### Description

The BGT24ATR12 is a Silicon Germanium MMIC for signal generation and reception, operating in the 24 GHz ISM band from 24.00 to 24.25 GHz. It is based on a 24 GHz fundamental voltage controlled oscillator. A switchable frequency prescaler is included with output frequencies of 1.5 GHz and 23 kHz. The main RF output delivers typ. 11 dBm signal power to feed an antenna. A RC polyphase filter (PPF) is used for LO quadrature phase generation of the homodyne quadrature downconversion mixer. Output power sensors as well as a temperature sensor are implemented for monitoring purposes. The device is controlled via SPI and is manufactured in a 0.18 $\mu$ m SiGe:C technology offering a cutoff frequency of 200 GHz. The MMIC is packaged in a 32 pin leadless RoHs compliant VQFN package.

## 2.6 Power Detector

For RF power indication, peak voltage detectors are connected to the output of the TX power amplifier and to the LO medium power amplifier. To eliminate temperature and supply voltage variations, a reference output  $V_{\text{REF}}$  is available through the ANA output for the TX and LO power sensor. The compensated detector output voltage is given by the difference between  $V_{\text{OUT}}$  and  $V_{\text{REF}}$  for both power sensors respectively. This voltage is proportional to the RF voltage swing at the individual amplifier outputs, its characteristic is non-directional.

SI (Data); CLK (Clock);  $\overline{CS}$  (Chip select)

2.) The data bits SI (MSB first) are read in the shift with falling edge of the CLK signal.

Please make sure, that the data is present at least 10 ns before and at least 10 ns after the falling edge of the clock signal.

3.) The CLK and  $\overline{CS}$  signals are combined internally.

At least 20 ns before first rising edge of the first CLK signal  $\overline{CS}$  needs to be in "low" state.

While the Data is read,  $\overline{CS}$  has to remain in "low" state.

4.) When Data read in is finished, the shift register content will be written in the latch at the rising edge of the  $\overline{CS}$  signal. The time between the last falling edge of the CLK signal and the rising edge of the  $\overline{CS}$  must be at least 20 ns.
