## 2.2.1 Package Pin Summary

The following general building block is used to describe each pin:

**Table 5 Package Pin Mapping Description**

Function	Package A	Package B	...	Pad Type
Px.y	N	N		Pad Class

The table is sorted by the “Function” column, starting with the regular Port pins (Px.y), followed by the supply pins.

The following columns, titled with the supported package variants, lists the package pin number to which the respective function is mapped in that package.

The “Pad Type” indicates the employed pad type:

- STD\_INOUT (standard bi-directional pads)
- STD\_INOUT/AN (standard bi-directional pads with analog input)
- High Current (high current bi-directional pads)
- STD\_IN/AN (standard input pads with analog input)
- Power (power supply)

Details about the pad properties are defined in the Electrical Parameters.

### 2.2.2 Port I/O Functions

The following general building block is used to describe each PORT pin:

**Table 7 Port I/O Function Description**

Function	Outputs			Inputs		
	ALT1	ALTn	HWO0	HWI0	Input	Input
P0.0		MODA.OUT	MODB.OUT	MODB.INA	MODC.INA	
Pn.y	MODA.OUT				MODA.INA	MODC.INB

Pn.y is the port pin name, defining the control and data bits/registers associated with it. As GPIO, the port is under software control. Its input value is read via Pn\_IN.y, Pn\_OUT defines the output value.

Up to seven alternate output functions (ALT1/2/3/4/5/6/7) can be mapped to a single port pin, selected by Pn\_IOCR.PC. The output value is directly driven by the respective module, with the pin characteristics controlled by the port registers (within the limits of the connected pad).

The port pin input can be connected to multiple peripherals. Most peripherals have an input multiplexer to select between different possible input sources.

The input path is also active while the pin is configured as output. This allows to feedback an output to on-chip resources without wasting an additional external pin.

By Pn\_HWSEL, it is possible to select between different hardware “masters” (HWO0/HWI0, HWO1/HWI1). The selected peripheral can take control of the pin(s). Hardware control overrules settings in the respective port pin registers.

#### **3.1 General Parameters**

##### **3.1.1 Parameter Interpretation**

The parameters listed in this section represent partly the characteristics of the XMC1100 and partly its requirements on the system. To aid interpreting the parameters easily when evaluating them for a design, they are indicated by the abbreviations in the "Symbol" column:

### 3.3.6 SPD Timing Requirements

The optimum SPD decision time between  $0_B$  and  $1_B$  is  $0.75 \mu\text{s}$ . With this value the system has maximum robustness against frequency deviations of the sampling clock on tool and on device side. However it is not always possible to exactly match this value with the given constraints for the sample clock. For instance for a oversampling rate of 4, the sample clock will be 8 MHz and in this case the closest possible effective decision time is 5.5 clock cycles ( $0.69 \mu\text{s}$ ).

**Table 22 Optimum Number of Sample Clocks for SPD**

Sample Freq.	Sampling Factor	Sample Clocks $0_B$	Sample Clocks $1_B$	Effective Decision Time <sup>1)</sup>	Remark
8 MHz	4	1 to 5	6 to 12	$0.69 \mu\text{s}$	The other closest option ( $0.81 \mu\text{s}$ ) for the effective decision time is less robust.

1) Nominal sample frequency period multiplied with  $0.5 + (\text{max. number of } 0_B \text{ sample clocks})$

For a balanced distribution of the timing robustness of SPD between tool and device, the timing requirements for the tool are:

- Frequency deviation of the sample clock is +/- 5%
- Effective decision time is between  $0.69 \mu\text{s}$  and  $0.75 \mu\text{s}$  (calculated with nominal sample frequency)

## 4 Package and Reliability

The XMC1100 is a member of the XMC1000 Derivatives of microcontrollers. It is also compatible to a certain extent with members of similar families or subfamilies.

Each package is optimized for the device it houses. Therefore, there may be slight differences between packages of the same pin-count but for different device types. In particular, the size of the exposed die pad may vary.

If different device types are considered or planned for an application, it must be ensured that the board layout fits all packages under consideration.

### 4.1 Package Parameters

**Table 29** provides the thermal characteristics of the packages used in XMC1100.

**Table 29 Thermal Characteristics of the Packages**

		Min.	Max.

		-	46.0	K/W	PG-VQFN-24-19 <sup>1)</sup>
		-	38.4	K/W	PG-VQFN-40-13 <sup>1)</sup>

1) Device mounted on a 4-layer JEDEC board (JESD 51-5); exposed pad soldered.

*Note: For electrical reasons, it is required to connect the exposed pad to the board ground  $V_{SSP}$ , independent of EMC and thermal requirements.*

#### 4.1.1 Thermal Considerations

When operating the XMC1100 in a system, the total heat generated in the chip must be dissipated to the ambient environment to prevent overheating and the resulting thermal damage.

The maximum heat that can be dissipated depends on the package and its integration into the target board. The “Thermal resistance  $R_{\Theta JA}$ ” quantifies these parameters. The power dissipation must be limited so that the average junction temperature does not exceed 115 °C.

The difference between junction temperature and ambient temperature is determined by  $\Delta T = (P_{INT} + P_{IOSTAT} + P_{IODYN}) \times R_{\Theta JA}$

The internal power consumption is defined as

$$P_{\text{INT}} = V_{\text{DDP}} \times I_{\text{DDP}} \text{ (switching current and leakage current).}$$

The static external power consumption caused by the output drivers is defined as

$$P_{\text{IOSTAT}} = \Sigma((V_{\text{DDP}} - V_{\text{OH}}) \times I_{\text{OH}}) + \Sigma(V_{\text{OL}} \times I_{\text{OL}})$$

The dynamic external power consumption caused by the output drivers ( $P_{\text{IODYN}}$ ) depends on the capacitive load connected to the respective pins and their switching frequencies.

If the total power dissipation for a given system configuration exceeds the defined limit, countermeasures must be taken to ensure proper system operation:

- Reduce  $V_{\text{DDP}}$ , if possible in the system
- Reduce the system frequency
- Reduce the number of output pins
- Reduce the load on active output drivers
