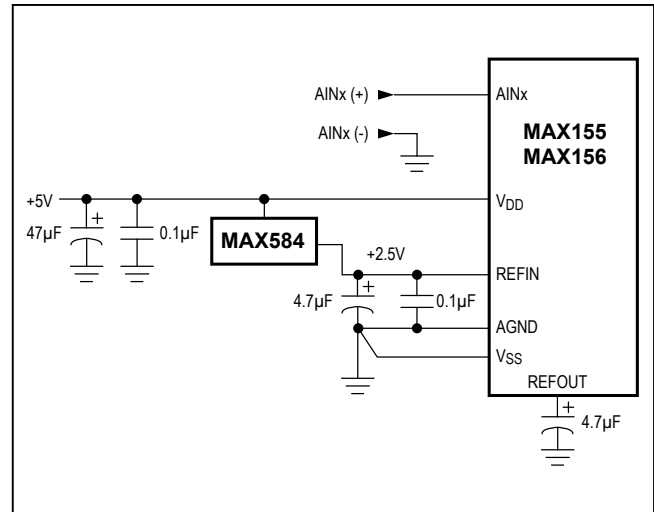

Figure 8b. External Reference, +2.5V Full Scale

**External Reference**

If an external voltage reference is used at REFIN, REFOUT must either be bypassed (Figure 8b) or disabled to prevent its output from oscillating and generating unwanted conversion noise elsewhere in the ADC. If component count is critical when using an external reference, REFOUT may be disabled by connecting it to VDD. In this case, the unused internal reference does not need a bypass cap. A disadvantage of tying REFOUT to VDD is that power-down current will be increased by about 250µA above the specification limits.

**Power-Down Mode**

The MAX155/MAX156 may be placed in a powered-down state by writing a 1 to the PD location in the configuration register (Table 1). The register may be updated while in this state (to change mux configurations or exit power-down mode) and all register contents are retained; however no data can be read from RAM and no conversions can be started. The power-down command is implemented on WR's rising edge.

To minimize current drain, the MAX155/MAX156 internal reference is turned off during power-down. When returning to normal operation (PD = 0), up to 5ms may be needed to allow the reference to recharge its 4.7µF bypass capacitor before a conversion is performed. If an external reference is used, and remains on during power-down, a conversion can be started within 50µs after loading PD with a 0.

**Bypassing**

A 47µF electrolytic and a 0.1µF ceramic capacitor should bypass VDD to AGND. If input signals below ground are expected, a negative supply is necessary. In that case, VSS should be bypassed to AGND with a 4.7µF and 0.1µF combination.

The internal reference requires a 4.7µF and 0.1µF combination. If an external voltage reference is used, bypass REFIN to AGND with a 4.7µF capacitor close to the chip. When an external reference is used, REFOUT must still be either bypassed or connected to VDD.

**Track/Hold Amplifiers**

The MAX155/MAX156 T/H amplifiers' high input impedance usually requires no input buffering. All T/Hs sample simultaneously. For best results, the analog inputs should not exceed the power-supply rails (VDD, VSS) by more than 50mV.

The time required for the T/H to acquire an input signal for one channel is a function of how quickly the channel input capacitance is charged. If the source impedance of the input signal is high, acquisition takes longer, and more time must be allowed between conversions. Acquisition time is calculated by:

$$t_{ACQ} = 8(R_S + R_{IN}) \times 4pF \text{ (but never less than 800ns)}$$

where  $R_{IN} = 15k\Omega$ , and  $R_S =$  source impedance of the ADC's input signal.

Figure 9a. Transfer Function—Unipolar Operation

Figure 9b. Transfer Function—Bipolar Operation

**Conversion Time**

Conversion time is calculated by:

$$t_{CONV} = (9 \times N \times 2) / f_{CLK}$$

where N is the number of channels converted. This includes one clock cycle of uncertainty. For a single channel and 5MHz clock, the conversion time is  $(9 \times 1 \times 2) / 5\text{MHz} = 3.6\mu\text{s}$ . For the MAX155, the maximum conversion time for 8 channels is  $(9 \times 8 \times 2) / 5\text{MHz} = 28.8\mu\text{s}$ . In the application example (Figure 10), six conversions are configured, and the conversion time is  $(9 \times 6 \times 2) / 5\text{MHz} = 21.6\mu\text{s}$ .

**Applications Information**

**9-Bit A/D Conversion**

In I/O mode, a 9th bit of resolution can be created by performing two unipolar differential conversions with opposite input polarities (i.e., first with AIN0[+] and AIN1[-], then with AIN0[-] and AIN1[+]). Only the A0 bit must be changed to reverse input channel polarity (Table 3). The sign reversal also occurs on the current write without a one conversion delay. For a differential input signal, one of the two conversions will read 0 while the other will contain an 8-bit result. The input polarity that provides the 8-bit result indicates the 9th (sign) bit. 4 channels can be measured this way. A major drawback of this technique is that many of the sampling features of the MAX155/MAX156 are defeated since two separate samples are needed

If only two 9-bit channels are needed, then two separate differential channels with reversed input polarities can be connected so that both input pairs sample at the same time. This way the simultaneous sampling advantages of the MAX155/MAX156 are retained.

**Typical I/O Mode Application**

The MAX155/MAX156 address and configuration inputs for this example were determined by selecting the desired channel configurations in Tables 2 and 3. Figure 10 illustrates the configuration outlined in Table 5.

**Table 5. Typical Multiplexer Configuration**

A2	A1	A0	DIFF	BIP	FUNCTION
0	0	1	1	1	Channel (1, 0) Differential Bipolar
0	1	0	0	0	Channel 2 Single-Ended, Unipolar
0	1	1	0	1	Channel 3 Single-Ended, Bipolar
1	0	0	0	1	Channel 4 Single-Ended, Bipolar
1	0	1	0	0	Channel 5 Single-Ended, Unipolar
1	1	0	1	0	Channel (6, 7) Differential, Unipolar

An A/D conversion in I/O mode involves the following steps:

- 1) Configure the mux by loading data into the configuration register based on selections from Table 2 and/or 3 (with INH = 1 and MODE = open circuit).

For this example, 6 write operations (with each address and data setting in Table 5 above) load the mux after power-up.

- 2) Sample all selected channels with a  $\overline{WR}$  pulse (and  $INH = 0$ ), and update or rewrite any one location of the configuration register.

This write operation may be skipped by loading  $INH$  with a 0 on the last  $\overline{WR}$  of the above step. The conversion then starts on the 6th  $\overline{WR}$ .  $DIFF$  and  $SIP$  cannot be changed on the 6th  $\overline{WR}$  in the conversion is started at that time.

When the conversion starts,  $\overline{BUSY}$  goes low while all selected channels are sequentially converted. Conversion results are stored in RAM and are ready to read when  $\overline{BUSY}$  returns high.

- 3) Data is read from RAM with  $INH = L$  and consecutive  $\overline{RD}$  strobes. Note that in the 6 channel configurations described in this example (Figure 10), 6  $\overline{RD}$  pulses access all available data, start with the differential channel (1, 0). Additional  $\overline{RD}$  pulses loop around, accessing the lowest channel data again.
- 4) To start a new conversion cycle with the same mux configuration, repeat steps 2 and 3.
